

A LOOP ANTENNA FOR MOBILE HANDSET AND OTHER APPLICATIONS

[0001] This invention relates to a loop antenna for mobile handset and other applications, and in particular to a loop antenna that is able to operate in more than one frequency band.

5

BACKGROUND

[0002] The industrial design of modern mobile phones leaves little printed circuit board (PCB) area for the antenna and often the antenna must be very low profile because of the increasing demand for slimline phones. At the same time the number of frequency bands that the antenna is expected to operate over is increasing.

10

[0003] When multiple radio protocols are used on a single mobile phone platform, the first problem is to decide whether a single wideband antenna should be used or whether multiple narrower band antennas would be more appropriate. Designing a mobile phone with a single wideband antenna involves problems not only with obtaining sufficient bandwidth to cover all the necessary bands but also with the difficulties associated with the insertion loss, cost, bandwidth and size of the circuits needed to diplex the signals together. On the other hand, multiple narrow-band antenna solutions are associated with problems dominated by the coupling between them and the difficulties of finding sufficient real estate for them on the handset. Generally, these multiple antenna problems are harder to solve than the wide-band single antenna problems.

15

20

[0004] Most mobile phones generally make use of monopole antennas or PIFAs (Planar Inverted F Antennas). Monopoles work most efficiently in areas free from the PCB groundplane or other conductive surfaces. In contrast, PIFAs will work well close to conductive surfaces. Considerable research effort goes into making monopoles and PIFAs operate as broadband antennas so as to avoid the issues associated with multiple antennas.

25

[0005] One way to increase bandwidth in an electrically small antenna is to use multi-moding. In the lowest bands, odd resonant modes may be created which may be variously designated as 'unbalanced modes', 'differential modes' or 'monopole-like'. At higher frequencies both even and odd resonant modes may be created. Even modes may be variously designated as 'balanced modes', 'common modes' or 'dipole-like'.

30

[0006] Loop antennas are well-understood and have been used in mobile phones before. An example is US 2008/0291100 which describes a single band grounded loop radiating in the low band together with a parasitic grounded monopole radiating in the high band. A further example is WO 2006/049382 which discloses a symmetrical loop antenna structure that has

been reduced in size by stacking the loop vertically. A broadband characteristic has been obtained in the high frequency band by attaching a stub to the top patch of the antenna. This arrangement creates a multi-moding antenna useful in wireless communication fields.

[0007] The idea of multi-moding an antenna is also not new. An example of good design practice here is the Motorola® Folded Inverted Conformal Antenna (FICA), which excites resonances in a structure that exhibits odd and even resonant modes [Di Nallo, C. and Faraone, A.: "Multiband internal antenna for mobile phones", Electronics Letters 28th April 2005 Vol. 41 No. 9]. Two modes are described as being synthesised for the high band: a 'differential mode', featuring opposite phased currents on the FICA arms and transverse currents on the PCB ground and a 'slot mode', which is a higher order common mode, featuring a strong excitation of the FICA slot. The combination of modes can be used to produce a wide, continuous radiating band. However, the FICA structure referred to is a variation of the PIFA and the Nallo and Faraone paper does not teach multi-moding of loop antennas.

BRIEF SUMMARY OF THE DISCLOSURE

[0008] Embodiments of the present invention make use of a loop antenna design that has been multi-moded. Embodiments of the present invention are useful in mobile phone handsets, and may also be used in mobile modem devices, for example USB dongles and the like for allowing a laptop computer to communicate with the internet by way of a mobile network.

[0009] According to a first aspect of the present invention there is provided a loop antenna comprising a dielectric substrate having first and second opposed surfaces and a conductive track formed on the substrate, wherein there is provided a feed point and a grounding point adjacent to each other on the first surface of the substrate, with the conductive track extending in generally opposite directions from the feed point and grounding point respectively, then extending towards an edge of the dielectric substrate, then passing to the second surface of the dielectric substrate and then passing across the second surface of the dielectric substrate along a path generally following the path taken on the first surface of the dielectric substrate, before connecting to respective sides of a conductive arrangement formed on the second surface of the dielectric substrate that extends into a central part of a loop formed by the conductive track on the second surface of the dielectric substrate, wherein the conductive arrangement comprises both inductive and capacitive elements.

