

CYCLIC OLEFIN POLYMER COMPOSITIONS AND POLYSILOXANE RELEASE
LAYERS FOR USE IN TEMPORARY WAFER BONDING PROCESSES

BACKGROUND OF THE INVENTION

5

Related Application

This application claims the priority benefit of provisional applications entitled CYCLIC
OLEFIN POLYMER COMPOSITIONS FOR USE IN TEMPORARY WAFER BONDING
PROCESSES, Application No. 61/924,442, filed January 7, 2014, and ULTRATHIN
10 POLYSILOXANE COATINGS AS LOW-FORCE MECHANICAL RELEASE LAYERS FOR
ADHESIVELY BONDED MICROELECTRONICS SUBSTRATES, Application No.
61/952,945, filed March 14, 2014, each of which is incorporated by reference herein.

Field of the Invention

15 This invention relates to release layers and bonding materials for temporary wafer
bonding processes.

Description of the Prior Art

Wafer bonding materials protect device features on the front side of a device substrate,
20 and provide adhesion to a carrier substrate and mechanical support for the thinned wafers during
backside processing. 3D-IC processing, especially with through-silicon via ("TSV") and through-
glass via ("TGV") technology, requires temporary wafer bonding materials to survive processes
at high temperatures and high vacuum, such as plasma-enhanced chemical vapor deposition
("PECVD"). This technology also requires that the materials can be removed easily from the
25 wafers after processing. Additionally, lower cost of ownership is needed for the 3D-IC to be
adopted by the manufacturers.

Integrated circuit and semiconductor packaging manufacturers are continually looking
for temporary wafer bonding technology with low cost of ownership, that uses materials capable
of surviving processing at high temperatures and under high vacuum, and that can be easily
30 cleaned after processing. So far, no single technology/material can satisfy all these requirements.
Cyclic olefin copolymer (COC) bonding materials are one class of materials that are commonly
used. These COCs, such as those formulated using TOPAS[®] and APEL[®] materials, are produced
by chain copolymerization of cyclic monomers with ethene. These COC materials are good for

some applications, but it is very difficult to obtain a clear solution in commonly-used solvents such as d-limonene and mesitylene, and it can also be difficult to clean them off the substrates after processing.

In some temporary bonding schemes, such as ZoneBOND® zonal bonding from Brewer Science, Inc. (described in US Patent Publication No. 2009/0218560 and Application No. 12/819,680, both of which are hereby incorporated by reference), carrier wafers may require pretreatment with a coating before the wafers are bonded together. Previously, a halogenated silane in a fluorinated solvent, such as 3M FC-40 Fluorinert™ electronic liquid, was used for carrier wafer preparation. However, the silane/FC-40 solution is not a practical coating material because it is unstable, and FC-40 is restricted for use in microelectronics manufacturing because of environmental concerns. Vapor deposition of fluorinated silanes has been used previously to treat the surfaces of silicon wafers. However, vapor deposition is a process that is costly because of both the time involved and the expensive, high-quality tooling it requires.

There is a need for additional bonding methods and materials that overcome the shortcomings described above.

SUMMARY OF THE INVENTION

In one embodiment, a temporary bonding method is provided. The method involves providing a stack comprising:

- a first substrate having a back surface and a front surface;
- a bonding layer adjacent the front surface, with the bonding layer being formed from a composition comprising a cyclic olefin polymer dissolved or dispersed in a solvent system; and
- a second substrate having a first surface. The first and second substrates are separated without subjecting the stack to heat.

In another embodiment, the invention provides a temporary bonding method comprising providing a stack comprising:

- a first substrate having a back surface and a front surface;
- a bonding layer adjacent the front surface; and
- a second substrate having a first surface, with the first surface including a polysiloxane nonstick layer adjacent the bonding layer.

The first and second substrates are then separated.

In a final embodiment, the invention provides an article comprising a first substrate having a back surface and a front surface. There is a bonding layer adjacent the front surface. The article also comprises a second substrate having a first surface, with the first surface
5 including a polysiloxane nonstick layer adjacent the bonding layer.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

20

Release Layers

In one embodiment, a release layer is utilized. Several types of release layers can be utilized with the present invention, as explained in more detail below, but one preferred type is a nonstick layer. Preferred compositions for use in forming a nonstick release layer according
25 to the invention comprise siloxane polymers and copolymers (both copolymers with siloxanes as well as copolymers with non-siloxanes). Preferred siloxanes are those selected from the group consisting of epoxyl, ethoxyl, acrylic, hydroxyl, vinyl, and amine, and mixtures thereof. Especially preferred siloxanes are epoxycyclohexylethylmethylsiloxane-dimethylsiloxane copolymers (ECMS-327 from Gelest), ECMS-924 (Gelest), VDT-5035 (Gelest), EBP-234
30 (Gelest), AMS-2202 (Gelest), AMS-1203 (Gelest), and mixtures thereof. The composition preferably comprises from about 0.01% to about 8.0% by weight, more preferably from about

0.05% to about 5.0% by weight, and even more preferably from about 0.1% to about 0.8% by weight siloxane, based upon the total weight of the composition taken as 100% by weight. Preferably, the polymer has a weight average molecular weight of from about 200 Daltons to about 4,000,000 Daltons, more preferably from about 1,000 Daltons to about 400,000 Daltons, and even more preferably from about 2,000 Daltons to about 40,000 Daltons.

The nonstick compositions also preferably comprise a catalyst. Suitable catalysts include those selected from the group consisting of photoacid generators, thermal acid generators, and mixtures thereof. Especially preferred catalysts include K-PURE® TAG-2689 from King Industries or 1, 1'-azobis(cyclohexanecarbonitrile). The nonstick composition preferably comprises from about 0.002% to about 0.1% by weight catalyst, more preferably from about 0.005% to about 0.1% by weight catalyst, and even more preferably from about 0.008% to about 0.1% by weight catalyst, based upon the total weight of the composition taken as 100% by weight.

The nonstick compositions also comprise an industry-accepted, safe solvent, which is typically a polar solvent. Suitable solvents include those selected from the group consisting of propylene glycol monomethyl ether ("PGME"), d-limonene, ethyl 3-ethoxypropionate, propoxy propanol ("PnP"), propylene glycol methyl ether acetate ("PGMEA"), ethyl lactate, and mixtures thereof. The composition preferably comprises from about 90% to about 99.99% by weight solvent, more preferably from about 92% to about 99.5% by weight solvent, and even more preferably from about 95% to about 99% by weight of this solvent, based upon the total weight of the nonstick composition taken as 100% by weight. One especially preferred solvent mixture is a mixture of PGME (from about 5% to about 40% by weight) and d-limonene (from about 60 to about 95% by weight).

