

MAXIMUM ALLOWED BLOCK SIZE FOR BDPCM MODE

[0001] This Application claims priority to U.S. Patent Application No. 16/905,100, filed 18 June 2020, which claims the benefit of U.S. Provisional Patent Application 62/863,734, filed 19 June 2019, the entire content of each being incorporated herein by reference.

TECHNICAL FIELD

[0002] This disclosure relates to video encoding and video decoding.

BACKGROUND

[0003] Digital video capabilities can be incorporated into a wide range of devices, including digital televisions, digital direct broadcast systems, wireless broadcast systems, personal digital assistants (PDAs), laptop or desktop computers, tablet computers, e-book readers, digital cameras, digital recording devices, digital media players, video gaming devices, video game consoles, cellular or satellite radio telephones, so-called “smart phones,” video teleconferencing devices, video streaming devices, and the like. Digital video devices implement video coding techniques, such as those described in the standards defined by MPEG-2, MPEG-4, ITU-T H.263, ITU-T H.264/MPEG-4, Part 10, Advanced Video Coding (AVC), ITU-T H.265/High Efficiency Video Coding (HEVC), and extensions of such standards. The video devices may transmit, receive, encode, decode, and/or store digital video information more efficiently by implementing such video coding techniques.

[0004] Video coding techniques include spatial (intra-picture) prediction and/or temporal (inter-picture) prediction to reduce or remove redundancy inherent in video sequences. For block-based video coding, a video slice (e.g., a video picture or a portion of a video picture) may be partitioned into video blocks, which may also be referred to as coding tree units (CTUs), coding units (CUs) and/or coding nodes. Video blocks in an intra-coded (I) slice of a picture are encoded using spatial prediction with respect to reference samples in neighboring blocks in the same picture. Video blocks in an inter-coded (P or B) slice of a picture may use spatial prediction with respect to reference samples in neighboring blocks in the same picture or temporal prediction with

respect to reference samples in other reference pictures. Pictures may be referred to as frames, and reference pictures may be referred to as reference frames.

SUMMARY

[0005] This disclosure describes techniques related to block-based delta pulse code modulation (BDPCM) mode, residual BDPCM mode, and transform skip mode. More specifically, this disclosure describes techniques that may be used to align the maximum block size used for BDPCM mode and residual BDPCM mode with the maximum block size used for transform skip mode by determining a maximum block size for BDPCM or residual BDPCM mode based on the maximum block size used for the transform skip mode. By aligning the maximum block size used for BDPCM mode and residual BDPCM mode with the maximum block size used for transform skip mode in this manner, the techniques of this disclosure may simplify aspects of BDPCM mode and residual BDPCM mode signaling and may prevent non-conforming bitstreams.

[0006] According to one example, a method of decoding video data includes receiving a syntax element indicating a maximum block size for a transform skip mode; determining a maximum block size for a BDPCM mode based on the syntax element; and decoding a block of video data based on the determined maximum block size for the BDPCM mode.

[0007] According to another example, a method of encoding video data includes determining a maximum block size used for a transform skip mode; determining a maximum block size for a BDPCM mode based on the maximum block size used for the transform skip mode; and encoding a block of video data based on the determined maximum block size for the BDPCM mode.

[0008] According to another example, a device for decoding video data includes a memory configured to store video data and one or more processors configured to receive a syntax element indicating a maximum block size for a transform skip mode; determine a maximum block size for a BDPCM mode based on the syntax element; and decode a block of video data based on the determined maximum block size for the BDPCM mode.

[0009] According to another example, a device for encoding video data includes a memory configured to store video data and one or more processors configured to determine a maximum block size used for a transform skip mode; determine a maximum block size for a BDPCM mode based on the maximum block size used for

the transform skip mode; and encode a block of video data based on the determined maximum block size for the BDPCM mode.

[0010] According to another example, a computer-readable storage medium stores instructions that when executed by one or more processors cause the one or more processor to receive a syntax element indicating a maximum block size for a transform skip mode; determine a maximum block size for a BDPCM mode based on the syntax element; and decode a block of video data based on the determined maximum block size for the BDPCM mode.

[0011] According to another example, a computer-readable storage medium stores instructions that when executed by one or more processors cause the one or more processor to determine a maximum block size used for a transform skip mode; determine a maximum block size for a BDPCM mode based on the maximum block size used for the transform skip mode; and encode a block of video data based on the determined maximum block size for the BDPCM mode.

[0012] According to another example, an apparatus for decoding video data includes means for receiving a syntax element indicating a maximum block size for a transform skip mode; means for determining a maximum block size for a BDPCM mode based on the syntax element; and means for decoding a block of video data based on the determined maximum block size for the BDPCM mode.

[0013] According to another example, an apparatus for encoding video data includes means for determining a maximum block size used for a transform skip mode; means for determining a maximum block size for a BDPCM mode based on the maximum block size used for the transform skip mode; and means for encoding a block of video data based on the determined maximum block size for the BDPCM mode.

[0014] The details of one or more examples are set forth in the accompanying drawings and the description below. Other features, objects, and advantages will be apparent from the description, drawings, and claims.

BRIEF DESCRIPTION OF DRAWINGS

[0015] FIG. 1 is a block diagram illustrating an example video encoding and decoding system that may perform the techniques of this disclosure.

[0016] FIGS. 2A and 2B are conceptual diagrams illustrating an example quadtree binary tree (QTBT) structure, and a corresponding coding tree unit (CTU).

[0017] FIG. 3 is a block diagram illustrating an example video encoder that may perform the techniques of this disclosure.

[0018] FIG. 4 is a block diagram illustrating an example video decoder that may perform the techniques of this disclosure.

[0019] FIG. 5 is a flowchart illustrating an example process performed by a video encoder.

[0020] FIG. 6 is a flowchart illustrating an example process performed by a video decoder.

[0021] FIG. 7 is a flowchart illustrating an example process performed by a video encoder, in accordance with one or more techniques of this disclosure.

[0022] FIG. 8 is a flowchart illustrating an example process performed by a video decoder, in accordance with one or more techniques of this disclosure.

DETAILED DESCRIPTION

[0023] Video coding (e.g., video encoding and/or video decoding) typically involves predicting a block of video data from either an already coded block of video data in the same picture (e.g., intra prediction) or an already coded block of video data in a different picture (e.g., inter prediction). Examples of intra prediction modes include various directional modes, as well as planar mode and DC mode. Block-based delta pulse code modulation (BDPCM) mode and residual domain BDPCM (RDPCM) mode, described in more detail below, are also types of intra prediction modes. In some instances, the video encoder also calculates residual data by comparing the prediction block to the original block. Thus, the residual data represents a difference between the prediction block and the original block. To reduce the number of bits needed to signal the residual data, the video encoder may transform and quantize the residual data and signal the transformed and quantized residual data in the encoded bitstream.

[0024] A video decoder decodes and adds the residual data to the prediction block to produce a reconstructed video block that matches the original video block more closely than the prediction block alone. The compression achieved by the transform and quantization processes may be lossy, meaning that the transform and quantization processes may introduce distortion into the decoded video data. Due to the loss introduced by the transforming and quantizing of the residual data, the first reconstructed block may have distortion or artifacts. One common type of artifact or

distortion is referred to as blockiness, where the boundaries of the blocks used to code the video data are visible.

[0025] To further improve the quality of decoded video, a video decoder can perform one or more filtering operations on the reconstructed video blocks. Examples of these filtering operations include deblocking filtering, sample adaptive offset (SAO) filtering, and adaptive loop filtering (ALF). Parameters for these filtering operations may either be determined by a video encoder and explicitly signaled in the encoded video bitstream or may be implicitly determined by a video decoder without needing the parameters to be explicitly signaled in the encoded video bitstream.