[0010] The conductive arrangement can be considered to be electrically complex, in that it includes both inductive and capacitive elements. The inductive and capacitive elements may

be lumped components (e.g. as discrete surface mount inductors or capacitors), but in preferred embodiments they are formed or printed as distributed components, for example as regions of appropriately shaped conductive track on or in the second surface of the substrate.

5 [0011] This arrangement differs from that disclosed in WO 2006/049382 in that the latter describes a folded loop antenna having a stub on the top surface that expands the bandwidth of the high frequency band of the antenna. WO 2006/049382 makes clear that 'the stub is a line that is additionally connected to a transmission line for the purpose of frequency tuning or broadband characteristic'. The stub is a 'shunt stub connected in parallel to the top patch and is the open stub whose length is smaller than $\lambda/4$ '. It is also made clear in WO 2006/049382
10 that 'when the length [stub] L is smaller than $\lambda/4$, the open stub acts as a capacitor'. In the present invention, the antenna includes a series complex structure at, or near, a centre of the loop instead of the simple capacitive shunt stub described in WO 2006/049382.

[0012] In both the lumped and the distributed cases, the conductive arrangement of embodiments of the present invention is smaller than the shunt stub described in WO
15 2006/049382 and allows the overall antenna structure to be made more compact. A further advantage of this structure is that it allows the impedance bandwidth of the high band to be tuned without any deleterious effects on the low band. This allows the high band match to be much improved.

[0013] Inductive and capacitive elements may be provided in the central region of the loop on
20 the second surface of the substrate by forming the conductive tracks on the second surface of the substrate to define at least one slot, for example by running one track into the central region and then generally parallel to the other track but not galvanically contacting the other track.

[0014] It will be appreciated that the conductive track forms a loop with two arms, the loop
25 starting at the feed point and terminating at the grounding point. The two arms of the loop initially extend away from each other starting at the feed point and grounding point respectively, before extending towards the edge of the dielectric substrate. In preferred embodiments, the arms are collinear when initially extending from the feed and grounding points, and generally or substantially parallel when extending towards the edge of the dielectric substrate, although other configurations (for example diverging or converging towards the
30 edge of the dielectric substrate) are not excluded.

[0015] In particularly preferred embodiments, the arms of the loop extend towards each other along or close to the edge of the dielectric substrate. The arms may extend so that they come close to each other (for example as close as or closer than the distance between the feed

point and the grounding point), or less close to each other. In other embodiments, one arm of the loop may extend along or close to the edge of the substrate while the other does not. In other embodiments, it is conceivable that the arms do not extend towards each other.

[0016] The conductive track on the first surface of the dielectric substrate may pass through the dielectric substrate to the second surface by means of vias or holes. Alternatively, the conductive track may pass over the edge of the dielectric substrate from one surface to the other. It will be appreciated that the conductive track passes from one side of the substrate to the other side of the substrate at two locations. Both of these passages may be through vias or holes, or both may be over the edge of the substrate, or one may be through a via or hole and the other may be over the edge.

[0017] The loop formed by the conductive track and the loading plate may be symmetrical in a mirror plane perpendicular to a plane of the dielectric substrate and passing between the feed point and the grounding point to the edge of the substrate. In addition, the conductive track, notwithstanding the loading plate, may be generally symmetrical about a mirror plane defined between the first and second surfaces of the substrate. However, other embodiments may not be symmetrical in these planes. Non-symmetrical embodiments may be useful in creating an unbalanced loop which may improve bandwidth, especially in higher bands. However, a consequence of this is that the antenna becomes less resistant to detuning when there is a change in the shape or size of the groundplane.

[0018] Advantageously, the conductive track may be provided with one or more spurs extending from the loop generally defined by the conductive track. The one or more spurs may extend into the loop, or out of the loop, or both. The additional spur or spurs act as radiating monopoles and contribute additional resonances in the spectrum, thereby increasing the bandwidth of the antenna.

