The present application claims the benefits of:

[1] CN201710488401.X, application date: June 23, 2017;

[2] CN201810596587.5, application date: June 11, 2018.

Field of the invention

[3] The present disclosure relates to a class of coumarin-like cyclic compounds as MEK inhibitors and a pharmaceutical composition containing the same, and a use thereof in manufacturing a medicament for treating a MEK-related disease, particularly relates to a compound represented by formula (I) and a pharmaceutically acceptable salt thereof.

Background of the invention

[4] MAPK pathway is involved in a series of cellular processes such as cell proliferation, differentiation, apoptosis and stress response. There are four known MAPK pathways: ERK1/2, JNK, p38 and ERK5. One of the most important and widely known MAPK pathways is the Ras/Raf kinase pathway. In this pathway, firstly extracellular growth factors (i.e., PDGF or EGF, etc.) combine with transmembrane receptors (i.e., PDGFR or EGFR or ErbB2, etc.), activating the receptors, and the activated receptors induce the intramembranous Ras to combine with GTP and be activated via a guanylate exchange factor (e.g., SOS); the activated Ras further indirectly phosphorylates and activates Raf (MAPKKK in this pathway); then, the activated Raf induces the phosphorylation of the two serine residues of MEK1/2 (MAPKK in this pathway) (MEK1 corresponds to S218 and S222; MEK2 corresponds to S222 and S226) (Ahn et al., *Methods in Enzymology*, 2001, 332, 417-431). The phosphorylated ERK dimerizes and accumulates in the nucleus (Khokhlatchev et al., *Cell*, 1998, 93, 605-615). The ERK in the nucleus involves in many cellular functions, including but not limited to nuclear transport, signal transduction, DNA repair, nucleosome assembly and migration, and mRNA processing and translation (Ahn et al., *Molecular Cell*, 2000, 6, 1343-1354).

[5] The RAF-MEK-ERK pathway can transmit proliferation and anti-apoptotic signals from growth factors and oncogenic factors, thereby promoting cell growth, development and metastasis; the mutations of the genes involved in the pathway or the overexpression of the growth factors, downstream signaling proteins or the protein kinases will lead to uncontrolled cell proliferation and eventually tumorigenesis. For example, mutations in cancer cells cause overexpression of growth factors, leading to continuous activation of the internal MAPK pathway; or the inability to deactivate the activated Ras complexes due to mutations also will cause continuous activation of the MAPK pathway; recently, bRaf mutations have been identified in more than 60% of melanomas (Davies, H. et al., *Nature*, 2002, 417, 949-954). These bRaf mutations lead to spontaneous activation of the MAPK cascade. Spontaneous or excessive activation of the MAPK pathway has also been observed in studies of primary tumor samples and cell lines such as pancreatic cancer, colon cancer, lung cancer, ovarian cancer and kidney cancer (Hoshino, R. et al., *Oncogene*, 1999, 18, 813-822). Therefore, there is a strong correlation between overactive MAPK pathway due to gene mutations and cancer.

[6] As the MAPK pathway locates at the central position of cell proliferation and differentiation, inhibition of this pathway will be beneficial for the treatment of a variety of hyperproliferative diseases, and MEK located downstream of Ras and Raf in the pathway has become a key role in this pathway. In addition, currently known substrates that can be phosphorylated and activated by MEK are only MAPK, namely ERK1 and ERK2. This strict selectivity and the unique ability of its bifunctional kinase make it become an attractive drug target, with potential and widespread therapeutic applications, such as malignant and benign hyperproliferative diseases, immune regulation and inflammation.