[0026] In some coding scenarios, a video encoder may encode a block of video data in a transform skip mode in which the transform process described above is not performed, i.e., the transform process is skipped. BDPCM mode and residual BDPCM mode are both examples of modes that utilize transform skipping, although transform skipping may also be used for other modes and other coding scenarios. For a block encoded in a transform skip mode, the residual data is not transformed but may still be quantized. Thus, a transform skip coefficient generally corresponds to a quantized representation of a residual value, whereas a transform coefficient generally corresponds to a residual value of a block that has been both quantized and transformed to generate a transform coefficient. As used in this disclosure, the term coefficients may refer to either a transform coefficient or a transform skip coefficient and may be either quantized or unquantized.

[0027] This disclosure describes techniques related to BDPCM mode, residual BDPCM mode, and transform skip mode. More specifically, this disclosure describes techniques that may be used to align the maximum block size used for BDPCM mode and residual BDPCM mode with the maximum block size used for transform skip mode by determining a maximum block size for BDPCM or residual BDPCM mode based on the maximum block size used for the transform skip mode. By aligning the maximum block size used for BDPCM mode and residual BDPCM mode with the maximum block size used for transform skip mode in this manner, the techniques of this disclosure may simplify aspects of BDPCM mode and residual BDPCM mode signaling and may prevent non-conforming bitstreams.

[0028] This disclosure may use the term delta pulse code modulation (DPCM) mode to generically refer to either a BDPCM mode or an RDPCM mode. Moreover, the term BDPCM mode may also be considered to include RDPCM mode as one type of

BDPCM mode. Moreover, it should be noted that the acronym RDPCM refers to any of residual BDPCM, residual domain BDPCM, and quantized residual domain BDPCM, which are alternative names that all refer to RDPCM.

[0029] The techniques of this disclosure may be applied to any of the existing video codecs, such as the High Efficiency Video Coding (HEVC) standard, the Versatile Video Coding (VVC) presently under development, or be an efficient coding tool in a future video coding standard.

[0030] FIG. 1 is a block diagram illustrating an example video encoding and decoding system 100 that may perform the techniques of this disclosure. The techniques of this disclosure are generally directed to coding (encoding and/or decoding) video data. In general, video data includes any data for processing a video. Thus, video data may include raw, unencoded video, encoded video, decoded (e.g., reconstructed) video, and video metadata, such as signaling data.

[0031] As shown in FIG. 1, system 100 includes a source device 102 that provides encoded video data to be decoded and displayed by a destination device 116, in this example. In particular, source device 102 provides the video data to destination device 116 via a computer-readable medium 110. Source device 102 and destination device 116 may each be any of a wide range of devices, including desktop computer, notebook (i.e., laptop) computer, tablet computer, set-top box, telephone handset such as a smartphone, television, camera, display device, digital media player, video gaming console, video streaming device, or the like. In some cases, source device 102 and destination device 116 may be equipped for wireless communication, and thus may be referred to as wireless communication devices.

[0032] In the example of FIG. 1, source device 102 includes video source 104, memory 106, video encoder 200, and output interface 108. Destination device 116 includes input interface 122, video decoder 300, memory 120, and display device 118. In accordance with this disclosure, video encoder 200 of source device 102 and video decoder 300 of destination device 116 may be configured to apply the techniques described in this disclosure. Thus, source device 102 represents an example of a video encoding device, while destination device 116 represents an example of a video decoding device. In other examples, a source device and a destination device may include other components or arrangements. For example, source device 102 may receive video data from an external video source, such as an external camera. Likewise,

destination device 116 may interface with an external display device, rather than including an integrated display device.

[0033] System 100 as shown in FIG. 1 is merely one example. In general, any digital video encoding and/or decoding device may perform techniques described in this disclosure. Source device 102 and destination device 116 are merely examples of such coding devices in which source device 102 generates encoded video data for transmission to destination device 116. This disclosure refers to a “coding” device as a device that performs coding (encoding and/or decoding) of data. Thus, video encoder 200 and video decoder 300 represent examples of coding devices, in particular, a video encoder and a video decoder, respectively. In some examples, devices 102, 116 may operate in a substantially symmetrical manner such that each of devices 102, 116 include video encoding and decoding components. Hence, system 100 may support one-way or two-way video transmission between source device 102 and destination device 116, e.g., for video streaming, video playback, video broadcasting, or video telephony.

[0034] In general, video source 104 represents a source of video data (i.e., raw, unencoded video data) and provides a sequential series of pictures (also referred to as “frames”) of the video data to video encoder 200, which encodes data for the pictures. Video source 104 of source device 102 may include a video capture device, such as a video camera, a video archive containing previously captured raw video, and/or a video feed interface to receive video from a video content provider. As a further alternative, video source 104 may generate computer graphics-based data as the source video, or a combination of live video, archived video, and computer-generated video. In each case, video encoder 200 encodes the captured, pre-captured, or computer-generated video data. Video encoder 200 may rearrange the pictures from the received order (sometimes referred to as “display order”) into a coding order for coding. Video encoder 200 may generate a bitstream including encoded video data. Source device 102 may then output the encoded video data via output interface 108 onto computer-readable medium 110 for reception and/or retrieval by, e.g., input interface 122 of destination device 116.

[0035] Memory 106 of source device 102 and memory 120 of destination device 116 represent general purpose memories. In some examples, memories 106, 120 may store raw video data, e.g., raw video from video source 104 and raw, decoded video data from video decoder 300. Additionally or alternatively, memories 106, 120 may store software instructions executable by, e.g., video encoder 200 and video decoder 300, respectively.

Although shown separately from video encoder 200 and video decoder 300 in this example, it should be understood that video encoder 200 and video decoder 300 may also include internal memories for functionally similar or equivalent purposes. Furthermore, memories 106, 120 may store encoded video data, e.g., output from video encoder 200 and input to video decoder 300. In some examples, portions of memories 106, 120 may be allocated as one or more video buffers, e.g., to store raw, decoded, and/or encoded video data.

[0036] Computer-readable medium 110 may represent any type of medium or device capable of transporting the encoded video data from source device 102 to destination device 116. In one example, computer-readable medium 110 represents a communication medium to enable source device 102 to transmit encoded video data directly to destination device 116 in real-time, e.g., via a radio frequency network or computer-based network. Output interface 108 may modulate a transmission signal including the encoded video data, and input interface 122 may demodulate the received transmission signal, according to a communication standard, such as a wireless communication protocol. The communication medium may comprise any wireless or wired communication medium, such as a radio frequency (RF) spectrum or one or more physical transmission lines. The communication medium may form part of a packet-based network, such as a local area network, a wide-area network, or a global network such as the Internet. The communication medium may include routers, switches, base stations, or any other equipment that may be useful to facilitate communication from source device 102 to destination device 116.

[0037] In some examples, source device 102 may output encoded data from output interface 108 to storage device 112. Similarly, destination device 116 may access encoded data from storage device 112 via input interface 122. Storage device 112 may include any of a variety of distributed or locally accessed data storage media such as a hard drive, Blu-ray discs, DVDs, CD-ROMs, flash memory, volatile or non-volatile memory, or any other suitable digital storage media for storing encoded video data.

[0038] In some examples, source device 102 may output encoded video data to file server 114 or another intermediate storage device that may store the encoded video data generated by source device 102. Destination device 116 may access stored video data from file server 114 via streaming or download.

[0039] File server 114 may be any type of server device capable of storing encoded video data and transmitting that encoded video data to the destination device 116. File

server 114 may represent a web server (e.g., for a website), a server configured to provide a file transfer protocol service (such as File Transfer Protocol (FTP) or File Delivery over Unidirectional Transport (FLUTE) protocol), a content delivery network (CDN) device, a hypertext transfer protocol (HTTP) server, a Multimedia Broadcast Multicast Service (MBMS) or Enhanced MBMS (eMBMS) server, and/or a network attached storage (NAS) device. File server 114 may, additionally or alternatively, implement one or more HTTP streaming protocols, such as Dynamic Adaptive Streaming over HTTP (DASH), HTTP Live Streaming (HLS), Real Time Streaming Protocol (RTSP), HTTP Dynamic Streaming, or the like.

