RELATED APPLICATIONS

[0001] This application claims priority to U.S. Provisional Application No. 62/776,301, filed December 6, 2018, the entire contents of which are incorporated herein by reference.

BACKGROUND

[0002] A potential immune therapy is needed for cancers related to the innate immune system recognition of non-self, and to detect and protect against potential danger. Cancer cells differ antigenically from their normal counterparts and emit danger signals to alert the immune system similar to viral infection. These signals, which include damage-associated molecular patterns (DAMPs) and pathogen-associated molecular patterns (PAMPs), further activate the innate immune system resulting in the protection of the host from a variety of threats (*Front. Cell Infect. Microbiol.* **2012**, 2, 168).

[0003] Ectopically expressed single stranded DNA (ssDNA) and double stranded DNA (dsDNA) are known PAMPs and/or DAMPs, which are being recognized by the cyclic GMP-AMP synthase (cGAS), a nucleic acid sensor (*Nature* **2011**, 478, 515-518). Upon sensing of cytosolic DNA, cGAS catalyzes the generation of the cyclic dinucleotide 2',3'-cGAMP, a potent second messenger and activator of the ER transmembrane adapter protein stimulator of interferon genes (STING) (*Cell Rep.* **2013**, 3, 1355-1361). STING activation triggers phosphorylation of IRF3 via TBK1 which in turn leads to type I interferon production and activation of interferon stimulated genes (ISGs); a pre-requisite to the activation of innate immunity and initiation of adaptive immunity. Production of type I interferons thus constitutes a key bridge between the innate and adaptive immunity (*Science* **2013**, 341, 903-906).

[0004] Excess type I IFN can be harmful to the host and induce autoimmunity, therefore, negative feedback mechanisms exist that keep type I IFN-mediated immune activation in check. Three prime repair exonuclease I (TREX1) is a 3'-5' DNA exonuclease responsible for the removal of ectopically expressed ssDNA and dsDNA and is therefore a key repressor of the cGAS/STING pathway (*PNAS* **2015**, 112, 5117-5122).

[0005] Type I interferons and downstream pro-inflammatory cytokine responses are critical to the development of immune responses and their effectiveness. Type I interferons enhance both the ability of dendritic cells and macrophages to take up, process, present, and cross-present antigens to T cells, and their potency to stimulate T cells by eliciting the up-

regulation of the co-stimulatory molecules such as CD40, CD80 and CD86 (*J. Exp. Med.* **2011**, 208, 2005-2016). Type I interferons also bind their own receptors and activate interferon responsive genes that contribute to activation of cells involved in adaptive immunity (*EMBO Rep.* **2015**, 16, 202-212).

[0006] From a therapeutic perspective, type I interferons and compounds that can induce type I interferon production have potential for use in the treatment of human cancers (*Nat. Rev Immunol.* **2015**, 15, 405-414). Interferons can inhibit human tumor cell proliferation directly. In addition, type I interferons can enhance anti-tumor immunity by triggering the activation of cells from both the innate and adaptive immune system. Importantly, the anti-tumor activity of PD-1 blockade requires pre-existing intratumoral T cells. By turning cold tumors into hot and thereby eliciting a spontaneous anti-tumor immunity, type I IFN-inducing therapies have the potential to expand the pool of patients responding to anti-PD-1 therapy as well as enhance the effectiveness of anti-PD1 therapy.

