CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims priority to U.S. Provisional Patent Application No. 63/156,073 filed on March 3, 2021, U.S. Provisional Patent Application No. 63/156,063 filed on March 3, 2021, U.S. Provisional Patent Application No. 63/156,067 filed on March 3, 2021, and U.S. Provisional Patent Application No. 63/156,076 filed on March 3, 2021, each of which are hereby incorporated by reference in its entirety.

BACKGROUND

FIELD OF DISCLOSURE

[0002] The present disclosure generally relates to a ducted propulsor with a variable exhaust area.

DESCRIPTION OF THE RELATED ART

[0003] Conventional propulsors have circular or otherwise round cross-sections at both the inlet and outlet ends. While the continuity of the circular shape throughout may allow for smooth air flow through the propulsor, having an outlet with a circular cross-section restricts the ways in which the outlet area can be manipulated. Some conventional examples having the circular outlet cross section use sliding plates to control the outlet area of the propulsor. However, due to the circular cross-section of the outlet, the arrangement of the sliding plates along the circular outlet and the control of the sliding plates is complex.

SUMMARY

[0004] A propulsor fan system is disclosed. In one embodiment, the propulsor fan system includes an exhaust control system and a propulsor fan. The exhaust control system is connected to the propulsor fan and is configured to vary an area of the exhaust of the propulsor fan system. By varying the area of the exhaust, a magnitude of thrust and/or a thrust direction may be adjusted.

[0005] In one embodiment, the exhaust control system includes a first end, a second end, and an exhaust area control mechanism. The first end is connected to the outlet of the

propulsor fan that is configured to generate thrust. The first end has a first cross-section shape that substantially matches a cross-section shape of the outlet of the propulsor fan. However, the second end of the exhaust control system has a cross-section shape that is different from the first cross-section shape. The cross-section shape of the second end of the exhaust control system reduces the complexity of the exhaust area control mechanism that is configured to vary an area of the second end of the exhaust control system.

[0006] In one embodiment, the exhaust control system connects to the propulsor fan and includes a variable length. An exhaust area control mechanism disposed at the end of the exhaust control system that connects to the propulsor fan is configured to vary the length of the exhaust control system. As the length of the exhaust control system changes, an area of the exhaust of the propulsor fan changes.

BRIEF DESCRIPTION OF DRAWINGS

[0007] FIG. 1 is a perspective view of a propulsor fan according to one embodiment.

[0008] FIG. 2A is a first exploded view of the propulsor fan according to one embodiment.

[0009] FIG. 2B is a second exploded view of the propulsor fan according to one embodiment.

[0010] FIGs. 3A, 3B, 3C, and 3D respectively illustrate a perspective view, a front view, a side view, and a cross-section view of a duct lip of the propulsor fan according to one embodiment.

[0011] FIGs. 4A, 4B, 4C, and 4D respectively illustrate a perspective view, a front view, a cross-section view, and a perspective view of the cross-section of a nose cone of the propulsor fan according to one embodiment.

[0012] FIGs. 5A and 5B respectively illustrate a front view and a side view of a hub of the propulsor fan according to one embodiment.

[0013] FIGs. 6A and 6B respectively illustrate a perspective view and a front view of a blade fan of the propulsor fan according to one embodiment.

[0014] FIGs. 7A, 7B, 7C, and 7D respectively illustrate a perspective view, a front view, a side view, and a top view of a blade included in the blade fan shown in FIGs. 6A and 6B according to one embodiment.

[0015] FIGs. 8A, 8B, and 8C respectively illustrate a perspective view, a front view, and a side view of a locking ring of the propulsor fan according to one embodiment.

[0016] FIGs. 9A and 9B respectively illustrate a perspective view and a side view of a

tension ring of the propulsor fan according to one embodiment.

[0017] FIGs. 10A, 10B, and 10C respectively illustrate a perspective view, a front view, and a side view of an inner duct body housing of the propulsor fan according to one embodiment.

[0018] FIGs. 11A, 11B, 11C, and 11D respectively illustrate a perspective view, a front view, a side view, and a cross section view of a stator of the propulsor fan according to one embodiment.

[0019] FIGs. 12A, 12B, 12C, and 12D respectively illustrate a perspective view, a front view, a side view, and a cross section view of a tail cone of the propulsor fan according to one embodiment.

[0020] FIGs. 13A, 13B, and 13C respectively illustrate a perspective view, a front view, and a side view of a circumferential drive system of the propulsor fan according to one embodiment.

[0021] FIG. 14 illustrates a circumferential drive system of the propulsor fan according to another embodiment.

[0022] FIG. 15A and 15B respectively illustrate a front view and a perspective view of an array of propulsor fans according to one embodiment.

[0023] FIG. 16 illustrates an example application of an array of propulsor fans according to one embodiment.

[0024] FIGs. 17A, 17B, and 17C respectively illustrate a front view, a side view, and a top view of a hover drone including an array of propulsor fans according to one embodiment.

[0025] FIGs. 18A, 18B, and 18C respectively illustrate a front view, a side view, and a top view of a cinema drone including an array of propulsor fans according to one embodiment.

[0026] FIGs. 19A, 19B, and 19C respectively illustrate a front view, a side view, and a top view of a transporter aircraft including an array of propulsor fans according to one embodiment.

[0027] FIGs. 20A, 20B, and 20C respectively illustrate a front view, a side view, and a top view of a vertical takeoff and landing (VTOL) aircraft including an array of propulsor fans according to one embodiment.

[0028] FIGs. 21A, 21B, and 21C respectively illustrate a front view, a side view, and a top view of a delivery drone including an array of propulsor fans according to one embodiment.

- [0029] FIG. 22 illustrate a first perspective view of the propulsor fan system having an exhaust control system according to a first embodiment.
- [0030] FIG. 23 illustrates a second perspective view of the propulsor fan system having the exhaust control system according to the first embodiment.
- [0031] FIG. 24 illustrates a cross-section view of the propulsor fan system having the exhaust control system according to the first embodiment.
- [0032] FIGs. 25A, 25B, and 25C illustrate different states of the exhaust control system according to the first embodiment.
- [0033] FIGs. 26A, 26B, and 26C illustrate cross-section views of a propulsor fan system having an exhaust control system according to a second embodiment.
- [0034] FIG. 27 illustrates a detailed view of the exhaust control system according to the second embodiment.
- [0035] FIG. 28 illustrates a cross-section view of a propulsor fan system having an exhaust control system according to a third embodiment.

DETAILED DESCRIPTION

[0036] The Figures (FIGS.) and the following description describe certain embodiments by way of illustration only. One skilled in the art will readily recognize from the following description that alternative embodiments of the structures and methods illustrated herein may be employed without departing from the principles described herein. Reference will now be made in detail to several embodiments, examples of which are illustrated in the accompanying figures. It is noted that wherever practicable similar or like reference numbers may be used in the figures and may indicate similar or like functionality.

Propulsor Fan and Drive System

[0037] In one embodiment, a propulsor fan and drive system is disclosed. Generally, the propulsor fan and drive system are configured to generate thrust. The propulsor fan and drive system may generate thrust for various applications from aircraft to hand tools such as a leaf blower. However, the applications of the propulsor fan and drive system are not limited those described herein.

[0038] FIG. 1 illustrates a perspective view of a propulsor fan 100 according to one embodiment. Generally, the propulsor fan 100 includes a plurality of components that collectively reduce noise emitted by the propulsor fan 100 during thrust generation. Thus, the propulsor fan 100 reduces noise pollution. For example, the propulsor fan 100 includes a tensioned blade fan that includes a plurality of fan blades. By tensioning the blade fan, the

angle of the fan blades is maintained to be substantially the same whether the propulsor fan is generating maximum thrust or is not operating (e.g., is at rest). As a result, noise pollution is reduced and thrust efficiency is increased compared to conventional propulsor fans. The propulsor fan 100 reduces noise pollution given that the angle of the fan blades is maintained within a predetermined tolerance range. For example, the propulsor fan 100 emits noise that is less than 65 dBA at 300 feet sideline/5,000 lbf.

[0039] FIG. 2A illustrates a first exploded view of the propulsor fan 100 and FIG. 2B illustrates a second exploded view of the propulsor fan 100 according to one embodiment. The propulsor fan 100 includes a plurality of different components as shown in FIGs. 2A and 2B. In one embodiment, the propulsor fan 100 includes a duct lip 201, a nose cone 203, a hub 205, a blade fan 209, a locking ring 210 (shown in FIGs. 8A to 8C), a tension ring 211, a motor 215, a body housing 217, a plurality of outer casings 213A and 213B, a stator 219, and a tail cone 221. Other embodiments of the propulsor fan 100 may include other components than shown in FIGs. 2A and 2B. In one embodiment, the duct lip 201, the outer casings 213, and a portion of the stator 219 (e.g., 219C) collectively form a circulation duct that houses the components of the propulsor fan, as shown in FIG. 1.

[0040] FIGs. 3A, 3B, 3C, and 3D respectively illustrate a perspective view, a front view, a side view, and a cross-section view of a duct lip 201 of the propulsor fan 100 according to one embodiment. In one embodiment, the duct lip 201 is configured to provide a clean inflow of air to the propulsor fan 100. The duct lip 201 is configured to connect to the body housing 217 in one embodiment. The duct lip 201 may include a plurality of mounting holes 223 on a rear surface of the duct lip 201 as shown in FIG. 2B. Fasteners (e.g., nuts and bolts, rivets, etc.) are placed in the mounting holes 223 to connect the duct lip 201 to a first end 1001 of the body housing 217 as will be further described below.

[0041] The duct lip 201 may comprise a plurality of panels that collectively form the duct lip 201. For example, the duct lip 201 may include a first plurality of panels that collectively form an inner surface 309 of the duct lip 201 and include a second plurality of panels that collectively form an outer surface 307 of the duct lip 201 such that the duct lip 201 has a hollow center through which air is channeled to the blade fan 209. The first and second plurality of panels may be connected to each other via various fastening means such as fasteners (e.g., screws, nuts, bolts) or via welding. The first and second plurality of panels may be made of metal such as aluminum or titanium or composite such as carbon fiber. Alternatively, the duct lip 201 may be made of a single piece of material and may be 3D printed for example.

