

[Document Name] Description

[Name of Invention] Method for producing a water-absorbent resin

[Technical Field]

5 [0001]

The present invention relates to a method for producing a water-absorbent resin, and to a water-absorbent resin obtained by the same.

10 More specifically, the present invention relates to a method for producing a water-absorbent resin by a reversed-phase suspension polymerization method, wherein an odor originating from a raw material component, in particular, a petroleum hydrocarbon dispersion medium, is further reduced as compared with a water-absorbent resin obtained by a
15 conventional method, and to a water-absorbent resin obtained by the method.

[Background Art]

[0002]

20 Water-absorbent resins are widely used in hygienic materials such as disposable diapers and sanitary napkins; daily commodities such as pet sheets; water absorbing sheets for food products; industrial materials such as water blocking materials for cables; water retention agents for greening/agriculture/horticulture; and the like.

25 [0003]

Hygienic materials such as disposable diapers and

sanitary napkins are generally constituted with a top sheet, a back sheet, a hot melt adhesive, an elastic material, a water-absorbent resin and a pulp fiber, various synthetic resins and modifiers are used. Therefore, an odor originating from raw material components is perceived from the hygienic materials, in some cases. Since these hygienic materials are put on the human body, the odor makes users uncomfortable even if it is subtle and, therefore, it is desired to develop an odor-free material.

[0004]

Among constituent materials of these hygienic materials, the water-absorbent resin has a subtle odor originating from the substances used in the production process, and since the odor tends to emit upon water absorption, it is considered to be desirable to reduce the odor.

[0005]

As water-absorbent resins used for hygienic materials, for example, a partially-neutralized product of polyacrylic acid, a neutralized product of a starch-acrylic acid graft polymer, a hydrolysate of a starch-acrylonitrile graft copolymer, a saponified product of a vinyl acetate-acrylic acid ester copolymer are known.

[0006]

As methods for producing such water-absorbent resins, an aqueous polymerization method and a reversed-phase

suspension polymerization method are known. In a case where a water-absorbent resin is produced by a reversed-phase suspension polymerization method in which polymerization is performed by suspending a water-soluble monomer in a dispersion medium, a major origin of the odor is considered to be the dispersion medium.

[0007]

As conventional methods for producing the water-absorbent resin by a reversed-phase suspension polymerization method, known are a method of polymerizing an aqueous solution of α,β -unsaturated carboxylic acid and alkali metal salt thereof in a petroleum hydrocarbon solvent using a radical polymerization initiator in the presence or absence of a internal-crosslinking agent in which a sucrose fatty acid ester is used as a protective colloid agent (see Patent Document 1), and a method of polymerizing a 25% by mass or more of aqueous solution of an α,β -unsaturated carboxylic acid and alkali metal salt thereof in a petroleum hydrocarbon solvent using a radical polymerization initiator in the presence or absence of a internal-crosslinking agent in which a polyglyceryl fatty acid ester with an HLB of 2 to 16 is used as a surfactant (see Patent Document 2). However, these production methods do not focus on reduction of an odor, and thus odors of the resultant water-absorbent resins are not sufficiently low.

[0008]

Moreover, on a purpose for reducing an odor of a water-absorbent resin, the present inventors found out that an odor originating from the dispersion medium upon water absorption can be reduced by dispersing an aqueous solution of a water-soluble ethylenically unsaturated monomer in the petroleum hydrocarbon dispersion medium to which surfactants are not added, and further adding a surfactant to the resultant dispersion liquid to further disperse and polymerize it (see Patent Document 3) in a reversed-phase suspension polymerization method; or by adding an surfactant to a dispersion liquid obtained by dispersing an aqueous solution of a water-soluble ethylenically unsaturated monomer in a petroleum hydrocarbon dispersion medium, in a first stage reversed-phase suspension polymerization upon multi-stages of two or more stages of reversed-phase suspension polymerizations (see Patent Document 4).

However, when a large amount of water-absorbent resins are used in these methods in the conventional method, an odor originating from the dispersion medium may be perceived upon water absorption, and thereby there is a need for further reducing the odor.

[Summary of the Invention]

5 [Problems to be solved by the Invention]

[0010]

10 An object of the present invention relates to a method for producing a water-absorbent resin, and a water-absorbent resin obtained by the method. More specifically, an object of the present invention is to provide a method for producing a water-absorbent resin by a reversed-phase suspension polymerization method, wherein an odor originating from a raw material component, in particular, a petroleum hydrocarbon dispersion medium, is further reduced as compared with a water-absorbent resin obtained by a conventional method, and to a water-absorbent resin obtained by the method.

15 [Means for Solving the Problems]

[0011]

20 The present inventors intensively studied about a relation between an odor originating from a petroleum hydrocarbon dispersion medium when the water-absorbent resin absorbs water, and a petroleum hydrocarbon dispersion medium used in production of the water-absorbent resin , and the like and, as a result, found out to be able to obtain a water-absorbent resin of single particles having a

25

significantly reduced odor as well as a larger particle size as compared with a water-absorbent resin obtained by a conventional method, by existing of a hydrophilic polymeric dispersion agent in an aqueous solution of the monomer, upon primarily dispersing the above-mentioned aqueous solution of the water-soluble ethylenically unsaturated monomer containing a water-soluble radical polymerization initiator in the absence of surfactants and in the presence of a hydrophobic polymeric dispersion agent in a petroleum hydrocarbon dispersion medium in reversed-phase suspension polymerization.

[0012]

That is, the present invention relates to a method for producing a water-absorbent resin shown below, and a water-absorbent resin obtained by the method.

Item 1. A method for producing a water-absorbent resin by performing a reversed-phase suspension polymerization of a water-soluble ethylenically unsaturated monomer in a petroleum hydrocarbon dispersion medium, comprising the following steps of:

(A) performing a primary dispersion in the absence of surfactants by adding an aqueous solution of a water-soluble ethylenically unsaturated monomer containing a hydrophilic polymeric dispersion agent to a petroleum hydrocarbon dispersion medium in which a hydrophobic polymeric dispersion agent is heat-dispersed or heat-

dissolved, under stirring;

(B) further performing a secondary dispersion by adding a surfactant to a dispersion liquid obtained after the primary dispersion; and

5 (C) performing the reversed-phase suspension polymerization by using a radical polymerization initiator.

Item 2. The method for producing a water-absorbent resin according to Item 1 wherein the surfactant is at least one kind selected from the group consisting of
10 polyglyceryl fatty acid ester, sucrose fatty acid ester, and sorbitan fatty acid ester.

Item 3. The method for producing a water-absorbent resin according to any one of Items 1 to 2, wherein the hydrophobic polymeric dispersion agent is at least one kind
15 selected from the group consisting of maleic anhydride-modified polyethylene, maleic anhydride-modified polypropylene, maleic anhydride-modified ethylene-propylene copolymer, maleic anhydride-propylene copolymer, maleic anhydride-ethylene-propylene copolymer, polyethylene,
20 polypropylene, ethylene-propylene copolymer, oxidized polyethylene, oxidized polypropylene, and an oxidized ethylene-propylene copolymer.

Item 4. The method for producing a water-absorbent resin according to any one of Items 1 to 3, wherein the
25 water-soluble ethylenically unsaturated monomer is at least one kind selected from the group consisting of acrylic acid

and its salt, methacrylic acid and its salt, and acrylamide.

Item 5. The method according to any one of Items 1 to 4, wherein the petroleum hydrocarbon dispersion medium is at least one kind selected from the group consisting of an aliphatic hydrocarbon and an alicyclic hydrocarbon, having a carbon number of 6 to 8.

Item 6. The method according to any one of Items 1 to 5, wherein the hydrophilic polymeric dispersion agent is at least one kind selected from the group consisting of polyvinyl alcohol and polyvinyl pyrrolidone.

Item 7. A water-absorbent resin obtained by the method according to any one of Items 1 to 6.

[Effects of the Invention]

[0013]

According to the present invention, a method for producing a water-absorbent resin, wherein an odor originating from a raw material component, in particular, a petroleum hydrocarbon dispersion medium, is reduced, and a water-absorbent resin obtained by the method are provided.

[Modes for Carrying Out the Invention]

[0014]

An origin of odor, when a water-absorbent resin obtained by a reversed-phase suspension polymerization absorbs water, is mainly a dispersion medium remained within particles of the water-absorbent resin. The present inventors have found out that a mechanism of a

dispersion medium remaining in water-absorbent resin particles is caused by generating so-called capsule-like water-absorbent resin particles which include the dispersion medium based on generating a liquid droplet having a shape in which the dispersion medium which is an oil phase is entrapped in a liquid droplet of the aqueous monomer solution, namely, an O/W/O (oil/water/oil) type droplet, and then stabilizing and polymerizing this O/W/O type droplet itself, upon dispersing the aqueous monomer solution in the dispersion medium by means of stirring and the like.

The method for producing a water-absorbent resin of the present invention is characterized in that a hydrophilic polymeric dispersion agent exists in an aqueous solution of a water-soluble ethylenically unsaturated monomer when the above-mentioned aqueous solution of monomer containing a water-soluble radical polymerization initiator is primarily dispersing in a petroleum hydrocarbon dispersion medium in the absence of surfactants and in the presence of a hydrophobic polymeric dispersion agent, upon performing a reversed-phase suspension polymerization, and thereby generation of O/W/O (oil/water/oil) type droplet is suppressed as compared with the conventional method, and polymerization is performed by using the water-soluble radical polymerization initiator after performing a secondary dispersion by adding a

surfactant. An O/W/O type droplet is an abbreviation of (Oil in Water) in Oil, and refers to a state in which fine oil droplets are dispersed in water droplets, and the water droplets are further dispersed in an oil phase. Namely, it is constituted of an innermost oil phase, an intermediate water phase and an outermost oil phase. In the present invention, the O/W/O type droplet exhibits a state in which droplets of the aqueous solution of the monomer (water phase) contain smaller droplets of dispersion medium (oil phase).

[0015]

As described in more detail, the present application is characterized by including the following steps (A)-(C):

step (A): performing a primary dispersion in the absence of surfactants by adding an aqueous solution of a water-soluble ethylenically unsaturated monomer containing a hydrophilic polymeric dispersion agent to a petroleum hydrocarbon dispersion medium in which a hydrophobic polymeric dispersion agent was heat-dispersed or heat-dissolved, under stirring;

step (B): further performing a secondary dispersion by adding a surfactant to a dispersion liquid obtained after the primary dispersion;

step (C): performing the reversed-phase suspension polymerization by using a radical polymerization initiator.

A water-absorbent resin which contains a reduced

amount of a remaining petroleum hydrocarbon dispersion medium, can be obtained by the production method comprising these reversed-phase suspension-polymerization steps.

In the present invention, the "amount of a remaining petroleum hydrocarbon dispersion medium" (Amount of remaining dispersion medium) is a value measured by a measuring method described hereinafter.

[0016]

The present invention comprises dispersing an aqueous solution of a water-soluble ethylenically unsaturated monomer in two steps of: a "primary dispersion" in which the aqueous solution of a water-soluble ethylenically unsaturated monomer (hereinafter, "aqueous monomer solution" means the "aqueous solution of the water-soluble ethylenically unsaturated monomer" unless otherwise expressly indicated) containing a hydrophilic polymeric dispersion agent is mixed and dispersed in a petroleum hydrocarbon dispersion medium (hereinafter, "dispersion medium" means the "petroleum hydrocarbon dispersion medium" unless otherwise expressly indicated) in the absence of surfactants and in the presence of a hydrophobic polymeric dispersion agent in the step (A), and a "secondary dispersion" in which a surfactant is added to intend a dispersion stabilization with the surfactant in the step (B), and thereby performs a reversed-phase suspension polymerization. The present invention is intended to

reduce an amount of the remaining dispersion medium by suppressing generation of O/W/O type droplet as compared with conventional methods.

[0017]

5 Examples of the water-soluble ethylenically unsaturated monomer used in the step (A) include monomers having an acid group, such as (meth)acrylic acid [“(meth)acrylic” means “acrylic” and “methacrylic”, the same shall apply hereinafter], 2-(meth)acrylamide-2-
10 methylpropanesulfonic acid and maleic acid, and salts thereof; nonionic unsaturated monomers such as (meth)acrylamide, N,N-dimethyl(meth)acrylamide, 2-hydroxyethyl (meth)acrylate and N-methylol(meth)acrylamide; and amino group-containing unsaturated monomers such as
15 diethylaminoethyl (meth)acrylate and diethylaminopropyl (meth)acrylate, and quaternized monomers thereof. These water-soluble ethylenically unsaturated monomers may be used alone, or two or more kinds of them may be used in combination.