[0007] Therapies that are currently in development that induce a potent type I interferon response require focal or intratumoral administration to achieve an acceptable therapeutic index. Thus, there remains a need for new agents with systemic delivery and lower toxicity to expand the benefit of type I IFN-inducing therapies to patients without peripherally treatment accessible lesions. Human and mouse genetic studies suggest that TREX1 inhibition might be amenable to a systemic delivery route and therefore TREX1 inhibitory compounds could play an important role in the anti-tumor therapy landscape. TREX1 is a key determinant for the limited immunogenicity of cancer cells responding to radiation treatment [*Trends in Cell Biol.*, **2017**, 27 (8), 543-4; *Nature Commun.*, **2017**, 8, 15618]. TREX1 is induced by genotoxic stress and involved in protection of glioma and melanoma cells to anticancer drugs [*Biochim. Biophys. Acta*, **2013**, 1833, 1832-43]. STACT-TREX1 therapy shows robust anti-tumor efficacy in multiple murine cancer models [Glickman et al, Poster P235, 33rd Annual Meeting of Society for Immunotherapy of Cancer, Washington DC, Nov. 7-11, **2018**].

2. Definitions

[0016] When used in connection to describe a chemical group that may have multiple points of attachment, a hyphen (-) designates the point of attachment of that group to the variable to which it is defined. For example, –NHC(O)OR^a and –NHC(S)OR^a mean that the point of attachment for this group occurs on the nitrogen atom.

[0026] The term “TREX1” refers to Three prime repair exonuclease 1 or DNA repair exonuclease 1, which is an enzyme that in humans is encoded by the TREX1 gene. *Mazur DJ, Perrino FW (Aug 1999). "Identification and expression of the TREX1 and TREX2 cDNA sequences encoding mammalian 3'-->5' exonucleases". J Biol Chem. 274 (28): 19655–60. doi:10.1074/jbc.274.28.19655. PMID 10391904; Hoss M, Robins P, Naven TJ, Pappin DJ, Sgouros J, Lindahl T (Aug 1999). "A human DNA editing enzyme homologous to the Escherichia coli DnaQ/MutD protein". EMBO J. 18 (13): 3868–75. doi:10.1093/emboj/18.13.3868. PMC 1171463. PMID 10393201.* This gene encodes the major 3'->5' DNA exonuclease in human cells. The protein is a non-processive exonuclease that may serve a proofreading function for a human DNA polymerase. It is also a component of the SET complex, and acts to rapidly degrade 3' ends of nicked DNA during granzyme A-mediated cell death. Cells lacking functional TREX1 show chronic DNA damage checkpoint activation and extra-nuclear accumulation of an endogenous single-strand DNA substrate. It appears that TREX1 protein normally acts on a single-stranded DNA polynucleotide species generated from processing aberrant replication intermediates. This action of TREX1 attenuates DNA damage checkpoint signaling and prevents pathological immune activation. TREX1 metabolizes reverse-transcribed single-stranded DNA of endogenous retroelements as a function of cell-intrinsic antiviral surveillance, resulting in a potent type I IFN response. TREX1 helps HIV-1 to evade cytosolic sensing by degrading viral cDNA in the cytoplasm.

[0027] The term “TREX2” refers to Three prime repair exonuclease 2 is an enzyme that in humans is encoded by the TREX2 gene. This gene encodes a nuclear protein with 3' to 5' exonuclease activity. The encoded protein participates in double-stranded DNA break repair, and may interact with DNA polymerase delta. Enzymes with this activity are involved in DNA replication, repair, and recombination. TREX2 is a 3'-exonuclease which is predominantly expressed in keratinocytes and contributes to the epidermal response to UVB-induced DNA damage. TREX2 biochemical and structural properties are similar to TREX1, although they are not identical. The two proteins share a dimeric structure and can process ssDNA and dsDNA substrates *in vitro* with almost identical k_{cat} values. However, several features related to enzyme kinetics, structural domains, and subcellular distribution distinguish TREX2 from TREX1. TREX2 present a 10-fold lower affinity for DNA substrates *in vitro* compared with TREX1. In contrast with TREX1, TREX2 lacks a COOH-terminal domain that can mediate protein-protein interactions. TREX2 is localized in both the cytoplasm and nucleus, whereas TREX1 is found in the endoplasmic reticulum, and is mobilized to the nucleus during granzyme A-mediated cell death or after DNA damage.