In one embodiment, the nonstick composition is essentially free of silanes. That is, the nonstick composition comprises less than about 0.5%, preferably less than about 0.1%, and more preferably about 0% by weight silanes, based upon the total weight of the nonstick composition taken as 100% by weight. In another embodiment, the nonstick composition consists essentially of, or even consists of, a siloxane, a catalyst, and solvent (preferably a polar solvent). The nonstick composition is formed by simply mixing the above ingredients together.

Bonding Compositions

The bonding material comprises a polymer or a blend of polymers dissolved or dispersed in a solvent system. Other additives such as antioxidants, surfactants, tackifiers, and toners may be included in the bonding material, depending upon the desired coating, bonding, and debonding performance.

In one embodiment, the polymer or blend of polymers are selected from the group consisting of polymers and oligomers of cyclic olefins, epoxies, acrylics, styrenics, vinyl halides, vinyl esters, polyamides, polyimides, polysulfones, polyethersulfones, cyclic olefins, polyolefin rubbers, polyurethanes, ethylene-propylene rubbers, polyamide esters, polyimide esters, polyacetals, and polyvinyl buterol, with the most preferred being cyclic olefin polymers. Suitable cyclic olefin polymers include those prepared from a single monomer, such as norbornene, by metathesis polymerization techniques and then hydrogenated to produce the final product. Particularly preferred COP materials include those commercialized under the names Zeonex[®] 5000 and Zeonex 480R.

The polymer or polymer blend should be present in the bonding composition at levels of from about 1% by weight to about 60% by weight, more preferably from about 20% by weight to about 40% by weight, and even more preferably from about 25% by weight to about 35% by weight, based upon the total weight of the bonding composition taken as 100% by weight. Preferably, the polymer has a weight average molecular weight of from about 1,000 Daltons to about 200,000 Daltons, more preferably from about 5,000 Daltons to about 150,000 Daltons, and even more preferably from about 10,000 Daltons to about 100,000 Daltons.

Suitable solvent systems include hydrocarbon solvents such as those selected from the group consisting of d-limonene, mesitylene, cyclooctane, and bicyclohexyl. The solvent or solvents should be present in the composition at levels of from about 40% by weight to about 99% by weight, more preferably from about 60% by weight to about 80% by weight, and even more preferably from about 65% by weight to about 75% by weight, based upon the total weight of the composition taken as 100% by weight.

Suitable antioxidants include phenolic antioxidants such as those selected from the group consisting of 1,3,5-trimethyl-2,4,6-tris (3,5-di-tert-butyl-4-hydroxybenzyl) benzene (sold as Irganox[®] 1330) and benzenepropanoic acid, 3,5-bis(1,1-dimethylethyl)-4-hydroxy-1,6-hexanediyl ester (Irganox[®] L-109). The antioxidant should be present in the composition from about 0.05%

by weight to about 10% by weight, more preferably from about 1% by weight to about 5% by weight, and even more preferably from about 2% by weight to about 4% by weight, based upon the total weight of the composition taken as 100% by weight.

5 In a preferred embodiment, the bonding compositions are essentially free of cyclic olefin copolymers. That is, the bonding composition comprises less than about 0.5%, preferably less than about 0.1%, and more preferably about 0% by weight cyclic olefin copolymers, based upon the total weight of the bonding composition taken as 100% by weight.

10 In another embodiment, the bonding compositions are essentially free of pinene and poly(pinene). That is, the bonding composition comprises less than about 0.5%, preferably less than about 0.1%, and more preferably about 0% by weight pinene and poly(pinene), based upon the total weight of the bonding composition taken as 100% by weight.

15 In another embodiment, the bonding compositions are essentially free of rosin esters. That is, the bonding composition comprises less than about 0.5%, preferably less than about 0.1%, and more preferably about 0% by weight rosin esters, based upon the total weight of the bonding composition taken as 100% by weight.

In another embodiment, the bonding compositions are essentially free of silicones. That is, the bonding composition comprises less than about 0.5%, preferably less than about 0.1%, and more preferably about 0% by weight silicones, based upon the total weight of the bonding composition taken as 100% by weight.

20 In one embodiment, the bonding compositions consist essentially of, or even consist of, a cyclic olefin polymer, antioxidant, and solvent. In a further embodiment, the bonding compositions consist essentially of, or even consist of, a cyclic olefin polymer, antioxidant, solvent, and any surfactants, toners, and/or tackifiers.

25 The compositions are formed by simply mixing the above ingredients so as to create a substantially uniform mixture of the ingredients. Preferably, any additional ingredients, such as antioxidants, are dissolved in the solvent first, and the polymer or polymers are added last. Advantageously, this results in the formation of visually clear solutions. Furthermore, wafer pairs bonded with these bonding compositions are able to survive (i.e., there are no defects in the bond line) treatment on a hot plate at about 300°C for about 30 minutes. These bonding materials also provide excellent overall total thickness variation ("TTV," less than about 3 μm for 50- μm bond line) and can survive a 200°C PECVD process.

30

Inventive Method

Referring to Fig. 1(a) (not to scale), a precursor structure 10 is depicted in a schematic and cross-sectional view. Structure 10 includes a first substrate 12. Substrate 12 has a front or device surface 14, a back surface 16, and an outermost edge 18. Although substrate 12 can be of any shape, it would typically be circular in shape. Preferred first substrates 12 include device wafers such as those whose device surfaces comprise arrays of devices (not shown) selected from the group consisting of integrated circuits, MEMS, microsensors, power semiconductors, light-emitting diodes, photonic circuits, interposers, embedded passive devices, and other microdevices fabricated on or from silicon and other semiconducting materials such as silicon-germanium, gallium arsenide, gallium nitride, aluminum gallium arsenide, aluminum indium gallium phosphide, and indium gallium phosphide. The surfaces of these devices commonly comprise structures (again, not shown) formed from one or more of the following materials: silicon, polysilicon, silicon dioxide, silicon (oxy)nitride, metals (e.g., copper, aluminum, gold, tungsten, tantalum), low k dielectrics, polymer dielectrics, and various metal nitrides and silicides. The device surface 14 can also include at least one structure selected from the group consisting of: solder bumps; metal posts; metal pillars; and structures formed from a material selected from the group consisting of silicon, polysilicon, silicon dioxide, silicon (oxy)nitride, metal, low k dielectrics, polymer dielectrics, metal nitrides, and metal silicides.

A composition is applied to the first substrate 12 to form a bonding layer 20 on the device surface 14, as shown in Fig. 1(a). Bonding layer 20 has an upper surface 21 remote from first substrate 12, and preferably, the bonding layer 20 is formed directly adjacent the device surface 14 (i.e., without any intermediate layers between the bonding layer 20 and substrate 12). Although bonding layer 20 is shown to cover the entire device surface 14 of first substrate 12, it will be appreciated that it could be present on only portions or "zones" of device surface 14, as shown in U.S. Patent Publication No. 2009/0218560.