20 [0018]

 Among water-soluble ethylenically unsaturated monomers, (meth)acrylic acid and a salt thereof, and (meth)acrylamide are preferable from a viewpoint of industrial availability.

25 When the water-soluble ethylenically unsaturated monomer has an acid group, it can also be used as a salt

after neutralizing the acid group.

Examples of an alkaline compound used when a monomer having an acid group is neutralized to a salt include compounds of lithium, sodium, potassium and ammonium.

5 More specifically, examples of the alkaline compound include sodium hydroxide, potassium hydroxide, lithium hydroxide, sodium carbonate and ammonium carbonate.

When the monomer having an acid group is neutralized, a neutralization degree is preferably from 30 to 90 mol% of
10 the acid group of the water-soluble ethylenically unsaturated monomer. When the neutralization degree is less than 30 mol%, the acid group is not easily ionized and water-absorption capacity deteriorates, and therefore it is not preferred. When the neutralization degree is more than
15 90 mol%, safety issues may arise when used as hygienic materials, and therefore it is not preferred. For the timing of neutralization, although it is common to be performed in a monomeric state from a viewpoint of a degree of homogeneity, neutralization by adding the above-
20 mentioned alkaline compound to a polymer after a monomer polymerization, so called post-neutralization, may be also used together.

[0019]

In the present invention, a water-soluble
25 ethylenically unsaturated monomer is used as an aqueous solution. The concentration of the monomer in the aqueous

solution of a water-soluble ethylenically unsaturated monomer is preferably from 20% by mass to saturation concentration. If necessary, the aqueous solution of a water-soluble ethylenically unsaturated monomer may contain a chain transfer agent and the like.

[0020]

Examples of the chain transfer agent include compounds such as thiols, thiolic acids, secondary alcohols, hypophosphorous acid and phosphorous acid. These chain transfer agents may be used alone, or two or more kinds of them may be used in combination.

[0021]

Examples of the petroleum hydrocarbon dispersion medium include aliphatic hydrocarbon having a carbon number of 6 to 8, such as n-hexane, n-heptane, 2-methylhexane, 3-methylhexane, 2,3-dimethylpentane, 3-ethylpentane and n-octane; alicyclic hydrocarbons having a carbon number of 6 to 8, such as cyclohexane, methylcyclohexane, cyclopentane, methylcyclopentane, trans-1,2-dimethylcyclopentane, cis-1,3-dimethylcyclopentane and trans-1,3-dimethylcyclopentane; and aromatic hydrocarbons such as benzene, toluene and xylene. Among these hydrocarbon dispersion media, aliphatic hydrocarbons having a carbon number of 6 to 8, such as n-heptane, 2-methylhexane, 3-methylhexane and n-octane; and alicyclic hydrocarbons having a carbon number of 6 to 8, such as cyclohexane,

methylcyclopentane and methylcyclohexane are preferably used from viewpoints of easy industrial availability and safety. These hydrocarbon dispersion media may be used alone, or two or more kinds of them may be used in combination.

Further, among these hydrocarbon dispersion media, n-heptane and cyclohexane are preferably used from a viewpoint that a state of W/O type reversed suspension is good, suitable particle size is easily obtained, and that an industrial availability is easy and a quality is stable. As an example of a mixture of the above-mentioned hydrocarbon, a commercially available Exxsol Heptane (manufactured by Exxon Mobil Co.: containing heptane and isomeric hydrocarbons of 75 to 85 %) and the like may be also used to obtain a suitable result.

[0022]

The amount of the petroleum hydrocarbon dispersion medium to be used is usually from 50 to 600 parts by mass, more preferably from 60 to 400 parts by mass, and still more preferably from 70 to 200 parts by mass, based on 100 parts by mass of the aqueous solution of a water-soluble ethylenically unsaturated monomer from a viewpoint of uniformly dispersing of the aqueous solution of a water-soluble ethylenically unsaturated monomer and facilitating control of the polymerization temperature.

[0023]

In the step (A), when the aqueous solution of a water-soluble ethylenically unsaturated monomer is added and primarily dispersed in the petroleum hydrocarbon dispersion medium in the absence of surfactants, the amount of the remaining petroleum hydrocarbon dispersion medium can be reduced to a lower level by dispersing the water-soluble ethylenically unsaturated monomer in the presence of a hydrophobic polymeric dispersion agent.

[0024]

As the hydrophobic polymeric dispersion agent, it is preferred to select and use those which are dissolved or dispersed in the petroleum hydrocarbon dispersion medium to be used, and examples of the hydrophobic polymeric dispersion agent include those having a viscosity-average molecular weight of 20,000 or less, preferably 10,000 or less, and more preferably 5,000 or less. Specific examples thereof include maleic anhydride-modified polyethylene, maleic anhydride-modified polypropylene, a maleic anhydride-modified ethylene-propylene copolymer, a maleic anhydride-ethylene copolymer, a maleic anhydride-propylene copolymer, a maleic anhydride-ethylene-propylene copolymer, polyethylene, polypropylene, an ethylene-propylene copolymer, oxidized polyethylene, oxidized polypropylene, an oxidized ethylene-propylene copolymer, an ethylene-acrylic acid copolymer, ethyl cellulose, ethylhydroxyethyl cellulose, anhydrous maleinated polybutadiene and anhydrous

maleinated EPDM (ethylene/propylene/diene terpolymer).

Among them, at least one kind selected from the group consisting of maleic anhydride-modified polyethylene, maleic anhydride-modified polypropylene, a maleic anhydride-modified ethylene-propylene copolymer, a maleic anhydride-ethylene copolymer, a maleic anhydride-propylene copolymer, a maleic anhydride-ethylene-propylene copolymer, polyethylene, polypropylene, an ethylene-propylene copolymer, oxidized polyethylene, oxidized polypropylene and an oxidized ethylene-propylene copolymer is preferred.

[0025]

The amount of the hydrophobic polymeric dispersion agent to be added is preferably 5 parts by mass or less, more preferably from 0.01 to 3 parts by mass, and still more preferably from 0.05 to 2 parts by mass, based on 100 parts by mass of the aqueous solution of a water-soluble ethylenically unsaturated monomer. When the amount of the hydrophobic polymeric dispersion agent to be added is more than 5 parts by mass, it is not economic, being not preferable.

[0026]

It is important that a hydrophobic polymeric dispersion agent is added to a petroleum hydrocarbon dispersion medium, and then the above dispersion medium is warmed once to establish a state where a part or whole of the hydrophobic polymeric dispersion agent is dissolved or

dispersed thereafter an aqueous monomer solution is added. There is no problem even if the above dispersion medium is cooled after heating to perform an addition of the aqueous monomer solution in a state where a part or whole of the hydrophobic polymeric dispersion agent is deposited to be dispersed in cloud state.

[0027]

When the aqueous solution of a water-soluble ethylenically unsaturated monomer is added to and dispersed in the petroleum hydrocarbon dispersion medium, the aqueous solution of the water-soluble ethylenically unsaturated monomer is dispersed by stirring. However, stirring conditions vary depending on a desired dispersed droplet diameter and, therefore cannot be determined unconditionally.

The dispersed droplet diameter can be adjusted dispersed droplet diameter can be adjusted by changing a type, size, rotation numbers of a stirring impeller.

[0028]

It is possible to use, as a stirring impeller, a propeller impeller, a paddle impeller, an anchor impeller, a turbine impeller, a Pfaudler impeller, a ribbon impeller, a FULLZONE impeller (manufactured by Shinko Pantech Co., Ltd.), a MAXBLEND impeller (manufactured by Sumitomo Heavy Industries, Ltd.) and Super-Mix (manufactured by Satake Chemical Equipment Mfg., Ltd.).

[0029]

The present invention is characterized by not only the presence of a hydrophobic polymeric dispersion agent in a dispersion medium, but also the presence of a hydrophilic polymeric dispersion agent in an aqueous monomer solution upon the primary dispersion. It is preferred that the hydrophilic polymeric dispersion agent is used in a state where it is previously added, dissolve to mix with an aqueous solution of the water-soluble ethylenically unsaturated monomer. Generation of O/W/O type particles can be suppressed at a lower level by primarily dispersing the aqueous monomer solution containing a hydrophilic polymeric dispersion agent into a petroleum hydrocarbon dispersion medium in the presence of the above-mentioned hydrophobic polymeric dispersion agent and in the absence of surfactants.

[0030]

As a hydrophilic polymeric dispersion agent, polyvinyl pyrrolidone (Abbreviated name "PVP"), polyvinyl alcohol (Abbreviated name "PVA"), polyglycerol, polyacrylate and the like can be used. These hydrophilic polymeric dispersion agents may be used alone, or two or more of them may be used in combination. Especially, polyvinyl pyrrolidone and polyvinyl alcohol are preferred since they can be easily handled from a viewpoint of solubility in water and the like, and they easily exert

their effect.

[0031]

An amount of the hydrophilic polymeric dispersion agent can not determined unconditionally, because its preferred amount varies depending on a kind and molecular weight of the hydrophilic polymeric dispersion agent to be used. However, it is preferably 0.1-7 parts by mass, more preferably 0.3-5 parts by mass, and most preferably 0.5-3 parts by mass based on 100 parts by mass of a water-soluble ethylene monomer. When the amount of the hydrophilic polymeric dispersion agent to be used is 0.1 part by mass or less, the reduction effect for the remaining amount of the dispersion medium can not be sufficiently acquired. When the amount of the hydrophilic polymeric dispersion agent to be used is more than 7.0 parts by mass, it is not preferred since the viscosity of an aqueous monomer solution increases, stirring rate is needed to be greatly increased in order to obtain a targeted droplet diameter, and thereby O/W/O type droplets are easily generated.

20 [0032]

Although molecular weight and the like of the hydrophilic polymeric dispersion agent are not limited in particular, they are within a range where the hydrophilic polymeric dispersion agent can be added to dissolve in an aqueous monomer solution. For example, for the polyvinyl pyrrolidone, the grade of K-15 to K-120 can be used, but K-

30 to K-90 are easily used from a viewpoint of the reduction effect of the remaining dispersion medium. Moreover, although the degrees of saponification and the like of polyvinyl alcohol are not limited in particular, the degrees of saponification of not less than 85 % is preferred from a viewpoint of reducing the remaining dispersion medium. Further, examples suitably used as polyvinyl alcohol include those having a degree of polymerization of approximate 100 to 3,000 from viewpoints of a reducing effect of the remaining dispersion medium and use after dissolving..

[0033]

Although hydrophilic polymeric dispersion agents, such as polyvinyl pyrrolidone and polyvinyl alcohol, may generally be used as a water-soluble thickener, the present invention utilizes effects different from those for so-called thickener of a water soluble polymer. According to the present inventors' study, for example cellulose derivatives, such as hydroxyethyl cellulose and ethyl cellulose, and the natural polysaccharides of guar gum and glucomannan, and the like do not have the reduction effect even by addition to a monomer aqueous solution, the amount of the remaining dispersion medium tends to increase. Thereby, it has been found that the generation of O/W/O type droplets is not suppressed only by simply increasing the viscosity of an aqueous monomer solution.

[0034]

Moreover, Although a mechanism for reduction in the amount of the remaining dispersion medium by using a hydrophilic polymeric dispersion agent, is not clear, it is speculated that with the technology of a statement, it is considered that for Patent Documents 3 and 4, when the aqueous monomer solution is dispersed in a dispersion medium in the absence of surfactants and in the presence of a hydrophobic polymeric dispersion agent, the hydrophobic polymeric dispersion agent protects the surface of an aqueous monomer solution droplet in a dispersion-medium phase, and thereby the aqueous solution droplet is stabilized to inhibit that the dispersion agent is included in the interior of the aqueous solution droplet by collisions of droplets. In contrast, it is speculated that when a hydrophilic polymeric dispersion agent is further used as in the present application, the hydrophilic polymeric dispersion agent can protect the surface of an aqueous solution droplet from the interior (water phase side) of the monomer aqueous solution droplet, and that the aqueous solution droplet is stabilized more than in the technologies of Patent documents 3 and 4, and thereby prevents not only inclusion but also dissolution into the droplet of the dispersion medium.

Furthermore, an addition of the hydrophilic polymeric dispersion agent has an advantage that viscosity of the

aqueous monomer solution is increased and the water-absorbent resin having a large particle size of single particles is obtained.