[0042] In one embodiment, the duct lip 201 includes a first end 303 (e.g., an inlet) and a second end 305 (e.g., an outlet). The first end 303 receives air and the air exits the second end 305. As shown in FIG. 3C, a diameter of the first end 303 is less than a diameter of the second end 305, but may be the same in other embodiments. The diameters of the first end 303 and second end 305 of duct lip 201 are dependent on the application of the propulsor fan 100. For example, the diameters of the first end 303 and the second 305 of the duct lip 201 are larger for aircraft applications compared to leaf blower applications.

[0043] FIG. 3D is a cross-section view of the duct lip 201 along plane A-A' shown in FIG. 3B according to one embodiment. As mentioned previously, the duct lip 201 includes an outer surface 307 and an inner surface 309. The outer surface 307 and the inner surface 309 both extend from the first end 303 of the duct lip 201 towards the second end 305 of the duct lip 201. Air flows through the inner surface 309 of the duct lip 201. A curvature 311A of the inner surface 309 of the duct lip 201 and a curvature 311B of the outer surface 307 of the duct lip 301 are designed to balance various factors such as different conditions (e.g., flying conditions such as cruise, takeoff, and landing) and Reynolds number. Those skilled in the art will be able to tailor the duct lip radius for favorable pressure gradients across speed regimes and flight modes of interest.

[0044] FIGs. 4A, 4B, 4C, and 4D respectively illustrate a perspective view, a front view, a cross-section view, and a perspective view of the cross-section of a nose cone 203 of the propulsor fan 100 according to one embodiment. The nose cone 203 is configured to modulate oncoming airflow behavior and reduce aerodynamic drag. The nose cone 203 may also be configured with an impeller to air in cooling air mass flow without contributing significantly to broadband or tonal noise.

[0045] In one embodiment, the nose cone 203 is configured to connect to the motor 215 with the hub 205 disposed between the nose cone 203 and the motor 215. The nose cone 203 may include a plurality of mounting holes on a rear surface of the nose cone 203 as shown in FIG. 2B. Fasteners 207 (e.g., nuts and bolts, rivets, etc.) are placed in the mounting holes to connect the nose cone 203 to a first end of the hub 205. As will be further described below, the fasteners 207 extend through the hub 205 and connect to a first end of the motor 215.

[0046] In one embodiment, the nose cone 203 is conical in shape. However, the nose cone 203 can have different shapes in other embodiments. As shown in FIGs. 4A to 4D, the nose cone 203 includes an opening 403 (e.g., a hole) at a first end of the nose cone 203. As the blade fan 209 spins, air is pulled through the opening 403 in the nose cone 203 to cool the motor 215. The secondary mass flow required to cool inner components sizes the inner

diameter of the nose cone 203 opening 403. Those skilled in the art will be able to derive this diameter subject to thermal requirements of different electric motors and the air required to cool them at the most constraining condition, typically max continuous operation.

[0047] FIG. 4C is a cross-section view of the nose cone 203 along plane B-B' shown in FIG. 4B according to one embodiment. In one embodiment, the nose cone 203 is not solid and includes a cavity. For example, the nose cone 203 comprises an air channel 405 in one embodiment. The air channel 405 extends from the opening 403 in the nose cone 203 to a plurality of openings 407 that are disposed around the circumference of the second end (e.g., the rear surface) of the nose cone 203. Air flows from the opening 403 through the air channel 405 and exits the plurality of openings 407 to cool the motor 215. In one embodiment, the air channel 405 is formed between an outer surface 409 of the nose cone 203 and a protrusion 411 formed within the nose cone 211 as shown in FIGs. 4C and FIG. 4D.

[0048] In one embodiment, the protrusion 411 protrudes from the second end of the nose cone 203 inward towards the opening 403 of the nose cone 203. The protrusion 411 may have a similar shape as the nose cone 203. For example, the protrusion 411 is also conically shaped. However, in other embodiments the protrusion 411 may have a different shape than the nose cone 203.

[0049] Generally, the protrusion 411 has a size and shape that is tuned for mass air flow to cool the motor 215. In one embodiment, the protrusion 411 includes an air channel 413 formed through the protrusion 411 through which air flows from an opening 415 of the air channel 413 to an opening 417 on the second end of the nose cone 203. In one embodiment, a center of the air channel 413 is aligned with a center of the opening 403 in the nose cone 203.

[0050] FIGs. 5A and 5B respectively illustrate a front view and a side view of a hub 205 of the propulsor fan 100 according to one embodiment. The hub 205 is the central portion of the propulsor fan 100 and is disposed at a center of the blade fan 209 as will be further described below. The hub 205 is configured to connect to the nose cone 203, the locking ring 210, and the motor 215 in one embodiment.

[0051] As shown in FIGs. 5A to 5C, the hub 205 is cylindrical in shape in one example. The diameter of a first end 507 of the hub 205 matches a diameter of the second end of the nose cone 203 in one embodiment. The first end 507 (e.g., a front surface) of the hub 205 includes a plurality of mounting holes 501A to 501F that are formed through a thickness of the hub 205. The position of the mounting holes 501 is such that the mounting holes 501 are

aligned with the mounting holes of the nose cone 203 when the second end of the nose cone 203 is mated to the first end 507 of the nose hub 205. The fasteners 207 are configured to pass through the mounting holes 501A to 501F and connect to a first end (e.g., a front surface) of the motor 215. For example, the fasteners 207 screw into threaded holes 225 on the first end of the motor 215.

[0052] In one embodiment, the hub 205 also includes a plurality of openings 503 that extend through the thickness of the hub 205 such as openings 503A and 503B. The plurality of openings 503 have a shape and size that match (e.g., are the same) as the openings 407 in the rear surface of the nose cone 203. The openings 503 are configured to align with the openings 407 in the rear surface of the nose cone 203 when the nose cone 203 and the hub 205 are mated to each other. Thus, air exiting the openings 407 of the nose cone 203 flow through the openings 503 included in the hub 205. In one embodiment, the plurality of openings 503 included in the hub have different sizes. For example, opening 503A is smaller than opening 503B.

[0053] In one embodiment, the hub 205 also includes an opening 505 that extends through a thickness of the hub 205. The opening 505 is positioned at a center of the hub 205. In one embodiment, a center of the opening 205 is configured to be aligned with a center of the air channel 413 of the nose cone 203. Thus, air flow exiting the air channel 413 of the nose cone 203 flows through the opening 505 in the hub 205 to cool the motor 215.

[0054] In one embodiment, a second end 511 of the hub 205 that is opposite the first end 507 includes a connection mechanism 509 around the outer circumference of the second end 511 of the hub 205. The connection mechanism 509 is configured to connect the hub 205 to the locking ring 210. In one embodiment, the connection mechanism 509 is threads such that the hub 205 screws into the locking ring 210. Once the hub 205 is connected to the locking ring 210, the locking ring 210 surrounds the outer circumference of the hub 205. The motor 215 is configured to mate to the outer face of the second end 511 of the hub 211.

[0055] In one embodiment, the hub 205 includes an intermediate area 511 disposed between the first end 507 and second end 511 of the hub 205. In one embodiment, the blade fan 209 is configured to be disposed around the circumference of the intermediate area 511 while the hub 205 is placed through a center of the blade fan 209.

[0056] FIGs. 6A and 6B respectively illustrate a perspective view and a front view of a blade fan 209 of the propulsor fan 100 according to one embodiment. As shown in FIGs. 6A to 6B, the blade fan 209 includes a plurality of blades 601. The total number of blades 601 included in the blade fan 209 is significantly more than the number of blades included in a

conventional propulsor fan that has 2 to 5 blades. In one embodiment, the blade fan 209 may include a range of blades 601 from 20 blades to 840 blades. However, any number of blades greater than five can be used. Generally, the total number of blades 601 included in the blade fan 209 is dependent on the application. In one embodiment, the material for the blades of the many-bladed fan is also dependent on the type of application of the many-bladed fan. The blades may be made of metal such as aluminum or titanium or a composite such as carbon fiber.

[0057] In one embodiment, the blade fan 209 reduces overall blade noise as the blade fan 209 spins at a low tip speed (around 300-450 ft/sec). As described herein, the tensioned fan blade 209 allows many more blades to exist within mechanical material limits and still achieve ultrasonic signatures and low subsonic tip speeds. Furthermore, the higher number of blades 601 raises the tonal noise into ultrasonic frequencies outside the upper limit of human audibility ($\geq 16,000$ Hz for typical adults). Furthermore, the low blade loading due to the higher blade count also reduces the severity of vortex-to-vortex collisions which cause broadband noise.

[0058] As shown in FIGs. 6A and 6B, the plurality of blades 601 are arranged to form a circular ring shape with a hollow center where the hub 205 is disposed. Each blade 601 is positioned such that at least a portion of the leading edge and trailing edge of the blade 601 are overlapped by neighboring blades 601. For example, a leading edge of a given blade is overlapped by the trailing edge of a blade to the left of the given blade and a trailing edge of the given blade is overlapped by a leading edge of a blade to the right of the given blade. The overlapping arrangement of the plurality of blades 601 provides increased solidity to perform work on the incoming stream of air. Tuning of this solidity takes into account localized aerodynamic effects and can be tuned to account for Reynolds number effects that may affect laminar attachment of flow in and between blades.

[0059] FIGs. 7A, 7B, 7C, and 7D respectively illustrate a perspective view, a front view, a side view, and a top view of a blade 601 included in the blade fan 209 shown in FIGs. 6A and 6B according to one embodiment. In one embodiment, each blade 601 comprises a first locking end 605, a second locking end 603, and an airfoil 607 disposed between the first locking end 605 and the second locking end 603. The blade 601 may include other features than those described herein in other embodiments.

[0060] In one embodiment, the first locking end 605 is located at the tip of the blade 601. The first locking end 605 is configured to be inserted into the tension ring 211 and lock the blade 601 into the tension ring 211 such that the tip of the blade 601 is tensioned. By

tensioning the tips of the blades 601, the pitch (e.g., angle) of the tips of the blades 601 is substantially the same during thrust generation or while the propulsor fan 100 is at rest thereby reducing noise pollution.

[0061] As shown in FIGs. 7A to 7D, the first locking end 605 is rectangular in shape with chamfered edges, but other shapes can be used for the first locking end 605. In one embodiment, the first locking end 605 has a width and thickness that is greater than a width and thickness of the tip of the airfoil 607. However, in other embodiments the first locking end 605 may be the same width or narrower than the tip of the blade 601. Those skilled in the art will tailor edges, chamfers, surfacing, and bezeling to account for localized stresses and strains due to tensioning.

