ABSTRACT

In a housing (1), an opening (11) through which an internal space and an outside communicate with each other is formed. Rails (2) in a pair maintain a gap between a face of the housing (1) and a cover (3) to have a size preventing the insect from passing through the gap. A sample holder retains a sample, and enables the sample to be exposed from the opening (11) to the internal space when being slidably retained by the rails (2). The cover (3) and the sample holder retaining the sample can be slid between the rails (2) in a state in which one side of the cover (3) and one side of the sample holder come into contact with each other, and can be moved between a position at which the cover (3) covers the opening (11) and a position at which the sample covers the opening (11).