[0035]

5 A surfactant is added to a primary dispersion liquid obtained in the step (A) and the aqueous solution of a water-soluble ethylenically unsaturated monomer is secondarily dispersed in the petroleum hydrocarbon dispersion medium (step (B)).

10 [0036]

 Examples of the surfactant used in the step (B) include nonionic surfactants such as sorbitan fatty acid ester, polyoxyethylene sorbitan fatty acid ester, polyglyceryl fatty acid ester, polyoxyethylene glyceryl
15 fatty acid ester, sucrose fatty acid ester, sorbitol fatty acid ester, polyoxyethylene sorbitol fatty acid ester, polyoxyethylene alkyl ether, polyoxyethylene alkyl phenyl ether, polyoxyethylene castor oil, polyoxyethylene hydrogenated castor oil, alkyl allyl formaldehyde condensed
20 polyoxyethylene ether, polyoxyethylene polyoxypropyl alkyl ether, polyethylene glycol fatty acid ester, alkyl glucoside, N-alkyl gluconamide, polyoxyethylene fatty acid amide and polyoxyethylene alkylamine; and anionic surfactants such as fatty acid salt, alkylbenzene sulfonate,
25 alkylmethyl taurate, polyoxyethylene alkyl phenyl ether sulfate, polyoxyethylene alkyl ether sulfate,

polyoxyethylene alkyl ether sulfonic acid and a salt thereof, polyoxyethylene alkyl phenyl ether phosphoric acid and a salt thereof, and polyoxyethylene alkyl ether phosphoric acid and a salt thereof. These surfactants may
5 be used alone, or two or more kinds of them may be used in combination.

[0037]

Among these surfactants, at least one kind selected from the group consisting of polyglyceryl fatty acid ester, sucrose fatty acid ester and sorbitan fatty acid ester are
10 preferred from a viewpoint of dispersion stability of the aqueous solution of a water-soluble ethylenically unsaturated monomer.

[0038]

15 The amount of the surfactant to be added in the step (B) is preferably from 0.01 to 5 parts by mass, and more preferably from 0.05 to 3 parts by mass, based on 100 parts by mass of the aqueous solution of a water-soluble ethylenically unsaturated monomer. When the amount of the
20 surfactant to be added is less than 0.01 part by mass, dispersion stability of the aqueous monomer solution deteriorates, and therefore it is not preferred. When the amount of the surfactant to be added is more than 5 parts by mass, it is not economic, being not preferable.

25 A form of the surfactant added in the step (B) is not limited in particular, but a method which uses a surfactant

previously diluted or dissolved in a small amount of the dispersion medium is preferred because the surfactant is dispersed and stabilized within a short period. Besides, after adding a surfactant in the step (B), a stirring rotation number of a stirring impeller may be increased. The final dispersed droplet diameter is determined by the stirring rotation number after an increased rate to determine the particle size of the first stage polymerization. By setting the stirring rotation number for the primary dispersion in the step (A) such that it is somewhat lower than the stirring rotation number of secondary dispersion in the step (B), it can be suppressed that a dispersion medium is included by an aqueous monomer solution droplet, and accordingly the amount of the remaining dispersion medium of water-absorbent resin can be more reduced.

[0039]

The dispersion liquid obtained in the step (B) is subjected to a radical polymerization to obtain water-absorbent resin particles in a hydrous gel state, in which the water-absorbent resin is dispersed in the petroleum hydrocarbon dispersion medium (step (C)).

[0040]

Examples of the water-soluble radical polymerization initiator include persulfates such as potassium persulfate, ammonium persulfate and sodium persulfate; peroxides such

as hydrogen peroxide; and azo compounds such as 2,2'-azobis(2-amidinopropane) dihydrochloride, 2,2'-azobis[N-(2-carboxyethyl)-2-methylpropiondiamine] tetrahydrate, 2,2'-azobis(1-imino-1-pyrrolidino-2-methylpropane)

5 dihydrochloride and 2,2'-azobis[2-methyl-N-(2-hydroxyethyl)-propionamide].

[0041]

Among these water-soluble radical polymerization initiators, potassium persulfate, ammonium persulfate, 10 sodium persulfate and 2,2'-azobis(2-amidinopropane) dihydrochloride are preferred from a viewpoint of availability and easiness of handling.

The water-soluble radical polymerization initiator may be used in combination with reducing agents such as 15 sulfite and ascorbic acid as a redox polymerization initiator.

[0042]

The amount of the water-soluble radical polymerization initiator to be used is usually from 0.01 to 20 1 part by mass based on 100 parts by mass of the water-soluble ethylenically unsaturated monomer. When the amount is less than 0.01 part by mass, a polymerization rate decreases, and when the amount is more than 1 part by mass, a rapid polymerization reaction arises. Therefore, both 25 cases are not preferred.

Timing of the addition of the water-soluble radical

polymerization initiator is not limited in particular, but it is preferred to previously add the water-soluble radical polymerization initiator to the aqueous solution of the water-soluble ethylenically unsaturated monomer from a viewpoint of homogeneity.

[0043]

Moreover, upon polymerization, an internal-crosslinking agent may be added to an aqueous solution of the monomer. Examples of the internal-crosslinking agent include polyols such as (poly)ethylene glycol ["(poly)" means a case where a prefix "poly" is attached or not, the same shall apply hereinafter], 1,4-butanediol, glycerol and trimethylolpropane; polyunsaturated esters having two or more vinyl groups obtained by reacting polyols with an unsaturated acid such as acrylic acid or methacrylic acid; bisacrylamides such as N,N'-methylenebisacrylamide; and polyglycidyl compounds having two or more glycidyl groups, such as (poly)ethylene glycol diglycidyl ether, (poly)ethylene glycol triglycidyl ether, (poly)glycerol diglycidyl ether, (poly)glycerol triglycidyl ether, (poly)propylene glycol polyglycidyl ether and (poly)glycerol polyglycidyl ether. These internal-crosslinking agents may be used alone, or two or more kinds of them may be used in combination.

[0044]

The amount of the internal-crosslinking agent to be

added is preferably 3 parts by mass or less, more preferably 1 part by mass or less, and still more preferably from 0.001 to 0.1 part by mass, based on 100 parts by mass of the water-soluble ethylenically unsaturated monomer. When the amount is more than 3 parts by mass, excess crosslinking arises and water-absorption capability excessively deteriorates, and therefore it is not preferred.

It is preferred that the internal-crosslinking agent is previously added to the aqueous solution of the water-soluble ethylenically unsaturated monomer.

[0045]

The reaction temperature during reversed-phase suspension polymerization in the present invention varies depending on the kind and amount of the polymerization initiator to be used, and therefore cannot be determined unconditionally. However, it is preferably from 20 to 100°C, and more preferably from 40 to 90°C. When the reaction temperature is lower than 20°C, the degree of polymerization may decrease, and when the reaction temperature is higher than 100°C, a rapid polymerization reaction arises. Therefore, both cases are not preferred.

[0046]

In the above-mentioned reversed-phase suspension polymerization, particles in a hydrous gel state which may become a water-absorbent resin with a small amount of

remaining dispersion medium are obtained. These resultant hydrous gel particles are dehydrated, dried, and post-crosslinked to obtain water-absorbent resin particles.

Moreover, this polymerization may be considered as the first stage polymerization, and an aqueous monomer solution may be added to a slurry with the dispersion medium containing the hydrous gel obtained from the polymerization to perform multi-stage polymerization such as two-stage polymerization or three-stage polymerization.

[0047]

If the multi-stage polymerization is performed, the particle size after the first stage of polymerization obtained by polymerization of a water-soluble ethylenically unsaturated monomer is preferably the median particle size of 20-200 μm , more preferably 30-150 μm , and still more preferably 40-100 μm , from a viewpoint of obtaining a proper aggregated particle size in the multi-stage polymerization. Besides, the median particle size of polymer particles after the first-stage polymerization is a value for particles obtained by dehydration and drying after completion of the first stage polymerization according to the measurement method described hereinafter.

[0048]

When the second stage polymerization is performed, the aqueous solution of the water-soluble ethylenically unsaturated monomer of the second stage polymerization is

added to the polymerization slurry obtained after completion of the step (C), and subsequently, reversed-phase suspension polymerization can be performed. Procedures are started from precipitations at least a part of the above-mentioned surfactant after completion of the first stage polymerization.

[0049]

Surfactants lose their essential capability to stabilize an aqueous phase droplet in an oil phase (or adversely, a capability to stabilize an oil phase droplet in an aqueous phase) when they deposite. Examples of a precipitating method include, but not limited to, a method of decreasing a temperature of slurry after polymerization by cooling. By precipitating at least a part of surfactants before adding the aqueous solution of a water-soluble ethylenically unsaturated monomer in the second stage polymerization, the droplet of the added aqueous monomer solution is not stabilized in a dispersion medium, and is absorbed in gel-like primary particles to enhance aggregation of the primary particles and thereby, a particle diameter suitable for use in hygienic materials is obtained. In addition, due to precipitation of the surfactants, generation of new O/W/O type droplets upon adding the aqueous monomer solution of the second stage polymerization is suppressed to prevent increase in an amount of the remaining dispersion medium. Therefore

obtained water absorbent resin has lower amount of remaining dispersion medium than that involved in the first stage polymerization, because amount of water absorbent resin substantially increases through the second stage polymerization which hardly increase in an amount of remaining dispersion medium. Besides, the hydrophobic polymeric dispersion agent dissolving together with the surfactants may precipitate in the dispersion medium upon adding the aqueous monomer solution in the second stage because the dispersion agent becomes impossible to be dissolved in a dispersion medium by cooling.

[0050]

After precipitating the surfactant, the aqueous solution of the water-soluble ethylenically unsaturated monomer of the second stage polymerization, which contains a water-soluble radical polymerization initiator, is stirred to mix to be absorbed and aggregated in the polymer gel in the first stage.

It is possible to use, as water-soluble ethylenically unsaturated monomer for the second-stage polymerization, the same as those exemplified as the water-soluble ethylenically unsaturated monomer for the first stage polymerization. Kinds, neutralization degree and neutralized salt of the monomer, and the concentration of the aqueous monomer solution may be the same as or different from those of the water-soluble ethylenically

unsaturated monomer in the first stage polymerization.

The polymerization initiator to be added to an aqueous solution of a water-soluble ethylenically unsaturated monomer in the second stage polymerization, any one may be selected from those exemplified as the polymerization initiator used in the first stage polymerization to use.

If necessary, an internal-crosslinking agent and a chain transfer agent may also be added to the aqueous solution of a water-soluble ethylenically unsaturated monomer in the second stage polymerization, and any one may be selected from those exemplified for the first stage polymerization to use.

The amount of the water-soluble ethylenically unsaturated monomer to be added in the second stage polymerization is preferably from 1.0 to 2.0-fold, and more preferably from 1.1 to 1.8-fold, based on the amount of the water-soluble ethylenically unsaturated monomer in the first stage polymerization from viewpoints of obtaining appropriate aggregated particles and reducing the amount of the remaining dispersion medium. When the amount of the water-soluble ethylenically unsaturated monomer to be added is less than 1.0-fold, the reduction effect by the amount of the remaining dispersion medium is low, being not preferable because the amount to be obtained decreases. When the amount of the water-soluble ethylenically

unsaturated monomer to be added is more than 2.0-fold, aggregated particles having a proper median particle size are not obtained, being not preferable because particles polymerized in the first stage polymerization cannot absorb
5 fully the aqueous monomer solution in the second stage polymerization to cause fine powders.

[0051]

It is sufficient that the entire components are mixed uniformly by stirring in the second stage of the reversed-
10 phase suspension polymerization. The median particle size of aggregated particles may be controlled depending on a deposition state of the surfactants and a ratio of the amount of the ethylenically unsaturated monomer in the second stage polymerization to the ethylenically
15 unsaturated monomer in the first stage polymerization.

Additionally, the median particle size of the aggregated particles suitable for use in hygienic materials is preferably from 200 to 600 μm , more preferably from 250 to 500 μm , and still more preferably from 300 to 450 μm .

20 [0052]

After adding the aqueous monomer solution for a second stage polymerization, polymerization is performed by means of a radical polymerization by warming and the like.

[0053]

25 The reaction temperature in reversed-phase suspension polymerization in the second stage polymerization cannot be

determined unconditionally because it depends on the kind and amount of the polymerization initiator. However, it is preferably from 20 to 100°C, and more preferably from 40 to 90°C.