[0019] Alternatively or in addition, there may be provided at least one parasitic radiating element. This may be formed on the first or second surface of the substrate, or on a different substrate (for example a motherboard on which the antenna and its substrate is mounted). The parasitic radiating element is a conductive element that may be grounded (connected to a groundplane) or ungrounded. By providing a parasitic radiating element, it is possible to add a further resonance that may be used for an additional radio protocol, for example Bluetooth® or GPS (Global Positioning System) operation.

[0020] In some embodiments, antennas of the present invention may operate in at least four, and preferably at least five different frequency bands.

[0021] According to a second aspect of the present invention there is provided a parasitic

loop antenna comprising a dielectric substrate having first and second opposed surfaces and a conductive track formed on the substrate, wherein there is provided a first ground point and a second ground point adjacent to each other on the first surface of the substrate, with the conductive track extending in generally opposite directions from the first and second ground points respectively, then extending towards an edge of the dielectric substrate, then passing to the second surface of the dielectric substrate and then passing across the second surface of the dielectric substrate along a path generally following the path taken on the first surface of the dielectric substrate, before connecting at a conductive loading plate formed on the second surface of the dielectric substrate that extends into a central part of a loop formed by the conductive track on the second surface of the dielectric substrate, and wherein there is further provided a separate, directly driven antenna configured to excite the parasitic loop antenna.

[0022] The separate driven antenna may take the form of a smaller loop antenna located on adjacent a portion of the conductive track extending from the first ground point, the second loop antenna having a feed point and a ground point and configured to drive the parasitic loop antenna by inductively coupling therewith. The drive antenna may be formed on a motherboard to which the parasitic loop antenna and its substrate is attached.

[0023] Alternatively, the separate drive antenna may take the form of a monopole antenna, preferably a short monopole, located and configured so as to drive the parasitic loop antenna by capacitively coupling therewith. The monopole may be formed on a reverse side of a motherboard to which the parasitic loop antenna and its substrate is attached.

[0024] WO 2006/049382 describes a classical half-loop antenna that has been compacted by means of a vertical stack structure. Typically a half-loop antenna comprises a conductive element that is fed at one end and grounded at the other. The second aspect of the present invention is a radiating loop antenna that is grounded at both ends and which is therefore parasitic. This parasitic loop antenna is excited by a separate driven antenna, generally smaller than the parasitic loop antenna. The driven or driving antenna may be configured to radiate at a higher frequency of interest, such as one of the WiFi frequency bands.

[0025] The loading plate may be generally rectangular in shape, or may have other shapes, for example taking a triangular form. The loading plate may additionally be provided with arms or spurs or other extensions extending from a main part of the loading plate. The loading plate is formed as a conductive plate on the second surface of the substrate, parallel to the substrate as a whole. One edge of the loading plate may follow, on the second surface, a line formed between the feed point and the grounding point on the first surface. An opposed edge of the loading plate may be located generally in the centre of the loop formed by the conductive track on the second surface.

[0026] According to a third aspect of the present invention there is provided a parasitic loop antenna comprising a dielectric substrate having first and second opposed surfaces and a conductive track formed on the substrate, wherein there is provided a first ground point and a second ground point adjacent to each other on the first surface of the substrate, with the conductive track extending in generally opposite directions from the first and second ground points respectively, then extending towards an edge of the dielectric substrate, then passing to the second surface of the dielectric substrate and then passing across the second surface of the dielectric substrate along a path generally following the path taken on the first surface of the dielectric substrate, before connecting to respective sides of a conductive arrangement formed on the second surface of the dielectric substrate that extends into a central part of a loop formed by the conductive track on the second surface of the dielectric substrate, wherein the conductive arrangement comprises both inductive and capacitive elements, and wherein there is further provided a separate, directly driven antenna configured to excite the parasitic loop antenna.

[0027] The third aspect of the present invention combines the parasitic excitation mechanism of the second aspect with the electrically complex conductive arrangement of the first aspect.

[0028] In a fourth aspect, which may be combined with any of the first to third aspect, the loop antenna, instead of being directly grounded, is grounded through a complex load selected from the list comprising: least one inductor, at least one capacitor; at least one length of transmission line; and any combination of these in series or in parallel.