[0040] Destination device 116 may access encoded video data from file server 114 through any standard data connection, including an Internet connection. This may include a wireless channel (e.g., a Wi-Fi connection), a wired connection (e.g., digital subscriber line (DSL), cable modem, etc.), or a combination of both that is suitable for accessing encoded video data stored on file server 114. Input interface 122 may be configured to operate according to any one or more of the various protocols discussed above for retrieving or receiving media data from file server 114, or other such protocols for retrieving media data.

[0041] Output interface 108 and input interface 122 may represent wireless transmitters/receivers, modems, wired networking components (e.g., Ethernet cards), wireless communication components that operate according to any of a variety of IEEE 802.11 standards, or other physical components. In examples where output interface 108 and input interface 122 comprise wireless components, output interface 108 and input interface 122 may be configured to transfer data, such as encoded video data, according to a cellular communication standard, such as 4G, 4G-LTE (Long-Term Evolution), LTE Advanced, 5G, or the like. In some examples where output interface 108 comprises a wireless transmitter, output interface 108 and input interface 122 may be configured to transfer data, such as encoded video data, according to other wireless standards, such as an IEEE 802.11 specification, an IEEE 802.15 specification (e.g., ZigBee™), a Bluetooth™ standard, or the like. In some examples, source device 102 and/or destination device 116 may include respective system-on-a-chip (SoC) devices. For example, source device 102 may include an SoC device to perform the functionality attributed to video encoder 200 and/or output interface 108, and destination device 116 may include an SoC device to perform the functionality attributed to video decoder 300 and/or input interface 122.

[0042] The techniques of this disclosure may be applied to video coding in support of any of a variety of multimedia applications, such as over-the-air television broadcasts, cable television transmissions, satellite television transmissions, Internet streaming video transmissions, such as dynamic adaptive streaming over HTTP (DASH), digital video that is encoded onto a data storage medium, decoding of digital video stored on a data storage medium, or other applications.

[0043] Input interface 122 of destination device 116 receives an encoded video bitstream from computer-readable medium 110 (e.g., storage device 112, file server 114, or the like). The encoded video bitstream may include signaling information defined by video encoder 200, which is also used by video decoder 300, such as syntax elements having values that describe characteristics and/or processing of video blocks or other coded units (e.g., slices, pictures, groups of pictures, sequences, or the like). Display device 118 displays decoded pictures of the decoded video data to a user. Display device 118 may represent any of a variety of display devices such as a cathode ray tube (CRT), a liquid crystal display (LCD), a plasma display, an organic light emitting diode (OLED) display, or another type of display device.

[0044] Although not shown in FIG. 1, in some examples, video encoder 200 and video decoder 300 may each be integrated with an audio encoder and/or audio decoder, and may include appropriate MUX-DEMUX units, or other hardware and/or software, to handle multiplexed streams including both audio and video in a common data stream. If applicable, MUX-DEMUX units may conform to the ITU H.223 multiplexer protocol, or other protocols such as the user datagram protocol (UDP).

[0045] Video encoder 200 and video decoder 300 each may be implemented as any of a variety of suitable encoder and/or decoder circuitry, such as one or more microprocessors, digital signal processors (DSPs), application specific integrated circuits (ASICs), field programmable gate arrays (FPGAs), discrete logic, software, hardware, firmware or any combinations thereof. When the techniques are implemented partially in software, a device may store instructions for the software in a suitable, non-transitory computer-readable medium and execute the instructions in hardware using one or more processors to perform the techniques of this disclosure. Each of video encoder 200 and video decoder 300 may be included in one or more encoders or decoders, either of which may be integrated as part of a combined encoder/decoder (CODEC) in a respective device. A device including video encoder 200 and/or video

decoder 300 may comprise an integrated circuit, a microprocessor, and/or a wireless communication device, such as a cellular telephone.

[0046] Video encoder 200 and video decoder 300 may operate according to a video coding standard. Video coding standards include ITU-T H.261, ISO/IEC MPEG-1 Visual, ITU-T H.262 or ISO/IEC MPEG-2 Visual, ITU-T H.263, ISO/IEC MPEG-4 Visual and ITU-T H.264 (also known as ISO/IEC MPEG-4 AVC), including its Scalable Video Coding (SVC) and Multi-view Video Coding (MVC) extensions.

[0047] In addition, a new video coding standard, namely High Efficiency Video Coding (HEVC) or ITU-T H.265, including its range extension, multiview extension (MV-HEVC) and scalable extension (SHVC), has recently been developed by the Joint Collaboration Team on Video Coding (JCT-VC) as well as Joint Collaboration Team on 3D Video Coding Extension Development (JCT-3V) of ITU-T Video Coding Experts Group (VCEG) and ISO/IEC Motion Picture Experts Group (MPEG).

[0048] Alternatively or additionally, video encoder 200 and video decoder 300 may operate according to other proprietary or industry standards, such as the Joint Exploration Test Model (JEM) or ITU-T H.266, also referred to as Versatile Video Coding (VVC). A recent draft of the VVC standard is described in Bross, et al. “Versatile Video Coding (Draft 5),” Joint Video Experts Team (JVET) of ITU-T SG 16 WP 3 and ISO/IEC JTC 1/SC 29/WG 11, 14th Meeting: Geneva, CH, 19-27 March 2019, JVET-N1001-v8 (hereinafter “VVC Draft 5”). The techniques of this disclosure, however, are not limited to any particular coding standard.

[0049] In general, video encoder 200 and video decoder 300 may perform block-based coding of pictures. The term “block” generally refers to a structure including data to be processed (e.g., encoded, decoded, or otherwise used in the encoding and/or decoding process). For example, a block may include a two-dimensional matrix of samples of luminance and/or chrominance data. In general, video encoder 200 and video decoder 300 may code video data represented in a YUV (e.g., Y, Cb, Cr) format. That is, rather than coding red, green, and blue (RGB) data for samples of a picture, video encoder 200 and video decoder 300 may code luminance and chrominance components, where the chrominance components may include both red hue and blue hue chrominance components. In some examples, video encoder 200 converts received RGB formatted data to a YUV representation prior to encoding, and video decoder 300 converts the YUV representation to the RGB format. Alternatively, pre- and post-processing units (not shown) may perform these conversions.

[0050] This disclosure may generally refer to coding (e.g., encoding and decoding) of pictures to include the process of encoding or decoding data of the picture. Similarly, this disclosure may refer to coding of blocks of a picture to include the process of encoding or decoding data for the blocks, e.g., prediction and/or residual coding. An encoded video bitstream generally includes a series of values for syntax elements representative of coding decisions (e.g., coding modes) and partitioning of pictures into blocks. Thus, references to coding a picture or a block should generally be understood as coding values for syntax elements forming the picture or block.

[0051] HEVC defines various blocks, including coding units (CUs), prediction units (PUs), and transform units (TUs). According to HEVC, a video coder (such as video encoder 200) partitions a coding tree unit (CTU) into CUs according to a quadtree structure. That is, the video coder partitions CTUs and CUs into four equal, non-overlapping squares, and each node of the quadtree has either zero or four child nodes. Nodes without child nodes may be referred to as “leaf nodes,” and CUs of such leaf nodes may include one or more PUs and/or one or more TUs. The video coder may further partition PUs and TUs. For example, in HEVC, a residual quadtree (RQT) represents partitioning of TUs. In HEVC, PUs represent inter-prediction data, while TUs represent residual data. CUs that are intra-predicted include intra-prediction information, such as an intra-mode indication.

[0052] As another example, video encoder 200 and video decoder 300 may be configured to operate according to JEM or VVC. According to JEM or VVC, a video coder (such as video encoder 200) partitions a picture into a plurality of coding tree units (CTUs). Video encoder 200 may partition a CTU according to a tree structure, such as a quadtree-binary tree (QTBT) structure or Multi-Type Tree (MTT) structure. The QTBT structure removes the concepts of multiple partition types, such as the separation between CUs, PUs, and TUs of HEVC. A QTBT structure includes two levels: a first level partitioned according to quadtree partitioning, and a second level partitioned according to binary tree partitioning. A root node of the QTBT structure corresponds to a CTU. Leaf nodes of the binary trees correspond to coding units (CUs).