The bonding composition can be applied by any known application method, including dip coating, roller coating, slot coating, die coating, screen printing, draw-down coating, or spray coating. Additionally, the coatings may be formed into free-standing films before application to the device substrate or carrier substrate surface. One preferred method involves spin-coating the composition at speeds of from about 200 rpm to about 3,000 rpm (preferably from about 500 rpm to about 2,000 rpm) for a time period of from about 5 seconds to about 120 seconds

(preferably from about 10 seconds to about 60 seconds). After the composition is applied, it is preferably heated to a temperature of from about 40°C to about 250°C, and more preferably from about 90°C to about 220°C and for time periods of from about 60 seconds to about 90 minutes (preferably from about 180 seconds to about 60 minutes). Depending upon the composition used to form the bonding layer 20, baking can also initiate a crosslinking reaction to cure the layer 20. In some embodiments, it is preferable to subject the layer to a multi-stage bake process, depending upon the composition utilized. Also, in some instances, the above application and bake process can be repeated on a further aliquot of the composition, so that the first bonding layer 20 is "built" on the first substrate 12 in multiple steps. The resulting layer 20 should have an average thickness (average taken over five measurements) of from about 1 μm to about 200 μm, more preferably from about 10 μm to about 150 μm, and even more preferably from about 30 μm to about 120 μm.

The materials from which bonding layer 20 is formed should be capable of forming a strong adhesive bond with the first and second substrates 12 and 24, respectively. Anything with an adhesion strength of greater than about 50 psig, preferably from about 80 psig to about 250 psig, and more preferably from about 100 psig to about 150 psig, as determined by ASTM D4541/D7234, would be desirable for use as bonding layer 20, with the exemplary compositions having been described above.

A second precursor structure 22 is also depicted in a schematic and cross-sectional view in Fig. 1(a). Second precursor structure 22 includes a second substrate 24. In this embodiment, second substrate 24 is a carrier wafer. That is, second substrate 24 has a front or carrier surface 26, a back surface 28, and an outermost edge 30. Although second substrate 24 can be of any shape, it would typically be circular in shape and sized similarly to first substrate 12. Preferred second substrates 24 include silicon, sapphire, quartz, metals (e.g., aluminum, copper, steel), and various glasses and ceramics.

A composition is applied to the second substrate 24 to form a release (preferably nonstick, in this embodiment) layer 32 on the carrier surface 26, as shown in Fig. 1(a). (Alternatively, structure 22 can be provided already formed.) Nonstick layer 32 has an upper surface 33 remote from second substrate 24, and a lower surface 35 adjacent second substrate 24. Preferably, the nonstick layer 32 is formed directly adjacent the carrier surface 26 (i.e., without any intermediate layers between the second bonding layer 32 and second substrate 24).

The nonstick composition can be applied by any known application method, with one preferred method being spin-coating the composition at speeds of from about 500 rpm to about 5,000 rpm (preferably from about 500 rpm to about 2,000 rpm) for a time period of from about 5 seconds to about 120 seconds (preferably from about 30 seconds to about 90 seconds). After the composition is applied, it is preferably heated to a temperature of from about 100°C to about 300°C, and more preferably from about 150°C to about 250°C and for time periods of from about 30 seconds to about 5 minutes (preferably from about 90 seconds to about 3 minutes). Nonstick layer 32 preferably has an average thickness of less than about 1 μm, preferably from about 0.1 μm to about 1 μm, and more preferably from about 1 nm to about 25 nm.

Referring to structure 22 of Fig. 1(a) again, although nonstick layer 32 is shown to cover the entire surface 26 of second substrate 24, it will be appreciated that it could be present on only portions or "zones" of carrier surface 26 similar to as was described with bonding layer 20. Regardless, the dried/cured layer 32 will have a high contact angle with water, which effects polymer release during the debonding step (discussed below). Typical contact angles (measured as described in Example 10) will be at least about 60°, preferably from about 60° to about 120°, more preferably from about 90° to about 110°, and even more preferably from about 100° to about 110°. The nonstick layer 32 also preferably has an adhesion strength of less than about 50 psig, preferably less than about 35 psig, and more preferably from about 1 psig to about 30 psig, determined as described above.

Structures 10 and 22 are then pressed together in a face-to-face relationship, so that upper surface 21 of bonding layer 20 is in contact with upper surface 33 of nonstick layer 32 (Fig. 1(b)). While pressing, sufficient pressure and heat are applied for a sufficient amount of time so as to effect bonding of the two structures 10 and 22 together to form bonded stack 34. The bonding parameters will vary depending upon the composition from which bonding layer 20 is formed, but typical temperatures during this step will range from about 100°C to about 400°C, and preferably from about 150°C to about 250°C, with typical pressures ranging from about 100 N to about 20,000 N, and preferably from about 1,000 N to about 10,000 N, for a time period of from about 1 minute to about 20 minutes, preferably from about 2 minutes to about 10 minutes, and more preferably from about 3 minutes to about 5 minutes.

In an alternative embodiment, it will be appreciated that bonding layer 20 could be applied to upper surface 33 of nonstick layer 32, using the application process described

previously, rather than being applied to surface 14 of first substrate 12. In this instance, the first substrate 12 would then be subjected to the above bonding process so as to bond surface 14 of first substrate 12 to bonding layer 20, which was previously formed on upper surface 33 of nonstick layer 32.

5 Regardless of which embodiment was used to form the bonded stack 34, the first substrate 12 can now be safely handled and subjected to further processing that might otherwise have damaged first substrate 12 without being bonded to second substrate 24. Thus, the structure can safely be subjected to backside processing such as back-grinding, chemical-mechanical polishing ("CMP"), etching, metallizing, dielectric deposition, patterning (e.g., photolithography,
10 via etching), passivation, annealing, and combinations thereof, without separation of substrates 12 and 24 occurring, and without infiltration of any chemistries encountered during these subsequent processing steps. Not only can bonding layer 20 survive these processes, it can also survive processing temperatures up to about 450°C, preferably from about 200°C to about 400°C, and more preferably from about 200°C to about 350°C.

15 Once processing is complete, the substrates 12 and 24 can be separated by any number of separation methods (not shown). One method involves dissolving the bonding layer 20 in a solvent (e.g., limonene, dodecene, PGME). Alternatively, substrates 12 and 24 can also be separated by first mechanically disrupting or destroying bonding layer 20 using laser ablation, plasma etching, water jetting, or other high energy techniques that effectively etch or decompose
20 bonding layer 20. It is also suitable to first saw or cut through the bonding layer 20 or cleave the layer 20 by some equivalent means. Furthermore, it will be appreciated that other layers (not shown) might be included in the stack, and debonding could take place at that other layer instead of at bonding layer 20. For example, a cleaning layer might be included, and debonding could be carried out by dissolving that cleaning layer. As another example, a laser release layer could
25 be included, and debonding could be effected by laser ablation across that laser release layer.

