

CHEMICAL COMPOUNDS AND USES

FIELD OF THE INVENTION

The present invention relates to novel compounds that are useful in the treatment and prevention of metabolic disorders, including diabetes mellitus (type I and type II), obesity, and related disorders, and also includes methods for making,
5 pharmaceutical compositions containing, and therapeutic uses for such compounds.

BACKGROUND OF THE INVENTION

Diabetes mellitus is an ever-increasing threat to human health. For example, in the United States current estimates maintain that about 16 million people suffer
10 from diabetes mellitus.

Type I diabetes, also known as insulin-dependent diabetes mellitus (IDDM), is caused by the autoimmune destruction of the insulin producing pancreatic β -cells, and necessitates regular administration of exogenous insulin. Without insulin, cells cannot absorb sugar (glucose), which they need to produce energy. Symptoms of
15 Type I diabetes usually start in childhood or young adulthood. People often seek medical help because they are seriously ill from sudden symptoms of high blood sugar (hyperglycemia).

Type II diabetes, also known as non-insulin-dependent diabetes mellitus (NIDDM), manifests with an inability to adequately regulate blood-glucose levels.
20 Type II diabetes may be characterized by a defect in insulin secretion or by insulin resistance, namely those that suffer from Type II diabetes have too little insulin or cannot use insulin effectively. Insulin resistance refers to the inability of body tissues to respond properly to endogenous insulin. Insulin resistance develops because of multiple factors, including genetics, obesity, increasing age, and having high blood
25 sugar over long periods of time. Type II diabetes, sometimes called mature or adult onset diabetes, can develop at any age, but most commonly becomes apparent during adulthood. The incidence of Type II diabetes in children, however, is rising.

In diabetics, glucose levels build up in the blood and urine causing excessive urination, thirst, hunger, and problems with fat and protein metabolism. If left
30 untreated, diabetes mellitus may cause life-threatening complications, including blindness, kidney failure, and heart disease.

Type II diabetes accounts for approximately 90-95% of diabetes cases, killing about 193,000 U.S. residents each year. Type II diabetes is the seventh leading cause of all deaths. In Western societies, Type II diabetes currently affects 6% of the
35 adult population with world-wide frequency expected to grow by 6% per annum.

Although there are certain inheritable traits that may predispose particular individuals to developing Type II diabetes, the driving force behind the current increase in incidence of the disease is the increased sedentary lifestyle, diet, and obesity now prevalent in developed countries. About 80% of diabetics with Type II diabetes are significantly overweight. As noted above, an increasing number of young people are developing the disease. Type II diabetes is now internationally recognized as one of the major threats to human health in the 21st century.

Type II diabetes currently is treated at several levels. A first level of therapy is through the use of diet and/or exercise, either alone or in combination with therapeutic agents. Such agents may include insulin or pharmaceuticals that lower blood glucose levels. About 49% of individuals with Type II diabetes require oral medication(s), about 40% of individuals require insulin injections or a combination of insulin injections and oral medication(s), and about 10% of individuals may use diet and exercise alone.

Current therapies for diabetes mellitus include: insulin; insulin secretagogues, such as sulphonylureas, which increase insulin production from pancreatic β -cells; glucose-lowering effectors, such as metformin which reduce glucose production from the liver; activators of the peroxisome proliferator-activated receptor- γ (PPAR- γ), such as the thiazolidinediones, which enhances insulin action; and α -glucosidase inhibitors which interfere with gut glucose production. There are, however, deficiencies associated with currently available treatments, including hypoglycemic episodes, weight gain, loss in responsiveness to therapy over time, gastrointestinal problems, and edema.

There are several areas at which research is being targeted in order to bring new, more effective, therapies to the marketplace. For example, on-going research includes exploring a reduction in excessive hepatic glucose production, enhancing the pathway by which insulin transmits its signal to the cells such that they take up glucose, enhancing glucose-stimulated insulin secretion from the pancreatic β -cells, and targeting obesity and associated problems with fat metabolism and accumulation.

One particular target is GPR119. GPR119 is a member of the rhodopsin family of G-protein-coupled receptors. In addition to the "GPR119" identifier, several other identifiers exist, including but not limited to RUP 3, Snorf 25, 19 AJ, GPR 116 (believed to be erroneous), AXOR 20, and PS1. GPR119 is expressed in human gastrointestinal regions and in human islets. Activation of GPR119 has been demonstrated to stimulate intracellular cAMP and lead to glucose-dependent GLP-1 and insulin secretion. See, T. Soga *et al.*, *Biochemical and Biophysical Research*

Communications 326 (2005) 744-751, herein incorporated by reference with regard to a background understanding of GPR119.

In type 2 diabetes the action of GLP-1 on the β -cell is maintained, although GLP-1 secretion, itself, is reduced. More recently, therefore, much research has been focused on GLP-1. Studies show glucose-lowering effects in addition to GLP-1's ability to stimulate glucose-dependent insulin secretion including, but not limited to, an inhibition of the release of the hormone glucagon following meals, a reduction in the rate at which nutrients are absorbed into the bloodstream, and a reduction of food intake. Studies demonstrate that treatments to increase GLP-1, therefore, may be used for a variety of conditions and disorders including but not limited to metabolic disorders, gastrointestinal disorders, inflammatory diseases, psychosomatic, depressive, and neuropsychiatric disease including but not limited to diabetes mellitus (Type 1 and Type 2), metabolic syndrome, obesity, appetite control and satiety, weight loss, stress, inflammation, myocardial ischemia/reperfusion injury, Alzheimer's Disease, and other diseases of the central nervous system.

The use of exogenous GLP-1 in clinical treatment is severely limited, however, due to its rapid degradation by the protease DPP-IV. There are multiple GLP-1 mimetics in development for type 2 diabetes that are reported in the literature, all are modified peptides, which display longer half-lives than endogenous GLP-1. For example, the product sold under the tradename BYETTA® is the first FDA-approved agent of this new class of medications. These mimetics, however, require injection. An oral medication that is able to elevate GLP-1 secretion is desirable. Orally available inhibitors of DPP-IV, which result in elevation in intact GLP-1, are now available, such as sitagliptin, marketed under the brand name JANUVIA®. Nevertheless, a molecule which may stimulate GLP-1 secretion would provide a therapeutic benefit. A molecule which could stimulate both GLP-1 secretion and insulin secretion through effects on the L-cell and direct effects on the β -cell would hold much promise for type 2 diabetes therapy.

