ABSTRACT OF THE DISCLOSURE

When a speed dial button is pressed by a user, a control section reads out speed-dial data from a memory section, and simultaneously judges whether a communication mode corresponding to the speed-dial data is the same as a communication mode in current use. When it is judged that the communication mode is the current communication mode, the control section controls the speed-dial data to be displayed in a display section. In a communication device having such a structure and a plurality of communication modes, only the speed-dial data corresponding to a desired communication mode are displayed. It is therefore possible to search for a desired telephone number in a short time.