 In situations where a bonding composition other than a cyclic olefin polymer-containing composition is utilized, a suitable separation method involves heating the bonded stack 34 to temperatures of at least about 100°C, preferably from about 150°C to about 220°C, and more preferably from about 180°C to about 200°C. It will be appreciated that at these temperatures,
30 the bonding layer 20 will soften, allowing the substrates 12 and 24 to be separated (e.g., by a

slide debonding method, such as that described in U.S. Patent Publication No. 2008/0200011, incorporated by reference herein).

It will be appreciated that embodiments using the inventive cyclic olefin polymer-containing compositions avoids the need to heat the bonding layer 20 prior to separation. That is, after processing has been completed, the stack 34 can be separated without any heat exposure, using a low-force mechanical debonding method. In this instance, the stack 34 is exposed to temperatures of less than about 100°C, preferably less than about 75°C, more preferably less than about 50°C, even more preferably less than about 30°C, and most preferably about ambient temperatures (and certainly no lower than ambient temperatures), prior to and during the separating. It will be understood that a lack of heat exposure during separation does not exclude heat exposure that occurs during the stack processing, prior to separation, but simply that heat exposure stops after processing is complete. So, for example, the heat exposure that might have occurred during stack processing will have ended at least about 60 seconds, and more preferably at least about 300 seconds prior to stack separation.

Regardless of which of the above means is utilized, a low mechanical force (e.g., finger pressure, gentle wedging) can then be applied to completely separate the substrates 12 and 24. After separation, any remaining bonding layer 20 can be removed with a solvent capable of dissolving the particular layer 20. In fact, the inventive bonding layer 20 is highly removable by conventionally-used solvents. That is, the bonding layer 20 can be at least about 95% removed, preferably at least about 98% removed, and more preferably about 100% removed, upon being in contact with a typical cleaning solvent (e.g., d-limonene) at ambient temperatures for a time period of from about 1 minute to about 10 minutes, and preferably from about 3 minutes to about 5 minutes.

In the above embodiments, the nonstick layer 32 is shown on a second substrate 24 that is a carrier wafer, while bonding layer 20 is shown on a first substrate 12 that is a device wafer. It will be appreciated that this substrate/layer scheme could be reversed. That is, the nonstick layer 32 could be formed on first substrate 12 (the device wafer) while bonding layer 20 is formed on second substrate 24 (the carrier wafer). The same compositions and processing conditions would apply to this embodiment as those described above. Additionally, the use of the nonstick layer 32 is optional. Bonding layer 20 could be used alone, without the presence of nonstick layer 32. Bonding layer 20 could also be used with additional bonding materials,

structural support layers, other types of release layers (as noted previously, including, but not limited to, mechanical debonding, laser debonding, and thermal or chemical debonding), lamination aid layers, tie layers (for adhesion to initial substrate), contamination control layers, and cleaning layers. Preferred structures and application techniques will be dictated by application and process flow.

Polymeric structural support layers that can be used in combination with the COP bonding materials can comprise monomers, oligomers, polymers, suspended particles, and/or combinations thereof. Examples of suitable monomers, oligomers, and polymers include those selected from the group consisting of cyclic olefin polymers and copolymers, polyimides, polyisobutylenes, hydrocarbon resins, epoxy resins, fluoropolymers, polysulfones, polyethersulfones, polyether ether ketones, polyhydroxyethers, and polyvinylbutyrals. Suitable suspended particles include those selected from the group consisting of alumina, ceria, titania, silica, zirconia, graphite, and nanoparticles, sol-gel particles, and mixtures thereof. Preferred compositions will be structurally rigid at the temperature of use as indicated by glass transition temperature, coefficient of thermal expansion, and modulus.

Mechanical carrier release layers (in addition to, or in lieu of, the polysiloxane layers discussed above) used in conjunction with the COP bonding materials can be composed of monomers, oligomers, and/or polymers. Examples of suitable monomers, oligomers, and polymers include cyclic olefin polymers and copolymers, polyisobutylenes, hydrocarbon resins, epoxy resins, fluoropolymers, polyimides, polysulfones, polyhydroxyethers, polyvinylbutyrals, amorphous fluoropolymers with high atomic fluorine content such as fluorinated siloxane polymers, fluorinated ethylene-propylene copolymers, tetrafluoroethylene hexafluoropropylene, vinylidene fluoride terpolymer, hexafluoropropylene, vinylidene fluoride copolymer, vinylidene fluoride polymer, and polymers with pendant perfluoroalkoxy groups.

Laser carrier release layers used in conjunction with the COP bonding materials can be composed of monomers, oligomers, and/or polymers. One example of a suitable laser release layer is polyimides.

EXAMPLES

The following examples set forth preferred methods in accordance with the invention. It is to be understood, however, that these examples are provided by way of illustration and nothing therein should be taken as a limitation upon the overall scope of the invention.

5

EXAMPLE 1

Formulation of a 0.5% ECMS-327 Siloxane Solution

To a 250 ml glass bottle, 0.02 gram of K-PURE® TAG-2689 (King Industries Inc. Norwalk, CT) and 19.9 grams of propylene glycol monomethyl ether ("PGME," Ultra Pure, Inc.,
 10 Castroville, CA) were added. The solution was mixed for 5-10 minutes until all of K-PURE® TAG-2689 dissolved. Next, 79.58 grams of d-limonene (Florida Chemical Co. Winter Haven, FL) and 0.5 gram of ECMS-327 (polysiloxane, structure shown below; Gelest, Morrisville, PA) were then added to the solution. The final solution was mixed for 30-60 minutes until all of polysiloxane was dissolved, after which the solution was filtered once through 0.1-μm disk filter
 15 (Whatman Inc., Florham Park NJ). The total concentration of polysiloxane in this solution was 0.5% by weight.

20

25

EXAMPLE 2

Formulation of a 0.5% ECMS-924 Siloxane Solution

To a 250 ml glass bottle, 0.02 gram of K-PURE® TAG-2689 (King Industries Inc. Norwalk, CT) and 19.9 grams of PGME (Ultra Pure, Inc., Castroville, CA) were added. The solution was mixed for 5-10 minutes until all of K-PURE® TAG-2689 dissolved. 79.58 grams
 30 of d-limonene (Florida Chemical Co. Winter Haven, FL) and 0.5 gram of ECMS-924 (polysiloxane, Gelest, Morrisville, PA) were then added to the solution. (The structure of this

polymer is similar to that shown for Example 1, with the difference in numbers denoting a difference in molecular weights.) The final solution was mixed for 30-60 minutes until all of polysiloxane dissolved and then was filtered once through 0.1- μ m disk filter (Whatman Inc., Florham Park NJ). The total concentration of polysiloxane in this solution was 0.5% by weight.