The present invention identifies agonists of GPR119 which increase glucose-disposal in part through elevation of GIP, GLP-1, and insulin. Moreover, studies demonstrate that GPR119 agonists such as the compounds of the present invention can stimulate incretins independently of glucose. GIP and GLP-1 are peptides, known as incretins, secreted from enteroendocrine K and L cells, respectively, in response to ingestion of nutrients, and have a wide variety of physiological effects that have been described in numerous publications over the past two decades. See, for example, Bojanowska, E. *et al.*, *Med. Sci. Monit.*, 2005, Aug 11(8): RA271-8; Perry, T. *et al.*, *Curr. Alzheimer Res.*, 2005, July 2(3): 377-85; and Meier, J.J. *et al.*,

Diabetes Metab. Res. Rev., 2005, Mar-Apr; 21(2); 91-117 (each herein incorporated by reference with regard to a background understanding of incretins). Moreover, although the mechanisms regulating GLP-1 secretion remain unclear, the initial rapid rise in GLP-1 following a meal may be a result of hormonal stimulation of neuronal afferents involving GIP. See, for example, J.N. Roberge and P.L. Brubaker, *Endocrinology* 133 (1993), pp. 233-240 (herein incorporated by reference with regard to such teaching). Furthermore, later increases in GLP-1 may involve direct activation of L-cells by nutrients in the distal small-intestine and the colon. GIP and GLP-1 are potent stimulators of the body's ability to produce insulin in response to elevated levels of blood sugar. In Type 2 diabetes, patients display a decreased responsiveness to GIP but not GLP-1, with respect to its ability to stimulate insulin secretion. The mechanism behind the decreased responsiveness to GIP remains unclear since type 2 diabetics retain sensitivity to a bolus administration of GIP but not to a continuous infusion (Meier *et al.* 2004 *Diabetes* 53 S220-S224). Moreover recent studies with a long-acting fatty-acid derivative of GIP showed beneficial effects on glucose homeostasis in ob/ob mice following 14 days of treatment (Irwin N. *et al.* (2006) *J. Med. Chem.* 49, 1047-1054.)

Agonists to GPR119 may be of therapeutic value for diabetes and associated conditions, particularly type II diabetes, obesity, glucose intolerance, insulin resistance, metabolic syndrome X, hyperlipidemia, hypercholesterolemia, and atherosclerosis.

Compounds of formula (I) may crystallize in more than one form, a
 30 characteristic known as polymorphism, and such polymorphic forms ("polymorphs") are within the scope of compounds of the invention. Polymorphism generally can occur as a response to changes in temperature, pressure, or both, and can also result from variations in the crystallization process. Polymorphs can be distinguished by various physical characteristics such as x-ray diffraction patterns, solubility, and
 35 melting point.

Certain of the compounds described herein may be capable of existing as stereoisomers such as by having a chiral carbon, sulfoxide sulfur or double bond

whereby the compounds may exist as R or S enantiomers or E or Z isomers. The scope of the present invention includes all such individual isomers, racemates, purified enantiomers, and enantiomerically enriched mixtures of the compounds of formula (I).

5 Typically, but not absolutely, the salts of the present invention are pharmaceutically acceptable salts. Salts encompassed within the term "pharmaceutically acceptable salts" refer to non-toxic salts of the compounds of this invention. Salts of the compounds of the present invention may comprise acid addition salts. Representative salts include acetate, benzenesulfonate, benzoate, 10 bicarbonate, bisulfate, bitartrate, borate, calcium edetate, camsylate, carbonate, clavulanate, citrate, dihydrochloride, edisylate, estolate, esylate, fumarate, gluceptate, gluconate, glutamate, glycolylarsanilate, hexylresorcinate, hydrabamine, hydrobromide, hydrochloride, hydroxynaphthoate, iodide, isethionate, lactate, lactobionate, laurate, malate, maleate, mandelate, mesylate, methylsulfate, 15 monopotassium maleate, mucate, napsylate, nitrate, N-methylglucamine, oxalate, pamoate (embonate), palmitate, pantothenate, phosphate/diphosphate, polygalacturonate, potassium, salicylate, sodium, stearate, subacetate, succinate, sulfate, tannate, tartrate, teoclate, tosylate, triethiodide, trimethylammonium, and valerate salts. Other salts, which are not pharmaceutically acceptable, may be useful 20 in the preparation of compounds of this invention and these should be considered to form a further aspect of the invention.

Included within the scope of the invention compounds are solvates of compounds of the depicted formula. "Solvate" refers to a complex of variable stoichiometry formed by a solute (in this invention, a compound of Formula (I), or a 25 salt or physiologically functional derivative thereof) and a solvent. Such solvents, for the purpose of the invention, should not interfere with the biological activity of the solute. Preferably the solvent used is a pharmaceutically acceptable solvent such as water, ethanol, and acetic acid.

"Physiologically functional derivative" refers to any pharmaceutically 30 acceptable derivative of a compound of the present invention that, upon administration to a mammal, is capable of providing (directly or indirectly) a compound of the present invention or an active metabolite thereof. Such derivatives, for example, esters and amides, will be clear to those skilled in the art, without undue experimentation. Reference may be made to the teaching of *Burger's Medicinal* 35 *Chemistry And Drug Discovery*, 5th Edition, Vol. 1: Principles and Practice, which is incorporated herein by reference to the extent that it teaches physiologically functional derivatives.

"Effective amount" means that amount of a drug or pharmaceutical agent that will elicit the biological or medical response of a tissue, system, animal, or human that is being sought, for instance, by a researcher or clinician.