[0028] The terms “subject” and “patient” may be used interchangeably, and means a mammal in need of treatment, *e.g.*, companion animals (*e.g.*, dogs, cats, and the like), farm animals (*e.g.*, cows, pigs, horses, sheep, goats and the like) and laboratory animals (*e.g.*, rats, mice, guinea pigs and the like). Typically, the subject is a human in need of treatment.

[0030] As used herein, the terms “treatment,” “treat,” and “treating” refer to reversing, alleviating, delaying the onset of, or inhibiting the progress of a disease or disorder, or one or more symptoms thereof, as described herein. In some aspects, treatment may be administered after one or more symptoms have developed, *i.e.*, therapeutic treatment. In other aspects, treatment may be administered in the absence of symptoms. For example, treatment may be administered to a susceptible individual prior to the onset of symptoms (*e.g.*, in light of a history of symptoms and/or in light of exposure to a particular organism, or other susceptibility factors), *i.e.*, prophylactic treatment. [0061] Step 1: Synthesis of methyl 3-(3-bromo-5-methylphenyl)-5-(2-methoxy-2-oxoethyl)-2-methyl-2,5-dihydro-1,2,4-oxadiazole-5-carboxylate

[0062] To a stirred solution of **SM** (5.16 g, 26.341 mmol, 2 equiv), N-methylhydroxylamine hydrochloride (1.10 g, 13.170 mmol, 1.00 equiv) in H₂O (25.00 mL), EtOH (25.00 mL) was added Na₂CO₃ (0.837 g, 7.902 mmol, 0.6 equiv) in portions at room temperature. The resulting solution was stirred for 2 hr at 80 °C. Until the reaction mixture is cooled to room temperature, 1,4-dimethyl but-2-ynedioate (2.06 g, 14.488 mmol, 1.1 equiv) was added dropwise. Then, the reaction mixture was stirred for 0.5 h at room temperature. The resulting solution was extracted with 3x30 mL of ethyl acetate and the organic layers combined washed with brine and concentrated under vacuum. The residue was applied onto a silica gel column with ethyl acetate/petroleum ether (1:5). This resulted in 1.3 g of **A1** (25% yield) as light yellow oil. ESI-MS *m/z* = 385.0 [M+H]⁺. This resulted in 90 g (crude) of ethyl 2-methoxy-2-[(4E)-1-methyl-2,5-dioxoimidazolidin-4-ylidene]acetate (2) as a brown solid. ¹H NMR (300 MHz, Chloroform-d) δ 8.75 (s, 1H), 7.47 (s, 0.4H), 5.09 (s, 2H), 4.51-4.30 (m, 3H), 3.85 (s, 1H), 3.84 (s, 3H), 3.12 (s, 3H), 3.07 (s, 1H), 2.14 (d, J = 12.9 Hz, 1H), 1.45-1.42 (m, 2H), 1.42-1.37 (m, 3H).

[0077] Step 3. Synthesis of 2-hydroxy-5-methoxy-1-methyl-6-oxopyrimidine-4-carboxylic acid (3)

[0078] Into a 2000-mL round-bottom flask, was placed ethyl 2-methoxy-2-[(4E)-1-methyl-2,5-dioxoimidazolidin-4-ylidene]acetate (2) (80.00 g, 350.6 mmol, 1.00 equiv), potassium hydroxide (1M in water) (1400.0 mL). The resulting solution was stirred for 3 h at 105 °C. The reaction mixture was cooled to 0 °C with a water/ice bath. The pH value of the solution was adjusted to 3 with hydrogen chloride (12 mol/L) at 0 °C, the solids were collected by filtration and the precipitate was dried in vacuo. This resulted in 40 g of 2-hydroxy-5-methoxy-1-methyl-6-oxopyrimidine-4-carboxylic acid (3) (yield 57%) as a white solid. ¹H NMR (300 MHz, DMSO-d₆) δ 14.35 (s, 1H), 10.91 (s, 1H), 3.68 (s, 3H), 3.14 (s, 3H).