[0062] In one embodiment, the second locking end 603 is located at the root of the blade 601. The second locking end 606 is configured to be inserted into the locking ring 210 and lock the blade 601 into the locking ring 210. By tensioning the roots of the blades 601, the pitch (e.g., angle) of the roots of the blades 601 is substantially the same during thrust generation or while the propulsor fan 100 is at rest thereby reducing noise pollution. As shown in FIGs. 7A to 7D, the second locking end 603 has a plurality of different surfaces (e.g., straight surfaces and curved surfaces) to increase the surface area that contacts the locking ring 210 to reduce blade deflection. In one embodiment, the second locking end 603 has a width that is greater than the root of the blade 601 and is wider than a width of the first locking end 605. However, in other embodiments the second locking end 603 may be the same width or narrower than the root of the blade 601.

[0063] The airfoil 607 is disposed between the first locking end 605 and the second locking end 603. In one embodiment, the airfoil 607 comprises a geometric twist 609 in the airfoil 607. The geometric twist 609 is a change in airfoil angle of incidence measured with respect to the root of the blade 601. That is, the airfoil 607 includes a plurality of different angles of incidence across the length of the airfoil 607 due to the geometric twist 609. For example, the airfoil 607 may have a first angle of incidence at a first side of the geometric twist 609 (e.g., below the geometric twist 609 in FIGs. 7A to 7C) and may have a second angle of incidence at a second side of the geometric twist 609 (e.g., above the geometric twist 609 in FIGs. 7A to 7C)

[0064] As a result of the geometric twist 609, the first locking end 605 and the second locking end 609 are misaligned from each other when viewed from the top view of the blade 601 as shown in FIG. 7D. In one embodiment, the geometric twist 609 begins at a portion of the airfoil 607 that is closer to the root of the blade 601 than the tip of the blade 601. The

geometric twist 609 between the root and tip chord may vary as much as 45 degrees.

[0065] Referring back to FIGs. 6A, and 6B, in one embodiment the blades 601 are positioned such that the second locking ends 603 are arranged in parallel with respect to each other around a circumference thereby forming the hole at the center of the blade fan 209. As a result, the first locking ends 605 are also arranged in parallel with each other and the airfoil 607 of each blade 601 overlaps another airfoil of an adjacent blade 601 due to the geometric twist 609 in the airfoil 607.

[0066] FIGs. 8A, 8B, and 8C respectively illustrate a perspective view, a front view, and a side view of a locking ring 210 of the propulsor fan 100 according to one embodiment. Generally, the locking ring 210 is configured to connect to the blade fan 209 and the hub 205 and beneficially tensions the roots of the blades 601. Thus, the blades 601 of the blade fan 209 are tensioned at both the tips and the roots to maintain the angle of the blades 601 during operation. The locking ring 210 may be made of metal such as aluminum or titanium or a composite such as carbon fiber.

[0067] The locking ring 210 includes a first end 801 and a second end 803. In one embodiment, the first end 801 has a diameter that is less than a diameter of the second end 803 thereby forming a conical shape. The tailoring of this shape is dictated by the needs of the primary internal flow to the fan (i.e., not the cooling flow) and may also take into account any boundary layer pressure gradients along the center body in the presence of the fan. In one embodiment, the first end 801 of the locking ring 210 is configured to directly connect the blade fan 209 to the locking ring 210 thereby locking the blade fan 209 to the locking ring 210. The first end 801 of the locking ring 210 includes a plurality of locking teeth 805. In one embodiment, the locking teeth 805 are protrusions that extend from a body of the locking ring 210 at an angle with respect to a reference that is perpendicular to the second end 803 of the locking ring.

[0068] A plurality of slots 807 are formed the locking teeth 805. For example, a slot 807 is formed between a pair of locking teeth including locking tooth 805A and locking tooth 805B. The slots 807 have a width and depth that match dimensions of the second locking ends 603 of the blade fan 209. The slots 807 extend partially through the thickness of the locking ring 210 such as $\frac{3}{4}$ of the thickness of the locking ring 210, for example.

[0069] In one embodiment, each of the plurality of slots 807 is configured to connect to a corresponding one of the plurality of blades 601 of the blade fan 209. In particular, the second locking end 603 of each blade 601 is inserted into one of the slots 807 thereby securing the blade 601 to the locking ring 210 through the direction contact of the surfaces of

the second locking end 603 and the locking teeth 805 that form the slots. In one embodiment, a fastener such as an epoxy is also applied to the second locking end 603 of each blade 601 to further strengthen the connection between the blades 601 and the locking ring 210. By locking the second locking end 603 of the blades 601 to the locking ring 210, the pitch of the roots of the blades 601 is maintained to be substantially the same during thrust generation or at rest thereby reducing audible noise that is emitted from the propulsor fan 100 since changes in pitch can be perceivable to the human ear.

[0070] In one embodiment, the second end 803 of the locking ring 210 includes a connection mechanism 809 at an inner circumference of the second end 803 of the locking ring 210. The connection mechanism 809 is configured to connect the locking ring 210 to the connection mechanism 509 of the hub 205, for example. In one embodiment, the connection mechanism 809 is threads that match the threads of the connection mechanism 509 of the hub 205 thereby allowing the hub 205 to be screwed into the locking ring 210. Since the motor 215 is connected to the hub 205, the hub 205 spins thereby causing the locking ring 210 and the blade fan 209 to also spin.

[0071] FIGs. 9A and 9B respectively illustrate a perspective view and a side view of a tension ring 211 of the propulsor fan 100 according to one embodiment. The tension ring 211 is configured to connect to the blade fan 209 by being placed around the circumference of the blade fan 209. More specifically, the tension ring 211 is configured to connect to all of the first locking ends 605 of the blade fan 209 according to one embodiment. By locking the first locking ends 605 of the blades 601 to the tension ring 211, the pitch of the tips of the blades 601 is maintained to be substantially the same during thrust generation and at rest thereby reducing audible noise that is emitted from the propulsor fan 100 since changes in pitch can be perceivable to the human ear. Thus, pretensioning the blades 601 using the tension ring 211 reduces inefficiencies due to tip gaps. In one embodiment, the tension ring 211 is made of metal such as aluminum or titanium or a composite such as carbon fiber. However, other materials may be used in other embodiments.

[0072] As shown in FIGs. 9A and 9B, the tension ring 211 includes a first end 903 and a second end 905. In one embodiment, the first end 903 has a diameter that is substantially the same as a diameter of the second end 905. The body 909 of the tension ring 211 is disposed between the first end 903 and the second end 905.

[0073] In one embodiment, the body 909 of the tension ring 211 includes a plurality of openings (e.g., slots) 907 that extend through the entire thickness of the tension ring 211. Each opening 907 is configured to connect to a first locking end 605 of one of the plurality of

blades 601. Thus, there is a one-to-one relationship between each opening 907 of the tension ring 211 and the blades 601. In one embodiment, a fastener such as an epoxy is also applied to the first locking end 605 of each blade 601 to further strengthen the connection between the blades 601 and the tension ring 211.

[0074] In one embodiment, the plurality of openings 907 are formed at an angle with respect to a reference that is perpendicular to the first end 903 or second end 905. The angle in which the openings 907 is formed matches the pitch of the first locking ends 605 of the blades 601. The dimensions of the openings 907 substantially match the dimensions of the first locking ends 605 such that the first locking ends 605 are locked to the tension ring 211 once the first locking ends 605 are inserted into the openings 907 of the tension ring 211 and the first locking ends 605 are in direct contact with the tension ring 211.

[0075] FIGs. 10A, 10B, and 10C respectively illustrate a perspective view, a front view, and a side view of an inner duct body housing 217 (hereinafter referred to a “body housing”) of the propulsor fan 100 according to one embodiment. In one embodiment, the body housing 217 is configured to house (e.g., partially surround) components of the propulsor fan 100. For example, the blade fan 209, hub 205, tension ring 211, locking ring 210, and motor 215 are housed within the body housing 217 in one embodiment. Other components of the propulsor fan 100 may be contained within the body housing 217 in other embodiments. In one embodiment, the body housing 217 is made of metal such as aluminum or titanium or a composite such as carbon fiber. However, other materials may be used in different embodiments.

[0076] In one embodiment, the body housing 217 is cylindrical in shape and includes a first end 1001 (e.g., an inlet) and a second end 1003 (e.g., an outlet). The first end 1001 has a diameter that is greater than a diameter of the second end 1003 in one embodiment. The first end 1001 includes a plurality of mounting holes 1005 that are formed around the circumference of the first end 1001 of the body housing 217. In one embodiment, the first end 1001 of the body housing 217 is configured to connect to the second end 305 of the duct lip 201 such that the mounting holes 223 in the duct lip 201 are aligned with the mounting holes 1005 of the body housing 217. As previously mentioned above, fasteners 207 may be used to secure the duct lip 201 to the first end 1001 of the duct body housing 217.

[0077] In one embodiment, the second end 1003 of the body housing 217 includes a plurality of mounting holes 1007 that are formed around the circumference of the second end 1003 of the body housing 217. In one embodiment, the second end 1003 of the body housing 217 is configured to connect to a first end (e.g., an inlet) the stator 219. While the second end

1003 of the body housing 217 is connected to the first end of the stator 219, the mounting holes 1007 in the second end 1003 of the body housing 217 are aligned with mounting holes on the first end of the stator 219. Fasteners (e.g., nuts, bolts, rivets) may be used to secure the second end 1003 of the body housing 217 to the first end of the stator 219.

[0078] In one embodiment, the body housing 217 includes a plurality of intermediate portions 1009 that are each configured to house different components of the propulsor fan. The plurality of intermediate portions 1009 include a first intermediate portion 1009A that extends from the first end 1001 and a second intermediate portion 1009B that extends from the second end 1003. The intermediate portions 1009 of the body housing 217 are disposed between the first and second ends 1001, 1003 of the body housing 217.

[0079] As shown in FIG. 10C, the first intermediate portion 1009A has a diameter that is different than a diameter of the second intermediate portion 1009B. For example, the diameter of the first intermediate portion 1009A is greater than the diameter of the second intermediate portion 1009B. Furthermore, the first intermediate portion 1009A has a diameter that is less than the first end 1001 and the second intermediate portion 1009B has a diameter that is less than the second end 1003.