"Therapeutically effective amount" means any amount which, as compared to
5 a corresponding subject who has not received such amount, results in improved treatment, healing, prevention, or amelioration of a disease, disorder, or side effect, or a decrease in the rate of advancement of a disease or disorder. The term also includes within its scope amounts effective to enhance normal physiological function. For use in therapy, therapeutically effective amounts of a compound of formula (I), as
10 well as salts, solvates, and physiological functional derivatives thereof, may be administered as the raw chemical. Additionally, the active ingredient may be presented as a pharmaceutical composition.

Accordingly, the invention further provides pharmaceutical compositions that include effective amounts of a compound of the formula (I) or a salt, solvate, or
15 physiological functional derivative thereof, and one or more pharmaceutically acceptable carriers, diluents, or excipients. The carrier(s), diluent(s) or excipient(s) must be acceptable, in the sense of being compatible with the other ingredients of the formulation and not deleterious to the recipient of the pharmaceutical composition.

20 In another aspect of the invention there is provided a process for the preparation of a pharmaceutical formulation including admixing a compound of the formula (I) or a salt, solvate, or physiological functional derivative thereof, with one or more pharmaceutically acceptable carriers, diluents or excipients.

A therapeutically effective amount of a compound of the present invention will
25 depend upon a number of factors. The species, age, and weight of the recipient, the precise condition requiring treatment and its severity, the nature of the formulation, and the route of administration are all factors to be considered. The therapeutically effective amount ultimately should be at the discretion of the attendant physician or veterinarian. An effective amount of a compound of formula (I) for the treatment of
30 humans or other mammals suffering from metabolic disorders such as diabetes and obesity, generally, should be in the range of about 0.1 to 100 mg/kg body weight of recipient (mammal) per day. More usually the effective amount should be in the range of 0.1 to 10 mg/kg body weight per day. Thus, for a 70 kg adult mammal the actual amount per day would usually be from 7 to 700 mg. This amount may be
35 given in a single dose per day or in a number (such as two, three, four, five, or more) of sub-doses per day such that the total daily dose is the same. An effective amount of a salt, solvate, or physiologically functional derivative thereof, may be determined

as a proportion of the effective amount of the compound of formula (I) *per se*. Similar dosages should be appropriate for treatment of the other conditions referred to herein and for prophylaxis.

Pharmaceutical formulations may be presented in unit dose forms containing
5 a predetermined amount of active ingredient per unit dose. Such a unit may contain, as a non-limiting example, 0.5 mg to 1 g of a compound of the formula (I), depending on the condition being treated, the route of administration, and the age, weight, and condition of the patient. Preferred unit dosage formulations are those containing a daily dose or sub-dose of an active ingredient. Such pharmaceutical formulations
10 may be prepared by any of the methods well known in the pharmacy art.

Pharmaceutical formulations may be adapted for administration by any appropriate route, for example by an oral (including buccal or sublingual), rectal, nasal, topical (including buccal, sublingual or transdermal), vaginal, or parenteral (including subcutaneous, intramuscular, intravenous or intradermal) route. Such
15 formulations may be prepared by any method known in the art of pharmacy, for example by bringing into association the active ingredient with the carrier(s) or excipient(s).

Pharmaceutical formulations adapted for oral administration may be presented as discrete units such as capsules or tablets; powders or granules;
20 solutions or suspensions, each with aqueous or non-aqueous liquids; edible foams or whips; or oil-in-water liquid emulsions or water-in-oil liquid emulsions. For oral administration in the form of a tablet or capsule, the active drug component can be combined with an oral, non-toxic pharmaceutically acceptable inert carrier such as ethanol, glycerol or water. Generally, powders are prepared by comminuting the
25 compound to a suitable fine size and mixing with an appropriate pharmaceutical carrier such as an edible carbohydrate, as, for example, starch or mannitol. Flavorings, preservatives, dispersing agents, and coloring agents can also be present.

Capsules are made by preparing a powder, liquid, or suspension mixture and
30 encapsulating with gelatin or some other appropriate shell material. Glidants and lubricants such as colloidal silica, talc, magnesium stearate, calcium stearate, or solid polyethylene glycol can be added to the mixture before the encapsulation. A disintegrating or solubilizing agent such as agar-agar, calcium carbonate or sodium carbonate can also be added to improve the availability of the medicament when the
35 capsule is ingested. Suitable binders, lubricants, disintegrating agents, and coloring agents can also be incorporated into the mixture. Examples of binders include starch, gelatin, natural sugars such as glucose or beta-lactose, corn sweeteners,

natural and synthetic gums such as acacia, tragacanth, or sodium alginate, carboxymethylcellulose, polyethylene glycol and waxes. Lubricants useful in these dosage forms include sodium oleate, sodium stearate, magnesium stearate, sodium benzoate, sodium acetate and sodium chloride. Disintegrators include starch, methyl
5 cellulose, agar, bentonite and xanthan gum.

Tablets are formulated, for example, by preparing a powder mixture, granulating or slugging, adding a lubricant and disintegrant, and pressing into tablets. A powder mixture may be prepared by mixing the compound, suitably comminuted, with a diluent or base as described above. Optional ingredients include binders such
10 as carboxymethylcellulose, alginates, gelatins, or polyvinyl pyrrolidone, solution retardants such as paraffin, resorption accelerators such as a quaternary salt, and/or absorption agents such as bentonite, kaolin, or dicalcium phosphate. The powder mixture can be wet-granulated with a binder such as syrup, starch paste, acacia mucilage, or solutions of cellulosic or polymeric materials, and forcing through a
15 screen. As an alternative to granulating, the powder mixture can be run through the tablet machine and the result is imperfectly formed slugs broken into granules. The granules can be lubricated to prevent sticking to the tablet-forming dies by means of the addition of stearic acid, a stearate salt, talc or mineral oil. The lubricated mixture is then compressed into tablets. Compounds of the present invention can also be
20 combined with a free flowing inert carrier and compressed into tablets directly without going through the granulating or slugging steps. A clear or opaque protective coating consisting of a sealing coat of shellac, a coating of sugar or polymeric material, and a polish coating of wax can be provided. Dyestuffs can be added to these coatings to distinguish different unit dosages.