5

EXAMPLE 3

Formulation of a 0.5% VDT-5035 Siloxane Solution

To a 250 ml glass bottle, 100 grams of PGME (Ultra Pure, Inc., Castroville, CA), 0.5 gram of VDT-5035 (Gelest, structure shown below; Morrisville, PA), and 0.025 gram of 1, 1'-azobis(cyclohexanecarbonitrile) (Sigma-Aldrich, St Louis, MO) were added. The final solution was mixed for 30-60 minutes until all of polysiloxane dissolved. The total concentration of polysiloxane in this solution was about 0.5% by weight.

15

20

EXAMPLE 4

Formulation of a 0.5% EBP-234 Siloxane Solution

To a 250 ml glass bottle, 100 grams of PGME (Ultra Pure, Inc., Castroville, CA), 0.5 gram of EBP-234 (Gelest, structure shown below; Morrisville, PA), and 0.027 gram of K-PURE® TAG-2689 were added. The final solution was mixed for 30-60 minutes until all of polysiloxane dissolved. The total concentration of polysiloxane in this solution was about 0.5% by weight.

30

EXAMPLE 5

Formulation of a 0.6% ECMS-327 Siloxane Solution

5 To a 250 ml plastic bottle, 0.02 gram of K-PURE® TAG-2689 (King Industries Inc. Norwalk, CT) and 4.969 grams of PGME (Ultra Pure, Inc., Castroville, CA) were added. The solution was mixed for 5-10 minutes until all of K-PURE® TAG-2689 dissolved. 94.411 grams of 3-ethoxypropionate (EEP, Sigma-Aldrich Inc., St. Louis, MO) and 0.6 gram of ECMS-327 (polysiloxane, Gelest, Morrisville, PA) were then added to the solution. The final solution was
10 mixed for 30-60 minutes until all of polysiloxane dissolved and then was filtered once through a 0.1-µm disk filter (Whatman Inc., Florham Park NJ). The total concentration of polysiloxane in this solution was 0.6% by weight.

EXAMPLE 6

15 Formulation of a 0.1% ECMS-327 Siloxane Solution

To a 250 ml plastic bottle, 0.004 gram of K-PURE® TAG-2689 (King Industries Inc. Norwalk, CT) and 4.9948 grams of PGME (Ultra Pure, Inc., Castroville, CA) were added. The solution was mixed for 5-10 minutes until all of K-PURE® TAG-2689 dissolved. Next, 94.9012 grams of 3-ethoxypropionate (EEP, Sigma-Aldrich Inc., St. Louis, MO) and 0.1 gram
20 of ECMS-327 (polysiloxane, Gelest, Morrisville, PA) were then added to the solution. The final solution was mixed for 30-60 minutes until all of polysiloxane dissolved and then was filtered once through 0.1-µm disk filter (Whatman Inc., Florham Park NJ). The total concentration of polysiloxane in this solution was 0.1% by weight.

25 EXAMPLE 7

Formulation of a 0.2% ECMS-327 Siloxane Solution

To a 250 ml plastic bottle, 0.008 gram of K-PURE® TAG-2689 (King Industries Inc. Norwalk, CT) and 4.9896 grams of PGME (Ultra Pure, Inc., Castroville, CA) were added. The solution was mixed for 5-10 minutes until all of K-PURE® TAG-2689 dissolved. Next,
30 94.8024 grams of 3-ethoxypropionate (EEP, Sigma-Aldrich Inc., St. Louis, MO) and 0.2 gram of ECMS-327 (polysiloxane, Gelest, Morrisville, PA) were added to the solution. The final

solution was mixed for 30-60 minutes until all of the polysiloxane had dissolved, followed by filtering once through 0.1- μ m disk filter (Whatman Inc., Florham Park NJ). The total concentration of polysiloxane in this solution was 0.2% by weight.

5

EXAMPLE 8

Formulation of a 0.6% AMS-2202 Siloxane Solution

To a 250 ml plastic bottle, 49.7 grams of PGME (Ultra Pure, Inc., Castroville, CA) and 0.3 gram of AMS-2202 (Gelest, structure shown below; Morrisville, PA) were added. The final solution was mixed for 30-60 minutes until all of polysiloxane dissolved. The total concentration of polysiloxane in this solution was about 0.6% by weight.

10

15

EXAMPLE 9

Formulation of a 0.6% AMS-1203 Siloxane Solution

To a 250 ml plastic bottle, 49.7 grams of PGME (Ultra Pure, Inc., Castroville, CA) and 0.3 gram of AMS-1203 (Gelest, Morrisville, PA) were added. The final solution was mixed for 30-60 minutes until all of polysiloxane dissolved. The total concentration of polysiloxane in this solution was about 0.6% by weight.

25

EXAMPLE 10

Testing of Siloxane Solutions

The solutions formulated in Examples 1 to 9 were spin-coated onto 100-mm silicon wafers by spinning at 1,500 rpm with 10,000 rpm/s ramp for 30 seconds, and then baked at 205 °C for 60 seconds. All wafers had good coat quality via visual observation. The thickness was measured with ellipsometer. The contact angle with water was measured using VCA Optima Tool from AST Products, Inc. Billerica, MA. The results are listed in the Table 1.

30

Table 1. Solution appearance, thickness, and contact angle of siloxane solutions.

Sample	Solution appearance	Thickness, Å	Contact angle
Example 1	Clear	123	105°
Example 2	Clear	105	101°
Example 3	Clear	108	106°
Example 4	Clear	104	96°
Example 5	Clear	120	104°
Example 6	Clear	16	96°
Example 7	Clear	32	106°
Example 8	Clear	287	103°
Example 9	Clear	305	103°

EXAMPLE 11

Bonding Testing of Siloxane Solution from

Example 1 with Cyclic Olefin Polymer

The solution formulated in Example 1 was spin-coated onto 200-mm silicon wafers by spinning at 1,500 rpm with 10,000 rpm/s ramp for 30 seconds, and then baked at 205°C for 60 seconds. The contact angle of the fully-coated wafer was determined to be 105. A 50-μm film of the cyclic olefin polymer bonding material from Example 16 was coated onto another 200-mm silicon wafer by spin-coating at 1,000 rpm with a 3,000 rpm/s ramp for 30 seconds, and then baking at 60°C for 3 minutes, 160°C for 2 minutes, and 205°C for 2 minutes.

The two wafers were bonded in a face-to-face relationship at 200°C for 3 minutes in a heated vacuum and under pressure chamber with 1,800 N of bonding pressure on an EVG510 bonder. After cooling to room temperature, the bonded wafers were separated easily by a peeling process using a ZoneBOND® separation tool.