[0029] Furthermore, the grounding point of the loop antenna may be switched between several different complex loads so as to enable the antenna to cover different frequency bands.

[0030] The various embodiments of the present invention already described may be configured as either surface mount (SMT) components that may be reflowed onto a ground-plane free area of a main PCB, or as elevated structures that work over a groundplane.

[0031] It has further been found that removing substrate material in the region of high electric field strength may be used to reduce losses. For example, a central notch may be cut into the substrate material of the loop antenna where the E-field is highest resulting in improved performance in the high frequency band.

[0032] For the antenna having a complex central loading structure, it has been found advantageous to make two cut-outs either side of the centre line. Again the efficiency benefits are mainly in the high frequency band.

[0033] The loop antenna may be arranged so as to leave a central area free for a cut-out

right through part of the antenna substrate. The objective here is not so much to reduce losses but rather to create a volume where a micro-USB connector or the like may be placed. It is often desirable to locate the antenna in the same place as connectors, for example at the bottom of a mobile phone handset.

5 **[0034]** In a further embodiment it has found that short capacitive or inductive stubs may be attached to a driven or parasitic loop antenna to improve the bandwidth, impedance match and/or efficiency. The idea of using a single shunt capacitive stubs has been previously been disclosed in GB0912368.8 and WO 2006/049382, however it has been found particularly advantageous to use several such stubs, as part of the central complex load. The stubs may
10 also be used advantageously when connected to other parts of the loop structure, as already described in the present Applicant's co-pending UK patent application no GB0912368.8 .

[0035] It has been found that embodiments of the present invention may be used in combination with an electrically small FM radio antenna tuned to band 88-108 MHz with one antenna disposed each side of the main PCB, i.e. one on the top surface and one directly
15 below it on the undersurface. It is usually a problem to use two antennas so closely spaced because of the coupling between them but it has been found that the loop design of embodiments of the present invention and the nature of the FM antenna (itself a type of loop) is such that very good isolation may exist between them.

[0036] Electrically small monopoles and PIFAs are characterised by a high reactive
20 impedance that is capacitive in nature in the same way that a short open-ended stub on a transmission line is capacitive. Most loop antenna configurations have a low reactive impedance that is inductive in nature in the same way that a short-circuited stub on a transmission line is inductive. There are difficulties in matching both these types of antenna to a 50 ohm radio system. Like monopoles and PIFAs, loop antennas can be short circuited to
25 ground so as to be unbalanced or monopole-like. In this case the loop may act as a half-loop and 'see' its image in the groundplane. Alternatively a loop antenna may be a complete loop with balanced modes requiring no groundplane for operation.

[0037] Embodiments of the present invention comprise a grounded loop that is driven in both odd and even modes so as to operate over a very wide bandwidth. The operation of the
30 antenna will be explained in more detail below.

BRIEF DESCRIPTION OF THE DRAWINGS

[0038] Embodiments of the invention are further described hereinafter with reference to the accompanying drawings, in which:

FIGURE 1 is a schematic outline of the structure of a prior art vertically stacked loop antenna;

FIGURE 2 shows an embodiment of the present invention with an electrically complex central load;

5 FIGURE 3 shows an alternative embodiment in which an electrically complex central load is formed by a slot;

10 FIGURE 4 shows an arrangement in which a separate feeding loop antenna is used to excite the main loop antenna by coupling inductively therewith;

FIGURE 5 is a plot showing the performance of the embodiment of Figure 4, both before and after matching;

15 FIGURE 6 is a schematic circuit diagram showing how embodiments of the present invention may be grounded through different loads;

20 FIGURE 7 shows an arrangement in which a loop antenna is vertically compacted across opposed sides of a dielectric substrate, and in which a central notch or cut-out is formed in the dielectric substrate;

FIGURE 8 shows a variation of the embodiment of Figure 2, in which portions of the substrate are cut out or removed on either side of the central complex load;

25 FIGURES 9 and 10 show a variation in which the loop antenna is arranged and the dielectric substrate cut through in such a way as to accommodate a connector, such as a micro USB connector;