25 Oral fluids such as solutions, syrups, and elixirs can be prepared in dosage unit form so that a given quantity contains a predetermined amount of the compound. Syrups can be prepared by dissolving the compound in a suitably flavored aqueous solution, while elixirs are prepared through the use of a non-toxic alcoholic vehicle. Suspensions can be formulated generally by dispersing the compound in a non-toxic
30 vehicle. Solubilizers and emulsifiers such as ethoxylated isostearyl alcohols and polyoxy ethylene sorbitol ethers, preservatives; flavor additives such as peppermint oil, or natural sweeteners, saccharin, or other artificial sweeteners; can also be added.

Where appropriate, dosage unit formulations for oral administration can be
35 microencapsulated. The formulation can also be prepared to prolong or sustain the release as for example by coating or embedding particulate material in polymers or wax.

Compounds of formula (I) and salts, solvates, and physiological functional derivatives thereof, can also be administered in the form of liposome delivery systems, such as small unilamellar vesicles, large unilamellar vesicles, and multilamellar vesicles. Liposomes can be formed from a variety of phospholipids, such as cholesterol, stearylamine, or phosphatidylcholines.

Compounds of formula (I) and salts, solvates, and physiologically functional derivatives thereof may also be delivered by the use of monoclonal antibodies as individual carriers to which the compound molecules are coupled.

The compounds may also be coupled with soluble polymers as targetable drug carriers. Such polymers can include polyvinylpyrrolidone (PVP), pyran copolymer, polyhydroxypropylmethacrylamide-phenol, polyhydroxyethyl-aspartamidephenol, or polyethyleneoxidepolylysine substituted with palmitoyl residues. Furthermore, the compounds may be coupled to a class of biodegradable polymers useful in achieving controlled release of a drug; for example, polylactic acid, polyeppilon caprolactone, polyhydroxy butyric acid, polyorthoesters, polyacetals, polydihydropyrans, polycyanoacrylates, and cross-linked or amphipathic block copolymers of hydrogels.

Pharmaceutical formulations adapted for transdermal administration may be presented as discrete patches intended to remain in intimate contact with the epidermis of the recipient for a prolonged period of time. For example, the active ingredient may be delivered from the patch by iontophoresis as described in *Pharmaceutical Research*, 3(6), 318 (1986).

Pharmaceutical formulations adapted for topical administration may be formulated as ointments, creams, suspensions, lotions, powders, solutions, pastes, gels, sprays, aerosols, or oils.

For treatments of the eye or other external tissues, for example mouth and skin, the formulations may be applied as a topical ointment or cream. When formulated in an ointment, the active ingredient may be employed with either a paraffinic or a water-miscible ointment base. Alternatively, the active ingredient may be formulated in a cream with an oil-in-water cream base or a water-in-oil base.

Pharmaceutical formulations adapted for topical administrations to the eye include eye drops wherein the active ingredient is dissolved or suspended in a suitable carrier, especially an aqueous solvent.

Pharmaceutical formulations adapted for topical administration in the mouth include lozenges, pastilles, and mouthwashes.

Pharmaceutical formulations adapted for nasal administration, where the carrier is a solid, include a coarse powder having a particle size for example in the

range 20 to 500 microns. The powder is administered in the manner in which snuff is taken, i.e., by rapid inhalation through the nasal passage from a container of the powder held close up to the nose. Suitable formulations wherein the carrier is a liquid, for administration as a nasal spray or as nasal drops, include aqueous or oil
5 solutions of the active ingredient.

Pharmaceutical formulations adapted for administration by inhalation include fine particle dusts or mists, which may be generated by means of various types of metered dose pressurized aerosols, nebulizers, or insufflators.

Pharmaceutical formulations adapted for rectal administration may be
10 presented as suppositories or as enemas.

Pharmaceutical formulations adapted for vaginal administration may be presented as pessaries, tampons, creams, gels, pastes, foams, or spray formulations.

Pharmaceutical formulations adapted for parenteral administration include
15 aqueous and non-aqueous sterile injection solutions which may contain anti-oxidants, buffers, bacteriostats, and solutes that render the formulation isotonic with the blood of the intended recipient; and aqueous and non-aqueous sterile suspensions which may include suspending agents and thickening agents. The formulations may be presented in unit-dose or multi-dose containers, for example sealed ampules and
20 vials, and may be stored in a freeze-dried (lyophilized) condition requiring only the addition of the sterile liquid carrier, for example water for injections, immediately prior to use. Extemporaneous injection solutions and suspensions may be prepared from sterile powders, granules, and tablets.

Compounds of the present invention and their salts, solvates, and
25 physiologically functional derivatives thereof, may be employed alone or in combination with other therapeutic agents. The compound(s) of formula (I) and the other pharmaceutically active agent(s) may be administered together or separately and, when administered separately, administration may occur simultaneously or sequentially, in any order. The amounts of the compound(s) of formula (I) and the
30 other pharmaceutically active agent(s) and the relative timings of administration will be selected in order to achieve the desired combined therapeutic effect. The administration in combination of a compound of formula (I) salts, solvates, or physiologically functional derivatives thereof with other treatment agents may be in combination by administration concomitantly in: (1) a unitary pharmaceutical
35 composition including both compounds; or (2) separate pharmaceutical compositions each including one of the compounds. Alternatively, the combination may be administered separately in a sequential manner wherein one treatment agent is

administered first and the other second or vice versa. Such sequential administration may be close in time or remote in time.

