

Abstract

A cable connector having improved strain relief and cable retention qualities disclosed. A separate strain relief member includes a ferrule or
5 anvil. This member is placed on a cable. The connector is then assembled and the shields are then attached to the connector parts, including the strain relief member. Latches are provided on a connector that mates with the cable connector. The latches engage the strain relief directly. In one embodiment, the latches engage lugs formed on the strain
10 relief member. In another embodiment, the latches have a plurality of protrusions that engage openings in a facing side wall of the cable connector to aid in maintaining the connectors in mated condition, under forces imparted by the cable. The latches can be removed by inserting latch parts or tools into removal openings in side walls or at the top of the
15 connector on which the latch is mounted. Alternatively, latches are mounted to the cable connector to engage latching elements on the mating connector. A mating connector housing is arranged to accommodate latches mounted thereon on the cable connector.