30 FIGURE 11 shows a variation in which short capacitive or inductive stubs are attached to the loop antenna;

FIGURE 12 shows an embodiment of the present invention combined with an FM radio antenna; and

35 FIGURE 13 is a plot showing coupling between the loop antenna and FM radio antenna of the embodiment of Figure 12.

DETAILED DESCRIPTION

[0039] Figure 1 shows in schematic form a prior art loop antenna generally similar to that disclosed in WO 2006/049382. The dielectric substrate, which will typically be a slab of FR4 PCB substrate material, is not shown in Figure 1 for the sake of clarity. The antenna 1 comprises a loop formed of a conductive track 2 extending between a feed point 3 and a grounding point 4 both located adjacent to each other on a first surface (in this case an underside) of the substrate. The conductive track 2 extends in generally opposite directions 5, 6 from the feed point 3 and grounding point 4 respectively, then extends 7, 8 towards an edge of the dielectric substrate, then passes 9, 10 along the edge of the dielectric substrate before passing 11, 12 to the second surface of the dielectric substrate. The conductive track 2 then passes across the second surface of the dielectric substrate along a path generally following the path taken on the first surface of the dielectric substrate, before connecting at a conductive loading plate 13 formed on the second surface of the dielectric substrate that extends into a central part 14 of a loop 15 formed by the conductive track 2 on the second surface of the dielectric substrate.

[0040] It can be seen that the conductive track 2 is folded so as to cover the upper and lower layers of the slab of FR4 substrate material. The feed point 3 and grounding point 4 are on the lower surface and may be interchanged if the groundplane is symmetrical through the same axis of symmetry as the antenna 1 as a whole. In other words, if the antenna 1 is symmetrical, then either terminal point 3, 4 may be used as the feed and the other for grounding. Generally, both feed point 3 and grounding point 4 will be on the same surface of the antenna substrate, since the motherboard on which the antenna 1 as a whole will be mounted can feed the points 3 and 4 from only one of its surfaces. However, it is possible to use holes or vias through the substrate so that feed tracks can be formed on either surface and still connect to the respective feed point 3 or grounding point 4. The conductive loading plate 13 is located on the upper surface of the antenna close to the electrical centre of the loop 15.

[0041] Given that the greatest dimension of the loop 15 is 40mm, it can be appreciated that the conductive track 2 as a whole is approximately half a wavelength long in the mobile communications low band (824 – 960MHz) where the wavelength is around 310-360 mm. In this situation the input impedance of the loop is capacitive in nature and leads to an increased radiation resistance and a lower Q (a larger bandwidth) than is common for a loop antenna. The antenna thus works well in the low band and it is not too difficult to match over required

bandwidth. Because the antenna 1 is formed as a loop that is folded over onto itself, its self-capacitance helps to reduce the operating frequency in certain embodiments.

[0042] Figure 2 shows an improvement over the prior art antenna of Figure 1. There is shown a PCB substrate 20 including a conductive groundplane 21. The PCB substrate 20 has an edge portion 22 that is free of the groundplane 21 for mounting an antenna structure 22 of an embodiment of the present invention. The antenna structure 22 comprises a dielectric substrate 23 (for example FR4 or Duroid® or the like) with first and second opposed surfaces. A conductive track 24 is formed (for example by way of printing) on the substrate 23 having a similar overall configuration to that shown in Figure 1, namely that of a vertically-compacted loop with a feed point 26 and a grounding point 25 adjacent to each other on the first surface of the substrate, with the conductive track 24 extending in generally opposite directions from the feed point 26 and grounding point 25 respectively, then extending towards an edge of the dielectric substrate 23, then passing to the second surface of the dielectric substrate 23 and then passing across the second surface of the dielectric substrate 23 along a path generally following the path taken on the first surface of the dielectric substrate 23. The two ends of the conductive track 24 on the second surface of the substrate 23 then connect to respective sides of a conductive arrangement 27 formed on the second surface of the dielectric substrate 23 that extends into a central part of a loop formed by the conductive track 24 on the second surface of the dielectric substrate 23, wherein the conductive arrangement 27 comprises both inductive and capacitive elements. In comparison with the arrangement of Figure 1, the high band match is much improved.