Compounds of the present invention may be used in the treatment of a variety of disorders and conditions. As such, the compounds of the present invention may be used in combination with a variety of other therapeutic agents useful in the treatment or prophylaxis of those disorders or conditions. The compounds of the present invention may be used in combination with diet, exercise, insulin, an insulin sensitivity enhancer, a glucose absorption inhibitor, a biguanide, an insulin secretion enhancer, a SGLT2 inhibitor, an insulin or insulin analogue, a glucagon receptor antagonist, an insulin receptor kinase stimulant, a tripeptidyl peptidase II inhibitor, a dipeptidyl peptidase IV inhibitor, a protein tyrosine phosphatase-1B inhibitor, a glycogen phosphorylase inhibitor, an AXOR 109 agonist, a glucose-6-phosphatase inhibitor, a fructose-bisphosphatase inhibitor, a pyruvate dehydrogenase inhibitor, a hepatic gluconeogenesis inhibitor, D-chiroinsitol, a glycogen synthase kinase-3 inhibitor, glucagon-like peptide-1, a glucagon-like peptide-1 analogue, a glucagon-like peptide-1 agonist, amylin, an amylin analogue, an amylin agonist, an aldose reductase inhibitor, an advanced glycation endproducts formation inhibitor, a protein kinase C inhibitor, a γ -aminobutyric acid receptor antagonist, a sodium channel antagonist, a transcript factor NF- κ B inhibitor, a lipid peroxidase inhibitor, an *N*-acetylated- α -linked-acid-dipeptidase inhibitor, insulin-like growth factor-I, platelet-derived growth factor, a platelet-derived growth factor analogue, epidermal growth factor, nerve growth factor, a carnitine derivative, uridine, 5-hydroxy-1-methylhydantoin, EGB-761, bimocimol, sulodexide, Y-128, antidiarrhoics, cathartics, a hydroxymethylglutaryl coenzyme A reductase inhibitor, a fibric acid derivative, a β_3 -adrenoceptor agonist, an acyl-coenzyme A cholesterol acyltransferase inhibitor, probucol, a thyroid hormone receptor agonist, a cholesterol absorption inhibitor, a lipase inhibitor, a microsomal triglyceride transfer protein inhibitor, a lipoxygenase inhibitor, a carnitine palmitoyl-transferase inhibitor, a squalene synthase inhibitor, a low-density lipoprotein receptor enhancer, a nicotinic acid derivative, a bile acid sequestrant, a sodium/bile acid cotransporter inhibitor, a cholesterol ester transfer protein inhibitor, an appetite suppressant, an angiotensin-converting enzyme inhibitor, a neutral endopeptidase inhibitor, an angiotensin II receptor antagonist, an endothelin-converting enzyme inhibitor, an endothelin receptor antagonist, a diuretic agent, a calcium antagonist, a vasodilating antihypertensive agent, a sympathetic blocking agent, a centrally acting antihypertensive agent, an α_2 -adrenoceptor agonist, an antiplatelets agent, a uric acid synthesis inhibitor, a uricosuric agent, and a urinary alkalinizer.

30 In the examples described below, protecting groups for sensitive or reactive groups are employed where necessary in accordance with general principles of synthetic chemistry. Protecting groups are manipulated according to standard methods of organic synthesis (T.W. Green and P.G.M. Wuts (1991) *Protective Groups in Organic Synthesis*, John Wiley & Sons, incorporated by reference with regard to protecting groups). These groups are removed at a convenient stage of the compound synthesis using methods that are readily apparent to those skilled in the

art. The selection of processes as well as the reaction conditions and order of their execution shall be consistent with the preparation of compounds of formula (I).

Those skilled in the art will recognize if a stereocenter exists in compounds of formula (I). Accordingly, the present invention includes all possible stereoisomers and includes not only racemic compounds but the individual enantiomers as well. When a compound is desired as a single enantiomer, such may be obtained by stereospecific synthesis, by resolution of the final product or any convenient intermediate, or by chiral chromatographic methods as are known in the art. Resolution of the final product, an intermediate, or a starting material may be affected by any suitable method known in the art. See, for example, *Stereochemistry of Organic Compounds* by E.L. Eliel, S.H. Wilen, and L.N. Mander (Wiley-Interscience, 1994), incorporated by reference with regard to stereochemistry.

The novel compounds of the present invention should not be limited by any specific synthetic process herein described.

Experimental Section

The symbols and conventions used in the following descriptions of processes, schemes, and examples are consistent with those used in the contemporary scientific literature, for example, the Journal of the American Chemical Society or the Journal of Biological Chemistry.

Unless otherwise indicated, all temperatures are expressed in °C (degrees Centigrade). All reactions were conducted at room temperature unless otherwise noted. Unless otherwise indicated, definitions for moieties in formulae (II) to (XXVIII) are as defined above for formula (I) and LG represents a leaving group such as hydroxyl. Abbreviations and definitions include HPLC (high pressure liquid chromatography), LC-MS (liquid chromatography-mass spectrometry), NMR (nuclear magnetic resonance), NMP (1-methyl-2-pyrrolidinone), HATU (O-(7-azabenzotriazol-1-yl)-N,N,N',N'-tetramethyluronium hexafluorophosphate), TBTU (O-benzotriazol-1-yl-N,N,N',N'-tetramethyluronium tetrafluoroborate); HOBT (1-hydroxybenzotriazole); TFA (trifluoroacetic acid); DMF (dimethylformamide); DIAD (di-isopropyl azodicarboxylate); DME (1,2-dimethoxyethane); THF (tetrahydrofuran); DMSO (dimethylsulfoxide); MeOH (methanol); EtOH (ethanol); Et₃N (triethylamine); AcOH (acetic acid); NMP (1-methyl-2-pyrrolidinone); EtOAc (ethyl acetate); aq (aqueous); and *m*-CPBA (meta-chloroperbenzoic acid); Tr (retention time); DAST ((diethylamino)sulfur trifluoride); BOC₂O (di-*tert*-butyl dicarbonate).

¹H-NMR spectra were recorded on a Varian VXR-300, a Varian Unity-300, a Varian Unity-400 instrument, or a General Electric QE-300. Chemical shifts are

expressed in parts per million (ppm, δ units). Coupling constants are in units of hertz (Hz). Splitting patterns describe apparent multiplicities and are designated as s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), or bs (broad singlet).

Mass spectra were obtained on Micromass Platform or ZMD mass spectrometers from Micromass Ltd., Altricham, UK, using either Atmospheric Chemical Ionization (APCI) or Electrospray Ionization (ESI).