[7] Targeting at the MAPK signaling pathway, multiple Raf and MEK inhibitors are currently developed in clinical and launching stages. For example, Sorafenib (Bay 43-9006) approved by the FDA in December 2005 is a non-specific serine/threonine and tyrosine kinase inhibitor, its targets include Raf, MEK, VEGFR2/3, Flt-3, PDGFR, c-Kit, etc. B-Raf specific inhibitors such as Dabrafenib (GSK21 18436) and Vemurafenib (PLX4032) have good clinical efficacy, but the duration is short, and clinical studies have found that the long-term treatment with B-Raf inhibitors can lead to acquired drug resistance of the patients. Therefore, MEK inhibitors are usually used in combination with B-Raf inhibitors clinically. Trametinib (GSK-1 120212), a specific inhibitor of MEK1/2, was approved by the FDA in May 2013, and was approved in January 2014 for the treatment of advanced melanoma in combination with Dabrafenib; Cobimetinib is an inhibitor that specifically inhibits MEK1/2 and was approved by the FDA in 2015 for the treatment of melanoma in combination with Vemurafenib. Binimetinib was applied to the FDA in 2016 for use in the treatment of N-RAS mutant melanoma. In addition, there are MEK1/2 inhibitors such as Selumetinib and Refametinib in clinical stage.

[8] Currently, a series of patent applications relating to MEK inhibitors are disclosed, including WO2007/096259, WO2010/003022, WO2012/162293, WO2014/169843, WO2015/058589, etc.

Definition and description

[69]Unless otherwise indicated, the following terms when used in the descriptions and the claims of the present disclosure have the following meanings. A specific term or phrase should not be considered indefinite or unclear in the absence of a particular definition, but should be understood in the ordinary sense. When a trade name appears herein, it is intended to refer to its corresponding commodity or active ingredient thereof. The term "pharmaceutically acceptable" is used herein in terms of those compounds, materials, compositions, and/or dosage forms, which are suitable for use in contact with human and animal tissues within the scope of reliable medical judgment, with no excessive toxicity, irritation, allergic reaction or other problems or complications, commensurate with a reasonable benefit/risk ratio.

[70]The term "pharmaceutically acceptable salt" refers to a salt of the compound of the present disclosure that is prepared by reacting the compound having a specific substituent of the present disclosure with a relatively non-toxic acid or base. When the compound of the present disclosure contains a relatively acidic functional group, a base addition salt can be obtained by bringing the neutral form of the compound into contact with a sufficient amount of base in a pure solution or a suitable inert solvent. The pharmaceutically acceptable base addition salt includes a salt of sodium, potassium, calcium, ammonium, organic amine or magnesium or similar salts. When the compound of the present disclosure contains a relatively basic functional group, an acid addition salt can be obtained by bringing the neutral form of the compound into contact with a sufficient amount of acid in a pure solution or a suitable inert solvent. Examples of the pharmaceutically acceptable acid addition salt include an inorganic acid salt, wherein the inorganic acid includes, for example, hydrochloric acid, hydrobromic acid, nitric acid, carbonic acid, bicarbonate, phosphoric acid, monohydrogen phosphate, dihydrogen phosphate, sulfuric acid, hydrogen sulfate, hydroiodic acid, phosphorous acid, and the like; and an organic acid salt, wherein the organic acid includes, for example, acetic acid, propionic acid, isobutyric acid, maleic acid, malonic acid, benzoic acid, succinic acid, suberic acid, fumaric acid, lactic acid, mandelic acid, phthalic acid, benzenesulfonic acid, *p*-toluenesulfonic acid, citric acid, tartaric acid, and methanesulfonic acid, and the like; and a salt of amino acid (e.g. arginine and the like), and a salt of an organic acid such as glucuronic

acid and the like. Certain specific compounds of the present disclosure that contain both basic and acidic functional groups can be converted to any base or acid addition salt.

[71] Preferably, salt is contacted with a base or acid in a conventional manner, and the parent compound is then isolated to regenerate the neutral form of the compound. The parent form of a compound differs from its various salt forms in certain physical properties, such as different solubility in polar solvents.