[0053] In an MTT partitioning structure, blocks may be partitioned using a quadtree (QT) partition, a binary tree (BT) partition, and one or more types of triple tree (TT) partitions. A triple tree partition is a partition where a block is split into three sub-blocks. In some examples, a triple tree partition divides a block into three sub-blocks

without dividing the original block through the center. The partitioning types in MTT (e.g., QT, BT, and TT), may be symmetrical or asymmetrical.

[0054] In some examples, video encoder 200 and video decoder 300 may use a single QTBT or MTT structure to represent each of the luminance and chrominance components, while in other examples, video encoder 200 and video decoder 300 may use two or more QTBT or MTT structures, such as one QTBT/MTT structure for the luminance component and another QTBT/MTT structure for both chrominance components (or two QTBT/MTT structures for respective chrominance components).

[0055] Video encoder 200 and video decoder 300 may be configured to use quadtree partitioning per HEVC, QTBT partitioning, MTT partitioning, or other partitioning structures. For purposes of explanation, the description of the techniques of this disclosure is presented with respect to QTBT partitioning. However, it should be understood that the techniques of this disclosure may also be applied to video coders configured to use quadtree partitioning, or other types of partitioning as well.

[0056] This disclosure may use “NxN” and “N by N” interchangeably to refer to the sample dimensions of a block (such as a CU or other video block) in terms of vertical and horizontal dimensions, e.g., 16x16 samples or 16 by 16 samples. In general, a 16x16 CU will have 16 samples in a vertical direction ($y = 16$) and 16 samples in a horizontal direction ($x = 16$). Likewise, an NxN CU generally has N samples in a vertical direction and N samples in a horizontal direction, where N represents a nonnegative integer value. The samples in a CU may be arranged in rows and columns. Moreover, CUs need not necessarily have the same number of samples in the horizontal direction as in the vertical direction. For example, CUs may comprise NxM samples, where M is not necessarily equal to N.

[0057] Video encoder 200 encodes video data for CUs representing prediction and/or residual information, and other information. The prediction information indicates how the CU is to be predicted in order to form a prediction block for the CU. The residual information generally represents sample-by-sample differences between samples of the CU prior to encoding and the prediction block.

[0058] To predict a CU, video encoder 200 may generally form a prediction block for the CU through inter-prediction or intra-prediction. Inter-prediction generally refers to predicting the CU from data of a previously coded picture, whereas intra-prediction generally refers to predicting the CU from previously coded data of the same picture. To perform inter-prediction, video encoder 200 may generate the prediction block using

one or more motion vectors. Video encoder 200 may generally perform a motion search to identify a reference block that closely matches the CU, e.g., in terms of differences between the CU and the reference block. Video encoder 200 may calculate a difference metric using a sum of absolute difference (SAD), sum of squared differences (SSD), mean absolute difference (MAD), mean squared differences (MSD), or other such difference calculations to determine whether a reference block closely matches the current CU. In some examples, video encoder 200 may predict the current CU using uni-directional prediction or bi-directional prediction.

[0059] Some examples of JEM and VVC also provide an affine motion compensation mode, which may be considered an inter-prediction mode. In affine motion compensation mode, video encoder 200 may determine two or more motion vectors that represent non-translational motion, such as zoom in or out, rotation, perspective motion, or other irregular motion types.

[0060] To perform intra-prediction, video encoder 200 may select an intra-prediction mode to generate the prediction block. Some examples of JEM and VVC provide sixty-seven intra-prediction modes, including various directional modes, as well as planar mode and DC mode. In general, video encoder 200 selects an intra-prediction mode that describes neighboring samples to a current block (e.g., a block of a CU) from which to predict samples of the current block. Such samples may generally be above, above and to the left, or to the left of the current block in the same picture as the current block, assuming video encoder 200 codes CTUs and CUs in raster scan order (left to right, top to bottom).

[0061] Video encoder 200 encodes data representing the prediction mode for a current block. For example, for inter-prediction modes, video encoder 200 may encode data representing which of the various available inter-prediction modes is used, as well as motion information for the corresponding mode. For uni-directional or bi-directional inter-prediction, for example, video encoder 200 may encode motion vectors using advanced motion vector prediction (AMVP) or merge mode. Video encoder 200 may use similar modes to encode motion vectors for affine motion compensation mode.

[0062] Following prediction, such as intra-prediction or inter-prediction of a block, video encoder 200 may calculate residual data for the block. The residual data, such as a residual block, represents sample by sample differences between the block and a prediction block for the block, formed using the corresponding prediction mode. Video encoder 200 may apply one or more transforms to the residual block, to produce

transformed data in a transform domain instead of the sample domain. For example, video encoder 200 may apply a discrete cosine transform (DCT), an integer transform, a wavelet transform, or a conceptually similar transform to residual video data.

Additionally, video encoder 200 may apply a secondary transform following the first transform, such as a mode-dependent non-separable secondary transform (MDNSST), a signal dependent transform, a Karhunen-Loeve transform (KLT), or the like. Video encoder 200 produces transform coefficients following application of the one or more transforms.

[0063] Although the above describes examples where transforms are preformed, in some examples, the transform may be skipped. For instance, video encoder 200 may implement transform skip mode in which the transform operation is skipped. In examples where transform is skipped, video encoder 200 may output coefficients corresponding to residual values instead of transform coefficients. The coefficients corresponding to residual values may, for example, correspond to quantized residual values. In the following description, the term “coefficient” should be interpreted to include either coefficients corresponding to residual values or transform coefficients generated from the result of a transform.

[0064] As noted above, video encoder 200 may perform quantization of the transform coefficients or, in the case of transform skip, quantization of the residual values. Quantization generally refers to a process in which coefficients are quantized to possibly reduce the amount of data used to represent the coefficients, providing further compression. By performing the quantization process, video encoder 200 may reduce the bit depth associated with some or all of the coefficients. For example, video encoder 200 may round an n -bit value down to an m -bit value during quantization, where n is greater than m . In some examples, to perform quantization, video encoder 200 may perform a bitwise right-shift of the value to be quantized.

[0065] Following quantization, video encoder 200 may scan the coefficients, producing a one-dimensional vector from the two-dimensional matrix including the quantized coefficients. For transform coefficients, the scan may be designed to place higher energy (and therefore lower frequency) coefficients at the front of the vector and to place lower energy (and therefore higher frequency) transform coefficients at the back of the vector. For transform skip coefficients, the same or a different scan may be used. In some examples, video encoder 200 may utilize a predefined scan order to scan the quantized coefficients to produce a serialized vector, and then entropy encode the

quantized coefficients of the vector. In other examples, video encoder 200 may perform an adaptive scan. After scanning the quantized coefficients to form the one-dimensional vector, video encoder 200 may entropy encode the one-dimensional vector, e.g., according to context-adaptive binary arithmetic coding (CABAC). Video encoder 200 may also entropy encode values for syntax elements describing metadata associated with the encoded video data for use by video decoder 300 in decoding the video data.

[0066] To perform CABAC, video encoder 200 may assign a context within a context model to a symbol to be transmitted. The context may relate to, for example, whether neighboring values of the symbol are zero-valued or not. The probability determination may be based on a context assigned to the symbol.

[0067] Video encoder 200 may further generate syntax data, such as block-based syntax data, picture-based syntax data, and sequence-based syntax data, to video decoder 300, e.g., in a picture header, a block header, a slice header, or other syntax data, such as a sequence parameter set (SPS), picture parameter set (PPS), or video parameter set (VPS). Video decoder 300 may likewise decode such syntax data to determine how to decode corresponding video data.

[0068] In this manner, video encoder 200 may generate a bitstream including encoded video data, e.g., syntax elements describing partitioning of a picture into blocks (e.g., CUs) and prediction and/or residual information for the blocks. Ultimately, video decoder 300 may receive the bitstream and decode the encoded video data.