[0043] Figure 3 shows a variation of the arrangement of Figure 2, with like parts labelled as for Figure 2. This embodiment provides an electrically complex (i.e. inductive and capacitive) load in the central region of the second surface of the substrate 23 by means of a stub 28 and slots 29, 30. This technique also adds inductance and capacitance near the center of the loop.

[0044] Figure 4 shows a variation (this time omitting the substrate 23 and top half of the antenna from the drawing for clarity) in which the main loop antenna defined by the conductive track 24 is connected at both terminals 25, 25' to ground 21. In other words, the main loop antenna is not directly driven by a feed 26 as in Figures 2 and 3. Instead, the main loop antenna is excited by a separate, smaller, driven loop antenna 33 formed on the end 22 of the PCB substrate 20 on which there is no groundplane 21, the driven loop antenna 33 having a feed 31 and a ground 32 connection. The smaller, driven loop antenna 33 may be configured to radiate at a higher frequency of interest, such as one of the WiFi frequency bands.

[0045] This inductively coupled feeding arrangement has many parameters that may be

varied in order to obtain optimum impedance matching. An example of the performance of the antenna, before and after matching, is shown in Figure 5. Lumped or tunable L and C elements may be added to the ground 32 of the small coupling loop 23 to adjust impedance response of the antenna as a whole.

- 5 **[0046]** In a variation of the inductive feeding of a parasitic loop antenna 33, the parasitic main loop may be fed capacitively by means of a short monopole on the underside of the main PCB substrate 20 coupling to a section of the antenna on the top side of the main PCB 20. This arrangement has been disclosed in a previous patent application, UK patent application No GB0914280.3 to the present applicant.
- 10 **[0047]** Instead of directly grounding the main loop antenna, it is sometimes advantageous to ground the antenna through a complex load comprising inductors, capacitors or lengths of transmission line or any combination of these in series or parallel. Furthermore, the grounding point of the antenna may be switched between several different complex loads so as to enable the antenna to cover different frequency bands as shown in Figure 6. Figure 6 shows the
- 15 grounding connection 25 and the groundplane 21 of the main PCB substrate 20. The grounding connection 25 connects to the groundplane 21 by way of a switch 34 that can switch in different inductive and/or capacitive components 35 or 36, or provide a direct connection 37. In the example shown below, the complex grounding loads were chosen so that in switch position 1 the low band of the antenna covered the LTE band 700-760 MHz; in
- 20 switch position 2, 750-800 MHz and in switch position 3, the GSM band 824-960 MHz.

[0048] It has been found that removing substrate 23 material in the region of high electric field strength may be used to reduce losses. In the example shown in Figure 7, a central notch 38 has been cut into the substrate material 23 where the E-field is highest, resulting in improved performance in the high frequency band.

- 25 **[0049]** Figure 8 shows a variation of the embodiment of Figure 2, where parts of the substrate 23 are cut out from the second surface on either side of the central complex load 27. In this example, the cut-outs are generally cuboidal in shape, although other shapes and volumes may be useful. The efficiency benefits are mainly in the high frequency band.

- [0050]** Figures 9 and 10 show a variation in which the main loop antenna is defined by the track 24 and complex load 27 on the substrate 23 is arranged so as to leave a central area 42 free for a cut-out 40 right through part of the antenna substrate 23. The objective here is not so much to reduce losses but rather to create a volume where a micro-USB connector 41 or similar may be located. It is often desirable to locate the antenna in the same place as connectors, for example at the bottom of a mobile phone handset.
- 30

[0051] In a further embodiment it has found that short capacitive or inductive stubs 43 may be attached to a driven or parasitic loop antenna 24 to improve the bandwidth, impedance match and/or efficiency, as shown in Figure 11. It has been found particularly advantageous to use several such stubs 43, as part of the central complex load 27. The stubs 43 may also
5 be used advantageously when connected to other parts of the loop structure 24. Cut-outs 39 in the substrate 23 may also be provided to improve efficiency.