[0080] In one embodiment, the first intermediate portion 1009A is configured to house the hub 205, the blade fan 209, the locking ring 210, and the tension ring 211. Since the tension ring 211 has the largest diameter of the components housed in the first intermediate portion 1009A, the diameter 1009A of the first intermediate portion 1009A is based on the diameter of the tension ring 211. In one embodiment, the diameter of the first intermediate portion 1009A is substantially the same as the diameter of the tension ring 211 thereby allowing the tension ring 211 to be securely fastened within the first intermediate portion 1009A due to a press fit, for example.

[0081] In one embodiment, the second intermediate portion 1009B is configured to house the motor 215 and a portion of the stator 219. The length of the second intermediate portion 1009B is based on a length of the motor 215 and a length of the portion of the stator 219 that are housed in the intermediate portion. The second intermediate portion 1009B has a length that is at least as long as the motor 215 and the portion of the stator 219 in order to contain the motor 215 and the portion of the stator 219 in the second intermediate portion 1009B. In one embodiment, the diameter of the second intermediate portion 1009B is based on the mass air flow of air entering and exiting the stator 219. Those skilled in the art will be able to tailor the diameter in order to induce favorable pressure gradients across a plurality of design speeds of interest to minimize flow separation or swirl. The inner cavity of the second

portion 1009B may also be tuned to reduce noise.

[0082] FIGs. 11A, 11B, 11C, and 11D respectively illustrate a perspective view, a front view, a side view, and a cross section view of a stator 219 of the propulsor fan 100 according to one embodiment. In one embodiment, the stator 219 comprises a plurality of stator blades 219A, a motor housing 219B, and a stator housing 219C. The stator 219 may include other components than those shown in FIGs. 11A to 11D in other embodiments.

[0083] In one embodiment, the motor housing 219B is cylindrical in shape and includes a first end 1101 and a second end 1103 as shown in FIG. 11D. FIG. 11D illustrates a cross-section view of the stator 219 along plane C-C' in FIG. 11B according to one embodiment. As shown in FIG. 11D, the motor housing 219B includes a cavity 1105 disposed between the first end 1101 and the second end 1103. The cavity 1105 may extend from the first end 1101 towards the second end 1103, but does not extend to the second end 1103. In one embodiment, the cavity 1105 is configured to house the motor 215. That is, the motor 215 is placed within the cavity 1105 of the motor housing 219B. Thus, the shape and size of the cavity 1105 is dependent on the shape and size of the motor 215. Since the motor 215 is placed within the cavity 1105 and the motor 215 is indirectly connected to the hub 205, the stator 219 also functions as a structural component to support the hub 205 and other components of the propulsor 100.

[0084] In one embodiment, the motor housing 219B includes a hole 1113 through a center of the motor housing 219B as shown in FIGs. 11B and 11D. The diameter of the hole 1113 is less than a diameter of the motor 215 to prevent the motor 215 from falling through the hole 1113. The hole 1113 is placed in the motor housing 219B to aid in heat dissipation thus cooling the motor 215.

[0085] Referring to FIG. 11B, the stator 219 includes a plurality of stator blades 219. The stator blades 219A extend radially from the motor housing 219B. That is, the root of each blade 219A is connected to the motor housing 219B and the airfoil of the stator blade 219 extends outward away from the motor housing 219B. In one embodiment, each blade 219A extends away from the motor housing 219B at an angle measured with respect to a reference line that extends perpendicular from a point on the motor housing 219B from which the stator blade 219A extends.

[0086] In one embodiment, the stator blades 219 conduct heat away from the motor 215. Since the blades 219 contact the motor housing 219B which houses the motor 215, air that passes over the blades 219 dissipates heat generated by the motor 215. In one embodiment, the arrangement of the blades 219 also reduces noise generated by the blade fan

209 and controls thrust generated by the propulsor fan 100. The blade count of the stator blades 219 can be selected so that the harmonics of the stator cancel out harmonics of the blade fan 209. For ultrasonic fans, because of the localized low Reynolds number along the blade, those skilled in the art will see that the blade fan 209 may carry a plurality of blades 601 that is higher in count (e.g., total amount) than the stator blades 219 for favorable acoustics. This may vary anywhere from 50% to 200% more blades for a particular set of design tones.

[0087] In one embodiment, the stator housing 219C is configured to house the stator blades 219 and the motor housing 219B. That is, the stator blades 219 are placed within the stator housing 219C such that the stator housing 219C surrounds the circumference of the blades 219. In one embodiment, the stator housing 219C includes a first end 1107 (e.g., an inlet) and a second end 1109 (e.g., an outlet). As shown in FIG. 11C, the first end 1107 has a diameter that is greater than a diameter of the second end 1109. Thus, the stator housing 219C may have a conical shape. However, the stator housing 219C may have other shapes in other embodiments.

[0088] Referring to FIG. 11D, in one embodiment the tips of the blades 219A are in contact with an inner surface 1111 of the stator housing 219C. Thus, the blades 219A of the stator are stationary. By contacting the blades 219A with the inner surface 1111 of the stator housing 219C, the position of each blade 219A is static.

[0089] FIGs. 12A, 12B, 12C, and 12D respectively illustrate a perspective view, a front view, a side view, and a cross section view of a tail cone 221 of the propulsor fan 100 according to one embodiment. The tail cone 221 is configured to produce the correct change of area of the stator housing 219C through which the air exits the propulsor fan 100 in one embodiment. The tail cone 221 may be made of metal such as aluminum or titanium or may be made of a composite such as carbon fiber.

[0090] The tail cone 221 includes a first end 1201 (e.g., an inlet) and a second end 1203 (e.g., an outlet). In one embodiment, the first end 1201 comprises a diameter that is greater than a diameter of the second end 1203. In one embodiment, the diameter of the tail cone 221 is different across a length of the tail cone 221. As shown in FIG. 12C, the diameter of the tail cone 221 reduces from the first end 1201 towards the second end 1203 until an intermediate point 1205 is reached. From the intermediate point 1205 to the second end 1203, the diameter of the tail cone 221 is relatively constant.

[0091] In one embodiment, the first end 1201 of the tail cone 221 is configured to connect to the second end 1103 of the motor housing 219B of the stator 219. Thus, the

diameter of the second end 1201 of the tail cone 221 substantially matches a diameter of the second end 1103 of the motor housing 219B of the stator 219. In one embodiment, the first end 1201 of the tail cone 221 includes a mounting surface 1209 that mates with (e.g., contacts) the second end 1103 of the motor housing 219B. The mounting surface 1209 may be attached to the motor housing 219B using fasteners for example. However, other attachment mechanisms may be used in other embodiments.

[0092] Referring to FIG. 12D, a cross-section view of the tail cone 221 along plane D-D' shown in FIG. 12B is shown. In one embodiment, the tail cone 221 includes a cavity 1207 formed through the length of the tail cone 221 starting from the first end 1201 of the tail cone to the second end 1203 of the tail cone. Shaping of the aft end of the tail cone 221 is governed by exhausted secondary flow from the interior of the tail cone 221 with respect to the expansion of the jet following the blade disk and/or stator.

[0093] In one embodiment, the propulsor fan 100 includes a center hub driven motor 215. That is, a single motor 215 is used to drive the propulsor fan 100 in one embodiment. An example motor used for the propulsor fan 100 is an electric motor. However, other types of motors such as a gas motor or jet turbine may be used in the propulsor fan 100 in other embodiments. Generally, different motor types and sizes may be used depending on the application of the propulsor fan 100.

Multi-Motor Drive System

[0094] In another embodiment, the propulsor fan 100 may be driven by a plurality of motors rather than just a single motor 215 described above. FIGs. 13A, 13B, and 13C respectively illustrate a perspective view, a front view, and a side view of a circumferential multi-motor drive system of the propulsor fan 100 according to one embodiment.

[0095] Instead of driving thrust with a single motor 215, a plurality of auxiliary motors 1303A, 1303B, 1303C, and 1303D are placed within the body housing 217 to drive the blade fan 209 via a ring gear 1303. The plurality of auxiliary motors 1303 may be electric motors in one embodiment. However, other types of motors may be used.

[0096] The ring gear 1303 may be connected to the tension ring 211 in one embodiment. The auxiliary motors 1303 may replace the motor 215 described above or may be used in conjunction with the motor 215. Multi-motor redundancy allows for exceptional fault tolerance of the propulsor fan 100 system. With four auxiliary motors 1303 for example, the loss of a single auxiliary motor is nearly inconsequential to the propulsor's normal operation. Even with the loss of another motor, the remaining auxiliary motors 1303 may be overspeed to generate sufficient thrust.

[0097] As shown in FIGs. 13A to 13C, the auxiliary motors 1301A to 1301D are spread radially around the circumference of the propulsor 100 instead of all being located at the hub 205 of the propulsor. The end of each auxiliary motor 1301 includes a gear that is connected to the ring gear 1303. The radial arrangement need not be limited to equal angular spacing. For example, the fan may be driven by three motors which are biased toward the lower quadrant of the duct. Furthermore, rather than requiring the stator 219 to support the hub 205 to support the centrally housed motor 215, the propulsor can leverage the duct structure itself to handle the motor and its load. In addition to removing weight and drag, this also results in less broadband noise typically caused by stator flow interaction. In one embodiment, the auxiliary motors 1303 operate more at a high 20,000 RPM where they can generate a superior 15 kW/kg specific power compared to heavier, lower speed motors at a 5 kW/kg specific power. The auxiliary motors 1303 drive the ring gear 1303 in unison to eliminate gear slippage (axial and radial directions). This low bearing results in lower gear noise.

[0098] FIG. 14 illustrates yet another embodiment of the circumferential drive system of the propulsor fan 100 according to another embodiment. The embodiment shown in FIG. 14 is similar to the example described in FIG. 13. However, the drive system shown in FIG. 14 omits the centrally driven motor 215 and relies upon the auxiliary motors 1303 for thrust generation.

Propulsor Array

[0099] FIGs. 15A and 15B respectively illustrate a front view and a perspective view of an array of propulsor fans 1500 according to one embodiment. In one embodiment, the array of propulsor fans 1500 includes a plurality of propulsor fans 100 that are laterally arranged to form a row of propulsor fans. In the example shown in FIGs. 15A and 15B, the array of propulsor fans 1500 include a first propulsor fan 100A, a second propulsor fan 100B, and a third propulsor fan 100C. Each of the plurality of propulsor fans 100A to 100C includes the propulsor fan structure described herein. While three propulsor fans 100 are included in the array of propulsor fans 1500, the array may include any number of propulsor fans greater than two.