5 [0054]

Furthermore, for the purpose of improving productivity, multi-stage reversed-phase suspension polymerization may be performed by performing a third or later stage polymerization reaction similar to the second stage reversed-phase suspension polymerization.

10 [0055]

In reversed-phase suspension polymerization using the hydrophilic polymeric dispersion agent shown in the present application, a dispersion medium can be added upon performing a dehydration process by refluxing a dispersion medium in azeotropic distillation after completion of the polymerization, in order to prevent aggregation of particles. Especially, when polyvinyl alcohol and polyglycerol are used as the hydrophilic polymeric dispersion agent, it is preferred that the a dispersion medium is added such that W/O ratio calculated by dividing the total amount (total of the aqueous monomer solution of the first stage plus the second stage polymerizations when it was polymerized in two stages) of the aqueous monomer solution used in the polymerization by the amount of a petroleum hydrocarbon dispersion medium, is less than 1.7,

and more specifically less than 1.4. When a dehydration is performed at an inner temperature of not less than 80°C by means of azeotropy dehydration in W/O ratio of not less than 1.7, a phenomenon that aggregated particles are further aggregated and precipitated is observed, and the median particle size of the resultant water-absorbent resin may be not less than 1000 μm . Although the detailed mechanism is unknown, it is presumed that aggregation of particles is promoted due to adherence of a hydrophilic polymeric dispersion agent such as polyvinyl alcohol and polyglycerol existing on the particle surfaces when there is not the sufficient amount of the dispersion medium relative to the hydrous gel particles obtained by the polymerization.

The timing for adding the dispersion medium is not particularly limited, it may be added in any time before the dehydration process. However, in the case of cooling for the purpose of deactivation of surfactants after completion of the first stage polymerization, and the like, it is preferred that the dispersion medium at a low temperature after completion of the first stage polymerization as well as considering a cooling effect.

[0056]

After completion of these multi-stages of reversed-phase suspension polymerization, it is preferred to add a post-crosslinking agent containing two or more functional

groups having reactivity with a functional group derived from a water-soluble ethylenically unsaturated monomer. The crosslinking density of the surface layer of water-absorbent resin particles and various properties such as water-absorption capacity under load, water-absorption rate and gel strength can be enhanced by adding post-crosslinking agent after the polymerization for reaction, and to impart properties suitable for use in hygienic materials.

[0057]

A post-crosslinking agent to be used in the post-crosslinking reaction is not particularly limited as long as it can react with a functional group derived from the water-soluble ethylenically unsaturated monomer used in the polymerization.

Examples of the post-crosslinking agent to be used include polyols such as ethylene glycol, propylene glycol, 1,4-butanediol, trimethylolpropane, glycerol, polyoxyethylene glycol, polyoxypropylene glycol and polyglycerol; polyglycidyl compounds such as (poly)ethylene glycol diglycidyl ether, (poly)ethylene glycol triglycidyl ether, (poly)glycerol diglycidyl ether, (poly)glycerol triglycidyl ether, (poly)propylene glycol polyglycidyl ether and (poly)glycerol polyglycidyl ether; haloepoxy compounds such as epichlorohydrin, epibromohydrin and α -methylepichlorohydrin; compound having two or more reactive

functional groups, for example, isocyanate compounds such as 2,4-tolylene diisocyanate and hexamethylene diisocyanate; oxetane compounds such as 3-methyl-3-oxetane methanol, 3-ethyl-3-oxetane methanol, 3-butyl-3-oxetane methanol, 3-methyl-3-oxetane ethanol, 3-ethyl-3-oxetane ethanol and 3-butyl-3-oxetane ethanol; oxazoline compounds such as 1,2-ethylenebisoxazoline; and carbonate compounds such as ethylene carbonate. These post-crosslinking agents may be used alone, or two or more kinds of them may be used in combination.

[0058]

Among them, polyglycidyl compounds such as (poly)ethylene glycol diglycidyl ether, (poly)ethylene glycol triglycidyl ether, (poly)glycerol diglycidyl ether, (poly)glycerol triglycidyl ether, (poly)propylene glycol polyglycidyl ether and (poly)glycerol polyglycidyl ether are preferred from a viewpoint of excellent reactivity.

[0059]

The amount of the post-crosslinking agent to be added is preferably from 0.01 to 5 parts by mass, and more preferably from 0.02 to 3 parts by mass, based on 100 parts by mass of the total amount of the water-soluble ethylenically unsaturated monomer subjected to the polymerization. When the amount of the post-crosslinking agent to be added is less than 0.01 part by mass, it is impossible to enhance various properties such as water-

absorption capacity under load, water-absorption rate and gel strength of the resultant water-absorbent resin, and when the amount to be added is more than 5 parts by mass, water-absorption capacity excessively deteriorates.

5 Therefore both cases are not preferred.

[0060]

The post-crosslinking agent may be added as it is, or added in a form of an aqueous solution. If necessary, the post-crosslinking agent may be added in a form of an aqueous solution containing a hydrophilic organic solvent. Examples of the hydrophilic organic solvent include lower alcohols such as methyl alcohol, ethyl alcohol, n-propyl alcohol, isopropyl alcohol and propylene glycol; ketones such as acetone and methyl ethyl ketone; ethers such as diethyl ether, dioxane and tetrahydrofuran; amides such as N,N-dimethylformamide; and sulfoxides such as dimethyl sulfoxide. These hydrophilic organic solvents may be used alone, or two or more kinds of them may be used in combination. Alternatively, these hydrophilic organic solvents may be used as a mixed solvent with water.

20 [0061]

The timing of the addition of the post-crosslinking agent may be after completion of the polymerization and is not particularly limited. The post-crosslinking reaction is preferably performed in a dehydration or drying step after the polymerization in the presence of water at an

amount within a range from 1 to 200 parts by mass, more preferably from 5 to 100 parts by mass, and still more preferably from 10 to 50 parts by mass, based on 100 parts by mass of the water-absorbent resin. By adjusting the amount of water during the addition of the post-crosslinking agent, post-crosslinking in the surface layer of particles of the water-absorbent resin can be more suitably performed and excellent water-absorption capability can be exhibited.

10 [0062]

The temperature in the post-crosslinking reaction is preferably from 50 to 250°C, more preferably from 60 to 180°C, still more preferably from 60 to 140°C, and even more preferably from 70 to 120°C.

15 [0063]

In the present invention, a drying step may be performed under a normal pressure or reduced pressure, or may be performed under a gas flow such as nitrogen gas flow in order to enhance drying efficacy. When the drying step is performed under a normal pressure, the drying temperature is preferably from 70 to 250°C, more preferably from 80 to 180°C, still more preferably from 80 to 140°C, and even more preferably from 90 to 130°C. When the drying step is performed under reduced pressure, the drying temperature is preferably from 60 to 100°C, and more preferably from 70 to 90°C.

[0064]

The water content of the water-absorbent resin after drying is 20% or less, and preferably 10% or less, from a viewpoint of imparting fluidity. Inorganic lubricant agents such as an amorphous silica powder and the like may also be added to the water-absorbent resin so as to improve fluidity.

[Examples]

[0065]

The median particle size, the water content, and the amount of the remaining dispersion medium (amount of petroleum hydrocarbon dispersion medium remaining in water-absorbent resin particles) of water-absorbent resins obtained in the respective Examples and Comparative Examples were evaluated by the following methods.

Besides for the amount of the remaining dispersion medium described in Patent Document 4, since the absolute value of the amount of the remaining dispersion medium is decreased to 500 ppm or less and there is a tendency that a sufficient extraction is not performed when the primary particle becomes larger, the measuring method was improved in order to extract more fully the water-absorbent resin.

[0066]

(1) Median particle size

A water-absorbent resin(50g) was passed through a JIS standard sieve having a sieve opening size of 250 μm . The

median particle size was measured using a combination of sieves (α) when 50% by mass or more of the resin remaining on the sieve, while using a combination of sieves (β) when less than 50% by mass of the resin remaining on the sieve.

5 (α) JIS standard sieves were combined in a downward order of; a sieve having a sieve opening size of 850 μm , a sieve having a sieve opening size of 600 μm , a sieve having a sieve opening size of 500 μm , a sieve having a sieve opening size of 425 μm , a sieve having a sieve opening size
10 of 300 μm , a sieve having a sieve opening size of 250 μm , a sieve having a sieve opening size of 150 μm and a tray.

 (β) JIS standard sieves were combined in a downward order of; a sieve having a sieve opening size of 425 μm , a sieve having a sieve opening of 250 μm , a sieve having a
15 sieve opening size of 180 μm , a sieve having a sieve opening size of 150 μm , a sieve with a sieve opening size of 106 μm , a sieve with a sieve opening size of 75 μm , a sieve having a sieve opening size of 45 μm and a tray.

 About 50 g of the water-absorbent resin was placed on
20 the uppermost sieve of the combination, and classified for 20 minutes using a Rotap-type shaking machine.

 After the sieve classification, the mass of the water-absorbent resin remaining on the respective sieves was calculated in terms of mass% based on the total mass of
25 resin, the values were integrated in an order from the resins with a larger particle size, and thereby the

relations between the sieve openings and integration values of the mass% of the water-absorbent resin remaining on the sieve were plotted on a logarithmic-probability paper. The plots on the logarithmic-probability paper were connected with a straight line, and the particle size corresponding to integrated mass% of 50% by mass was defined as the median particle size.

[0067]

(2) Water content

About 2.5 g of the water-absorbent resin was accurately weighed (X g) into an aluminum cup, and after drying at 105°C with a hot air dryer for 2 hours, the mass of the dried water-absorbent resin was measured (Y g), and then the water content was calculated by the following equation. Besides, it is assumed that tare mass of the aluminium cup does not change before and after drying.

$$\text{Water content (\%)} = (X - Y)/X \times 100$$

[0068]

(3) Amount of remaining dispersion medium

In order to more fully extract the amount of the remaining dispersion medium from the water-absorbent resin charged in the sample bottle relative to the conventional measuring method of Patent Document 4 and the like such that measurement of the amount of the remaining dispersion medium at a lower level may be enabled, it is improved as follows such that swelling magnification is raised, and

phosphoric acid is added to easily dissolve a swelling gel.

[0069]

(a) Formation of calibration curve

Approximate 10 g of the petroleum hydrocarbon
5 dispersion medium (hereinafter referred to as a "dispersion
medium") used to polymerize a sample for measuring a
remaining dispersion medium, is placed into a screw vial or
the like to cool the vial with an ice-water bath.
Similarly, 60 g of DMF (dimethylformamide) and 60 g of 25 %
10 by mass of an aqueous phosphoric acid solution is also
cooled with an ice-water bath. (Charging is performed after
sufficiently cooling because of transpiration inhibition
for the dispersion medium during charging.)

0.2 g of the above dispersion medium was accurately
15 weighed into a 50 ml volumetric screw vial and then the
above cooled DMF was added thereto to accurately make 20 g,
followed by stirring with a magnetic stirrer bar to obtain
Standard sample solution 1. This Standard sample solution
1 was also cooled with an ice-water bath. 0.2 g of the
20 above Standard sample solution 1 was then accurately
weighed into a 50 ml volumetric screw vial and the above
cooled DMF was added thereto to accurately make 20 g,
followed by stirring with a magnetic stirrer bar to obtain
Standard sample solution 2. This Standard sample solution
25 2 was also cooled with an ice-water bath.

In a 20 ml volumetric vial bottle (No. 5,

manufactured by Maruemu Corporation), 0.02, 0.05, 0.1 or 0.5 g of the above Standard sample solution 2 and 0.02 g of the above Standard sample solution 1 were accurately weighed and the cooled DMF was added thereto to make the amount of contents in each vial bottle to a total amount of 3.8 g (4 ml). Furthermore, each vial bottle was charged with 5 ml of 25 % by mass of the aqueous phosphoric acid solution, sealed and tightened with a septum rubber and an aluminium cap, and then stirring was performed by shaking each the bottle.

In addition, attention has been paid to perform quickly procedures from charging of the sample into the 20-ml volumetric vial to the sealing, to prevent a dispersion medium from transpiring from the vial as possible as much as possible. Moreover, attention has been paid also to fully cool DMF and 25% by mass of an aqueous phosphoric acid solution such that the dispersion medium did not transpire due to generation of heat at the time of mixing the both reagents, and to fully mix them after sealing with an aluminium cap or the like.

