

RELAY DEVICE, RELAY METHOD, AND PROGRAM

{Abstract}

Provided are a relay device capable of appropriate access management, a relay method, and a program. The relay device (10): receives a user ID and password for logging on to a server (a desired server) in a financial information system (41), a client information system (42), or an inventory management system (43), on the basis of a connection request from a work terminal (20) (client terminal); and relays a connection without performing user verification using the received user ID and password, when establishing a session with the desired server. The relay device connects to the server using processing that differs from the processing for relaying this connection, confirms the appropriateness of the received user ID and password combination, and establishes a session with the desired server if the user ID and password combination is confirmed to be correct.