[00100] FIG. 16 illustrates an example application of an array of propulsor fans 1600 according to one embodiment. As shown in FIG. 16, the array of propulsor fans 1600 includes a plurality of propulsor fans as described herein. The array of propulsor fans 1600 is integrated into a duct wing 1603 of an aircraft 1605 in one embodiment. Multiple propulsor fans can be combined laterally to form a duct wing 1603. The duct wing 1603 can be shaped

to create a passive lifting biplane where biplane stagger, sweep, taper, and dihedral can be added as needed. The total number of propulsor fans and size of the propulsor fans to include in the array 1600 is dependent on the requirements of the aircraft such as the number of passengers that will be on the aircraft, speed requirements, and altitude requirements of the aircraft 1605 for example.

[00101] The combination of the propulsor fans into an array opens up several control and thrust vectoring opportunities. Thrust can simply be varied between each individual propulsor fan 100 to induce yawing, rolling, or pitching moments. Relative spanwise pitch differences between the propulsor fans can be used to catalyze faster climbs and descents. This can be further augmented with additional control surfaces installed at the trailing edge.

[00102] The spanwise combination of ducts lend themselves well to integration along the wing or even as a biplane wing itself. The array can be arranged and extended as a biplanar wing with sweep, stagger, dihedral and taper to fit system needs. The choice to integrate the array of propulsor fans as a full biplanar wing is dependent on the amount of thrust (minus drag) required as well as the relative size of the propulsor fan.

Propulsor Fan Applications

[00103] FIGs. 17A, 17B, and 17C respectively illustrate a front view, a side view, and a top view of a hover drone 1700 according to one embodiment. The hover drone 1700 includes an array of propulsor fans including a first propulsor fan 100A, a second propulsor fan 100B, and a third propulsor fan 100C. Although only three propulsor fans are included in the hover drone 1700, the hover drone 1700 can include additional propulsor fans or less propulsor fans than shown in FIGs. 17A to 17C.

[00104] The hover drone 1700 is a quiet, electric vertical takeoff and landing (VTOL) drone that includes an array of propulsor fans as described herein. The hover drone 1700 may be used for close quarters such as in urban settings. The hover drone 1700 may have 360 degree cameras and sensors and may be used for hover flight times greater than 15 minutes, for example. In one example, the propulsor fans 100A to 100C may each have a 1 ft diameter with an augmented disc loading of 6.4 lb/ft². The hover drone 1700 may have a maximum takeoff weight of 30 pounds.

[00105] In the example shown in FIG. 17A, each propulsor fan 100A to 100C includes a hub driven centrally located motor 215 as well as auxiliary motors 1301 as previously described above. However, the hover drone 1700 may omit the auxiliary motors 1301 and include only the centrally located motor 215 or may omit the centrally located motor 215 and include only the auxiliary motors 1301.

[00106] FIGs. 18A, 18B, and 18C respectively illustrate a front view, a side view, and a top view of a cinema drone 1800 including an array of propulsor fans according to one embodiment. Generally, the cinema drone 1800 is a quiet deflected slipstream VTOL drone used for cinema needs. The cinema drone 1800 may be all electric or hybrid. The cinema drone 1800 may have a Gimbaled payload (e.g., a main camera) up to 35 pounds for example. The cinema drone 1800 may have secondary cameras and sensors. The cinema drone 1800 may be used for hover flight times greater than 20 minutes. The cinema drone may have a maximum cruise speed of greater than 50 mph in one embodiment.

[00107] In one embodiment, the cinema drone 1800 is a biplane and has a neutral stagger. As shown in FIGs. 18A, the cinema drone 1800 includes a first wing 1801 and a second wing 1803. Each of the first wing 1801 and the second wing 1803 includes an array of propulsor fans that includes a plurality of propulsor fans. For example, the array of propulsor fans included in wing 1801 includes propulsor fans 100A, 100B, 100C, and 100D whereas the array of propulsor fans included in wing 1803 includes propulsor fans 100E, 100F, 100G, and 100H. Thus, half of the propulsor fans are at a first side of the fuselage 1805 and the remaining half of the propulsor fans are at a second side of the fuselage 1805. In the example shown in FIGs. 18A to 18C, the array of propulsors includes eight propulsors, but any number of propulsors may be used.

[00108] Each wing 1801, 1803 of the cinema drone 1800 shown in FIGs. 18A to 18C has angular sweep formed between the two wings towards the front of the fuselage 1805. In the example shown in FIG. 18 to 18C, wings 1801 and 1803 may have a wing anhedral of 20 degrees and a wing sweep of 30 degrees. However, other angles may be used in different embodiments.

[00109] In one embodiment, the cinema drone 1800 shown in FIGs. 18A to 18C has a maximum takeoff weight of 75 pounds and a target max payload weight of 30 pounds in one example. Each propulsor fan 100 may have a fan diameter of 1 ft with an augmented disc loading of 6.0 lb/ft² for example. The fuselage 1805 of the cinema drone 1800 may have a length of 5.5 ft and a width of 0.6 ft. The wingspan of the cinema drone 1800 may be 8.8 ft with a wing area of 17.4 ft² with a wing loading of 4.3 lb/ft² for example.

[00110] FIGs. 19A, 19B, and 19C respectively illustrate a front view, a side view, and a top view of a transporter aircraft 1900 including an array of propulsor fans according to one embodiment. The transporter aircraft 1900 is an optionally-manned VTOL plane. The transporter aircraft 1900 may be hybrid or full electric. The transporter aircraft 1900 may have a range of 20-60 nautical miles with a cruising speed of 130 to 250 knots at an operating

altitude of 1,000 to 2,000 feet, for example.

[00111] In one embodiment, the transporter aircraft 1900 is a biplane and has a slight negative stagger. The transporter aircraft 1900 includes a first wing 1901 and a second wing 1903. An angle is formed between the two wings 1901 and 1903 towards the front of the fuselage 1905. In the example shown in FIGs. 19A to 19C, the wings may have a wing dihedral of 5 degrees and a wing sweep of -25 degrees. However, other angles may be used in different embodiments.

[00112] In one embodiment, an array of propulsor fans are integrated into each wing 1901 and 1903. A first array of propulsor fans is at a first side of the fuselage 1905 and is integrated into wing 1901 and a second array of propulsor fans is at a second side of the fuselage 1905 and is integrated into wing 1903. For example, the array of propulsor fans included in wing 1901 includes propulsor fans 100A, 100B, 100C, and 100D whereas the array of propulsor fans included in wing 1903 includes propulsor fans 100E, 100F, 100G, and 100H. Thus, half of the propulsor fans are at a first side of the fuselage 1905 and the remaining half of the propulsor fans are at a second side of the fuselage 1905. In the example shown in FIGs. 19A to 19C, the arrays of propulsors includes eight propulsor fans, but any number of propulsor fans may be used.

[00113] In one embodiment, the transporter aircraft 1900 has a maximum takeoff weight of 1,000 pounds and a target max payload weight of 220 pounds in one example. Each propulsor fan 100 may have a fan diameter of 3 ft with an augmented disc loading of 6.0 lb/ft². The fuselage 1905 of the transporter plane 1900 may have a length of 9.2 ft and a width of 3.75 ft. The wingspan of the transporter aircraft 1900 may be 28.7 ft with a wing area of 106.3 ft² with a wing loading of 9.4 lb/ft².

[00114] FIGs. 20A, 20B, and 20C respectively illustrate a front view, a side view, and a top view of a vertical takeoff and landing (VTOL) aircraft 2000 including an array of propulsor fans according to one embodiment. The VTOL aircraft 2000 is an optionally-manned VTOL plane. The VTOL aircraft 2000 may be hybrid or full electric. The VTOL aircraft 2000 may have a range of 20-400 nautical miles with a cruising speed of 130 to 250 knots at an operating altitude of 1,000 to 2,000 feet. In one embodiment, the VTOL aircraft 2000 is capable of hovering.

[00115] In the example shown in FIGs. 20A to 20C, the VTOL aircraft 2000 is a biplane and has a slight negative stagger. The VTOL aircraft 2000 includes a first wing 2001 and a second wing 2003. In one embodiment, an angle is formed between the two wings 2001, 2003 towards the front of the fuselage 2005. The wings 2001, 2003 may have a wing

dihedral of 5 degrees and a wing sweep of -25 degrees. However, other angles may be used in different embodiments.

[00116] In one embodiment, an array of propulsor fans are integrated into each wing 2001 and 2003. A first array of propulsor fans is at a first side of the fuselage 2005 and is integrated into wing 2001 and a second array of propulsor fans is at a second side of the fuselage 2005 and is integrated into wing 2003. For example, the array of propulsor fans included in wing 2001 includes propulsor fans 100A, 100B, 100C, and 100D whereas the array of propulsor fans included in wing 2003 includes propulsor fans 100E, 100F, 100G, and 100H. Thus, half of the propulsor fans are at a first side of the fuselage 2005 and the remaining half of the propulsor fans are at a second side of the fuselage 2005. In the example shown in FIGs. 20A to 20C, the arrays of propulsors includes eight propulsor fans, but any number of propulsor fans may be used.

[00117] The VTOL aircraft 2000 has a maximum takeoff weight of 5,000 pounds and a target max payload weight of 1,000 pounds (e.g., 3-4 passengers) in one example. Each propulsor fan 100 may have a fan diameter of 5 ft with an augmented disc loading of 11.0 lb/ft². The fuselage 2005 of the VTOL aircraft 2000 may have a length of 24.7 ft and a width of 5 ft, for example. The wingspan of the VTOL aircraft 2000 may be 49 ft with a wing area of 300 ft² with a wing loading of 16.7 lb/ft² for example.

[00118] FIGs. 21A, 21B, and 21C respectively illustrate a front view, a side view, and a top view of a delivery drone 2100 including an array of propulsor fans according to one embodiment. The delivery drone 2100 may have 360 degree cameras and sensors and may be used for hover flight times greater than 20 minutes. The delivery drone 2100 may have a maximum cruise speed of greater than 50 mph in one embodiment.

[00119] The delivery drone 2100 is an example of an electric tail sitter VTOL drone configured to deliver an internal package. In the example shown, the delivery drone 2100 is a biplane and has a neutral stagger. The delivery drone 2100 includes a first wing 2101 and a second wing 2103 with angular sweep formed between the two wings towards the rear of the fuselage 2105 in one embodiment.