[0070]

This vial bottle was warmed at 110°C for 2 hours, and 1 ml of a vapor phase portion was collected such that the vapor phase portion was not cooled, and then it was injected into a gas chromatograph to obtain a chromatogram. (Use of head space autosampler)

The amount to be charged of the dispersion medium in each vial bottle was calculated to prepare a calibration curve based on the amount to be charged and a peak area of the chromatogram. (When a mixture of petroleum hydrocarbons was used as the dispersion medium, plural peaks appeared and therefore a calibration curve was prepared based on a total value of the areas and the amount to be charged).

[0071]

10 (b) Measurement of amount of dispersion medium remaining in sample

About 2 g of a sample to be measured was charged into an aluminium cup and then dried with a hot air dryer at 105°C for 2 hours to adjust the water content.

15 Required amounts of DMF (dimethylformamide) and 25 % by mass of an aqueous phosphoric acid solution used for the measurement, were also charged into a screw bottle, and cooled with an ice-water bath.

20 Into a 20 ml volumetric vial bottle (No.5, manufactured by Maruemu Corporation), 0.10 g of the above sample was accurately weighed, and the bottom of the vial bottle was dipped in an ice bath to cool the vial bottle and the water-absorbent resins.

25 To this vial bottle were added 4 ml of the above cooled DMF and, further 5 ml of 25 % by mass of the above cooled aqueous phosphoric acid solution. The vial bottle

was quickly tightened by sealing with a septum rubber and an aluminium cap and, then gently shaken to mix. After allowing to stand for 10 min, it was confirmed that the water-absorbent resin in the vial bottle was swelled, the vial bottle was vigorously shaken to agitate the inside strongly. This vial bottle was pre-heated at 110°C for 2 hours to strongly agitate the inside again after heating.

In addition, attention has been paid to perform quickly procedures from charging of the sample into the 20-ml volumetric vial to the sealing, to prevent a dispersion medium from transpiring from the vial as possible as much as possible.

[0072]

This vial bottle was warmed at 110°C for 2 hours, and 1 ml of a vapor phase portion was collected such that the vapor phase portion was not cooled, and then it was injected into a gas chromatograph to obtain a chromatogram. (Use of head space autosampler)

The amount of the dispersion medium contained in the amount (0.10 g of observed values) of the charged sample was calculated from the calibration curve made based on the peak area of the resultant chromatogram, and then converted into the amount [ppm] of the dispersion medium contained per 1 g of the sample.

[0073]

The conditions of a gas chromatograph used in the

measurement of the amount of the remaining dispersion medium in the present invention are as follows.

Model: GC-14A + HSS2B (HEADSPACE Autosampler)
manufactured by Shimadzu Corporation

5 Filler: Squalane 25% Shimalite (NAW) (101)

80-100 mesh

Column: 3.2 mm in diameter × 2 m

Column temperature: 80°C

Injection port temperature: 180°C

10 Detector temperature: 180°C

Detector: FID

Gas carrier: Nitrogen gas

Vial bottle heating temperature: 110°C

Syringe setting temperature: 110°C

15 [0074]

Moreover, each of Examples and Comparative Examples was performed 3 times, and the amount of the remaining dispersion medium of each group was shown as Mean ± Standard deviation. Statistical evaluation of differences between each groups was performed using Student's t-test (* shows $p < 0.05$).

[0075]

(c) Comparison with conventional measuring method

25 As a result of measuring the amount of the remaining dispersion medium for the same sample, the above-mentioned measuring method of the present application could have

measured the amount of the remaining dispersion medium by high sensitivity more as compared with the conventional method. For example, for Reference Example 1 of the present application, while the measuring method of the present application exhibits 100 ppm of the amount of the remaining dispersion medium, the conventional method inhibits only 80 ppm of the amount of the remaining dispersion medium.

[0076]

(d) Measurement of amount of dispersion medium dissolved in aqueous monomer solution in the absence of surfactants and the like

The following experiment was conducted for the purpose of investigating the amount of dispersion medium dissolved in an aqueous monomer solution in the absence of surfactants and the like.

[Reference Experimental Example]

A measurement of a dissolved amount of a dispersion medium in an aqueous monomer solution was performed by the following procedures:

1) Into a 500 mL Erlenmeyer flask, 46.0 g of 80% by mass of acrylic acid was charged and neutralized by adding dropwise 51.1 g of 30 % by mass sodium hydroxide under stirring while cooling the flask from the outside. To this were added 21.9 g of ion exchange water to prepare an aqueous solution of a water-soluble ethylenically

unsaturated monomer. (the aqueous monomer solution having a neutralization degree of 75 mol% and a concentration of 38% by mass)

2) In a 2 L volumetric five-necked cylindrical separable round-bottom flask (hereinafter referred to as a "round-bottom flask") equipped with a stirrer with two steps of 50 mm in diameter pitched blade paddle impellers, a thermometer and a condenser, 171 g of n-heptane was weighted.

3) The above-mentioned round bottom flask was dipped in a water bath, and n-heptane was agitated at 500 rpm, and maintained to an inside temperature of $40 \pm 1^\circ\text{C}$.

4) The acrylic acid neutralization aqueous solution prepared in Procedure 1) was supplied, and the temperature of the water bath was adjusted to maintain the temperature such that it becomes an inside temperature of $40 \pm 1^\circ\text{C}$ while stirring at 500 rpm for 30 minutes.

5) After stirring for 30 minutes, the stirrer is stopped, and the round bottom flask is allowed to stand for 30 minutes while maintaining the same water bath temperature.

6) Only lower layer neutralization liquid layer was gently withdrawn such that two-layer separation is not mixed.

7) According to the measuring method of the amount of remaining dispersion medium, about 0.26 g (corresponding to

about 0.1 g in the amount of the monomer) of the neutralized liquid withdrawn in 20 mL volumetric vial bottle was accurately weighted to add cooled DMF and phosphoric acid solution.

5 8) After sealing with a vial cap and stirring, preheating at 110°C for 2 hours is performed, and according to the measuring method of the amount of remaining dispersion medium, the amount of n-heptane in the neutralized liquid was measured.

10 [0077]

As experimental results, the same conditions as in the first stage polymerization described in the present application, namely, the amount of n-heptane (dispersion medium) dissolved in the acrylic acid neutralization aqueous solution (aqueous monomer solution) at 40°C, was 80 ppm on the monomer mass basis.

Therefore, this amount (80 ppm) of the dispersion medium was considered to be the minimum amount of the remaining dispersion medium which can be reduced by the conventional method (in Patent Document 4 and the like).

20 [0078]

The present invention will be described in detail by way of Examples, but the present invention is not limited only to these Examples.

25 [0079]

[Reference Example 1]

The example 8 of WO2009/025235 (Patent document 4) was performed as Reference Example 1. In addition, the example is an example with the lowest amount of the remaining dispersion medium in Patent Document 4.

5 Into a 500 mL Erlenmeyer flask, 92.0 g of 80% by mass of acrylic acid was charged and neutralized by adding dropwise 102.2 g of 30 % by mass sodium hydroxide under stirring while cooling the flask from the outside. To this were added 0.11 g of potassium persulfate, 8.3 mg of
10 ethylene glycol diglycidyl ether and 43.6 g of ion-exchange water to prepare an aqueous solution of a water-soluble ethylenically unsaturated monomer (hereinafter referred to as "aqueous monomer solution").

15 In a 2 L volumetric five-necked cylindrical round-bottom separable flask (hereinafter referred to as a "round-bottom flask") equipped with a stirrer having a two-stage pitched blade paddle impellers of 50 mm in diameter, a thermometer, a reflux condenser and a nitrogen gas introducing tube, 334 g of n-heptane was weighted as a
20 petroleum hydrocarbon dispersion medium. To the round-bottom flask were added 0.46 g of an oxidized ethylene-propylene copolymer (manufactured by Mitsui Chemicals, Inc., trade name: HIWAX 4052E) and 0.46 g of a maleic anhydride-modified ethylene-propylene copolymer (manufactured by
25 Mitsui Chemicals, Inc., trade name: HIWAX 1105A) as a hydrophobic polymeric dispersion agent, and then this was

warmed up to 83 to 86°C with a water bath at 90°C at a stirring rate of 300 rpm to dissolve and disperse it before air cooling to an inner temperature of 61°C. The above-mentioned aqueous monomer solution was charged once into the above heptane while stirring them at 300 rpm by using a funnel made of SUS, having an inside diameter of 8 mm at opening at the tip. After adding the aqueous monomer solution, it was agitated at an inner temperature of 40°C for 10 minutes and primarily dispersed.

Next, a solution separately prepared by warming 0.92 g of a sucrose fatty acid ester (manufactured by Mitsubishi-Kagaku Foods Corporation, trade name: S-370) as a surfactant to dissolve it in 8.28 g of heptane by warming at 60°C or higher was added to the round-bottom flask through a funnel and then a stirring rate was increased to 500 rpm to secondly disperse the aqueous monomer solution.

The atmosphere in the system was well substituted with nitrogen while maintaining the inner temperature of the round-bottom flask containing the dispersion at 40°C, and a radical polymerization reaction was performed by warming for 1 hour with a hot water bath at 70°C.

After completion of the first stage polymerization, the stirring rate was increased to 1,000 rpm and the inner temperature was cooled to near room temperature to precipitate at least a part of the surfactant.

[0080]

Separately, to a 500 mL Erlenmeyer flask, 128.8 g of 80 mass% acrylic acid was added and neutralized by adding dropwise 142.9 g of 30 mass% sodium hydroxide under stirring while cooling the flask from the outside. To this
5 were added 0.15 g of potassium persulfate, 11.6 mg of ethylene glycol diglycidyl ether and 16.7 g of distilled water to prepare an aqueous monomer solution in the second stage polymerization. Next, the aqueous monomer solution for the above-mentioned second stage was added to the
10 above-mentioned cooled polymerization slurry through the dropping funnel, and stirred to mix for some time, and absorbed into a polymerization gel in the first stage to aggregate hydrous gel particles. Then, the atmosphere in the system was well substituted with nitrogen while
15 maintaining the inner temperature of the round-bottom flask near room temperature, and a radical polymerization reaction was performed by warming for 1 hour with a hot water bath at 70°C.

After the polymerization reaction in the second stage,
20 the reaction suspension was heated using an oil bath at 120°C and 260 g of water was removed off from the system by azeotropic distillation while refluxing heptane in the flask to obtain a dehydrated polymer dispersed in heptane. To the resultant heptane dispersed dehydrated polymer, 8.2
25 g of a 2% aqueous solution of ethylene glycol diglycidyl ether as a post-crosslinking agent was added and the post-

crosslinking reaction was performed at 83°C for 2 hours.

Then, heating is performed using an oil bath at 120°C, heptane and water were removed off from the system by distillation, followed by drying under a nitrogen gas flow to obtain 235 g of a water-absorbent resin having in a form of aggregated spherical particles by passing through a sieve of 850 µm. This water-absorbent resin had a median particle size of 356 µm, and a water content of 4.5%.

[0081]

10 [Comparative Example 1]

At the complete time of the first stage polymerization of the examples 8 of WO2009/025235 (Patent Document 4), dehydration, post-crosslinking, and drying were performed to make Comparative Example 1.

15 The first stage polymerization was performed in the same manner as that of Reference Example 1, and after the first stage polymerization, the stirring rate was increased to 1000 rpm, and then the reaction suspension was heated using an oil bath at 120°C and about 125 g of water was removed off from the system by azeotropic distillation while refluxing heptane in the flask to obtain a dehydrated polymer dispersed in heptane. To the resultant heptane dispersed dehydrated polymer, 3.4 g of a 2% aqueous solution of ethylene glycol diglycidyl ether as a post-crosslinking agent was added and the post-crosslinking reaction was performed at 83°C for 2 hours.

Then, heating is performed using an oil bath at 120°C, heptane and water were removed off from the system by distillation, followed by drying under a nitrogen gas flow to obtain 89 g of a water-absorbent resin having a spherical shape (partially in a form of aggregated spherical particles) by passing through a sieve of 850 μm. This water-absorbent resin had a median particle size of 61 μm, and a water content of 3.1%.

[0082]

10 [Example 1]

0.7% by mass of polyvinyl alcohol (hereinafter abbreviated to "PVA") as a hydrophilic polymeric dispersion agent based on a mass of a monomer was added to perform a polymerization experiment.

15 Gosenol GH-17 (manufactured by Nippon Synthetic Chemical Industry Co., Ltd.: Degree of polymerization of 1700 and Degree of saponification of 86.5-89.0 mol%) as PVA was heated, stirred, dissolved in distilled water, and allowed to stand to prepare 100g of 5 % by mass aqueous solution of PVA prior to the preparation of an aqueous monomer solution.