[72] As used herein, the "pharmaceutically acceptable salt" is a derivative of the compound of the present disclosure, wherein the parent compound is modified by forming a salt with an acid or with a base. Examples of pharmaceutically acceptable salts include, but are not limited to, base such as inorganic or organic acid salts of amines, acid such as alkali or organic salt of carboxylic acid, and the like. Pharmaceutically acceptable salts include conventional non-toxic salts or quaternary ammonium salts of the parent compound, such as salts formed from non-toxic inorganic or organic acids. Conventional non-toxic salts include, but are not limited to, those derived from inorganic and organic acids selected from the group consisting of 2-acetoxybenzoic acid, 2-hydroxyethanesulfonic acid, acetic acid, ascorbic acid, benzenesulfonic acid, benzoic acid, bicarbonate, carbonic acid, citric acid, edetic acid, ethanedisulfonic acid, ethanesulfonic acid, fumaric acid, glucoheptose, gluconic acid, glutamic acid, glycolic acid, hydrobromic acid, hydrochloric acid, hydroiodate, hydroxyl, hydroxynaphthalene, isethionate, lactic acid, lactose, dodecylsulfonic acid, maleic acid, malic acid, mandelic acid, methanesulfonic acid, nitric acid, oxalic acid, panic acid, pantothenic acid, phenylacetic acid, phosphoric acid, polygalactaldehyde, propionic acid, salicylic acid, stearic acid, acetic acid, succinic acid, aminosulfonic acid, *p*-aminobenzenesulfonic acid, sulfuric acid, tannin, tartaric acid and *p*-toluenesulfonic acid.

[73] The pharmaceutically acceptable salts of the present disclosure can be synthesized from the parent compound containing an acid or a base by a conventional chemical method. Generally, such salts are prepared by reacting these compounds in the form of a free acid or base with a stoichiometric appropriate base or acid in water or an organic solvent or a mixture of both. Generally, a non-aqueous medium such as ether, ethyl acetate, ethanol, isopropanol, or acetonitrile is preferred.

[74] Certain compounds of the present disclosure may have asymmetric carbon atoms (optical centers) or double bonds. Racemates, diastereomers, geometric isomers and individual isomers are all included within the scope of the present disclosure.

[75] Unless otherwise specified, the absolute configuration of a stereogenic center is represented by a wedged solid bond () and a wedged dashed bond (), a wave line () represents a wedged solid bond () or a wedged dashed bond (), and the relative configuration of a stereogenic center is represented by a straight solid bond () and a straight dashed bond (). When the compounds described herein contain olefinic double bonds or other centers of geometric asymmetry, unless otherwise specified, they include *E*, *Z* geometric isomers. Likewise, all tautomeric forms are included within the scope of the disclosure.

[76] The term "enriched in one isomer" refers to the content of one of the isomers is <100%,

and $\geq 60\%$, preferably $\geq 70\%$, preferably $\geq 80\%$, preferably $\geq 90\%$, preferably $\geq 95\%$, preferably $\geq 96\%$, preferably $\geq 97\%$, preferably $\geq 98\%$, preferably $\geq 99\%$, preferably $\geq 99.5\%$, preferably $\geq 99.6\%$, preferably $\geq 99.7\%$, preferably $\geq 99.8\%$, preferably $\geq 99.9\%$.

[77] The excess of isomer refers to the difference between the relative percentages of the two isomers. For example, wherein, the content of one of the isomers is 90%, and the other one is 10%, then the excess of isomer is 80%.

[78] "(+)" stands for dextrorotation, "(-)" stands for levorotation, or "(±)" stands for racemization.

[79] The compounds of the present disclosure may exist in specific geometric or stereoisomeric forms. This disclosure contemplates all such compounds, including *cis* and *trans* isomers, (-)- and (+)-enantiomers, (*R*)- and (*S*)-enantiomers, diastereomer isomers, (*D*)-isomers, (*L*)-isomers, and racemic and other mixtures thereof, such as enantiomers or diastereomeric enriched mixtures, all of which are within the scope of the present disclosure. Additional asymmetric carbon atoms may be present in substituents such as alkyl. All these isomers and their mixtures are included in the scope of the present disclosure.