The microwave reactions were conducted using EmrysTM Optimizer / SmithSynthesizer from Biotage using standard protocols that are known in the art.

The absolute stereochemistry of chiral enantiopure sulfoxides was determined using Vibrational Circular Dichroism (VCD), a spectroscopic technique capable of reliably assigning absolute stereochemistry (Freedman *et al.*, *Chirality*, 2003, 15:743-758). Experimental VCD spectra were acquired using a BioTools Chiral/RTM VCD spectrometer equipped with a dual photoelastic modulator (PEM) and operating at 4 cm⁻¹ resolution in the mid-infrared region (2000-800 cm⁻¹).

Absolute configurations were assigned by comparing the sign (+/-) of an intense VCD band at 954 cm⁻¹ in experimental VCD spectra to the sign of the corresponding band in reference spectra. The sign (+/-) of this VCD band is known to be highly diagnostic for the absolute stereochemistry of the aromatic methyl sulfinyl group (Stephens, P.J. *et al. J. Org. Chem.*, 2001, 66, 3671).

Biaryl-based compounds can be prepared by following the general synthetic Scheme 1. A Suzuki coupling reaction under conditions a) between a substituted aryl boronic acid (II) and an appropriately substituted aryl bromide or heteroaryl halide (bromide or chloride) (III) can provide the compound of (VI). For Suzuki reaction conditions, see N. Miyaura and A. Suzuki, *Chem. Rev.*, 1995, 95, 2457-2483; A. Suzuki, *J. Organometallic Chem.* 1999, 576, 147-168; and A. Suzuki, in *Metal-catalyzed Cross-coupling Reactions*, F. Diederich and P.J. Stang., Eds.; Wiley-VCH: New York, 1998, 49-97. Compounds of formula (VI) can also be prepared via

When Q is -O-, the compound (VI) can react with an intermediate (VII) where LG is HO- under Mitsunobu reaction conditions b) to give the compound of formula (I), see Mitsunobu, *Synthesis*, 1981, 1, and for a Mitsunobu reaction review see D.L. Hughes *Organic Reactions* 42, 335. Treatment of the compound (VI) with an intermediate of formula (VII) where LG- is mesyl under b) conditions in the presence of a base (such as K_2CO_3) in DMF can also provide the compound (I). For the formation of mesylate (VII) from its corresponding alcohol, see R.K. Crossland and K.L. Servis, *J. Org. Chem.*, 1970, 35, 3195-3196. For reaction conditions for displacement of mesylate, see P.J. Gilligan, *et al.*, *J. Med. Chem.*, 1992, 35, 4344-4361.

An alternative synthetic approach for making compounds of formula (I) is shown in Scheme 2. The compound (VIII) can be made from (III) and alcohol (VII)

where LG- is HO- using Mitsunobu reaction conditions a), or from (III) and mesylate (VII) wherein LG- is mesyl in the presence of a suitable base such as K_2CO_3 . In addition, following Scheme 3, sulfone-containing compound (XII) can be obtained through sulfonation of the compound (X) using a substituted sulphinic acid sodium salt in the presence of CuI depicted as a), see W. Zhu and D. Ma., *J. Org. Chem.*, 2005, 70, 2696-2700, and K.R. Campos, *et al.*, *J. Org. Chem.*, 2005, 70, 268-274, for the conversion of aryl or alkyl halides to the corresponding sulfones. Secondly, sulfide (XI), upon oxidation with Oxone®, also yields the compound (XII), summarized as b), see I.K. Khanna, *et al.*, *J. Med. Chem.*, 1997, 40, 1619-1633. The compound (XI) can also be treated, as summarized by c), with an oxidant such as 30% aqueous H_2O_2 in 1,1,1,3,3,3-hexafluoro-2-propanol to give the racemic sulfoxide (XIII), see K.S. Ravikumar, *et al.*, *Eur. J. Org. Chem.*, 1998, 2937-2940. The racemic sulfoxides can be separated using chiral HPLC methods to give the pure or enriched (R and S) enantiomers.

In Scheme 3, Y is either -H or -C(R³R⁴)-Ring C-R⁶ whereby (XII) and (XIII) are types of (VI) and (I), respectively.

Coupling reaction of (XV) and (XVII) in the presence of $ZnCl_2$ would result in formation of N-oxadiazol 4-hydroxymethyl piperidine (XVIII) after acidic workup, which can be subsequently used, as a compound of formula (VII), in Scheme 1 and Scheme 2. For reaction conditions, see R.M. Jones, *et al.*, WO 2005/121121A2.

- Various groups at R⁶ of formula (XX) can be introduced by a sequence involving deprotection of a suitable protecting group, such as a Boc group in compound (XIX), with TFA or HCl, summarized as a). Once deprotected, this can be followed by reaction with a variety of electrophiles, including but not limited to benzyl or benzyl-like halides, chloroformates, acyl chlorides and sulfonyl chlorides depicted as b), isocyanates and thioisocyanates depicted as c) and α-halo heteroaryls depicted as d). Reactions with electrophiles can be performed in a suitable solvent such as dichloromethane, chloroform, tetrahydrofuran, acetonitrile or DMSO under conditions known to those skilled in the art.

- The deprotected (XIX) can also be reacted with cyanogen bromide to give the corresponding cyanoamine derivative which in turn can be converted to a heterocycle, including but not limited to an oxadiazole, summarized as e). For synthesis of 3-amino-1,2,4-oxadiazole, see R. Cadilla, *et al.*, WO2003/74495A1. For synthesis of 3,5-diamino-1,2,4-oxadiazole, see E. Cohnen and B. Armah, US4446142A1. - Alternatively, compounds (XX) wherein R⁶ is ArCH₂- can be made from the deprotected (XIX) and aryl aldehydes using a cyanoborohydride resin/AcOH reductive amination protocol, summarized as f).