25 Into a 500 mL Erlenmeyer flask, 92.0 g of 80% by mass of acrylic acid was charged and neutralized by adding dropwise 102.2 g of 30 % by mass sodium hydroxide under stirring while cooling the flask from the outside. To this were added 0.073 g of potassium persulfate, 10.1 mg of

ethylene glycol diglycidyl ether, 12.6 g of the above-mentioned 5 mass% PVA aqueous solution and 10 g of ion exchange water to prepare an aqueous monomer solution.

[0083]

5 In a 2 L volumetric five-necked cylindrical round-bottom separable flask equipped with a stirrer having a two-stage pitched blade paddle impellers of 50 mm in diameter, a thermometer, a reflux condenser and a nitrogen gas introducing tube, 275 g of heptane was weighted as a
10 petroleum hydrocarbon dispersion medium. To the round-bottom flask was added 0.74 g of a maleic anhydride-modified ethylene-propylene copolymer (manufactured by Mitsui Chemicals, Inc., trade name: HIWAX 1105A) as a hydrophobic polymeric dispersion agent, and then this was
15 warmed up to 75 to 80°C with a water bath at 85°C at a stirring rate of 300 rpm to dissolve and disperse it before air cooling to an inner temperature of 64°C. The above-mentioned aqueous monomer solution was charged once into the above heptane while stirring them at 300 rpm by using a
20 funnel made of SUS, having an inside diameter of 8 mm at opening at the tip.

After adding the aqueous monomer solution, it was agitated at an inner temperature of 40°C for 10 minutes and primarily dispersed. (step (A))

25 Next, a solution separately prepared by warming 0.74 g of a sucrose fatty acid ester (manufactured by

Mitsubishi-Kagaku Foods Corporation, trade name: S-370) as a surfactant to dissolve it in 6.62 g of heptane by warming at 60°C or higher was added to the round-bottom flask through a funnel and then a stirring rate was increased to 500 rpm to secondly disperse the aqueous monomer solution. (step (B))

The atmosphere in the system was well substituted with nitrogen while maintaining the inner temperature of the round-bottom flask containing the dispersion at 40°C, and a radical polymerization reaction was performed by warming for 1 hour with a hot water bath at 70°C. (step (C)) [0084]

After the polymerization reaction, the stirring rate was increased to 1,000 rpm (while timely increasing the stirring rate when stirring the content becomes inadequate by proceeding with dehydration), the reaction suspension was heated using an oil bath at 120°C and 125 g of water was removed off from the system by azeotropic distillation while refluxing heptane in the flask to obtain a dehydrated polymer dispersed in heptane. To the resultant heptane dispersed dehydrated polymer, 3.4 g of a 2% aqueous solution of ethylene glycol diglycidyl ether as a post-crosslinking agent was added and the post-crosslinking reaction was performed at 83°C for 2 hours.

Then, heating is performed using an oil bath at 120°C, heptane and water were removed off from the system by

distillation, followed by drying under a nitrogen gas flow to obtain 90 g of a water-absorbent resin having a spherical shape (partially in a form of aggregated spherical particles) by passing through a sieve of 850 μm .

5 This water-absorbent resin had a median particle size of 69 μm , and a water content of 2.5%.

[0085]

[Example 2]

1.0 % by mass of Gosenol GH-20 (manufactured by
10 Nippon Synthetic Chemical Industry Co., Ltd.: Degree of polymerization of 2000 and Degree of saponification of 86.5-89.0 mol%) was used substituted for Gosenol GH-17 in Example 1.

PVA (Gosenol GH-20) was heated, stirred, dissolved in
15 distilled water, and allowed to stand to prepare 100g of 5 % by mass aqueous solution of PVA prior to the preparation of an aqueous monomer solution.

Into a 500 mL Erlenmeyer flask, 92.0 g of 80% by mass of acrylic acid was charged and neutralized by adding
20 dropwise 102.2 g of 30 % by mass sodium hydroxide under stirring while cooling the flask from the outside. To this were added 0.11 g of potassium persulfate, 8.3 mg of ethylene glycol diglycidyl ether, 18.1 g of the above-mentioned 5 mass% PVA aqueous solution and 25.8 g of ion
25 exchange water to prepare an aqueous solution of the water-soluble ethylenically unsaturated monomer.

Then, the same polymerization as in Example 1 was performed to obtain 88 g of a water-absorbent resin having a spherical shape (partially in a form of aggregated spherical particles). This water-absorbent resin had a median particle size of 80 μm , and a water content of 3.4%.

[0086]

[Example 3]

0.7% by mass of Gosenol GH-23 (manufactured by Nippon Synthetic Chemical Industry Co., Ltd.: Degree of polymerization of 2300 and Degree of saponification of 86.5-89.0 mol%) was used substituted for Gosenol GH-17 as PVA in Example 1.

The above-mentioned PVA (Gosenol GH-23) was heated, stirred, dissolved in distilled water, and allowed to stand to prepare 100g of 5 % by mass aqueous solution of PVA prior to the preparation of an aqueous monomer solution.

Into a 500 mL Erlenmeyer flask, 92.0 g of 80% by mass of acrylic acid was charged and neutralized by adding dropwise 102.2 g of 30 % by mass sodium hydroxide under stirring while cooling the flask from the outside. To this were added 0.11 g of potassium persulfate, 8.3 mg of ethylene glycol diglycidyl ether, 12.6 g of the above-mentioned 5 mass% PVA aqueous solution and 31.4 g of ion exchange water to prepare an aqueous solution of the water-soluble ethylenically unsaturated monomer.

Subsequently, the same manner as in Example 1 was

performed to obtain 87 g of a water-absorbent resin having a spherical shape (partially in a form of aggregated spherical particles). This water-absorbent resin had a median particle size of 88 μm , and a water content of 3.3%.

5 [0087]

[Example 4]

As a hydrophilic polymeric dispersion agent, 2.0% by mass of PVA based on a mass of a monomer was used.

10 Into a 500 mL Erlenmeyer flask, 92.0 g of 80% by mass of acrylic acid was charged and neutralized by adding dropwise 102.2 g of 30 % by mass sodium hydroxide under stirring while cooling the flask from the outside. To this were added 32.1 g of ion exchange water, followed by 1.81 g of PVA: Poval 403 (manufactured by Kuraray Co., Ltd.:
15 Degree of polymerization of 300 and Degree of saponification of 78-83 mol%) as a hydrophilic polymeric dispersion agent to dissolve it by stirring. To this were added 0.073 g of potassium persulfate, 10.1 mg of ethylene glycol diglycidyl ether and 10 g of ion exchange water to
20 prepare an aqueous monomer solution.

[0088]

25 In a 2 L volumetric five-necked cylindrical round-bottom separable flask equipped with a stirrer having a two-stage pitched blade paddle impellers of 50 mm in diameter, a thermometer, a reflux condenser and a nitrogen gas introducing tube, 275 g of heptane was weighted as a

petroleum hydrocarbon dispersion medium. To the round-bottom flask was added 0.74 g of a maleic anhydride-modified ethylene-propylene copolymer (manufactured by Mitsui Chemicals, Inc., trade name: HIWAX 1105A) as a hydrophobic polymeric dispersion agent, and then this was warmed up to 75 to 80°C with a water bath at 85°C at a stirring rate of 300 rpm to dissolve and disperse it before air cooling to an inner temperature of 64°C. A dropping injection of the above-mentioned aqueous monomer solution was performed into the above-mentioned heptane stirring at 300 rpm by using a dropping funnel. After adding the aqueous monomer solution, it was agitated at an inner temperature of 40°C for 10 minutes and primarily dispersed.(step (A))

Next, a solution separately prepared by warming 0.74 g of a sucrose fatty acid ester (manufactured by Mitsubishi-Kagaku Foods Corporation, trade name: S-370) as a surfactant to dissolve it in 6.62 g of heptane by warming at 60°C or higher was added to the round-bottom flask through a funnel and then a stirring rate was increased to 700 rpm to secondly disperse the aqueous monomer solution.(step (B))

The atmosphere in the system was well substituted with nitrogen while maintaining the inner temperature of the round-bottom flask containing the dispersion at 40°C, and a radical polymerization reaction was performed by

warming for 1 hour with a hot water bath at 70°C. (step (C))
[0089]

After the polymerization reaction, the reaction suspension was heated using an oil bath at 120°C and 121 g of water was removed off from the system by azeotropic distillation while refluxing heptane in the flask to obtain a dehydrated polymer dispersed in heptane. To the resultant heptane dispersed dehydrated polymer, 1.84 g of a 2% aqueous solution of ethylene glycol diglycidyl ether as a post-crosslinking agent was added and the post-crosslinking reaction was performed at 83°C for 2 hours.

Then, heating is performed using an oil bath at 120°C, heptane and water were removed off from the system by distillation, followed by drying under a nitrogen gas flow to obtain 90 g of a water-absorbent resin having a spherical shape (partially in a form of aggregated spherical particles) by passing through a sieve of 850 μm . This water-absorbent resin had a median particle size of 51 μm , and a water content of 3.0%.

[0090]

[Comparative Example 2]

As Comparative Example, 0.3 % by mass of hydroxyethyl cellulose (hereinafter abbreviated to "HEC") based on a mass of a monomer was used as a thickener to perform a polymerization.

Into a 500 mL Erlenmeyer flask, 92.0 g of 80% by mass

of acrylic acid was charged and neutralized by adding dropwise 102.2 g of 30 % by mass sodium hydroxide under stirring while cooling the flask from the outside. To this were added 32.1 g of water, followed by 1.81 g of HEC
5 (manufactured by Sumitomo Seika Chemicals Co., Ltd.: AW-15F) to dissolve it by stirring.

To this were added 0.073 g of potassium persulfate, 8.3 mg of ethylene glycol diglycidyl ether and 10 g of ion exchange water to prepare an aqueous monomer solution.

10 In a 2 L volumetric five-necked cylindrical round-bottom separable flask equipped with a stirrer having a two-stage pitched blade paddle impellers of 50 mm in diameter, a thermometer, a reflux condenser and a nitrogen gas introducing tube, 275 g of heptane was weighted as a
15 petroleum hydrocarbon dispersion medium. To the round-bottom flask was added 0.74 g of a maleic anhydride-modified ethylene-propylene copolymer (manufactured by Mitsui Chemicals, Inc., trade name: HIWAX 1105A) as a hydrophobic polymeric dispersion agent, and then this was
20 warmed up to 75 to 80°C with a water bath at 85°C at a stirring rate of 300 rpm to dissolve and disperse it before air cooling to an inner temperature of 61°C. The above-mentioned aqueous monomer solution was charged once into the above heptane while stirring them at 300 rpm by using a
25 funnel made of SUS, having an inside diameter of 8 mm at opening at the tip. After adding the aqueous monomer

solution, it was agitated at an inner temperature of 40°C for 10 minutes and primarily dispersed.

Next, a solution separately prepared by warming 0.74 g of a sucrose fatty acid ester (manufactured by Mitsubishi-Kagaku Foods Corporation, trade name: S-370) as a surfactant to dissolve it in 6.62 g of heptane by warming at 60°C or higher was added to the round-bottom flask through a funnel and then a stirring rate was increased to 500 rpm to secondly disperse the aqueous monomer solution.

The atmosphere in the system was well substituted with nitrogen while maintaining the inner temperature of the round-bottom flask containing the dispersion at 40°C, and a radical polymerization reaction was performed by warming for 1 hour with a hot water bath at 70°C.

[0091]

After the polymerization reaction, the reaction suspension was heated using an oil bath at 120°C and 125 g of water was removed off from the system by azeotropic distillation while refluxing heptane in the flask to obtain a dehydrated polymer dispersed in heptane. To the resultant heptane dispersed dehydrated polymer, 3.4 g of a 2% aqueous solution of ethylene glycol diglycidyl ether as a post-crosslinking agent was added and the post-crosslinking reaction was performed at 83°C for 2 hours.

Then, heating is performed using an oil bath at 120°C, heptane and water were removed off from the system by

distillation, followed by drying under a nitrogen gas flow to obtain 87 g of a water-absorbent resin having a spherical shape (partially in a form of aggregated spherical particles) by passing through a sieve of 850 μm .

5 This water-absorbent resin had a median particle size of 87 μm , and a water content of 2.8%.

[0092]

[Comparative Example 3]

0.1 % by mass of xanthan-gum was used substituted for
10 0.3 % by mass of HEC as a thickener in Comparative Example 2 to perform a polymerization.