[0079] Step 4. Synthesis of ethyl 2-hydroxy-5-methoxy-1-methyl-6-oxopyrimidine-4-carboxylate (4)

[0080] Into a 1000-mL 3-necked round-bottom flask purged and maintained with an inert atmosphere of argon, was placed 2-hydroxy-5-methoxy-1-methyl-6-oxopyrimidine-4-carboxylic acid (3) (20 g, 0.10 mmol, 1.00 equiv), ethanol (400.0 mL). This was followed by the addition of acetyl chloride (117.7 g, 1.500 mmol, 15.00 equiv) dropwise with stirring at 0 °C. The resulting solution was heated to reflux for 1 overnight. The reaction mixture was cooled with a water/ice bath. The solids were collected by filtration. This resulted in 16 g of ethyl 2-hydroxy-5-methoxy-1-methyl-6-oxopyrimidine-4-carboxylate (4) (yield: 70%) as a white solid. ¹H NMR (400 MHz, DMSO-d₆) δ 11.08 (s, 1H), 4.32 (q, J = 7.1 Hz, 2H), 3.70 (s, 3H), 3.15 (s, 3H), 1.31 (t, J = 7.1 Hz, 3H).

[0081] Step 5. Synthesis of ethyl 2-chloro-5-methoxy-1-methyl-6-oxopyrimidine-4-carboxylate (5)

[0082] Into a 1-L 3-necked round-bottom flask purged and maintained with an inert atmosphere of argon, was placed ethyl 2-hydroxy-5-methoxy-1-methyl-6-oxopyrimidine-4-carboxylate (4) (16.0 g, 70.1 mmol, 1.00 equiv), dimethylaniline (1.20 g, 98.2 mmol, 1.40 equiv), phosphoryl trichloride (320.0 mL). The resulting solution was stirred for 1 overnight at 100 °C. The resulting mixture was concentrated under vacuum. The residue was applied onto a silica gel column with ethyl acetate/petroleum ether (1/10-1/4). This resulted in 13.3 g of ethyl 2-chloro-5-methoxy-1-methyl-6-oxopyrimidine-4-carboxylate (5) (yield 77.0%) as a yellow solid. ¹H NMR (300 MHz, DMSO-d₆) δ 4.32 (q, J = 7.1 Hz, 2H), 3.84 (s, 3H), 3.54 (s, 3H), 1.30 (t, J = 7.1 Hz, 3H).

[0083] Step 6. Synthesis of 2-chloro-5-methoxy-1-methyl-N-(1, 2-oxazol-4-yl)-6-oxopyrimidine-4-carboxamide (6)

[0084] To a stirred solution of ethyl 2-chloro-5-methoxy-1-methyl-6-oxopyrimidine-4-carboxylate (5) (1.00 g, 4.05 mmol, 1.00 equiv) and 1,2-oxazol-4-amine (340.9 mg, 4.050 mmol, 1.00 equiv) in toluene (15.0 mL) was added trimethylaluminum (2 mol in toluene) (4.1 mL, 8.10 mmol, 2.00 equiv) at room temperature under argon atmosphere. The resulting solution was stirred with microwave radiation for 15 min at 80 °C. The reaction mixture was quenched with water/ice at 0 °C. The resulting solution was extracted with 3x40 mL of ethyl acetate, the combined organic layers were washed with brine (1x30 mL), dried over anhydrous sodium sulfate and concentrated under vacuum. The residue was applied onto a silica gel column with ethyl acetate/petroleum ether (1/10-1/1). This resulted in 650 mg of 2-chloro-5-methoxy-1-methyl-N-(1, 2-oxazol-4-yl)-6-oxopyrimidine-4-carboxamide (6) (yield 53.0%) as a light yellow solid. ESI-MS $m/z = 285.2$ $[M+H]^+$. Biochemical Assays