Scheme 6

- Reagents and conditions: a) $\text{Cl}_3\text{CC(O)Cl}$ [or $(\text{Cl}_3\text{CCO})_2\text{O}$], pyridine, CH_2Cl_2 , -15°C ; b) R^3MgBr in ether or THF CH_2Cl_2 , -78 to 0°C ; c) (XXI), MeOH, RT; d) when $R^b = \text{CBz}$: H_2 , Pd/C, EtOH.

Intermediates (XXIII) and (XXIV) can be made according to Scheme 6. Treatment of N-hydroxy alkylimidamide (XV) with trichloroacetyl chloride or its related anhydride in pyridine and dichloromethane at low temperature gives the intermediate (XXI). Alkyl Grignard addition to aldehyde (XXII) affords the secondary alcohol as a racemate. When $R^b = \text{H}$, coupling (XXIII) with the intermediate (XXI) in methanol at room temperature affords (XXIV). Preparation of the NH derivative of (XXIII) can be accomplished by the removal of R^b group, providing it is a suitable protecting group (P), such as a benzyl carbamate (CBz), by using hydrogenolysis conditions (hydrogen, Pd/C, solvent).

Enantioenriched or enantiopure intermediates of the type (XXVIII) can be prepared according to Scheme 7. 4-Acetylpyridine can be enantioselectively reduced with a ruthenium catalyst (see reference: Uematsu, N.; Fujii, A.; Hashiguchi, S.; Ikariya, T.; Noyori, R; *J. Am. Chem. Soc.* 1996, 118, 4916-4917) and TEA and formic acid to afford secondary alcohol (XXVI). Reduction of the pyridine ring can be performed with a transition-metal catalyst, such as platinum oxide (PtO₂), in methanol and acetic acid under an atmosphere of hydrogen. Conversion of the NH into a suitable group (for example, a carbamate) can be accomplished with an alkylchloroformate in dichloromethane in the presence of a base or a heterocycle using a similar sequence described in Scheme 6.

Enantioselective reductions of more general intermediates (ketones other than methyl aryl ketones, such as ethyl ketones) can be accomplished by those skilled in the art using methods described in, but not limited to, reviews on asymmetric reductions; see: Ohkuma, Takeshi; Noyori, Ryoji. Reagents and conditions: a) Ph₃P, DIAD, THF; or K₂CO₃, DMF, heating.

Enantioenriched or enantiopure biaryl-based compounds of the type (I) compounds can be prepared by following the general synthetic Scheme 8. As has been described previously, when Q is -O-, the compound (VI) can react with an intermediate (VII) where LG is HO- under Mitsunobu reaction conditions under a) to give the compound of formula (I), see Mitsunobu, *Synthesis*, 1981, 1, and for a Mitsunobu reaction review see D.L. Hughes *Organic Reactions* 42, 335. Treatment of the compound (VI) with an intermediate of formula (VII) where LG- is mesyl under

30

a) conditions in the presence of a base (such as K_2CO_3) in DMF can also provide the compound (I). This sequence proceeds with inversion of stereochemistry at the stereogenic carbon under both conditions (LG = OH or OMs).

Compounds of formula (I) can also be prepared in enantioenriched fashion through chiral separation of racemic or enantioenriched material using, but not limited to, preparative chiral SFC technology. For a review, see: Christopher Welch, *et al.*, LCGC North America January 2005, 23(1), 16 - 29.

In addition to the above general synthetic approaches and standard modifications thereto as known in the art, compounds of formula (I) can be obtained by reacting other compounds of formula (I) such as by conversion among the various R^1 , R^3 , R^4 , R^5 , R^6 and R^7 groups. For example, see Larock, R.C. In *Comprehensive Organic Transformations: A Guide to Functional Group Preparations*, VCH Publishers: New York, 1990.

Also within the scope of the invention are novel intermediates described above and in the Examples.

 25 mL, 3.91 mol) with overhead stirring while maintaining the internal temperature below 60 °C with ice-bath cooling. Neat 4-acetylpyridine (100 mL, 0.904 mol) was then added rapidly while maintaining the temperature below 50 °C. Following this addition,

the reaction was allowed to cool to 28 °C and the chiral ruthenium catalyst [N-
[(1*R*,2*R*)-2-(amino-N)-1,2-diphenylethyl]-2,4,6-trimethylbenzenesulfonamido-
N]chloro[(1,2,3,4,5,6-*n*)-1-methyl-4-(1-methylethyl)benzene]ruthenium (CAS#
177552-91-9; for catalyst preparation, see: Uematsu, N.; Fujii, A.; Hashiguchi, S.;
5 Ikariya, T.; Noyori, R.; *J. Am. Chem. Soc.* **1996**, *118*, 4916-4917) (3 g, 4.46 mmol)
was added. The mixture was stirred under house vacuum for 4 h and then overnight
under an atmosphere of nitrogen. The reaction mixture was added dropwise to a
stirred solution of 10% Na₂CO₃ (4 L) and then extracted with EtOAc (3 x 1 L). The
combined EtOAc layers were washed once with brine (1 L), treated with MgSO₄ and
10 Darco G-60 decolorizing charcoal and filtered through a 100 g plug of silica gel
washing with 10% MeOH/EtOAc (1 L). The filtrate was concentrated to provide a
dark oil that crystallized upon standing. The solid was dissolved in warm *t*-butyl
methyl ether (250 mL) and the warm solution was filtered to remove a small amount
of insoluble material. The filtrate was allowed to stir with cooling to room temperature
15 and then to -15 °C. The solids were collected by filtration, washing with cold *t*-butyl
methyl ether and heptane, and then dried under high vacuum to yield (1*R*)-1-(4-
pyridinyl)ethanol as a dark beige solid (62 g, 52.9% yield). This solid material was
96% ee based on chiral HPLC (HPLC conditions: AS-H column, 5% MeOH/CO₂, 40
°C, 140 bar, 2 mL/min). The filtrate was combined with the insoluble solid from the
20 crystallization and concentrated *in vacuo* to yield additional (1*R*)-1-(4-
pyridinyl)ethanol as a dark oil (37.5 g, 32% yield). This oily material was 78% ee
based on chiral HPLC (see HPLC conditions above). ¹H NMR (400 MHz, DMSO-*d*₆):

1.44 (d, 3H, *J* = 6.6 Hz).