Specifically, into a 500 mL Erlenmeyer flask, 92.0 g of 80% by mass of acrylic acid was charged and neutralized by adding dropwise 102.2 g of 30 % by mass sodium hydroxide
15 under stirring while cooling the flask from the outside. To this were added 32.3 g of water, followed by 0.091 g of xanthan-gum (manufactured by Sansho Co., Ltd.: KELZAN) to dissolve and disperse it by stirring. To this were added 0.11 g of potassium persulfate, 8.3 mg of ethylene glycol
20 diglycidyl ether and 10 g of ion exchange water to prepare an aqueous monomer solution.

Subsequently, in the same manner as that of Comparative Example 2, water-absorbent resin passed through a sieve of 850 μm to obtain 88 g of water-absorbent
25 resin having a spherical shape (partially in a form of aggregated spherical particles). This water-absorbent

resin had a median particle size of 84 μm , and a water content of 2.9%.

[0093]

[Comparative Example 4]

5 0.5 % by mass of guar-gum was used substituted for
0.3 % by mass of HEC as a thickener in Comparative Example
2 to perform a polymerization.

Specifically, into a 500 mL Erlenmeyer flask, 92.0 g
of 80% by mass of acrylic acid was charged and neutralized
10 by adding dropwise 102.2 g of 30 % by mass sodium hydroxide
under stirring while cooling the flask from the outside.
To this were added 31.9 g of water, followed by 0.45 g of
guar-gum (manufactured by Sansho Co., Ltd.: MEYPROGA) to
dissolve it by stirring. To this were added 0.11 g of
15 potassium persulfate, 8.3 mg of ethylene glycol diglycidyl
ether and 10 g of ion exchange water to prepare an aqueous
monomer solution.

Subsequently, when a polymerization was performed in
the same manner as that of Comparative Example 2, a polymer
20 winded to the stirring impeller to cause an unusual
polymerization during raising an inner temperature by
dipping it in a hot water bath at 70°C. Therefore, this
experiment was canceled at the time.

[0094]

25 [Comparative Example 5]

1.0 % by mass of pullulan was used substituted for

0.3 % by mass of HEC as a thickener in Comparative Example 2 to perform a polymerization.

Specifically, into a 500 mL Erlenmeyer flask, 92.0 g of 80% by mass of acrylic acid was charged and neutralized by adding dropwise 102.2 g of 30 % by mass sodium hydroxide under stirring while cooling the flask from the outside. To this were added 31.5 g of water, followed by 0.905 g of pullulan (Hayashibara trading company: Pullulan PI-20) to dissolve it by stirring. To this were added 0.11 g of potassium persulfate, 8.3 mg of ethylene glycol diglycidyl ether and 10 g of ion exchange water to prepare an aqueous monomer solution.

Subsequently, in the same manner as that of Comparative Example 2, water-absorbent resin passed through a sieve of 850 μm to obtain 90 g of water-absorbent resin having a spherical shape (partially in a form of aggregated spherical particles). This water-absorbent resin had a median particle size of 96 μm , and a water content of 3.1%.

[0095]

[Comparative Example 6]

The stirring rate at the time of polymerization was decreased to a lower speed to perform a reversed-phase suspension polymerization.

Into a 500 mL Erlenmeyer flask, 92.0 g of 80% by mass of acrylic acid was charged and neutralized by adding

dropwise 102.2 g of 30 % by mass sodium hydroxide under stirring while cooling the flask from the outside. To this were added 0.11 g of potassium persulfate, 8.3 mg of ethylene glycol diglycidyl ether and 43.8 g of ion exchange water to prepare an aqueous monomer solution. In a 2 L volumetric five-necked round-bottom flask equipped with a stirrer having a two-stage pitched blade paddle impellers of 50 mm in diameter, a thermometer, a reflux condenser and a nitrogen gas introducing tube, 334 g of heptane was weighted as a petroleum hydrocarbon dispersion medium.

To the round-bottom flask was added 0.92 g of a maleic anhydride-modified ethylene-propylene copolymer (manufactured by Mitsui Chemicals, Inc., trade name: HIWAX 1105A) as a hydrophobic polymeric dispersion agent, and then this was warmed up to 75 to 80°C with a water bath at 85°C at a stirring rate of 300 rpm to dissolve and disperse it before air cooling to an inner temperature of 61°C. The above-mentioned aqueous monomer solution was charged once into the above heptane while stirring them at 300 rpm by using a funnel made of SUS, having an inside diameter of 8 mm at opening at the tip. After adding the aqueous monomer solution, it was agitated at an inner temperature of 40°C for 10 minutes and primarily dispersed.

Next, a solution separately prepared by warming 0.92 g of a sucrose fatty acid ester (manufactured by Mitsubishi-Kagaku Foods Corporation, trade name: S-370) as

a surfactant to dissolve it in 8.28 g of heptane by warming at 60°C or higher was added to the round-bottom flask through a funnel and then a stirring rate was increased to 300 rpm to secondly disperse the aqueous monomer solution.

5 The atmosphere in the system was well substituted with nitrogen while maintaining the inner temperature of the round-bottom flask containing the dispersion at 40°C, and a radical polymerization reaction was performed by warming for 1 hour with a hot water bath at 70°C.

10 [0096]

After the polymerization reaction, the reaction suspension was heated using an oil bath at 120°C and 125 g of water was removed off from the system by azeotropic distillation while refluxing heptane in the flask to obtain
15 a dehydrated polymer dispersed in heptane. To the resultant heptane dispersed dehydrated polymer, 3.4 g of a 2% aqueous solution of ethylene glycol diglycidyl ether as a post-crosslinking agent was added and the post-crosslinking reaction was performed at 83°C for 2 hours.

20 Then, heating is performed using an oil bath at 120°C, heptane and water were removed off from the system by distillation, followed by drying under a nitrogen gas flow to obtain 87 g of a water-absorbent resin having a spherical shape (partially in a form of aggregated
25 spherical particles) by passing through a sieve of 850 µm. This water-absorbent resin had a median particle size of

124 μ m, and a water content of 3.2%.

[0097]

[Comparative Example 7]

5 The stirring rate at the time of polymerization in Comparative Example 6 was further decreased to a lower speed to try to produce a sample having a larger particle size.

10 According to the same manner as that of Comparative Example 6, except that the stirring rate of 300 rpm is changed to 250 rpm, a polymerization was performed. As a result, a polymer winded to the stirring impeller to cause an unusual polymerization during raising an inner temperature by dipping it in a hot water bath at 70°C. Therefore, this experiment was canceled at that time.

15 [0098]

[Comparative Example 8]

The thickener HEC in Comparative Example 6 was added at 0.3 % by mass based on a mass of the monomer to try to produce a sample having a larger particle size.

20 Into a 500 mL Erlenmeyer flask, 92.0 g of 80% by mass of acrylic acid was charged and neutralized by adding dropwise 102.2 g of 30 % by mass sodium hydroxide under stirring while cooling the flask from the outside. To this were added 32.1 g of water, followed by 0.276 g of HEC
25 (manufactured by Sumitomo Seika Chemicals Co., Ltd.: AW-15F) to dissolve it by stirring. To this were added 0.11

g of potassium persulfate, 8.3 mg of ethylene glycol diglycidyl ether and 11.4 g of ion exchange water to prepare an aqueous monomer solution.

5 In a 2 L volumetric five-necked round-bottom flask equipped with a stirrer having a two-stage pitched blade paddle impellers of 50 mm in diameter, a thermometer, a reflux condenser and a nitrogen gas introducing tube, 334 g of heptane was weighted as a petroleum hydrocarbon dispersion medium. To the round-bottom flask was added
10 0.92 g of a maleic anhydride-modified ethylene-propylene copolymer (manufactured by Mitsui Chemicals, Inc., trade name: HIWAX 1105A) as a hydrophobic polymeric dispersion agent, and then this was warmed up to 75 to 80°C with a water bath at 85°C at a stirring rate of 300 rpm to
15 dissolve and disperse it before air cooling to an inner temperature of 61°C. The above-mentioned aqueous monomer solution was charged once into the above heptane while stirring them at 300 rpm by using a funnel made of SUS, having an inside diameter of 8 mm at opening at the tip.
20 After adding the aqueous monomer solution, it was agitated at an inner temperature of 40°C for 10 minutes and primarily dispersed.

Next, a solution separately prepared by warming 0.92 g of a sucrose fatty acid ester (manufactured by
25 Mitsubishi-Kagaku Foods Corporation, trade name: S-370) as a surfactant to dissolve it in 8.28 g of heptane by warming

at 60°C or higher was added to the round-bottom flask through a funnel and then a stirring rate was increased to 300 rpm to secondly disperse the aqueous monomer solution.

5 The atmosphere in the system was well substituted with nitrogen while maintaining the inner temperature of the round-bottom flask containing the dispersion at 40°C, and a radical polymerization reaction was performed by warming for 1 hour with a hot water bath at 70°C. As a result, since it was observed that polymer particles in the
10 polymerization tank were precipitated when polymerization progressed to exceed an inner temperature of 81°C, stirring rate was increased to 600 rpm.

After the polymerization reaction, the reaction suspension was heated using an oil bath at 120°C and 125 g
15 of water was removed off from the system by azeotropic distillation while refluxing heptane in the flask to obtain a dehydrated polymer dispersed in heptane. To the resultant heptane dispersed dehydrated polymer, 3.4 g of a 2% aqueous solution of ethylene glycol diglycidyl ether as
20 a post-crosslinking agent was added and the post-crosslinking reaction was performed at 83°C for 2 hours.

Then, heating is performed using an oil bath at 120°C, heptane and water were removed off from the system by distillation, followed by drying under a nitrogen gas flow
25 to obtain 88 g of a water-absorbent resin having a spherical shape (partially in a form of aggregated

spherical particles) by passing through a sieve of 850 μm . This water-absorbent resin had a median particle size of 195 μm , and a water content of 3.2%.

[0099]

5 [Comparative Example 9]

The amount of the thickener HEC of Comparative Example 8 was increased to 0.5 % by mass, and that of Comparative Example 8 was changed to the lattice-like stirring impeller which can stir the system widely to
10 perform a polymerization.

Into a 500 mL Erlenmeyer flask, 92.0 g of 80% by mass of acrylic acid was charged and neutralized by adding dropwise 102.2 g of 30 % by mass sodium hydroxide under stirring while cooling the flask from the outside. To this
15 were added 33.4 g of water, followed by 0.46 g of HEC (manufactured by Sumitomo Seika Chemicals Co., Ltd.: AW-15F) to dissolve it by stirring. To this were added 0.11 g of potassium persulfate, 8.3 mg of ethylene glycol diglycidyl ether and 10 g of ion exchange water to prepare
20 an aqueous monomer solution.

In a 2 L volumetric five-necked round-bottom flask equipped with a stirrer with the lattice-like impellers having a width of 58 mm, a maximum height of 104 mm and a total of four slits of 65 mm in length, a thermometer, a
25 reflux condenser and a nitrogen gas introducing tube, 334 g of heptane was weighted as a petroleum hydrocarbon

dispersion medium. To the round-bottom flask was added 0.92 g of a maleic anhydride-modified ethylene-propylene copolymer (manufactured by Mitsui Chemicals, Inc., trade name: HIWAX 1105A) as a hydrophobic polymeric dispersion agent, and then this was warmed up to 75 to 80°C with a water bath at 85°C at a stirring rate of 200 rpm to dissolve and disperse it before air cooling to an inner temperature of 61°C. A dropping injection of the above-mentioned aqueous monomer solution was performed into the above-mentioned heptane stirring at 200 rpm by using a dropping funnel. After adding the aqueous monomer solution, it was agitated at an inner temperature of 40°C for 10 minutes and primarily dispersed.

Next, a solution separately prepared by warming 0.92 g of a sucrose fatty acid ester (manufactured by Mitsubishi-Kagaku Foods Corporation, trade name: S-370) as a surfactant to dissolve it in 8.28 g of heptane by warming at 60°C or higher was added to the round-bottom flask through a funnel and then a stirring rate was increased to 300 rpm to secondly disperse the aqueous monomer solution. The atmosphere in the system was well substituted with nitrogen while maintaining the inner temperature of the round-bottom flask containing the dispersion at 40°C, and a radical polymerization reaction was performed by warming for 1 hour with a hot water bath at 70°C.