[00120] In one embodiment, an array of propulsor fans are integrated into each wing 2101 and 2103. A first array of propulsor fans is at a first side of the fuselage 2105 and is integrated into wing 2101 and a second array of propulsor fans is at a second side of the fuselage 2105 and is integrated into wing 2103. For example, the array of propulsor fans included in wing 2101 includes propulsor fans 100A, 100B, and 100C whereas the array of propulsor fans included in wing 2103 includes propulsor fans 100D, 100E, and 100F. Thus,

half of the propulsor fans are at a first side of the fuselage 2105 and the remaining half of the propulsor fans are at a second side of the fuselage 2105. In the example shown in FIGs. 21A to 21C, the arrays of propulsors includes six propulsor fans, but any number of propulsor fans may be used.

[00121] The delivery drone 2100 has a maximum takeoff weight of 55 pounds and a target max payload weight of 5.5 pounds in one example. Each propulsor fan 100 may have a fan diameter of 1 ft with an augmented disc loading of 6.0 lb/ft^2 . The fuselage 2105 of the delivery drone 2100 may have a length of 6.7 ft and a width of 1.3 ft. The wingspan of the delivery drone 2100 may be 8.8 ft with a wing area of 21.9 ft^2 with a wing loading of 2.5 lb/ft^2 for example.

Free Blade

[00122] Since the propulsor fan 100 described herein has higher speed capability above 150 mph, there is a desire to provide increased propulsive efficiency through either blade angle variability or mass flow throttling. As described above, the propulsor fan 100 includes significantly higher blade count than conventional propulsors. Implementing a typical variable pitch propeller mechanism would be overly burdensome from a mechanical complexity perspective.

[00123] In one embodiment, an array of the propulsor fans as described above is incorporated into an aircraft using a free wing blade structure. The free wing blade structure may be implemented in any of the aircraft described above in FIGs. 17 to 21, for example. Free-wing blades are propulsor fans which are able to rotate freely along their radial axis due to mass balancing ahead of each blade's aerodynamic center. That is, the blade fan 209 is able to rotate freely along their radial axis due to mass balancing ahead of each blade's aerodynamic center. Free-wing blades combine airfoil design, wing mass balancing, and a wing pivot to achieve a capability where a wing is free to pivot as it self-trims to a zero pitching moment at a constant CL across all flight conditions.

[00124] The combination of the free blade structure with the propulsor fan 100 creates a passive system for blade angle of attack (AoA) variability while maintaining a constant blade loading. This could provide a unique synergy to electric motor driven propulsor fans 100 since electric motors can operate at a high efficiency across a broad range of rpm. The electric motors could operate at higher or lower radial velocities across different inflow velocities, with the blades 'floating' to align their AoA to maintain the same trimmed coefficient of lift (CL). This capability may also provide value to achieve lower noise, as a method of avoiding blade stall, which results in high noise at different flight conditions and

turbulence levels.

[00125] The usage of free blades results in a number of benefits. For example, free blades are pitch balanced to always be at an AoA near their L/Dmax CL (typically .5 to 1.0) through the addition of leading edge blade mass. This ensures the blade AoA is always matched to align with the inflow and there's never separated flow. Furthermore, mass balancing is possible with the propulsor fan 100 when the inner hub area is empty since it is rim driven, providing volume ahead of the blade for the lightest mass balancing counterweights (and without being exposed to the flow). This permits the propulsor fan 100 to vary its rpm on the order of ~50% during different flight segments to enable blades to always be near their optimum advance ratio. Use of free blades in combination with an electric motor offers particular benefit because unlike turbines or IC engines, electric motors have a broad rpm of high efficiency. Therefore, turbines or IC engines need to operate at a fixed rpm for a given power, while electric motors do not. This permits the propulsor to vary its rpm on the order of ~50% during different flight segments to enable blades to always be near their optimum advance ratio. Lastly, free blades may also be helpful in enabling larger scale VTOL integrations due to wider AoA variations and thrust needs.

Circulation Duct Control

[00126] In one embodiment, a circulation control mechanism is placed at the duct lip 201. The circulation control mechanism is configured to blow a jet of air at the duct lip 201. By applying air to the duct lip 201, the amount of lip suction that the duct lip 201 is able to achieve is augmented. In one embodiment, electric motors in combination with centrifugal or axial compressors would be embedded in the remaining duct volume to increase circulation control blowing and/or suction at the duct lip 201. By applying distributed electric propulsion (DEP) for internal circulation control blowing at the duct lip 201, static and low speed thrust augmentation can be achieved with a lower power than putting additional power into the propulsor. This internal application of DEP maximizes aero integration benefits, both at the propulsor fan 100 and aircraft integration levels. Applying circulation control at the duct lip 201 results in up to a 40% increase in static thrust at the same fan power, for example.

[00127] In one embodiment, an emergency power ram air turbine with a high PR and intake velocities that required high circulation control jet blowing velocities (i.e., nearly sonic noisy jets). Quiet low velocity jets (~300 ft/sec) may be used and could be powered by small internal duct electrical centrifugal blowers.

[00128] A lower velocity circulation control jet could be equally impactful in terms of thrust augmentation for the propulsor considering the much lower PR and static duct inflow

velocities. Circulation control effectiveness is a function of V_{jet}/V_{intake} . Another intriguing aspect of circulation control duct lip blowing is the avoidance of duct inner lip separation at high angles of attack (i.e., during transition). This is an important consideration for ducted eVTOL - if the inlet air flow separates at the duct lip, a considerable increase in noise results as the fan blades experience oscillating flow conditions that result in cyclic blade loading.

[00129] Through application of circulation control blowing at the duct lip 201 with jet speeds of about 300 ft/sec, the duct lip suction force can be increased to account for ~75% of the total static thrust. Blowing air at the duct lip 201 effectively provides aerodynamic shape morphing on the duct lip to entrain additional ambient air. With the blowing turned on, the inflow air 'sees' a far larger bell mouth duct lip which is desired at static conditions. Having an actual bell mouth duct inlet would cause significant drag at cruise. The duct circulation control blowing can be turned off during cruise flight when the blowing is relatively ineffective. A compact high speed centrifugal blower operates at ultrasonic blade passage frequencies to provide internal blowing. While circulation control blowing is most effective at high nozzle jet speeds (near sonic is best), our nozzle jet has been designed for lower jet speeds to achieve low noise (jet noise varies to the 10th power of the nozzle speed). With this application to the duct leading edge the goal is maximizing the inflow turning angle and preventing leading edge duct lip stall.

[00130] In one embodiment, the circulation control duct may be applied to the duct lip 201 in any of the aircraft embodiments discussed herein.

Exhaust Area Control Systems

[00131] As mentioned previously, the second end 1109 of the stator housing 219C is an exhaust (e.g., the outlet) of the propulsor fan 100. The exhaust is an area through which air flows out of the propulsor fan 100 and into an open environment in one embodiment. For example, the exhaust is the cross section defined by the second end 1109 of the stator body 219C that is furthest from the nose cone 203 where the air flows out of the propulsor fan 100.

[00132] In one embodiment, an exhaust control system is connected to the propulsor fan 100 to vary an area of the exhaust (exhaust area) of the propulsor fan 100. The exhaust control system varies the exhaust area of the propulsor fan 100 to modulate the mass flow thereby modulating the magnitude of thrust and/or a direction of thrust from an individual propulsor fan 100. For example, increasing the exhaust area through which air exits the propulsor fan 100 results in increased thrust with respect to a default exhaust area thrust, whereas decreasing the exhaust area through which air exits the propulsor fan results with respect to the default exhaust area reduces thrust. Different configurations of the exhaust

control system are further described below. Although the description below is with respect to different embodiments of an exhaust control system that is coupled to an individual propulsor fan 100, the exhaust control system may be added to the array of propulsor fans previously described above.

[00133] FIG. 22 illustrates a first perspective view of the propulsor fan system 2200 having an exhaust control system 2201 according to a first embodiment and FIG. 23 illustrates a second perspective view of the propulsor fan system 2200 having the exhaust control system 2201 according to the first embodiment. The propulsor fan system 2200 includes the propulsor fan 100 as previously described above and an exhaust control system 2201 connected to an exhaust of the propulsor fan 100 in one embodiment.

[00134] As described above, the second end 1109 of the stator 219 is the exhaust of the propulsor fan 100. The cross-section of the exhaust area of the propulsor fan 100 has a first shape such as a circle. In the first embodiment of the propulsor fan system 2200, the exhaust control system 2201 is connected to the second end 1109 of the stator 219 to modify a shape of the cross-section of the exhaust of the propulsor fan system 2200 to have a second shape that is different than the first shape. In one embodiment, the second shape is any shape in which it is easier to vary the area of the exhaust compared to varying the area of the first shape. For example, the second shape is any shape having straight edges that form a closed area such as a square, rectangle, parallelogram, or triangle, for example. Controlling the area of a circle is more complicated than controlling the area of a rectangle due to the curved nature of the circle.

[00135] In the first embodiment, the exhaust control system 2201 includes a transition body 2202, a plurality of flaperons 2205, and a flaperon control mechanism (e.g., motors 2401 and rods 2403). The exhaust control system 2201 may have other components than described herein. In one embodiment, the transition body 2202 is configured to transition a shape of the exhaust from the first shape corresponding to the exhaust of the propulsor fan 100 to the second shape corresponding to the exhaust of the exhaust control system 2201.

[00136] In one embodiment, the transition body 2202 includes a first end 2203 that is connected to the second end 1109 of the stator body 219C. The first end 2203 of the transition body 2202 has a shape that matches the shape of the second end 1109 of the stator body (e.g., the first shape). For example, the first end 2203 of the transition body 2202 has a circular shape with a diameter that matches a diameter of the second end 1109 of the stator body. The second end 2204 of the transition body 2202 is the exhaust of the propulsor fan system 2200 and has the second shape.

[00137] In some embodiments, the area of the first end 2203 of the transition body 2201 is substantially the same (e.g., within 10%) as the area of the second end 2204 of the transition body 2202 to ensure that the air flow remains steady throughout the transition body 2202. To ensure smooth and non-noisy flow, the transition body 2202 is shaped to have no internal seams or edges or at least reduce the number of internal seams or edges. The transition body 2202 gently slopes or flares from the first end 2203 having the first shape (e.g., a circular cross section) to the second end 2204 having the second shape (e.g., a rectangular cross section). The transition body 2202 is made of the same material as the stator body 219C and may be a metal or composite, for example. Therefore, the transition body 2202 provides a smooth transition to change the exhaust area shape of the propulsor fan system 2200.