[0069] In general, video decoder 300 performs a reciprocal process to that performed by video encoder 200 to decode the encoded video data of the bitstream. For example, video decoder 300 may decode values for syntax elements of the bitstream using CABAC in a manner substantially similar to, albeit reciprocal to, the CABAC encoding process of video encoder 200. The syntax elements may define partitioning information of a picture into CTUs, and partitioning of each CTU according to a corresponding partition structure, such as a QTBT structure, to define CUs of the CTU. The syntax elements may further define prediction and residual information for blocks (e.g., CUs) of video data.

[0070] The residual information may be represented, for example, by quantized transform coefficients, quantized transform skip coefficients, or unquantized transform skip coefficients. Video decoder 300 may inverse quantize and, if coded in a transform mode, inverse transform the quantized coefficients of a block to reproduce a residual block for the block. Video decoder 300 uses a signaled prediction mode (intra- or inter-

prediction) and related prediction information (e.g., motion information for inter-prediction) to form a prediction block for the block. Video decoder 300 may then combine the prediction block and the residual block (on a sample-by-sample basis) to reproduce the original block. Video decoder 300 may perform additional processing, such as performing a deblocking process to reduce visual artifacts along boundaries of the block.

[0071] As described in greater detail below, video encoder 200 may be configured to determine a maximum block size used for a transform skip mode and determine a maximum block size for a BDPCM mode based on the maximum block size used for the transform skip mode. Video encoder 200 may generate a syntax element, for inclusion in a sequence parameter set syntax structure of the video data, indicating the maximum block size used for the transform skip mode. Video decoder 300 may be configured to receive a syntax element indicating a maximum block size for a transform skip mode and determining a maximum block size for a BDPCM mode based on the syntax element. By aligning the maximum block size used for BDPCM mode and residual BDPCM mode with the maximum block size used for transform skip mode in this manner, the techniques of this disclosure, as implemented by video encoder 200 and video decoder 300, may simplify aspects of BDPCM mode and residual BDPCM mode signaling and prevent non-conforming bitstreams.

[0072] This disclosure may generally refer to “signaling” certain information, such as syntax elements. The term “signaling” may generally refer to the communication of values for syntax elements and/or other data used to decode encoded video data. That is, video encoder 200 may signal values for syntax elements in the bitstream. In general, signaling refers to generating a value in the bitstream. As noted above, source device 102 may transport the bitstream to destination device 116 substantially in real time, or not in real time, such as might occur when storing syntax elements to storage device 112 for later retrieval by destination device 116.

[0073] FIGS. 2A and 2B are conceptual diagram illustrating an example quadtree binary tree (QTBT) structure 130, and a corresponding coding tree unit (CTU) 132. The solid lines represent quadtree splitting, and dotted lines indicate binary tree splitting. In each split (i.e., non-leaf) node of the binary tree, one flag is signaled to indicate which splitting type (i.e., horizontal or vertical) is used, where 0 indicates horizontal splitting and 1 indicates vertical splitting in this example. For the quadtree splitting, there is no need to indicate the splitting type, since quadtree nodes split a block horizontally and

vertically into 4 sub-blocks with equal size. Accordingly, video encoder 200 may encode, and video decoder 300 may decode, syntax elements (such as splitting information) for a region tree level of QTBT structure 130 (i.e., the solid lines) and syntax elements (such as splitting information) for a prediction tree level of QTBT structure 130 (i.e., the dashed lines). Video encoder 200 may encode, and video decoder 300 may decode, video data, such as prediction and transform data, for CUs represented by terminal leaf nodes of QTBT structure 130.

[0074] In general, CTU 132 of FIG. 2B may be associated with parameters defining sizes of blocks corresponding to nodes of QTBT structure 130 at the first and second levels. These parameters may include a CTU size (representing a size of CTU 132 in samples), a minimum quadtree size (MinQTSIZE, representing a minimum allowed quadtree leaf node size), a maximum binary tree size (MaxBTSIZE, representing a maximum allowed binary tree root node size), a maximum binary tree depth (MaxBTDepth, representing a maximum allowed binary tree depth), and a minimum binary tree size (MinBTSIZE, representing the minimum allowed binary tree leaf node size).

[0075] The root node of a QTBT structure corresponding to a CTU may have four child nodes at the first level of the QTBT structure, each of which may be partitioned according to quadtree partitioning. That is, nodes of the first level are either leaf nodes (having no child nodes) or have four child nodes. The example of QTBT structure 130 represents such nodes as including the parent node and child nodes having solid lines for branches. If nodes of the first level are not larger than the maximum allowed binary tree root node size (MaxBTSIZE), then the nodes can be further partitioned by respective binary trees. The binary tree splitting of one node can be iterated until the nodes resulting from the split reach the minimum allowed binary tree leaf node size (MinBTSIZE) or the maximum allowed binary tree depth (MaxBTDepth). The example of QTBT structure 130 represents such nodes as having dashed lines for branches. The binary tree leaf node is referred to as a coding unit (CU), which is used for prediction (e.g., intra-picture or inter-picture prediction) and transform, without any further partitioning. As discussed above, CUs may also be referred to as “video blocks” or “blocks.”

[0076] In one example of the QTBT partitioning structure, the CTU size is set as 128x128 (luma samples and two corresponding 64x64 chroma samples), the MinQTSIZE is set as 16x16, the MaxBTSIZE is set as 64x64, the MinBTSIZE (for both

width and height) is set as 4, and the MaxBTDepth is set as 4. The quadtree partitioning is applied to the CTU first to generate quad-tree leaf nodes. The quadtree leaf nodes may have a size from 16x16 (i.e., the MinQTSIZE) to 128x128 (i.e., the CTU size). If the quadtree leaf node is 128x128, it will not be further split by the binary tree, since the size exceeds the MaxBTSize (i.e., 64x64, in this example). Otherwise, the quadtree leaf node will be further partitioned by the binary tree. Therefore, the quadtree leaf node is also the root node for the binary tree and has the binary tree depth as 0. When the binary tree depth reaches MaxBTDepth (4, in this example), no further splitting is permitted. The binary tree node having width equal to MinBTSize (4, in this example), implies that no further horizontal splitting is permitted. Similarly, a binary tree node having a height equal to MinBTSize implies that no further vertical splitting is permitted for that binary tree node. As noted above, leaf nodes of the binary tree are referred to as CUs and are further processed according to prediction and transform without further partitioning.

[0077] Video encoder 200 and video decoder 300 may be configured to code blocks in a transform skip mode. Transform skip mode skips a transform process for residual signals before a quantization step on the encoder side and an inverse transform step after the dequantization step on the decoder side. For each transform block, transform skip mode may or may not be applied. Video decoder 300 can determine whether the transform skip is to be applied to the current block by rules predefined for both encoder and decoder or by parsing information from the bit-stream. In the current VVC design, for some modes, such as residual BDPCM, transform skip is implicitly used, so no flag is needed in the bitstream. For other modes in which transform-skip may be applied, video encoder 200 has the freedom of selecting from a few candidates transforms, including transform skip mode. In this case, when a transform block has non-zero coded block flag (CBF), a flag is needed to indicate whether transform skip mode should be used for the current block. When CBF is zero, there is no residual information coded for the corresponding transform block.

[0078] Video encoder 200 and video decoder 300 may be configured to code blocks in a BDPCM mode. BDPCM mode uses reconstructed samples to predict the rows or columns line by line. That is, video encoder 200 and video decoder 300 may, for example, predict a first line of a block, i.e., a first row or first column of the block, from a reconstructed line in a neighboring block, as with typical intra prediction. Video encoder 200 and video decoder 300 may, however, predict the second line of the block

based on the reconstructed samples for the first line, meaning that video encoder 200 and video decoder 300 predict the second line of the block based on the predicted samples for the first line plus residual values for the first line. Video encoder 200 and video decoder 300 may then predict the third row of the block based on reconstructed samples for the second line, and so on. A signaled BDPCM direction indicates whether a vertical prediction direction or horizontal prediction direction is used. The reference pixels used are unfiltered samples. The prediction error is quantized in the spatial domain. Pixels are reconstructed by adding the dequantized prediction error to the prediction.