EXAMPLE 12

Bonding Testing of Siloxane Solution
from Example 5 with Cyclic Olefin Polymer

The solution formulated in Example 5 was spin-coated onto 200-mm silicon wafers by spinning at 1,500 rpm with 10,000 rpm/s ramp for 30 seconds, and then baked at 205°C for 60 seconds. The contact angle of the fully-coated wafer was measured to be 105. A 50-μm film of the cyclic olefin polymer bonding material from Example 16 was coated onto another 200-mm silicon wafer by spin-coating at 1,000 rpm with a 3,000 rpm/s ramp for 30 seconds, and then baking at 60°C for 3 minutes, 160°C for 2 minutes, and 205°C for 2 minutes.

The two wafers were bonded in a face-to-face relationship at 200°C for 3 minutes in a heated vacuum and under pressure chamber with 1,800 N of bonding pressure on an EVG510 bonder. After cooling to room temperature, the bonded wafers were separated easily by a peeling process using a ZoneBOND® separation tool.

EXAMPLE 13

Bonding and Backside Processing Testing of Siloxane Solution
from Example 5 with Cyclic Olefin Polymer

The solution formulated in Example 5 was spin-coated onto 200-mm silicon wafers by spinning at 1,500 rpm with 10,000 rpm/s ramp for 30 seconds, and then baked at 205°C for 60 seconds. The contact angle of the fully-coated wafer was measured to be 105. A 50-μm film of the cyclic olefin polymer bonding material from Example 16 was coated onto another 200-mm silicon wafer by spin-coating at 1,000 rpm with a 3,000 rpm/s ramp for 30 seconds, and then baking at 60°C for 3 minutes, 160°C for 2 minutes, and 205°C for 2 minutes.

The two wafers were bonded in a face-to-face relationship at 200°C for 3 minutes in a heated vacuum and under pressure chamber with 1,800 N of bonding pressure on an EVG510 bonder. The wafer pair was then cooled down to room temperature. The wafer pair was subjected to a backgrinding process, which thinned the device wafer to 50 μm in thickness. The wafer pair was then heat-treated for 30 minutes at 260°C and cooled again to room temperature.

The bonded wafers were separated easily by a peeling process using a ZoneBOND® separation tool.

EXAMPLE 14

Bonding Testing of Siloxane Solution from
Example 5 with WaferBOND® HT-10.10 Material

The solution formulated in Example 5 was spin-coated onto 200-mm silicon wafers by spinning at 1,500 rpm with a 10,000 rpm/s ramp for 30 seconds, and then baked at 205°C for 60 seconds. The contact angle of the fully-coated wafer was measured to be 105. A 50-μm film of WaferBOND® HT-10.10 material (Brewer Science, Inc.) was coated onto another 200-mm silicon wafer by spin-coating at 400 rpm with a 500 rpm/s ramp for 35 seconds, and then baking at 120°C for 3 minutes and 180°C for 4 minutes.

The two wafers were bonded in a face-to-face relationship at 180°C for 3 minutes in a heated vacuum and under pressure chamber with 1,800 N of bonding pressure on an EVG510 bonder. After cooling down to room temperature, the bonded wafers were separated easily by a peeling process using a ZoneBOND® separation tool.

EXAMPLE 15

Bonding and Backside Processing Testing of Siloxane
Solution from Example 5 with WaferBOND® HT-10.10 Material

The solution formulated in Example 5 was spin-coated onto 200-mm silicon wafers by spinning at 1,500 rpm with 10,000 rpm/s ramp for 30 seconds, and then baked at 205°C for 60 seconds. The contact angle of the fully-coated wafer was measured to be 105. A 50-μm film of WaferBOND® HT-10.10 material (Brewer Science, Inc.) was coated onto another 200-mm silicon wafer by spin-coating at 400 rpm with a 500 rpm/s ramp for 35 seconds, and then baking at 120°C for 3 minutes and 180°C for 4 minutes.

The two wafers were bonded in a face-to-face relationship at 180°C for 3 minutes in a heated vacuum and under pressure chamber with 1,800 N of bonding pressure on an EVG510 bonder. The wafer pair was then cooled down to room temperature. The wafer pair was subjected to a backgrinding process, which thinned the device wafer to 50 μm thickness. The wafer pair was then heat treated for 30 minutes at 260°C and cooled again to room temperature. The bonded wafers were then separated easily by a peeling process using a ZoneBOND® separation tool.

EXAMPLE 16

Formulation of Bonding Material 1

First, 1.8 grams of Irganox® 1330 antioxidant (Sigma-Aldrich, MO) was dissolved in 138.2 grams of d-limonene (Florida Chemical Company, FL). Then, 60 grams of ZEONEX® 5000 cyclic olefin polymer (Zeon Corporation, Japan) was added to the solution, and the solution was rotated on a rotating wheel until the polymer was fully dissolved. The solution was then filtered with a 0.2-μm Meissner Vanguard filter.

EXAMPLE 17

Formulation of Bonding Material 2

First, 1.8 grams of Irganox® 1330 antioxidant was dissolved in 140 grams of d-limonene. Then, 54 grams of ZEONEX® 5000 and 6 grams of ZEONEX® 480R cyclic olefin polymers (Zeon Corporation, Japan) were added to the solution, and the solution was rotated on a rotating wheel until the polymer was fully dissolved. The solution was then filtered with a 0.2-μm Meissner Vanguard filter.

EXAMPLE 18

Thermal Stability Testing of Bonding Material

The bonding material from Example 16 was spin coated onto an eight-inch wafer at 750 rpm, with 3,000 rpm/s acceleration for 30 seconds. The wafer was then baked at 60°C for 2 minutes, 160°C for 2 minutes, and 200°C for 13 minutes. The film was scratched off of the wafer for TGA. TGA was performed using a 10°C/min ramp in air. The result is in Fig. 2. The decomposition temperature was 436°C, and the 2% weight loss point was at 363°C.

EXAMPLE 19

Bonding of Substrates Using Bonding Material

In this Example, a 50-μm coat of the bonding material from Example 16 was coated on an eight-inch Si wafer by spin coating the material at 1,000 rpm, with 3,000 rpm/s acceleration for 30 seconds. The wafer was then baked at 60°C for 3 minutes, 160°C for 2 minutes, and 200°C for 2 minutes. A carrier Si wafer was coated with Brewer Science® ZoneBOND® 3500-02 anti-stiction material by spin coating at 1,250 rpm, with 250 rpm/s acceleration for 30 seconds.

The carrier wafer was then baked at 160°C for 3 minutes. The wafer pair was then bonded at 200°C, 1,800 N for 3 minutes under vacuum (< 5 mbar) using an EVG Model 510 bonder. The bonded pair was examined with a scanning acoustic microscope from Sonoscan. The images showed that the wafer pair was bonded well, and there were no voids detected (Fig. 3).