[0052] Figure 12 shows an embodiment of the present invention corresponding generally to that of Figures 9 and 10 in combination with an electrically small FM radio antenna 44 tuned to band 88-108 MHz and mounted on the reverse side of the main PCB 20 to the side on which
10 the loop antenna 24 is mounted. In other words, one antenna is on the top surface of the PCB 20 and the other is directly below it on the undersurface of the main PCB 20. It is usually a problem to use two antennas so closely spaced because of the coupling between them but it has been found that the loop design of embodiments of the present invention and the nature of the FM antenna (itself a type of loop) is such that very good isolation may exist between
15 them.

[0053] Figure 13 shows that the coupling between the two antennas 24 and 44 (the lower plot) is lower than -30 dB across the whole of the cellular band.

[0054] Throughout the description and claims of this specification, the words “comprise” and “contain” and variations of them mean “including but not limited to”, and they are not intended
20 to (and do not) exclude other moieties, additives, components, integers or steps. Throughout the description and claims of this specification, the singular encompasses the plural unless the context otherwise requires. In particular, where the indefinite article is used, the specification is to be understood as contemplating plurality as well as singularity, unless the context requires otherwise.

[0055] Features, integers, characteristics, compounds, chemical moieties or groups described in conjunction with a particular aspect, embodiment or example of the invention are to be understood to be applicable to any other aspect, embodiment or example described herein unless incompatible therewith. All of the features disclosed in this specification (including any accompanying claims, abstract and drawings), and/or all of the steps of any
30 method or process so disclosed, may be combined in any combination, except combinations where at least some of such features and/or steps are mutually exclusive. The invention is not restricted to the details of any foregoing embodiments. The invention extends to any novel one, or any novel combination, of the features disclosed in this specification (including any accompanying claims, abstract and drawings), or to any novel one, or any novel combination,
35 of the steps of any method or process so disclosed.

[0056] The reader's attention is directed to all papers and documents which are filed concurrently with or previous to this specification in connection with this application and which are open to public inspection with this specification, and the contents of all such papers and documents are incorporated herein by reference.

CLAIMS:

1. A loop antenna comprising a dielectric substrate having first and second opposed surfaces and a conductive track formed on the substrate, wherein there is provided a feed point and a grounding point adjacent to each other on the first surface of the substrate, with the conductive track extending in generally opposite directions from the feed point and grounding point respectively, then extending towards an edge of the dielectric substrate, then passing to the second surface of the dielectric substrate and then passing across the second surface of the dielectric substrate along a path generally following the path taken on the first surface of the dielectric substrate, before connecting to respective sides of a conductive arrangement formed on the second surface of the dielectric substrate that extends into a central part of a loop formed by the conductive track on the second surface of the dielectric substrate, wherein the conductive arrangement comprises both inductive and capacitive elements.
2. An antenna as claimed in claim 1, wherein the inductive and capacitive components are discrete or lumped components.
3. An antenna as claimed in claim 1, wherein the inductive and capacitive components are distributed components.
4. An antenna as claimed in claim 3, wherein the inductive and capacitive components are formed as tracks or printed conductive areas on the second surface of the dielectric substrate.
5. An antenna as claimed in claim 3 or 4, wherein at least some of the inductive and capacitive components are defined by slots formed between conductive tracks.
6. An antenna as claimed in any preceding claim, wherein the conductive track is arranged so as to define two arms, one on each side of the conductive arrangement.
7. An antenna as claimed in claim 6, wherein the arms are symmetrically arranged.
8. An antenna as claimed in claim 6, wherein the arms are not symmetrically arranged.
9. An antenna as claimed in claim 8, wherein one arm is longer than the other.

10. An antenna as claimed in any preceding claim, wherein the conductive track on the first surface of the dielectric substrate passes through the dielectric substrate to the second surface by means of vias or holes.

5 11. An antenna as claimed in any preceding claim, wherein the conductive track passes over the edge of the dielectric substrate from one surface to the other.

12. An antenna as claimed in any preceding claim, wherein the conductive track, notwithstanding the conductive arrangement, is generally symmetrical about a mirror plane
10 defined between the first and second surfaces of the substrate.