[80] Optically active (*R*)- and (*S*)-isomer, or *D* and *L* isomer can be prepared using chiral synthesis or chiral reagents or other conventional techniques. If one kind of enantiomer of certain compound of the present disclosure is to be obtained, the pure desired enantiomer can be obtained by asymmetric synthesis or derivative action of chiral auxiliary followed by separating the resulting diastereomeric mixture and cleaving the auxiliary group. Alternatively, when the molecule contains a basic functional group (e.g., amino) or an acidic functional group (e.g., carboxy), the compound reacts with an appropriate optically active acid or base to form a salt of the diastereomeric isomer which is then subjected to diastereomeric resolution through the conventional method in the art to give the pure enantiomer. In addition, the enantiomer and the diastereoisomer are generally isolated through chromatography which uses a chiral stationary phase and optionally combines with a chemical derivative method (e.g., carbamate generated from amine).

[81] The compound of the present disclosure may contain an unnatural proportion of atomic isotope at one or more than one atom(s) that constitute the compound. For example, the compound can be radiolabeled with a radioactive isotope, such as tritium (^3H), iodine-125 (^{125}I) or C-14 (^{14}C). All of the transformations formed by the isotopic compositions of the present disclosure, whether radioactive or not, are included within the scope of the present disclosure.

[82] The term "substituted" means one or more than one hydrogen atom(s) on a specific atom is(are) substituted with the substituent, including deuterium and hydrogen variants, as long as the valence of the specific atom is normal and the substituted compound is stable. When the substituent is an oxygen (i.e. =O), it means two hydrogen atoms are substituted. Positions on an aromatic ring cannot be substituted with a ketone. The term "optionally substituted" means an atom can be substituted with a substituent or not, unless otherwise specified, the type and number of the substituent may be arbitrary as long as being chemically achievable.

[83] When any variable (e.g., R) occurs in the constitution or structure of the compound more than once, the definition of the variable at each occurrence is independent. Thus, for example, if a group is substituted with 0-2 R, the group can be optionally substituted with up to two R,

wherein the definition of R at each occurrence is independent. Moreover, a combination of the substituent and/or the variant thereof is allowed only when the combination results in a stable compound.

[84] When the number of a linking group is 0, such as $-(CRR)_0-$, it means that the linking group is a single bond.

[85] When one of the variables is selected from a single bond, it means that the two groups linked by the single bond are connected directly. For example, when L in A-L-Z represents a single bond, the structure of A-L-Z is actually A-Z.

[86] When a substituent is vacant, it means that the substituent does not exist, for example, when X is vacant in A-X, the structure of A-X is actually A. When a substituent can be attached to more than one atoms on a ring, the substituent can be bonded to any of the atom on

the ring, for example, the structural unit  represents for the substitution by the substituent R can take place at any position on the cyclohexyl or cyclohexadiene. When the enumerated substituents do not indicate through which atom they are attached to the substituted group, such substituents may be bonded through any one of the atoms, for example, pyridyl as a substituent can be attached to the substituted group through any one of the carbon atom on the pyridine ring. When the enumerative linking group does not indicate the direction for linking, the direction for linking is arbitrary, for example, the

linking group L contained in  is -M-W-, then -M-W- can link ring A and ring

B to form  in the direction same as left-to-right reading order, and form

 in the direction contrary to left-to-right reading order. Combinations of the linking groups, substituents and/or variants thereof are permissible only if such combinations result in stable compounds.

[87] Unless otherwise specified, the term "hetero" represents a heteroatom or a heteroatomic group (e.g., an atomic group containing a heteroatom), including the atom except carbon (C) and hydrogen (H) and the atomic group containing the above heteroatom, for example, including oxygen (O), nitrogen (N), sulfur (S), silicon (Si), germanium (Ge), aluminum (Al), boron (B), -O-, -S-, =O, =S, -C(=O)O-, -C(=O)-, -C(=S)-, -S(=O), -S(=O)₂-, and the group consisting of -C(=O)N(H)-, -N(H)-, -C(=NH)-, -S(=O)₂N(H)- and -S(=O)N(H)-, each of which is optionally substituted.