[00138] In one embodiment, an elongated duct is formed from components of the propulsor fan 100 and the exhaust control system 2201. As shown in FIGs. 22 and 23, the elongated duct comprises the duct lip 201, outer casings 213A and 213B, stator body 219C, and the transition body 2202.

[00139] FIG. 23 illustrates the plurality of flaperons 2205 that are included in the exhaust control system 2201. The flaperons 2205 are an example of an exhaust area control mechanism that is adjusted to vary the exhaust area of the propulsor fan system 2200. As shown in FIG. 23, the plurality of flaperons 2205 are connected to the second end 2204 of the transition body 2202. In the example, shown in FIG. 23, the plurality of flaperons 2205 include a total of four flaperons. However, any number of flaperons 2205 may be included in the exhaust control system 2201.

[00140] In one embodiment, each flaperon 2205 is an airfoil having a leading edge and a trailing edge. The flaperons 2205 may have rectangular cross sections and are made of a metal or composite material for example, but other cross section shapes may be used. The leading edge of each of the plurality of flaperons 2205 is connected to the second end 2204 of the transition body 2201. In one embodiment, the leading edge of each flaperon 2205 is connected to the second end 2204 of the transition body 2201 by a hinge 2405 (shown in FIG. 24) thereby allowing the angle of position or state of the flaperon 2205 to change thereby varying the area of the exhaust of the propulsor fan system 2200. That is, the flaperons 2205 are actuatable such that as they move, the flaperons 2205 may block parts of the exhaust area and constrict the area or may move to a position that does not restrict the exhaust area.

[00141] Thus, in the first embodiment of the propulsor fan system 2200, air flows into the propulsor fan 100 through the duct lip 201, past the blade fan 209 (not shown), tail cone

221, and stator 219A, into the transition body 2202, and out of the exhaust area of the transition body 2201 having the second shape created by the second distal end of the transition body 2202. The flaperons 2205 that are connected to the second end 2204 of the transition body 2202 are actuatable such that as they move, the area of the exhaust of the propulsor fan system 2200 is varied to control the magnitude of thrust and/or thrust direction.

[00142] In some embodiments, the flaperons 2205 are individually controllable such that the position of each flaperon can be varied independently of the other flaperons. For example, each of flaperon 2205A, 2205B, 2205C, and 2205D may each move in different directions from each other. In other embodiments, parallel flaperons 2205 may be actuated together such that, for example, as a top flaperon 2205A moves inward toward the tail cone 221, the bottom flaperon 2205C moves inward toward the tail cone 221 by the same amount, and as a left flaperon 2205D moves inward toward the tail cone 221 the right flaperon 2205B moves inward toward the tail cone 221 by the same amount. In embodiments in which there is an array of propulsor fans each having an exhaust control system 2201, the flaperons 2205 of each exhaust control system 2201 may be individually controllable. In other embodiments, flaperons 2205 in the same position (e.g., the top flaperon 2205A of each propulsor of the array) may be actuatable together.

[00143] FIG. 24 illustrates a cross-section view of the propulsor fan system 2200 along plane A-A' shown in FIG. 22 according to one embodiment. The flaperons 2205 are shaped to smoothly continue the airfoil shape of the duct. In one embodiment, each flaperon 2205 is actuated by a flaperon control mechanism including a motor 2401 and rod 2403. The motor 2401 is a torque motor or servo that pushes the rod 2403 to elongate the rod 2403 thereby causing the flaperon 2205 to move inward toward the tail cone 221 or pulls the rod 2403 to contract the rod 2403 thereby causing the flaperon 2205 to move outward away from the tail cone 221.

[00144] In the shown embodiment, when the motor 2401 pushes the rod 2403, the flaperon 2205 rotates around the hinge 2405, resulting in the flaperon being angled inward (e.g., toward the tail cone 221). As the motor 2401 pulls the rod 2403 to contract it, the flaperon rotates around the hinge 2405 to be angled outward (e.g., away from the tail cone). Thus, as the flaperons 2205 move inward, the cross-section of the area of the exhaust of the propulsor fan system 2200 decreases thereby decreasing thrust assuming that the blade fan 209 spins at a constant RPM. Likewise, as the flaperons 2205 move outward the cross-section of the area of the exhaust of the propulsor fan system 2200 increases thereby increasing thrust assuming that the blade fan 209 spins at the constant RPM. Thus, power can be saved as

additional power is not required to increase the speed of the blade fan 209 to generate more thrust which consumes more power than the power required to actuate the exhaust control system 2200.

[00145] While a single motor 2401 per flaperon 2205 is shown in the figures for simplicity, other embodiments of the propulsor having flaperons 2205 will include at least two motors 2401 or servos per flaperon 2205 to ensure that the flaperon still be controllable in the event of motor or servo failure. In some embodiments the rod 2403 is a screw that, when the motor 2401 rotates, translates forward or backward depending on the direction of rotation of the motor 2401.

[00146] In one embodiment, the motor 2401 of each flaperon 2205 is housed in a cavity (e.g., a hollow space) of the stator body 219C and the rod 2401 runs from the hollow stator body 219C into the hollow body of the flaperon 2205 where it is anchored to an edge of the flaperon 2205. Note that the rod 2403 as currently shown is attached to the inward edge of the flaperon 2205. In other embodiments where the rod 2403 is instead anchored to the outward-facing edge of the flaperon 2205, the expanding and contracting of the rod 2403 will move the flaperon 2205 in directions opposite to those described above (e.g., extending results in outward rotation and contracting results in inward rotation).

[00147] In one embodiment, the hinge 2405 is similar to that of a door hinge wherein a pin is threaded through a socket connected to the stator body 219C and a socket connected to the flaperon 2205, thereby holding the stator body 219C and the flaperon 2205 together at the hinge 2405. The hinge 2405 may be placed on either of the inward-facing or outward facing edge of the flaperon 2205. Other means of rotation such as ball and socket joints may also be used.

[00148] Actuating the flaperons 2205 may vary the size of the exhaust area to vary thrust and additionally can be actuated to change the direction of air flow to vary lift. FIGs. 25A, 25B, and 25C illustrate different positions of the flaperons 2205 according to one embodiment. For simplicity, the nose cone 203, motor housing 219B and tail cone 221 are shown in FIGs. 25A-C as a single central portion 2503. In FIG. 25A the top flaperon 2205A is angled inward toward the central portion 2503 while the bottom flaperon 2205C is angled outward. In a use case in which the propulsor is horizontal, the positions of the flaperons 2205 in 25A will result in air being directed downward, increasing lift such as for vertical takeoff.

[00149] Conversely, the positions of the flaperons 2205 in FIG. 25B (the top flaperon 2205A angled outward and the bottom 2205C flaperon angled inward) will result in air being

pushed upwards, causing downward thrust and a net moment, such as to lower and/or rotate the aircraft. The outward rotation of the flaperons 2205 is represented by α and can be up to 90° , while the inward rotation is represented by β and can be up to 90° .

[00150] FIG. 25C shows the flaperons 2205 both rotated inward at approximately the maximum angle, resulting in a smallest exhaust area possible for the propulsor fan system 2200, and therefore a lowest force of thrust as the air exits the propulsor fan system 2200. In one embodiment, the maximum inward angle for the flaperons is approximately 60 degrees, but other maximum inward angles may be used.

[00151] In one embodiment, the flaperons 2205 may have a default position at 0° such that when no signal is sent to the motor the flaperons go to the default position. The default position of the flaperons is shown in FIG. 24 for example.

[00152] FIGs. 26A, 26B, and 26C illustrate a cross-section view of the propulsor fan system 2600 according to a second embodiment. In one embodiment, the propulsor fan system 2600 includes the propulsor fan 100 and an exhaust control system 2601. In contrast to the exhaust control system 2201 according to the first embodiment, the exhaust control system 2601 of the second embodiment includes an actuatable tail cone 2609 and a control mechanism for the actuatable tail cone 2609. In the second embodiment, the actuatable tail cone 2609 is configured to vary the area of the exhaust of the propulsor fan system 2600 by varying the length of the actuatable tail cone 2609 according to second embodiment.

[00153] In the second embodiment, the actuatable tail cone 2609 replaces the tail cone 221 previously described above. FIG. 27 illustrates a detailed view of the actuatable tail cone 2609 according to the second embodiment. The actuatable tail cone 2609 includes a first end 2701 and a second end 2703 where the second end is connected to the stator 219 in a similar manner as the tail cone 221 previously described above. In one embodiment, the second end of the tail cone 221 includes a plurality of concentric rings 2607 where each ring 2607 includes at least one end that is at least partially overlapped by another one of the concentric rings. The plurality of concentric rings 2607 may be considered an exhaust area control mechanism as will be further described below. Between each pair of rings is a flexible seal that prevents air from entering the hollow body of the tail cone 2609.

[00154] In the example actuatable tail cone 2609, the plurality of concentric rings includes a first ring 2607A and a second ring 2607B. The first ring 2607A has a first end that corresponds to the first end 2701 of the actuatable tail cone 2609 and connects to the stator 219, and a second end that connects to a first end of the second ring 2607B. The second end of the first ring 2607A is partially overlapped by a first end of the second ring 2607B such

that the second end of the first ring 2607A is disposed within the second ring 2607B. As will be further described below, the amount of overlap between the concentric rings 2607 may vary thereby changing the length of the actuatable tail cone 2609 to change the area of the exhaust of the propulsor fan system 2600.

[00155] In one embodiment, the actuatable tail cone 2609 includes an intermediate portion 2705 between the first end 2701 and the second end 2703 of the actuatable tail cone 2609 that has a diameter that is larger than a diameter of the first end and the second end. Thus, the intermediate portion 2705 of the actuatable tail cone 2609 has a flared shape similar to that of the lower half of a bowling pin. As the actuatable tail cone 2609 is elongated, the intermediate portion 2705 having the largest diameter is moved into the exhaust area towards the stator 219 thereby decreasing the exhaust area and decreasing thrust.

[00156] Referring to FIG. 26A, the actuatable tail cone 2609 is shown in a fully retracted state (e.g., position) according to the second embodiment. In the fully retracted state, the positions of the concentric rings 2607 are adjusted such that the maximum amount of overlap occurs between the concentric rings 2607. In the fully retracted state, the exhaust control system 2601 increases the exhaust area of the propulsor fan system 2600 to an area corresponding to maximum thrust of the propulsor fan system 2600. For example, the thrust is increased at the most constraining design speed. The exhaust area is increased since the intermediate portion 2705 of the actuatable tail cone 2609 is moved inward, toward the stator 219.