[0079] As an additional or alternative scheme to BDPCM, video encoder 200 and video decoder 300 may be configured to code video blocks in an RDPCM mode, which is currently included in VVC Draft 5. The signaling and prediction directions used are the same as for BDPCM. In RDPCM, video encoder 200 and video decoder 300 first intra predict the entire block by copying samples of a neighboring block according to a prediction direction (e.g., horizontal or vertical prediction) similar to intra prediction. The residual is quantized, and the difference between the quantized residual and a predictor (horizontal or vertical) quantized value is coded. That is, for a first line of a block, video encoder 200 and video decoder 300 receive a residual value representing a difference between a predicted sample for the first line and a corresponding original sample. For a second line of the block, however, video encoder 200 and video decoder 300 use the residual value for the first line as a predictor for a residual value of the second line. Thus, video encoder 200 and video decoder 300 signal the residual for a sample of the second line as a difference between the residual value for a neighboring sample in the first line and the residual value for the sample in the second line. Video encoder 200 and video decoder 300 signal the residual for a sample of the third line as a difference between the residual value for a neighboring sample in the second line and the residual value for the sample in the third line, and so on.

[0080] A benefit of this scheme is that video encoder 200 and video decoder 300 may perform the inverse DPCM on the fly during coefficient parsing simply by adding the predictor as the coefficients are parsed or video decoder 300 may perform inverse DPCM after parsing. The splitting of $4 \times N$ and $N \times 4$ blocks into 2 parallel processed blocks can be eliminated.

[0081] Residual domain BDPCM was adopted at the 14th JVET meeting. In VVC, the maximum block size for BDPCM/RDPCM is 32×32 . BDPCM mode always uses

Transform Skip (TS). The maximum size of TS is signaled in a PPS RBSP and is defined as below:

log2_transform_skip_max_size_minus2 specifies the maximum block size used for transform skip, and shall be in the range of 0 to 3.

When not present, the value of **log2_transform_skip_max_size_minus2** is inferred to be equal to 0.

The variable **MaxTsSize** is set equal to $1 \ll (\text{log2_transform_skip_max_size_minus2} + 2)$.

[0082] As BDPCM mode and RDPCM mode always use transform skip, this disclosure proposes techniques for aligning the designs of BDPCM mode and RDPCM mode with the design of transform skip mode.

[0083] According to one example technique of this disclosure, the design of the prediction modes which use transform skip may be aligned with the transform skip (TS) design. As one example, in VVC Draft 5, a maximum TS block size is signaled in a PPS. According to techniques of this disclosure, video encoder 200 and video decoder 300 may be configured to set the maximum block size for BDPCM (or RDPCM) equal to the maximum TS size, which may be equal to:

$$1 \ll (\text{log2_transform_skip_max_size_minus2} + 2).$$

[0084] Additionally, the presence of an RDPCM mode flag may depend on the maximum allowed TS size. In this example, the maximum TS size can be set as a value signaled from video encoder 200 to video decoder 300 at a sequence level, picture level, slice level. For example, this value can be signaled in an SPS, PPS, or slice header (SH). In some example, the RDPCM mode flag may specify a direction for the RDPCM mode. In other examples, the RDPCM mode flag may additionally or alternatively specify whether RDPCM mode is used for a specific block.

[0085] According to another example technique of this disclosure, the maximum block size for BDPCM (or RDPCM) may be signalled separately from TS. In one example, the maximum block size for BDPCM or RDPCM may be predefined by video encoder 200 and video decoder 300 or be set as a value signaled from video encoder 200 to video decoder 300 at a sequence level, a picture level, or a slice level. For example, this value can be signaled in an SPS, a PPS, or an SH.

[0086] According to another example technique of this disclosure, video encoder 200 to video decoder 300 may signal a maximum block size for BDPCM or RDPCM as a difference between the maximum block size for BDPCM or RDPCM and maximum

block size for TS. This difference can be represented by the syntax element $\log_2_diff_max_BDPCM_max_TS$. In this example, video encoder 200 and video decoder 300 may be configured to set the maximum block size for BDPCM or RDPCM equal to $1 \ll (\log_2_transform_skip_max_size_minus2 + 2 - \log_2_diff_max_BDPCM_max_TS)$. In another example, video encoder 200 may be configured to signal a value for $\log_2_diff_max_BDPCM_max_TS$. In this example, video encoder 200 and video decoder 300 may be configured to set the maximum block size for BDPCM or RDPCM equal to $1 \ll (\log_2_transform_skip_max_size_minus2 + 2 + \log_2_diff_max_BDPCM_max_TS)$. In another example, video encoder 200 may be configured to signal a sign and a value for $\log_2_diff_max_BDPCM_max_TS$. In this example, video encoder 200 and video decoder 300 may be configured to set the maximum size of BDPCM or RDPCM equal to $1 \ll (\log_2_transform_skip_max_size_minus2 + 2 + sign * \log_2_diff_max_BDPCM_max_TS)$. In another example, video encoder 200 can signal the maximum block size for BDPCM or RDPCM to video decoder 300 at a sequence level, a picture level, or a slice level. For example, the maximum block size can be signaled in an SPS, a PPS, or an SH.

[0087] According to another example technique of this disclosure, the techniques of this disclosure may be extended to any prediction mode that uses transform skip. Furthermore, the techniques of this disclosure may also be used to signal a minimum block size instead of or in addition to a maximum block size.

[0088] FIG. 3 is a block diagram illustrating an example video encoder 200 that may perform the techniques of this disclosure. FIG. 3 is provided for purposes of explanation and should not be considered limiting of the techniques as broadly exemplified and described in this disclosure. For purposes of explanation, this disclosure describes video encoder 200 in the context of video coding standards such as the HEVC video coding standard and the H.266/VVC video coding standard in development. However, the techniques of this disclosure are not limited to these video coding standards and are applicable generally to video encoding and decoding.

[0089] In the example of FIG. 3, video encoder 200 includes video data memory 230, mode selection unit 202, residual generation unit 204, transform processing unit 206, quantization unit 208, inverse quantization unit 210, inverse transform processing unit 212, reconstruction unit 214, filter unit 216, decoded picture buffer (DPB) 218, and entropy encoding unit 220. Any or all of video data memory 230, mode selection unit

202, residual generation unit 204, transform processing unit 206, quantization unit 208, inverse quantization unit 210, inverse transform processing unit 212, reconstruction unit 214, filter unit 216, DPB 218, and entropy encoding unit 220 may be implemented in one or more processors or in processing circuitry. Moreover, video encoder 200 may include additional or alternative processors or processing circuitry to perform these and other functions.

[0090] Video data memory 230 may store video data to be encoded by the components of video encoder 200. Video encoder 200 may receive the video data stored in video data memory 230 from, for example, video source 104 (FIG. 1). DPB 218 may act as a reference picture memory that stores reference video data for use in prediction of subsequent video data by video encoder 200. Video data memory 230 and DPB 218 may be formed by any of a variety of memory devices, such as dynamic random access memory (DRAM), including synchronous DRAM (SDRAM), magnetoresistive RAM (MRAM), resistive RAM (RRAM), or other types of memory devices. Video data memory 230 and DPB 218 may be provided by the same memory device or separate memory devices. In various examples, video data memory 230 may be on-chip with other components of video encoder 200, as illustrated, or off-chip relative to those components.

[0091] In this disclosure, reference to video data memory 230 should not be interpreted as being limited to memory internal to video encoder 200, unless specifically described as such, or memory external to video encoder 200, unless specifically described as such. Rather, reference to video data memory 230 should be understood as reference memory that stores video data that video encoder 200 receives for encoding (e.g., video data for a current block that is to be encoded). Memory 106 of FIG. 1 may also provide temporary storage of outputs from the various units of video encoder 200.