After the polymerization reaction, the reaction

suspension was heated using an oil bath at 120°C and 125 g of water was removed off from the system by azeotropic distillation while refluxing heptane in the flask to obtain a dehydrated polymer dispersed in heptane. To the resultant heptane dispersed dehydrated polymer, 3.4 g of a 2% aqueous solution of ethylene glycol diglycidyl ether as a post-crosslinking agent was added and the post-crosslinking reaction was performed at 83°C for 2 hours.

Then, heating is performed using an oil bath at 120°C, heptane and water were removed off from the system by distillation, followed by drying under a nitrogen gas flow to obtain 88 g of a water-absorbent resin having a spherical shape (partially in a form of aggregated spherical particles) by passing through a sieve of 850 µm. This water-absorbent resin had a median particle size of 168 µm, and a water content of 2.7%.

[0100]

[Example 5]

1.0 % by mass, polyvinyl pyrrolidone (hereinafter abbreviated to "PVP") of the hydrophilic polymeric dispersion agent based on an amount of the monomer substituted for the thickener HEC in Comparative Example 9 was added based on an amount of the monomer.

100 g of 5 % by mass aqueous solution of PVP (manufactured by ISP Japan Co. Ltd.: K-90) was prepared by dissolving it in ion exchange water prior to the

preparation of an aqueous monomer solution. Into a 500 mL Erlenmeyer flask, 92.0 g of 80% by mass of acrylic acid was charged and neutralized by adding dropwise 102.2 g of 30 % by mass sodium hydroxide under stirring while cooling the flask from the outside. To this were added 0.11 g of potassium persulfate, 8.3 mg of ethylene glycol diglycidyl ether, 18.1 g of the above-mentioned 5 mass% PVP aqueous solution and 25.8 g of ion exchange water to prepare an aqueous monomer solution.

[0101]

In a 2 L volumetric five-necked round-bottom flask equipped with a stirrer with the lattice-like impellers having a width of 58 mm, a maximum height of 104 mm and a total of four slits of 65 mm in length, a thermometer, a reflux condenser and a nitrogen gas introducing tube, 334 g of heptane was weighted as a petroleum hydrocarbon dispersion medium. To the round-bottom flask were added 0.46 g of an oxidized ethylene-propylene copolymer (manufactured by Mitsui Chemicals, Inc., trade name: HIWAX 4052E) and 0.46 g of a maleic anhydride-modified ethylene-propylene copolymer (manufactured by Mitsui Chemicals, Inc., trade name: HIWAX 1105A) as a hydrophobic polymeric dispersion agent, and then this was warmed up to 83 to 86°C with a water bath at 90°C at a stirring rate of 300 rpm to dissolve and disperse it before air cooling to an inner temperature of 61°C. A dropping injection of the above-

mentioned aqueous monomer solution in it was performed into the above-mentioned heptane stirring at 200 rpm by using a dropping funnel. After adding the aqueous monomer solution, it was agitated at an inner temperature of 40°C for 10 minutes and primarily dispersed.

Next, a solution separately prepared by warming 0.92 g of a sucrose fatty acid ester (manufactured by Mitsubishi-Kagaku Foods Corporation, trade name: S-370) as a surfactant to dissolve it in 8.28 g of heptane by warming at 60°C or higher was added to the round-bottom flask through a funnel and then a stirring rate was increased to 300 rpm to secondly disperse the aqueous monomer solution.

The atmosphere in the system was well substituted with nitrogen while maintaining the inner temperature of the round-bottom flask containing the dispersion at 40°C, and a radical polymerization reaction was performed by warming for 1 hour with a hot water bath at 70°C.

After the polymerization reaction, the reaction suspension was heated using an oil bath at 120°C and 125 g of water was removed off from the system by azeotropic distillation while refluxing heptane in the flask to obtain a dehydrated polymer dispersed in heptane. To the resultant heptane dispersed dehydrated polymer, 3.4 g of a 2% aqueous solution of ethylene glycol diglycidyl ether as a post-crosslinking agent was added and the post-crosslinking reaction was performed at 83°C for 2 hours.

Then, heating is performed using an oil bath at 120°C, heptane and water were removed off from the system by distillation, followed by drying under a nitrogen gas flow to obtain 90 g of a water-absorbent resin having a spherical shape (partially in a form of aggregated spherical particles) by passing through a sieve of 850 µm. This water-absorbent resin had a median particle size of 110 µm, and a water content of 3.0%.

[0102]

10 [Example 6]

The amount of PVP to be added in Examples 5 was increased to 2 % by mass.

100 g of 5 % by mass aqueous solution of PVP (manufactured by ISP Japan Co. Ltd.: K-90) was prepared by dissolving it in ion exchange water prior to the preparation of an aqueous monomer solution. Into a 500 mL Erlenmeyer flask, 92.0 g of 80% by mass of acrylic acid was charged and neutralized by adding dropwise 102.2 g of 30 % by mass sodium hydroxide under stirring while cooling the flask from the outside.

Subsequently, in the same manner as that of Example 5, water-absorbent resin passed through a sieve of 850 µm to obtain 91 g of water-absorbent resin having a spherical shape (partially in a form of aggregated spherical particles). This water-absorbent resin had a median particle size of 158 µm, and a water content of 3.3%.

[0103]

[Comparative Example 10]

The amount of the thickener HEC in Comparative Example 2 was increased to 1.0 % by mass.

5 Specifically, into a 500 mL Erlenmeyer flask, 92.0 g of 80% by mass of acrylic acid was charged and neutralized by adding dropwise 102.2 g of 30 % by mass sodium hydroxide under stirring while cooling the flask from the outside. To this were added 31.5 g of water, followed by 0.905 g of
10 HEC (manufactured by Sumitomo Seika Chemicals Co., Ltd.: AW-15F) to dissolve it by stirring. To this were added 0.073 g of potassium persulfate, 8.3 mg of ethylene glycol diglycidyl ether and 10 g of ion exchange water to prepare an aqueous monomer solution.

15 Subsequently, in the same manner as that of Comparative Example 2, water-absorbent resin passed through a sieve of 850 μm to obtain 90 g of water-absorbent resin having a spherical shape (partially in a form of aggregated spherical particles). This water-absorbent
20 resin had a median particle size of 215 μm , and a water content of 3.4%.

[0104]

Each of Examples 1-6, Reference Example, and Comparative Examples 1-3, 5-6, and 8-10 were carried out
25 three times. For each of the resultant water-absorbent resins, amounts of an remaining dispersion medium was

measured by using a measuring method of measuring an amount of a remaining dispersion medium, Mean $\pm$ Standard deviation for them are shown in Table 1.

[0105]

5 [Table 1]

	Aqueous monomer solution additives		Stirring rate [rpm]	Median particle size [μ m]	Amount of remaining dispersion medium [ppm]	Remarks
	Additives	Amount added [Mass %]

PVA...Polyvinyl alcohol

PVP...Polyvinyl pyrrolidone

HEC...Hydroxyethyl cellulose

Remaining dispersion medium is shown by Mean ± Standard
5 deviation.

* P<0.05 (vs. Reference Example 1, and Comparative Examples
1-3, 5-6, and 8-10)

[0106]

As shown in Table 1, any water-absorbent resin of
10 Examples 1-6 had an amount of the remaining dispersion
medium reduced significantly as compared with those of
Reference Example and Comparative Examples. More
specifically, even when the production methods of Examples
1-4 which use a hydrophilic polymeric dispersion agent to
15 perform only the one-stage reversed-phase suspension
polymerization are compared with the conventional method
(Reference Example 1, 104 ppm) which exhibits the lowest

level of the amount of the remaining dispersion medium by performing a two-stages polymerization, a further reduction in the amount of the remaining dispersion medium could be accomplished ($P < 0.05$).

5 Moreover, in comparison of the median particle size of the obtained water-absorbent resins, the particles obtained only by control of stirring rate without using a thickener, has a median particle size up to about 120 μm (Comparative Examples 1 and 6), and when hydroxyethyl
10 cellulose (HEC) which is a thickener well-known in reversed-phase suspension polymerization, was used, it was identified that those having a larger particle size are obtained and however, the amount of the remaining dispersion medium increases simultaneously (Comparative
15 Examples 2, 8, 9, and 10).

On the other hand, the spherical water-absorbent resin (Examples 6) having a particle size of 150 μm or more could also be obtained by the production method of the present invention, and the water-absorbent resin having the
20 amount of the remaining dispersion medium reduced significantly as compared with those of Reference Example and Comparative Examples has been further provided.

[Industrial applicability]

[0107]

25 The present invention provides a method for producing a water-absorbent resin, wherein an amount of a remaining

petroleum hydrocarbon dispersion medium used in a reversed phase suspension polymerization, which is contained in the water-absorbent resin and an odor originated from the petroleum hydrocarbon dispersion medium is further reduced, and a water-absorbent resin obtained by the method.

[Document Name] Claims

[Claim 1]

A method for producing a water-absorbent resin by performing a reversed-phase suspension polymerization
5 of a water-soluble ethylenically unsaturated monomer in a petroleum hydrocarbon dispersion medium, comprising the following steps of:

(A) performing a primary dispersion in the absence of surfactants by adding an aqueous solution of a water-
10 soluble ethylenically unsaturated monomer containing a hydrophilic polymeric dispersion agent to a petroleum hydrocarbon dispersion medium in which a hydrophobic polymeric dispersion agent is heat-dispersed or heat-dissolved, under stirring;

15 (B) further performing a secondary dispersion by adding a surfactant to a dispersion liquid obtained after the primary dispersion; and

(C) performing the reversed-phase suspension polymerization by using a radical polymerization initiator.

20 [Claim 2]

The method for producing a water-absorbent resin according to claim 1, wherein the surfactant is at least one kind selected from the group consisting of polyglyceryl fatty acid ester, sucrose fatty acid ester,
25 and sorbitan fatty acid ester.

[Claim 3]

The method for producing a water-absorbent resin according to any one of claims 1 to 2, wherein the hydrophobic polymeric dispersion agent is at least one kind selected from the group consisting of maleic anhydride-
5 modified polyethylene, maleic anhydride-modified polypropylene, maleic anhydride-modified ethylene-propylene copolymer, maleic anhydride-ethylene copolymer, maleic anhydride-propylene copolymer, maleic anhydride-ethylene-propylene copolymer, polyethylene, polypropylene, ethylene-propylene copolymer, oxidized polyethylene, oxidized
10 polypropylene, and an oxidized ethylene-propylene copolymer.

[Claim 4]

The method for producing a water-absorbent resin according to any one of claims 1 to 3, wherein the water-
15 soluble ethylenically unsaturated monomer is at least one kind selected from the group consisting of acrylic acid and its salt, methacrylic acid and its salt, and acrylamide.

[Claim 5]

The method according to any one of claims 1 to 4,
20 wherein the petroleum hydrocarbon dispersion medium is at least one kind selected from the group consisting of an aliphatic hydrocarbon and an alicyclic hydrocarbon, having a carbon number of 6 to 8.

[Claim 6]

25 The method according to any one of claims 1 to 5, wherein the hydrophilic polymeric dispersion agent is at

least one kind selected from the group consisting of polyvinyl alcohol and polyvinyl pyrrolidone.

[Claim 7]

A water-absorbent resin obtained by the method
5 according to any one of claims 1 to 6.

Method for producing a water-absorbent resin

[Abstract]

The present invention provides a method for producing a water-absorbent resin and a water-absorbent resin obtained by the method, more specifically, to provide a method for producing a water-absorbent resin by a reversed-phase suspension polymerization method, wherein an odor originating from a raw material component, in particular, a petroleum hydrocarbon dispersion medium, is further reduced as compared with a water-absorbent resin obtained by a conventional method, and to a water-absorbent resin obtained by the method. More specifically, the present invention provides A method for producing a water-absorbent resin by performing a reversed-phase suspension polymerization of a water-soluble ethylenically unsaturated monomer in a petroleum hydrocarbon dispersion medium, comprising the following steps of: (A) performing a primary dispersion in the absence of surfactants by adding an aqueous solution of a water-soluble ethylenically unsaturated monomer containing a hydrophilic polymeric dispersion agent to a petroleum hydrocarbon dispersion medium in which a hydrophobic polymeric dispersion agent was heat-dispersed or heat-dissolved, under stirring; (B) further performing a secondary dispersion by adding a surfactant to a dispersion liquid obtained after the primary dispersion; and (C) performing the reversed-phase

suspension polymerization by using a radical polymerization initiator; and the water-absorbent resin obtained by the method.