13. An antenna as claimed in any one of claims 1 to 11, wherein the conductive track, notwithstanding the loading plate, is not symmetrical about a mirror plane defined between the first and second surfaces of the substrate.

15 14. An antenna as claimed in any preceding claim, wherein the conductive track is provided with arms or spurs or other extensions extending into or away from the central part of the loop.

15. An antenna as claimed in any preceding claim, further provided with at least one
20 parasitic radiating element.

16. An antenna as claimed in claim 15, wherein the parasitic radiating element is grounded (connected to a groundplane).

25 17. An antenna as claimed in claim 15, wherein the parasitic radiating element is ungrounded.

18. An antenna as claimed in any preceding claim, mounted on a groundplane-free region of a motherboard.

30 19. A parasitic loop antenna comprising a dielectric substrate having first and second opposed surfaces and a conductive track formed on the substrate, wherein there is provided a first ground point and a second ground point adjacent to each other on the first surface of the substrate, with the conductive track extending in generally opposite directions from the first
35 and second ground points respectively, then extending towards an edge of the dielectric substrate, then passing to the second surface of the dielectric substrate and then passing

across the second surface of the dielectric substrate along a path generally following the path taken on the first surface of the dielectric substrate, before connecting at a conductive loading plate formed on the second surface of the dielectric substrate that extends into a central part of a loop formed by the conductive track on the second surface of the dielectric substrate, and
5 wherein there is further provided a separate, directly driven antenna configured to excite the parasitic loop antenna.

20. A parasitic loop antenna comprising a dielectric substrate having first and second opposed surfaces and a conductive track formed on the substrate, wherein there is provided a
10 first ground point and a second ground point adjacent to each other on the first surface of the substrate, with the conductive track extending in generally opposite directions from the first and second ground points respectively, then extending towards an edge of the dielectric substrate, then passing to the second surface of the dielectric substrate and then passing
15 across the second surface of the dielectric substrate along a path generally following the path taken on the first surface of the dielectric substrate, before connecting to respective sides of a conductive arrangement formed on the second surface of the dielectric substrate that extends into a central part of a loop formed by the conductive track on the second surface of the dielectric substrate, wherein the conductive arrangement comprises both inductive and capacitive elements, and wherein there is further provided a separate, directly driven antenna
20 configured to excite the parasitic loop antenna.

21. An antenna as claimed in claim 19 or 20, wherein the separate driven antenna takes the form of a smaller loop antenna located adjacent a portion of the conductive track extending from the first ground point, the second loop antenna having a feed point and a ground point
25 and configured to drive the parasitic loop antenna by inductively coupling therewith.

22. An antenna as claimed in claim 19 or 20, wherein the separate drive antenna takes the form of a monopole antenna located and configured so as to drive the parasitic loop antenna by capacitively coupling therewith.

23. An antenna as claimed in any preceding claim, wherein the loop antenna is grounded through a complex load selected from the list comprising: least one inductor, at least one capacitor; at least one length of transmission line; and any combination of these in series or in parallel.

24. An antenna as claimed in claim 23, wherein the grounding point of the loop antenna is

switchable between different complex loads so as to enable the antenna to cover different frequency bands.

25. An antenna as claimed in any preceding claim, wherein a central notch is formed in the dielectric substrate.

26. An antenna as claimed in any preceding claim, wherein a cut-out is formed in the second surface of the dielectric substrate on either side of a centre line thereon.

27. An antenna as claimed in any preceding claim, wherein a cut-out is formed through the dielectric substrate so as to create a volume in which a connector may be located.

28. An antenna as claimed in claim 28, further comprising a connector located in the volume.

29. An antenna as claimed in any preceding claim, further comprising at least one capacitive or inductive stub mounted on the dielectric substrate.

30. An antenna as claimed in any preceding claim mounted on one side of a main dielectric substrate, in combination with a second antenna mounted in opposition on the other side of the main dielectric substrate.

31. An antenna as claimed in claim 30, wherein the second antenna is an FM radio antenna.