5

EXAMPLE 20

Heat Treatment of Wafer Pair Bonded

with Bonding Material from Example 16

In this Example, a 50-μm coating of the bonding material from Example 16 was coated on an eight-inch silicon wafer by spin coating the material at 1,000 rpm, with 3,000 rpm/s acceleration for 30 seconds. The wafer was then baked at 60°C for 3 minutes, 160°C for 2 minutes, and 205°C for 2 minutes. A glass carrier wafer was coated with Brewer Science® ZoneBOND® 3500-02 anti-stiction material by spin coating at 1,250 rpm, with 250 rpm/s acceleration for 30 seconds. The carrier wafer was then baked at 160°C for 3 minutes. The wafer pair was then bonded at 200°C, 1,800 N for 3 minutes under vacuum (< 5 mbar) in an EVG510 bonder. The bonded pair was then placed on a hot plate at 300°C for 30 minutes. There were no voids or defects observed after the heat treatment, as can be seen in Fig. 4. After heat treatment, the wafers were separated with a Brewer Science® peel debonder without edge soaking or cleaning.

20

EXAMPLE 21

PECVD of Bonded, Thinned Wafer Pair

In this Example, a 50-μm coat of the bonding material from Example 16 was coated on an eight-inch Si wafer by spin coating the material at 1,000 rpm, with 3,000 rpm/s acceleration for 30 seconds. The wafer was then baked at 60°C for 3 minutes, 160°C for 2 minutes, and 200°C for 2 minutes. A glass carrier was coated with Brewer Science® ZoneBOND® 3500-02 anti-stiction material by spin coating at 1,250 rpm, with 250 rpm/s acceleration for 30 seconds. The carrier wafer was then baked at 160°C for 3 minutes. The wafer pair was then bonded at 200°C, 1,800 N for 3 minutes under vacuum (< 5 mbar) in EVG510 bonder. The device wafer was thinned to 50-μm thickness using a commercial DISCO® brand wafer grinding tool. A SiOx

30

layer was deposited on the thinned wafer in a PECVD chamber at 200°C for 2 minutes. The wafer pair was bonded very well, and there were no voids detected by IR observation (Fig. 5).

EXAMPLE 22

Cleaning of Bonding Material After Debonding

In this Example, a 50- μ m film of the material from Example 16 was coated on an eight-inch blank silicon wafer. The silicon carrier wafer was coated with Brewer Science® ZoneBOND® 3500-02 anti-stiction material. The wafer pair was then bonded at 210°C, 1,800 N for 3 min under vacuum (< 5 mbar) using an EVG Model 510 bonder. The wafer pair was then debonded on Brewer Science peel debonder at room temperature. The device wafer was then cleaned on a Brewer Science® Cee® 200FX spin coater with 400 ml of d-limonene using a central dispense process with the conditions listed in Table 2. After cleaning, the wafer was visually clean under green light with no residue.

Table 2. Cleaning process to remove 50- μ m layer of bonding material after debonding.

	Spin speed	Acceleration	Time	Dispense
Step	rpm	rpm/sec	second	
1	500	250	10	d-limonene
2	20	300	20	d-limonene
3	0	20	60	
4	1000	750	240	d-limonene
5	1200	500	35	

EXAMPLE 23

Heat Treatment of Wafer Pair Bonded with Material from Example 17

In this Example, a 44- μ m coating of the bonding material from Example 17 was coated on an eight-inch silicon wafer by spin coating the material at 1,000 rpm, with 3,000 rpm/s acceleration for 30 seconds. The wafer was then baked at 60°C for 3 minutes, 160°C for 2 minutes, and 200°C for 2 minutes. A carrier Si wafer was coated with the release material of Example 7 by spin coating at 1,500 rpm, with 10,000 rpm/s acceleration for 30 seconds. The

carrier wafer was then baked at 205 °C for 1 minutes. The wafer pair was then bonded at 200 °C, 1,800 N for 3 minutes under vacuum (< 5 mbar) using an EVG510 bonder. The bonded pair was then placed on a hot plate at 260 °C for 30 minutes. There were no voids or defects observed after the heat treatment as can be seen in Fig. 6. After heat treatment, the wafers were separated with a Brewer Science® peel debonder without edge soaking or cleaning.

EXAMPLE 24

Laser Debonding of Wafer Pair Bonded

with Material from Example 16 after Heat Treatment

In this example, a 50-μm coating of the bonding material from Example 16 was coated on an eight-inch silicon wafer by spin coating the material at 1,000 rpm, with 3,000 rpm/s acceleration for 30 seconds. The wafer was then baked at 60 °C for 3 minutes, 160 °C for 2 minutes, and 200 °C for 2 minutes. A carrier glass wafer was coated with an experimental polyimide laser release material (Brewer Science, Inc.) by spin coating at 2,500 rpm with 5,000 rpm/s acceleration for 60 seconds. The carrier wafer was baked at 300 °C for 5 minutes, and the wafer pair was then bonded at 200 °C and 1,800 N for 3 minutes under vacuum (< 5 mbar) using an EVG510 bonder. There were no voids or defects observed by visual inspection after bonding. The wafer pair was then laser debonded at a wavelength of 308 nm and a fluence of 175 mJ/cm² on a SUSS laser debonding tool. A second wafer pair, coated and bonded at the same conditions as above, was also successfully laser debonded on a Kingyoup laser debonding tool at 3.2 W. The wavelength of the Kingyoup tool was 355 nm.

We claim:

1. A temporary bonding method comprising:
providing a stack comprising:
 - a first substrate having a back surface and a front surface;
 - a bonding layer adjacent said front surface, said bonding layer being formed from a composition comprising a cyclic olefin polymer dissolved or dispersed in a solvent system; and
 - a second substrate having a first surface; andseparating said first and second substrates without subjecting said stack to heat, wherein said stack is exposed to a temperature of less than about 100° C. for about 60 seconds prior to said separating.
2. The method of claim 1, wherein said stack is exposed to a temperature of less than about 100° C. prior to and during said separating.
3. The method of claim 1, further comprising subjecting said stack to processing prior to said separating, wherein said stack is exposed to a temperature of less than about 100° C. after said processing is complete.
4. The method of claim 3, wherein said processing is selected from the group consisting of back-grinding, chemical-mechanical polishing, etching, metallizing, dielectric deposition, patterning, passivation, annealing, and combinations thereof, prior to separating said first and second substrates.
5. The method of claim 1, said composition being essentially free of cyclic olefin copolymers.
6. The method of claim 1, said composition being essentially free of pinene and poly(pinene).
7. The method of claim 1, said composition being essentially free of rosin esters.

8. The method of claim 1, said composition being essentially free of silicones.

9. The method of claim 1, said first surface including a release layer formed thereon.

10. The method of claim 9, wherein said release layer is a nonstick layer.

11. The method of claim 9, wherein said release layer is a laser release layer.

12. The method of claim 10, said nonstick layer being formed from a composition comprising a polysiloxane dissolved or dispersed in a solvent system.