1. Silencing TREX1 in tumor cells

[00143] Activation of the cGAS/STING pathway upon sensing of cytosolic DNA and subsequent type I IFN production can occur in both tumor cells and innate immune cells, particularly dendritic cells. To evaluate whether TREX1 keeps in check the production of type I IFN by a well described, cold syngeneic tumor model that undergoes immune-mediated rejection upon activation of type I IFN by STING agonists, TREX1 was knocked down in B16F10 tumor cells using CRISPR (**FIG. 1A**). Accumulation of cytosolic DNA via DNA transfection of the tumor cells resulted in an about 5-fold increase in IFN β production by the TREX1 knockout B16F10 cells relative to the parental tumor cells, demonstrating that TREX1 attenuated the activation of the cGAS/STING pathway in B16F10 tumor cells (**FIG. 1B**).

2. Growth of TREX1-Competent and -Deficient B16F10 Tumor Cells In Vivo

[00144] The growth of TREX1-competent and -deficient B16F10 tumor cells in vivo was evaluated. C57BL/6J mice were inoculated subcutaneously on the right flank with 300,000 parental or TREX1 knockout B16F10 tumor cells. Body weights were collected two times per week, and tumor measurements, two to three times per week, starting when tumors became measurable and for the remaining duration of the study. Tumors in which TREX1 had been silenced presented with remarkably smaller volumes than the parental B16F10 tumors (**FIG. 2**).

[00145] Tumors were harvested on day 19, upon termination of the study, and digested into single cell suspensions to enable flow cytometry quantification of tumor-infiltrating immune populations. TREX1 knockout B16F10 tumors were found to exhibit a significant increase in overall immune cells, which reflected an increase in the number of tumor infiltrating CD4 and CD8 T cells as well as in plasmacytoid dendritic cells (pDCs) (**FIG. 3**). pDCs are known to play a central role in the induction of antigen-specific anti-tumor immune responses whereas T cells are known to be major effectors of anti-tumor efficacy in mice and

humans. The profound change in the immune infiltrate of the tumors deficient in TREX1 thus suggest that the inhibition of the growth of the latter tumors is at least in part immune-mediated.

TREX1 Biochemical Assay

[00146] Compound potency was assessed through a fluorescence assay measuring degradation of a custom dsDNA substrate possessing a fluorophore-quencher pair on opposing strands. Degradation of the dsDNA liberates free fluorophore to produce a fluorescent signal. Specifically, 7.5 μ L of N- terminally His-Tev tagged full length human TREX1 (expressed in *E. coli* and purified in house) in reaction buffer (50 mM Tris (pH 7.4), 150 mM NaCl, 2 mM DTT, 0.1 mg/mL BSA, 0.01% (v/v) Tween-20 and 100 mM MgCl₂ were added to a 384-well Black ProxiPlate Plus (Perkin Elmer) which already contained compound (150 nL) at varying concentrations as a 10 point dose-response in DMSO. To this was added 7.5 μ L of dsDNA substrate (Strand A: 5' TEX615/GCT AGG CAG 3'; Strand B: 5' CTG CCT AGC/IAbRQSp (Integrated DNA Technologies)) in reaction buffer. Final concentrations were 150 pM TREX1, 60 nM dsDNA substrate in reaction buffer with 1.0% DMSO (v/v). After 25 minutes at room temperature, reactions were quenched by the addition of 5 μ L of stop buffer (same as reaction buffer plus 200 mM EDTA). Final concentrations in the quenched reaction were 112.5 pM TREX1, 45 nM DNA and 50 mM EDTA in a volume of 20 μ L. After a 5-minute incubation at room temperature, plates were read in a laser sourced Envision (Perkin-Elmer), measuring fluorescence at 615 nm following excitation w/ 570 nm light. IC₅₀ values were calculated by comparing the measured fluorescence at 615 nm ratio relative to control wells pre-quenched w/ stop buffer (100% inhibition) and no inhibitor (0% inhibition) controls as using non-linear least square four parameter fits and either Genedata or GraphPad Prism (GraphPad Software, Inc.).