[88] Unless otherwise specified, the term "ring" refers to a substituted or unsubstituted cycloalkyl, heterocycloalkyl, cycloalkenyl, heterocycloalkenyl, cycloalkynyl, heterocycloalkynyl, aryl or heteroaryl. The so called ring includes a single ring, a double ring, a spiral ring, a fused ring or a bridged ring. The number of the atom on the ring is usually defined as the member number of the ring, for example, a "5-7 membered ring" means that 5 to 7 atoms are arranged on a ring. Unless otherwise specified, the ring optionally contains 1 to 3 heteroatoms. Therefore, a "5-7 membered ring" includes, for example, phenyl, pyridinyl and piperidinyl; on the other hand, the term "5-7 membered heterocycloalkyl ring" includes pyridyl and piperidinyl, but excluding phenyl. The term "ring" also includes a ring system containing at least one ring, wherein each ring independently meets the above definition.

[89] Unless otherwise specified, the term "heterocycle" or "heterocyclyl" refers to a stable monocyclic, bicyclic or tricyclic ring containing a heteroatom or a heteroatom group, which can be saturated, partially unsaturated or unsaturated (aromatic) and can contain carbon atoms and 1, 2, 3 or 4 ring heteroatoms independently selected from N, O and S, wherein any of the above heterocycle can be fused to a benzene ring to form a bicyclic ring. Nitrogen and sulfur heteroatoms can optionally be oxidized (i.e., NO and S(O)_p, p is 1 or 2). Nitrogen atom can be substituted or unsubstituted (i.e., N or NR, wherein R is H or other substituents already defined herein). The heterocycle can be attached to the pendant group of any heteroatom or carbon atom to form a stable structure. If the resulting compound is stable, the heterocycle described herein may have a substitution at a carbon or nitrogen position. Nitrogen atom on the heterocycle is optionally quaternized. In a preferred embodiment, when the total number of S and O atom of the heterocycle is more than 1, the heteroatom is not adjacent to each other. In another preferred embodiment. The total number of S and O atom of the heterocycle is not more than 1. As used herein, the term "aromatic heterocyclic group" or "heteroaryl" refers to a stable 5-, 6- or 7-membered monocyclic or bicyclic or 7-, 8-, 9- or 10-membered bicyclic heterocyclic aromatic ring which contains carbon atoms and 1, 2, 3 or 4 ring heteroatoms independently selected from N, O and S. Nitrogen atom can be substituted or unsubstituted (i.e., N or NR, wherein R is H or other substituents already defined herein). Nitrogen and sulfur heteroatoms may optionally be oxidized (i.e., NO and S(O)_p, p is 1 or 2). It is worth noting that the total number of S and O atom of an aromatic heterocycle is not more than one. The bridged ring is also included in the definition of the heterocycle. A bridged ring is formed when one or more than one atom (i.e., C, O, N or S) link two non-adjacent carbon or nitrogen atoms. A preferred bridged ring includes, but not limited to one carbon atom, two carbon atoms, one nitrogen atom, two nitrogen atoms and one carbon-nitrogen group. [580] **Biological experiment**

[581] **Biological test method 1: MEK Lance Ultra experiment**

[582] Compounds were serially diluted three-fold to 10 concentrations, two duplicates were

set. Final test concentrations of the compounds ranged from 10 μ M to 0.51 nM. 0.07 nM activated MEK1 (Millipore # 14-429) and 2 nM non-activated ERK (Millipore # 14-515) were mixed with the compounds or DMSO, the mixture was incubated at 23°C for 30 minutes. Then 50 nM ULight labeled MBP (PerkinElmer # TRF0109-M) and 50 μ M ATP (Invitrogen # PV3227) were added to initiate the reaction, and the mixture was incubated at 23°C for 90 minutes. After the reaction was stopped by adding EDTA at a final concentration of 15 mM, 2 nM Eu-labeled anti-phosphorylated antibody (PerkinElmer # TRF0201-M) was added and incubated for 1 hour. The fluorescence signal data (excitation band: 320 nm; emission band: 665 nm/615 nm) was determined by an Envision microplate reader (PerkinElmer). XLfit5 software was used for data analysis and mapping. The experimental results are shown in Table 5.