[0092] The various units of FIG. 3 are illustrated to assist with understanding the operations performed by video encoder 200. The units may be implemented as fixed-function circuits, programmable circuits, or a combination thereof. Fixed-function circuits refer to circuits that provide particular functionality, and are preset on the operations that can be performed. Programmable circuits refer to circuits that can be programmed to perform various tasks, and provide flexible functionality in the operations that can be performed. For instance, programmable circuits may execute software or firmware that cause the programmable circuits to operate in the manner defined by instructions of the software or firmware. Fixed-function circuits may

execute software instructions (e.g., to receive parameters or output parameters), but the types of operations that the fixed-function circuits perform are generally immutable. In some examples, the one or more of the units may be distinct circuit blocks (fixed-function or programmable), and in some examples, the one or more units may be integrated circuits.

[0093] Video encoder 200 may include arithmetic logic units (ALUs), elementary function units (EFUs), digital circuits, analog circuits, and/or programmable cores, formed from programmable circuits. In examples where the operations of video encoder 200 are performed using software executed by the programmable circuits, memory 106 (FIG. 1) may store the object code of the software that video encoder 200 receives and executes, or another memory within video encoder 200 (not shown) may store such instructions.

[0094] Video data memory 230 is configured to store received video data. Video encoder 200 may retrieve a picture of the video data from video data memory 230 and provide the video data to residual generation unit 204 and mode selection unit 202. Video data in video data memory 230 may be raw video data that is to be encoded.

[0095] Mode selection unit 202 includes a motion estimation unit 222, motion compensation unit 224, and an intra-prediction unit 226. Mode selection unit 202 may include additional functional units to perform video prediction in accordance with other prediction modes. As examples, mode selection unit 202 may include a palette unit, an intra-block copy unit (which may be part of motion estimation unit 222 and/or motion compensation unit 224), an affine unit, a linear model (LM) unit, or the like.

[0096] Mode selection unit 202 generally coordinates multiple encoding passes to test combinations of encoding parameters and resulting rate-distortion values for such combinations. The encoding parameters may include partitioning of CTUs into CUs, prediction modes for the CUs, transform types for residual data of the CUs, quantization parameters for residual data of the CUs, and so on. Mode selection unit 202 may ultimately select the combination of encoding parameters having rate-distortion values that are better than the other tested combinations.

[0097] Video encoder 200 may partition a picture retrieved from video data memory 230 into a series of CTUs and encapsulate one or more CTUs within a slice. Mode selection unit 202 may partition a CTU of the picture in accordance with a tree structure, such as the QTBT structure or the quad-tree structure of HEVC described above. As described above, video encoder 200 may form one or more CUs by

partitioning a CTU according to the tree structure. Such a CU may also be referred to generally as a “video block” or “block.”

[0098] In general, mode selection unit 202 also controls the components thereof (e.g., motion estimation unit 222, motion compensation unit 224, and intra-prediction unit 226) to generate a prediction block for a current block (e.g., a current CU, or in HEVC, the overlapping portion of a PU and a TU). For inter-prediction of a current block, motion estimation unit 222 may perform a motion search to identify one or more closely matching reference blocks in one or more reference pictures (e.g., one or more previously coded pictures stored in DPB 218). In particular, motion estimation unit 222 may calculate a value representative of how similar a potential reference block is to the current block, e.g., according to sum of absolute difference (SAD), sum of squared differences (SSD), mean absolute difference (MAD), mean squared differences (MSD), or the like. Motion estimation unit 222 may generally perform these calculations using sample-by-sample differences between the current block and the reference block being considered. Motion estimation unit 222 may identify a reference block having a lowest value resulting from these calculations, indicating a reference block that most closely matches the current block.

[0099] Motion estimation unit 222 may form one or more motion vectors (MVs) that defines the positions of the reference blocks in the reference pictures relative to the position of the current block in a current picture. Motion estimation unit 222 may then provide the motion vectors to motion compensation unit 224. For example, for uni-directional inter-prediction, motion estimation unit 222 may provide a single motion vector, whereas for bi-directional inter-prediction, motion estimation unit 222 may provide two motion vectors. Motion compensation unit 224 may then generate a prediction block using the motion vectors. For example, motion compensation unit 224 may retrieve data of the reference block using the motion vector. As another example, if the motion vector has fractional sample precision, motion compensation unit 224 may interpolate values for the prediction block according to one or more interpolation filters. Moreover, for bi-directional inter-prediction, motion compensation unit 224 may retrieve data for two reference blocks identified by respective motion vectors and combine the retrieved data, e.g., through sample-by-sample averaging or weighted averaging.

[0100] As another example, for intra-prediction, or intra-prediction coding, intra-prediction unit 226 may generate the prediction block from samples neighboring the

current block. For example, for directional modes, intra-prediction unit 226 may generally mathematically combine values of neighboring samples and populate these calculated values in the defined direction across the current block to produce the prediction block. As another example, for DC mode, intra-prediction unit 226 may calculate an average of the neighboring samples to the current block and generate the prediction block to include this resulting average for each sample of the prediction block. As another example, intra-prediction unit 226 may, for example, generate a prediction block using BDPCM and RDPCM as described above.

[0101] Mode selection unit 202 provides the prediction block to residual generation unit 204. Residual generation unit 204 receives a raw, unencoded version of the current block from video data memory 230 and the prediction block from mode selection unit 202. Residual generation unit 204 calculates sample-by-sample differences between the current block and the prediction block. The resulting sample-by-sample differences define a residual block for the current block. In some examples, residual generation unit 204 may also determine differences between sample values in the residual block to generate a residual block using residual differential pulse code modulation (RDPCM). In some examples, residual generation unit 204 may be formed using one or more subtractor circuits that perform binary subtraction.

[0102] In examples where mode selection unit 202 partitions CUs into PUs, each PU may be associated with a luma prediction unit and corresponding chroma prediction units. Video encoder 200 and video decoder 300 may support PUs having various sizes. As indicated above, the size of a CU may refer to the size of the luma coding block of the CU and the size of a PU may refer to the size of a luma prediction unit of the PU. Assuming that the size of a particular CU is $2N \times 2N$, video encoder 200 may support PU sizes of $2N \times 2N$ or $N \times N$ for intra prediction, and symmetric PU sizes of $2N \times 2N$, $2N \times N$, $N \times 2N$, $N \times N$, or similar for inter prediction. Video encoder 200 and video decoder 300 may also support asymmetric partitioning for PU sizes of $2N \times nU$, $2N \times nD$, $nL \times 2N$, and $nR \times 2N$ for inter prediction.

[0103] In examples where mode selection unit does not further partition a CU into PUs, each CU may be associated with a luma coding block and corresponding chroma coding blocks. As above, the size of a CU may refer to the size of the luma coding block of the CU. The video encoder 200 and video decoder 300 may support CU sizes of $2N \times 2N$, $2N \times N$, or $N \times 2N$.

[0104] For other video coding techniques such as an intra-block copy mode coding, an affine-mode coding, and linear model (LM) mode coding, as few examples, mode selection unit 202, via respective units associated with the coding techniques, generates a prediction block for the current block being encoded. In some examples, such as palette mode coding, mode selection unit 202 may not generate a prediction block, and instead generate syntax elements that indicate the manner in which to reconstruct the block based on a selected palette. In such modes, mode selection unit 202 may provide these syntax elements to entropy encoding unit 220 to be encoded.

[0105] As described above, residual generation unit 204 receives the video data for the current block and the corresponding prediction block. Residual generation unit 204 then generates a residual block for the current block. To generate the residual block, residual generation unit 204 calculates sample-by-sample differences between the prediction block and the current block.