25 Step 2: A solution of (1*R*)-1-(4-pyridinyl)ethanol (37 g, 0.3 mol, 78% ee) in MeOH (2
L) was charged with PtO₂ (5 g) under nitrogen atmosphere followed by acetic acid
(19 mL). The mixture was evacuated and purged with hydrogen several times and
then stirred under an atmosphere of hydrogen for 2 d at room temperature. The
mixture was filtered to remove catalyst and the filtrate was concentrated *in vacuo* and
30 triturated with EtOAc to yield a cream-colored solid which was collected by filtration.
The filter cake was dissolved in MeOH (500 mL) and 50% NaOH (15.8 g) was added.
The resulting solution was stirred at 25 °C for 30 min and concentrated. The
resulting solid was triturated with Et₂O (700 mL) and stirred at 25 °C for 30 min, the
solids were removed by filtration and the filtrate was dried over MgSO₄ and filtered
35 again. The final filtrate was concentrated to yield (1*R*)-1-(4-piperidinyl)ethanol (22 g,
57% yield) as a light beige solid. ¹H NMR (400 MHz, CDCl₃): δ 3.50 (quint, 1H, *J* =

Example A

In vivo effects of GPR119 agonists on incretin hormone release and glucose homeostasis in mice

GPR119 agonists improves glucose tolerance in normal mice

Male C57/Bl6 mice of 9 weeks of age were fasted for 16 hrs and randomly grouped (n=10) to receive vehicle (0.5%HPMC/0.1%Tween), the products of Examples 77 and 83 (30mg/kg) or a positive control (10mg/kg), namely vildagliptin, a DPP-IV inhibitor known to stimulate glucose-dependent insulin. Vehicle or compounds were delivered orally *via* a gavage needle (p.o. at 10mls/kg). The effect of the GPR119 agonists on glucose homeostasis was assessed by conducting an oral glucose tolerance test (OGTT; 2g dextrose per kg body weight) one hour after administration of vehicle or test compounds. Whole blood glucose levels were determined prior to compound administration, immediately before and 10, 20, 30, 45, 60, 90 and 120 after glucose administration, using a Glucometer (Freestyle, Therasense).

Table 1 summarizes the glucose excursions during the OGTT as the average baseline corrected glucose area under the curve (cAUC; ± s.e.m.) from the animals in each treatment group. These results illustrate that compounds of the present invention, as demonstrated with the products of Examples 77 and 83 and the positive

control DPP-IV compound significantly lowered the glucose area-under-the curve (AUC) over the 120 minute time course of the experiment:

Table 1: Baseline corrected Glucose area under the curve (cAUC) during an oral glucose tolerance test in C57Bl6/J mice conducted one hour after oral administration of compounds or vehicle:

Treatment	Dose (mg/kg)	Glucose cAUC (mg/dl *min)	% of Vehicle	n	P-value vs Veh
Vehicle		8718 ± 330		10	
Example 77	30	6884 ± 694	21%	10	<0.05
Example 83	30	6754 ± 286	23%	10	<0.05
vildagliptin	10	4185 ± 455	52%	10	<0.0001

10 GPR119 agonists elevate GIP and GLP-1 in normal mice

Male C57/Bl6 mice 10 weeks of age were fasted for 15hrs and randomly grouped (n=6-10) to receive vehicle (0.5%HPMC/0.1%Tween) or a GPR119 agonists of the present invention at 30mg/kg. 1 hr after compound administration blood was collected by cardiac-stick following iso-fluorane anaesthesia. Blood for analysis of plasma levels of total GLP-1 and total GIP was placed in a K₂-EDTA containing tubes supplemented with a DPP-IV inhibitor to prevent degradation of the incretin hormones (30 μ M final concentration). Total GLP-1 was determined using an assay from Meso Scale Discovery (Gaithersburg, Maryland). GIP was determined using an ELISA assay from Linco (St. Charles, Missouri). For each treatment group Table 2 summarizes the average plasma levels of total GLP-1 ($\pm$ s.e.m.) from the number of animals in each treatment group as indicated.

Vehicle		83 ± 13			8
Example 77	30	182 ± 12	<0.0001	2.2	10

5 Review of Examples A and B

These results illustrate that the GPR119 agonists of the present invention, as illustrated by Example 77 and Example 83, increase total circulating GLP-1 and GIP levels 1hr after giving the GPR119 compound compared to vehicle. Treatment with GPR119 agonists resulted in a 3-fold increase in total GLP-1 and 2-3 fold increase in total GIP levels. In humans treated with DPP-IV inhibitor, increases in GLP-1 and GIP levels of similar magnitudes improves β -cell function in patients with type 2 diabetes which can be expected to improved glycemic control following long term treatment.

Tests for agonists of GPR119

- 30 The assay consists of CHO-K1 6CRE-luciferase cells that stably express human GPR119 receptor plated at 15000 cells/well in Dulbecco's Modified Eagle Medium: Nutrient Mixture F-12 (DMEM/F12), 5% Fetal Bovine Serum (FBS), 2 mM l-glutamine in black 384-well assay plates. On the following day, the media is removed by aspiration and replaced with 20 L of DMEM/F12, 2 mM l-glutamine (no FBS) utilizing

a Matrix Multidrop. Test compounds (25 μ L) are then pipetted into the assay plate using a Packard Minitrak. The plates are then incubated for 5 hours at 37 °C. Under subdued light conditions, 15 μ L of a 1:1 solution containing SteadyLite™ and Dulbecco's Phosphate Buffered Saline with 1 mM CaCl₂ and 1 mM MgCl₂ is added to
5 the plates using a Matrix Multidrop. Plates are then sealed with self-adhesive clear plate seals and the amount of luciferase generated is quantified in a Wallac Viewlux™. This assay system was validated using known GPR119 agonists described in WO2004/065380 A1. Compounds are also tested in the same manner against cells without the GPR119 receptor so as to check for false positives.