13. The method of claim 12, wherein said polysiloxane is selected from the group consisting of epoxyl, ethoxyl, acrylic, hydroxyl, vinyl, and amine siloxanes, and mixtures of the foregoing.

14. A temporary bonding method comprising:

providing a stack comprising:

- a first substrate having a back surface and a front surface;

- a bonding layer adjacent said front surface; and

- a second substrate having a first surface, said first surface including a polysiloxane nonstick layer adjacent said bonding layer; and

separating said first and second substrates, wherein said stack is exposed to a temperature of less than about 100° C. for about 60 seconds prior to said separating.

15. The method of claim 14, wherein said polysiloxane nonstick layer is formed from a composition comprising a polysiloxane dissolved or dispersed in a solvent system.

16. The method of claim 15, said composition further comprising a solvent selected from the group consisting of propylene glycol monomethyl ether, d-limonene, ethyl 3-ethoxypropionate, propoxy propanol ("PnP"), propylene glycol methyl ether acetate, ethyl lactate, and mixtures thereof.

17. The method of claim **14**, wherein said polysiloxane is selected from the group consisting of epoxyl, ethoxyl, acrylic, hydroxyl, vinyl, and amine siloxanes, and mixtures of the foregoing.

18. The method of claim **14**, wherein said nonstick layer is free of silanes.

19. The method of claim **15**, wherein said composition further comprises a catalyst.

20. The method of claim **15**, further comprising forming said nonstick layer by applying said composition to said first surface.

21. The method of claim **20**, wherein said applying comprises spin-coating said layer on said first surface.

22. The method of claim **14**, wherein said bonding layer is formed from a composition comprising a polymer or oligomer dissolved or dispersed in a solvent system, said polymer or oligomer being selected from the group consisting of polymers and oligomers of cyclic olefins, epoxies, acrylics, styrenics, vinyl halides, vinyl esters, polyamides, polyimides, polysulfones, polyethersulfones, cyclic olefins,

polyolefin rubbers, polyurethanes, ethylene-propylene rubbers, polyamide esters, polyimide esters, polyacetals, and polyvinyl buterol.

23. The method of claim **22**, wherein said polymer or oligomer comprises a cyclic olefin polymer.

24. The method of claim **23**, wherein said stack is exposed to a temperature of less than about 100° C. prior to and during said separating.

25. The method of claim **23**, further comprising subjecting said stack to processing prior to said separating, wherein said stack is exposed to a temperature of less than about 100° C. after said processing is complete.

26. The method of claim 14, wherein said front surface is a device surface that comprises an array of devices selected from the group consisting of integrated circuits; MEMS; microsensors; power semiconductors; light-emitting diodes; photonic circuits; interposers; embedded passive devices; and microdevices fabricated on or from silicon, silicon-germanium, gallium arsenide, and gallium nitride.

27. The method of claim 14, wherein said first surface is a device surface that comprises an array of devices selected from the group consisting of integrated circuits; MEMS; microsensors; power semiconductors; light-emitting diodes; photonic circuits; interposers; embedded passive devices; and microdevices fabricated on or from silicon, silicon-germanium, gallium arsenide, and gallium nitride.

28. The method of claim 14, wherein said second substrate comprises a material selected from the group consisting of silicon, sapphire, quartz, metal, glass, and ceramics.

29. The method of claim 14, wherein said first substrate comprises a material selected from the group consisting of silicon, sapphire, quartz, metal, glass, and ceramics.

30. The method of claim 14, wherein said front surface is a device surface comprising at least one structure selected from the group consisting of: solder bumps; metal posts; metal pillars; and structures formed from a material selected from the group consisting of silicon, polysilicon, silicon dioxide, silicon (oxy)nitride, metal, low k dielectrics, polymer dielectrics, metal nitrides, and metal silicides.

31. The method of claim 14, wherein said first surface is a device surface comprising at least one structure selected from the group consisting of: solder bumps; metal posts; metal pillars; and structures formed from a material selected from the group consisting of silicon, polysilicon, silicon dioxide, silicon (oxy)nitride, metal, low k dielectrics, polymer dielectrics, metal nitrides, and metal silicides.

32. The method of claim 14, further comprising subjecting said stack to processing selected from the group consisting of back-grinding, chemical-mechanical polishing, etching, metallizing, dielectric deposition, patterning, passivation, annealing, and combinations thereof, prior to separating said first and second substrates, prior to separating said first and second substrates.

33. The method of claim 14, wherein said separating comprises heating said stack to a temperature sufficiently high so as to soften said bonding layer sufficiently to allow said first and second substrates to be separated.

34. The method of claim 14, further comprising removing said bonding layer from said first substrate after said separating.

35. A temporary bonding method comprising:
providing a stack comprising:

- a first substrate having a back surface and a front surface;

- a bonding layer adjacent said front surface, said bonding layer being formed from a composition comprising a cyclic olefin polymer dissolved or dispersed in a solvent system; and

- a second substrate having a first surface; and

separating said first and second substrates without subjecting said stack to heat, wherein said stack is exposed to a temperature of less than about 100° C. prior to and during said separating.

36. A temporary bonding method comprising:

providing a stack comprising:

- a first substrate having a back surface and a front surface;
 - a bonding layer adjacent said front surface, said bonding layer being formed from a composition comprising a cyclic olefin polymer dissolved or dispersed in a solvent system; and
 - a second substrate having a first surface; and
- separating said first and second substrates without subjecting said stack to heat, wherein said stack is subjected to processing prior to said separating, and said stack is exposed to a temperature of less than about 100° C. after said processing is complete.

37. A temporary bonding method comprising:

providing a stack comprising:

- a first substrate having a back surface and a front surface;
 - a bonding layer adjacent said front surface; and
 - a second substrate having a first surface, said first surface including a polysiloxane nonstick layer adjacent said bonding layer, wherein said polysiloxane nonstick layer is formed from a composition comprising a polysiloxane dissolved or dispersed in a solvent system comprising a solvent selected from the group consisting of propylene glycol monomethyl ether, d-limonene, ethyl 3-ethoxypropionate, propoxy propanol ("PnP"), propylene glycol methyl ether acetate, ethyl lactate, and mixtures thereof; and
- separating said first and second substrates.

38. A temporary bonding method comprising:
providing a stack comprising:
 a first substrate having a back surface and a front surface;
 a bonding layer adjacent said front surface, wherein said bonding layer is formed from a composition comprising a cyclic olefin polymer dissolved or dispersed in a solvent system; and
 a second substrate having a first surface, said first surface including a polysiloxane nonstick layer adjacent said bonding layer; and
separating said first and second substrates, wherein said stack is subjected to processing prior to said separating, and said stack is exposed to a temperature of less than about 100° C. after said processing is complete.