TREX2 Biochemical Assay

[00147] Compound potency was assessed through a fluorescence assay measuring degradation of a custom dsDNA substrate possessing a fluorophore-quencher pair on opposing strands. Degradation of the dsDNA liberates free fluorophore to produce a fluorescent signal. Specifically, 7.5 μ L of N- terminally His-Tev tagged human TREX2 (residues M44-A279, expressed in *E. coli* and purified in house) in reaction buffer (50 mM Tris (pH 7.4), 150 mM NaCl, 2 mM DTT, 0.1 mg/mL BSA, 0.01% (v/v) Tween-20 and 100mM MgCl₂) was added to a 384-well Black ProxiPlate Plus (Perkin Elmer) which already contained compound (150 nL) at varying concentrations as a 10 point dose-response in

DMSO. To this was added 7.5 μ L of dsDNA substrate (Strand A: 5' TEX615/GCT AGG CAG 3'; Strand B: 5' CTG CCT AGC/IAbRQSp (IDT)) in reaction buffer. Final concentrations were 2.5 nM TREX2, 60 nM dsDNA substrate in reaction buffer with 1.0% DMSO (v/v). After 25 minutes at room temperature, reactions were quenched by the addition of 5 μ L of stop buffer (same as reaction buffer plus 200 mM EDTA). Final concentrations in the quenched reaction mixture were 1.875 pM TREX2, 45 nM DNA and 50 mM EDTA in a volume of 20 μ L. After a 5-minute incubation at room temperature, plates were read in a laser sourced Envision (Perkin-Elmer), measuring fluorescence at 615 nm following excitation w/ 570 nm light. IC₅₀ values were calculated by comparing the measured fluorescence at 615 nm ratio relative to control wells pre-quenched w/ stop buffer (100% inhibition) and no inhibitor (0% inhibition) controls as using non-linear least square four parameter fits and either Genedata or GraphPad Prism (GraphPad Software, Inc.).

[00148] Results are shown in Table 1. TREX1 IC₅₀ : A = <0.1 μ M; B = 0.1 to 1 μ M; C = 1 to 10 μ M; D = >10 μ M. TREX2 IC₅₀ : A = <1 μ M, B = 1 to 10 μ M, C = 10 to 100 μ M, D = >100 μ M.

HCT116 cell assay

[00149] HCT116 dual cells (Invivogen, San Diego, CA, USA) are derived from the human HCT116 colorectal carcinoma cell line. Cells have been selected for the stable integration of SEAP and Luciferase reporter genes, which expression is under the control of 5 tandem response elements for NF-KB/AP1 and STAT1/STAT2, respectively. The cell line was used to monitor Type I interferon induction and subsequent signaling by measuring the activity of the Lucia luciferase secreted in the culture medium.

[00150] HCT116 cells were plated in 96-well plate(s) at 40,000 cells/well in 100uL DMEM supplemented with 10% FBS and 25mM Hepes (pH 7.2 – 7.5). After overnight settling, cells were treated with TREX1i for 4h (maximum DMSO fraction was 0.1%) before 1ug/mL pBR322/BstNI restriction digest (New England Biolabs, Ipswich, MA, USA) was transfected with Lipofectamine LTX (ThermoFisher, Grand Island, NY, USA), according to product manual recommendations. Briefly, Lipofectamine LTX (0.35uL/well) was diluted in OptiMEM (5uL/well). pBR322/BstNI (100ng/well) was diluted in OptiMEM (5uL/well) before Plus reagent (0.1uL/100ng DNA) was added. After 5min incubation at room temperature, the DNA mixture was mixed dropwise with the diluted Lipofectamine LTX. After an additional 10 min incubation, the transfection mix (10uL/well) was added to the cells. Cells were maintained at 37C for 48h before monitoring the Lucia Luciferase activity from the cell culture medium.