[583] Biological test method 2: Cell viability experiment

[584] HT29 and A375 cells were plated in a 96-well cell culture plate at a density of 40,000 cells/well and 20,000 cells/well respectively, and the cells were cultured overnight. The compounds were serially diluted in a gradient of 1:3, the dilutions were added to the cell culture medium, and incubated with the cells in a 37°C incubator for 3 days. The 96-well cell culture plate was taken from the incubator and equilibrated at room temperature for 30 minutes, then Cell Titer-Glo reagent (Promega Cat # G7573) was added at a ratio of 1:2, and the mixture was mixed thoroughly on a shaker for 2 minutes to promote cell lysis. The cell culture plate was incubated at room temperature for 10 minutes and then read on an Envision microplate reader (PerkinElmer). XLfit5 software was used for data analysis and mapping. The experimental results are shown in Table 5.

[587] Biological test method 3: *In vivo* pharmacodynamics study on HT-29 cell subcutaneous xenograft tumor model in BALB/c nude mouse

[588] Human colon cancer HT-29 cells (ATCC-HTB-38) were cultured in monolayer *in vitro*, with McCoy's 5a medium (Gibco, 1835937) supplemented with 10% fetal bovine serum, 100 U/mL penicillin and 100 µg/mL streptomycin, at 37°C under 5% CO₂. The cells were conventionally digested with trypsin-EDTA and passaged twice a week. When the cell saturation was 80%-90%, the cells were collected, counted and inoculated. 0.1 mL (5×10⁶) of HT-29 cells was subcutaneously inoculated into the right back of each nude mouse. When the average tumor volume reached 100-180 mm³, the animals were grouped and administration was started (QD, 14-21 days). The diameter of the tumor was measured twice a week with a vernier caliper. The tumor volume is calculated by the formula: $V = 0.5a \times b^2$, wherein a and b represent the length and width respectively. The antitumor activity of the compounds was evaluated by TGI (%), which reflects the tumor growth inhibition rate. Calculation of TGI (%): $TGI (\%) = [(1 - (\text{average tumor volume at the end of administration in a treatment group} - \text{average tumor volume at the start of treatment in this treatment group})) / (\text{average tumor volume at the end of treatment in the solvent control group} - \text{average tumor volume at the start of treatment in the solvent control group})] \times 100\%$. The experimental results are shown in Table 6.

[589] Table 6: Pharmacodynamic test results:

Embodiment	Compound	Dose (mpk)	TGI (%)	Dosage regimen
16	WX034	3	90.6	QD, 21 days
20	WX071	0.5	91	QD, 21 days

37	WX113	0.2	82.8	QD, 25 days (5 days administration, and 2 days break)
50	WX066	0.5	89	QD, 21 days

[590] Conclusion: The compounds of the present disclosure have a good tumor growth inhibitory activity.

[591] Biological test method 4: Pharmacokinetics study of the compounds in C57BL/6 mice

[592] Experimental materials:

[593] C57BL/6 mice (male, 18-22 g, 7-9 weeks old, Shanghai Lingchang)

[594] Experimental procedure:

[595] The pharmacokinetic characteristics of the compounds in rodents were determined

after intravenous and oral administration of the compounds by standard protocols. In the experiment, candidate compounds were formulated into clear solutions, and intravenously and orally administered to rats in a single dose. The menstruum for intravenous and oral administration was DMSO, PEG and water at a certain ratio or Solutol, HPMC and SLS aqueous solutions at a certain ratio. The whole blood samples within 24 hours were collected, centrifuged at 3,000 rpm for 15 minutes, and the supernatants were isolated to obtain plasma samples. An acetonitrile solution containing an internal standard with a volume of 4 times as the plasma sample volume was added to precipitate the protein. After centrifugation, the supernatant was collected and an equal volume of water was added. After centrifugation, the supernatant was collected and injected to quantitatively analyze the blood drug concentration by LC-MS/MS analysis method, and the pharmacokinetic parameters were calculated, e.g., peak concentration, peak time, clearance, half-life, area under the drug concentration-time curve, bioavailability, etc.