[00157] In FIG. 26C illustrates the actuatable tail cone 2609 in the fully extended state according to the second embodiment. In the fully extended state, the positions of the concentric rings 2607 are adjusted such that the minimum amount of overlap occurs between the concentric rings 2607. In the fully extended state, the exhaust control system 2601 decreases the exhaust area of the propulsor fan system 2600 to an area corresponding to minimum thrust of the propulsor fan system 2600. For example, the thrust is decreased at a constraining design speed. The exhaust area is decreased since the intermediate portion 2705 of the actuatable tail cone 2609 is moved outward, away from the stator 219, thereby increasing the exhaust area.

[00158] FIG. 26B illustrates the actuatable tail cone 2609 in an intermediate state that is between the fully extended state and the fully retracted state according to the second embodiment. In the intermediate state, the positions of the concentric rings 2607 are adjusted such that an intermediate amount of overlap occurs between the concentric rings 2607. The intermediate amount of overlap is greater than the minimum amount of overlap in the fully

extended stated but less than the maximum amount of overlap in the fully contracted state. While only a single intermediate state is shown, the actuatable tail cone 2609 may be positioned in a plurality of different intermediate states that are between the fully extended state and the fully retracted state.

[00159] In one embodiment, the minimum and maximum lengths of the actuatable tail cone 2609 vary with the application in which it is used. For example, when the propulsor fan system 2600 is used in a small drone, the actuatable tail cone 2609 may have a length range that is less than the length range of the actuatable tail cone 2609 used in an aircraft configured to transport people.

[00160] In the second embodiment of the propulsor fan system 2600, an end of the duct 2603 of the embodiment shown in FIGs. 26 are different in form than the ducts 2501 of the propulsor fan system 2200 shown in FIG. 25. The exhaust area of the duct 2603 in the second embodiment of the propulsor fan system 2600 may have a similar or same shape as the outlet of the propulsor fan 100. Thus, the exhaust area of the propulsor fan system 2600 may be round whereas the exhaust area of the propulsor fan system 2200 is rectangular for example. In one embodiment, an inner surface of the duct 2603 is shaped (e.g., contoured) based on a shape of the outer surface of the intermediate portion 2705 of the actuatable tail cone 2609 (e.g., such that the inner surface of the duct 2603 is concave where the tail cone 2609 is convex).

[00161] As mentioned above, the exhaust control system 2600 of the second embodiment includes a control mechanism for actuating the actuatable tail cone 2609. The control mechanism may include a motor 2605 and rod 2611 for example. The control mechanism may include other components in other embodiments.

[00162] The motor 2605 may be a servo or torque motor for example. A first end of the rod 2611 is connected to the motor and a second end of the rod 2611 is connected to a tip of the actuatable tail cone 2609. The rod 2611 may be a screw for example. The motor 2605 moves the rod 2611 such that the rod pushes or pulls on the second end of the tail cone 2609, causing the rings 2607 to slide past each other to change the length of the tail cone 2609. Although a single motor 2605 is shown, in other embodiments there are multiple motors 2605 actuating a single tail cone 2609 to reduce loss of control in the event of a motor failure.

[00163] FIG. 28 illustrates cross-section view a propulsor fan system 2800 according to a third embodiment. The third embodiment of the propulsor fan system 2800 includes a plurality of exhaust control systems. For example, the third embodiment of the propulsor fan system 2800 includes both the exhaust control system 2200 having the flaperons 2205 as

shown in FIGs. 22 to 25 and the exhaust control system 2600 having the actuatable tail cone 2609 as shown in FIGs. 26 to 27.

[00164] The exhaust control system 2200 and the exhaust control system 2600 may be individually controlled to vary the area of the exhaust of the propulsor fan system 2800 in the third embodiment. For example, FIG. 28 illustrates that the flaperons 2205 included in the exhaust control system 2200 and the actuatable tail cone 2609 included in the exhaust control system 2600 are individually actuatable. Both or either can be varied to change the thrust as previously described above with respect to the first and second embodiments of the exhaust control systems 2200, 2600. In some use cases, the flaperons 2205 may be used to change lift while the tail cone 2609 is used to vary thrust. In other cases, such as during takeoff when high thrust is needed, both the tail cone 2609 and flaperons 2205 may be actuated to decrease the exhaust area as much as possible.

Conclusion

[00165] Reference in the specification to “one embodiment” or to “an embodiment” means that a particular feature, structure, or characteristic is included in at least one embodiment of the disclosure. The appearances of the phrase “in one embodiment” in various places in the specification are not necessarily referring to the same embodiment.

[00166] While the disclosure has been particularly shown and described with reference to one embodiment and several alternate embodiments, it will be understood by persons skilled in the relevant art that various changes in form and details can be made therein without departing from the spirit and scope of the invention.

WHAT IS CLAIMED IS:

1. An exhaust control system comprising:
 - a first end configured to connect to an outlet of a propulsor fan that is configured to generate thrust, the first end having a first cross-section shape that substantially matches a cross-section shape of the outlet of the propulsor fan;
 - a second end having a second cross-section shape that is different from the first cross-section shape, exhaust generated by the propulsor fan configured to exit the second end of the exhaust control system; and
 - an exhaust area control mechanism configured to vary an area of the second end of the exhaust control system from a first area to a second area that is less than the first area.
2. The exhaust control system of claim 1, wherein the exhaust area control mechanism comprises a plurality of flaperons that are connected to the second end of the exhaust control system.
3. The exhaust control system of claim 2, further comprising:
 - a transition body configured to transition the exhaust control system from having the first end having the first cross-section shape to the second end having the second cross-section shape that is different from the first cross-section shape, the transition body comprising the first end and the second end,
 - wherein each of the plurality of flaperons is connected to one of a plurality of edges on the second end of the transition body.
4. The exhaust control system of claim 2, wherein at least one of the plurality of flaperons is configured to actuate independent from another one of the plurality of flaperons.
5. The exhaust control system of claim 2, wherein the plurality of flaperons are configured to actuate simultaneously.
6. The exhaust control system of claim 2, wherein the plurality of flaperons are configured to actuate toward a center of the second end such that an area of the second end is reduced thereby decreasing the thrust of the propulsor fan, and wherein the plurality of flaperons are configured to actuate away from the center of the second end such that the area of the second end is increased thereby increasing the thrust of the propulsor fan.

7. The exhaust control system of claim 2, wherein first cross-section shape comprises a circular cross-section and the second cross-section shape comprises a rectangular cross-section.

8. An exhaust control system comprising:

- a first end configured to connect to a propulsor fan that generates thrust;
- a second end opposite the first end;
- an intermediate portion disposed between the first end and the second end, the intermediate portion having a diameter that is greater than a diameter of the first end and a diameter of the second end; and
- an exhaust area control mechanism disposed at the first end, the exhaust area control mechanism configured to adjust a length of the exhaust control system such that a position of the intermediate portion within an outlet of the propulsor fan changes thereby varying an area of the outlet of the propulsor fan.

9. The exhaust control system of claim 8, wherein the exhaust area control mechanism comprises:

- a plurality of overlapping concentric rings disposed at the first end, at least a portion of each of the plurality of concentric rings overlapping a portion of another one of the plurality of concentric ring,
- wherein the length of the exhaust control system is adjusted responsive to an adjustment of an amount of overlap between the plurality of concentric rings.

10. The exhaust control system of claim 9, further comprising:

- a control mechanism connected to the second end, the control mechanism configured to adjust the amount of overlap between the plurality of concentric rings to vary the area of the outlet of the propulsor fan.

11. The exhaust control system of claim 10, wherein the control mechanism is configured to increase the amount of overlap between the plurality of concentric rings to reduce the length of the exhaust control system such that the intermediate portion is closer to the first end thereby increasing the area of the outlet of the propulsor fan to increase thrust.

12. The exhaust control system of claim 10, wherein the control mechanism is configured to decrease the amount of overlap between the plurality of concentric rings to increase the length of the exhaust control system such that the intermediate portion is farther

from the first end thereby decreasing the area of the outlet of the propulsor fan to decrease thrust.

13. A propulsor system comprising:
 - a propulsor fan configured to generate thrust, the propulsor fan including an outlet having a first cross-section shape; and
 - an exhaust control system configured to vary an area of an outlet of the propulsor system, the exhaust control system comprising:
 - an inlet connected to the outlet of the propulsor fan, the outlet of the propulsor fan and the inlet of the exhaust control system having a first cross-section shape;
 - an outlet having a second cross-section shape that is different from the first cross-section shape, exhaust generated by the propulsor system configured to exit the outlet of the exhaust control system; and
 - a first exhaust area control mechanism configured to vary an area of the outlet of the exhaust control system from a first area to a second area that is less than the first area
14. The propulsor system of claim 13, wherein the first exhaust area control mechanism comprises a plurality of flaperons that are connected to the outlet of the exhaust control system.
15. The propulsor system of claim 14, wherein the first exhaust control system further comprises:
 - a transition body configured to transition the exhaust control system from having the inlet having the first cross-section shape to the outlet having the second cross-section shape that is different from the first cross-section shape,
 - wherein each of the plurality of flaperons is connected to one of a plurality of edges on the outlet of the transition body.
16. The propulsor system of claim 14, wherein at least one of the plurality of flaperons is configured to actuate independent from another one of the plurality of flaperons.
17. The propulsor system of claim 14, wherein the plurality of flaperons are configured to actuate simultaneously.
18. The propulsor system of claim 14, wherein the plurality of flaperons are configured to actuate toward a center of the outlet of the exhaust control system such that an area of the outlet of the exhaust control system is reduced thereby decreasing the thrust of the propulsor fan, and wherein the plurality of flaperons are configured to actuate away from the

center of the outlet of the exhaust control system such that the area of the outlet of the exhaust control system is increased thereby increasing the thrust of the propulsor fan.

19. The propulsor system of claim 13, wherein first cross-section shape comprises a circular cross-section and the second cross-section shape comprises a rectangular cross-section.

20. The propulsor system of claim 13, further comprising a second exhaust control system disposed within the outlet of the propulsor fan, wherein a length of the second exhaust control system is adjusted to vary an area of the outlet of the propulsor fan.