[0106] Transform processing unit 206 may apply one or more transforms to the residual block to generate a block of transform coefficients (referred to herein as a “transform coefficient block”). Transform processing unit 206 may apply various transforms to a residual block to form the transform coefficient block. For example, transform processing unit 206 may apply a discrete cosine transform (DCT), a directional transform, a Karhunen-Loeve transform (KLT), or a conceptually similar transform to a residual block. In some examples, transform processing unit 206 may perform multiple transforms to a residual block, e.g., a primary transform and a secondary transform, such as a rotational transform. In some examples, transform processing unit 206 does not apply transforms to a residual block. In other words, the residual block is coded using a transform skip mode. For a block of video data coded in the transform skip mode, transform processing unit 206 may be viewed as a pass-through unit that does not alter the residual block. However, this disclosure refers to elements in a transform skip block as “coefficients” instead of residual values after passing through transform processing unit 206.

[0107] Quantization unit 208 may quantize the coefficients in a coefficient block to produce a quantized coefficient block. Quantization unit 208 may quantize coefficients of a coefficient block according to a quantization parameter (QP) value associated with the current block. Video encoder 200 (e.g., via mode selection unit 202) may adjust the degree of quantization applied to the coefficient blocks associated with the current block by adjusting the QP value associated with the CU. Quantization may introduce loss of

information, and thus, quantized coefficients may have lower precision than the original coefficients.

[0108] Inverse quantization unit 210 and inverse transform processing unit 212 may apply inverse quantization and inverse transforms to a quantized coefficient block, respectively, to reconstruct a residual block from the coefficient block. For a block of video data coded in a transform skip mode, inverse transform processing unit 212 may be viewed as a pass-through unit that does not alter the dequantized coefficient block. Reconstruction unit 214 may produce a reconstructed block corresponding to the current block (albeit potentially with some degree of distortion) based on the reconstructed residual block and a prediction block generated by mode selection unit 202. For example, reconstruction unit 214 may add samples of the reconstructed residual block to corresponding samples from the prediction block generated by mode selection unit 202 to produce the reconstructed block.

[0109] Filter unit 216 may perform one or more filter operations on reconstructed blocks. For example, filter unit 216 may perform deblocking operations to reduce blockiness artifacts along edges of CUs. Operations of filter unit 216 may be skipped, in some examples.

[0110] Video encoder 200 stores reconstructed blocks in DPB 218. For instance, in examples where operations of filter unit 216 are not performed, reconstruction unit 214 may store reconstructed blocks to DPB 218. In examples where operations of filter unit 216 are performed, filter unit 216 may store the filtered reconstructed blocks to DPB 218. Motion estimation unit 222 and motion compensation unit 224 may retrieve a reference picture from DPB 218, formed from the reconstructed (and potentially filtered) blocks, to inter-predict blocks of subsequently encoded pictures. In addition, intra-prediction unit 226 may use reconstructed blocks in DPB 218 of a current picture to intra-predict other blocks in the current picture.

[0111] In general, entropy encoding unit 220 may entropy encode syntax elements received from other functional components of video encoder 200. For example, entropy encoding unit 220 may entropy encode quantized coefficient blocks from quantization unit 208. As another example, entropy encoding unit 220 may entropy encode prediction syntax elements (e.g., motion information for inter-prediction or intra-mode information for intra-prediction) from mode selection unit 202. Entropy encoding unit 220 may perform one or more entropy encoding operations on the syntax elements, which are another example of video data, to generate entropy-encoded data. For

example, entropy encoding unit 220 may perform a context-adaptive variable length coding (CAVLC) operation, a CABAC operation, a variable-to-variable (V2V) length coding operation, a syntax-based context-adaptive binary arithmetic coding (SBAC) operation, a Probability Interval Partitioning Entropy (PIPE) coding operation, an Exponential-Golomb encoding operation, or another type of entropy encoding operation on the data. In some examples, entropy encoding unit 220 may operate in bypass mode where syntax elements are not context encoded.

[0112] Video encoder 200 may output a bitstream that includes the entropy encoded syntax elements needed to reconstruct blocks of a slice or picture. In particular, entropy encoding unit 220 may output the bitstream.

[0113] The operations described above are described with respect to a block. Such description should be understood as being operations for a luma coding block and/or chroma coding blocks. As described above, in some examples, the luma coding block and chroma coding blocks are luma and chroma components of a CU. In some examples, the luma coding block and the chroma coding blocks are luma and chroma components of a PU.

[0114] In some examples, operations performed with respect to a luma coding block need not be repeated for the chroma coding blocks. As one example, operations to identify a motion vector (MV) and a reference picture for a luma coding block need not be repeated for identifying a MV and reference picture for the chroma blocks. Rather, the MV for the luma coding block may be scaled to determine the MV for the chroma blocks, and the reference picture may be the same. As another example, the intra-prediction process may be the same for the luma coding block and the chroma coding blocks.

[0115] Video encoder 200 represents an example of a device configured to encode video data including a memory configured to store video data, and one or more processing units implemented in circuitry and configured to determine a maximum block size used for transform skip and determine a maximum size for a BDPCM or RDPCM mode based on the maximum block size used for transform skip. In other examples, video encoder 200 may separately determine a maximum size for a BDPCM or RDPCM mode based on the second syntax element or use a maximum size for a BDPCM or RDPCM mode defined in a CODEC being executed by video encoder 200.

[0116] FIG. 4 is a block diagram illustrating an example video decoder 300 that may perform the techniques of this disclosure. FIG. 4 is provided for purposes of

explanation and is not limiting on the techniques as broadly exemplified and described in this disclosure. For purposes of explanation, this disclosure describes video decoder 300 according to the techniques of JEM, VVC, and HEVC. However, the techniques of this disclosure may be performed by video coding devices that are configured to other video coding standards.

[0117] In the example of FIG. 4, video decoder 300 includes coded picture buffer (CPB) memory 320, entropy decoding unit 302, prediction processing unit 304, inverse quantization unit 306, inverse transform processing unit 308, reconstruction unit 310, filter unit 312, and decoded picture buffer (DPB) 314. Any or all of CPB memory 320, entropy decoding unit 302, prediction processing unit 304, inverse quantization unit 306, inverse transform processing unit 308, reconstruction unit 310, filter unit 312, and DPB 314 may be implemented in one or more processors or in processing circuitry. Moreover, video decoder 300 may include additional or alternative processors or processing circuitry to perform these and other functions.

[0118] Prediction processing unit 304 includes motion compensation unit 316 and intra-prediction unit 318. Prediction processing unit 304 may include addition units to perform prediction in accordance with other prediction modes. As examples, prediction processing unit 304 may include a palette unit, an intra-block copy unit (which may form part of motion compensation unit 316), an affine unit, a linear model (LM) unit, or the like. In other examples, video decoder 300 may include more, fewer, or different functional components.

[0119] CPB memory 320 may store video data, such as an encoded video bitstream, to be decoded by the components of video decoder 300. The video data stored in CPB memory 320 may be obtained, for example, from computer-readable medium 110 (FIG. 1). CPB memory 320 may include a CPB that stores encoded video data (e.g., syntax elements) from an encoded video bitstream. Also, CPB memory 320 may store video data other than syntax elements of a coded picture, such as temporary data representing outputs from the various units of video decoder 300. DPB 314 generally stores decoded pictures, which video decoder 300 may output and/or use as reference video data when decoding subsequent data or pictures of the encoded video bitstream. CPB memory 320 and DPB 314 may be formed by any of a variety of memory devices, such as DRAM, including SDRAM, MRAM, RRAM, or other types of memory devices. CPB memory 320 and DPB 314 may be provided by the same memory device or separate memory

devices. In various examples, CPB memory 320 may be on-chip with other components of video decoder 300, or off-chip relative to those components.

[0120] Additionally or alternatively, in some examples, video decoder 300 may retrieve coded video data from memory 120 (FIG. 1. Memory 120 may additionally or alternatively store instructions to be executed by video decoder 300, when some or all of the functionality of video decoder 300 is implemented in software to be executed by processing circuitry of video decoder 300.

[0121] The various units shown in FIG. 4 are illustrated to assist with understanding the operations performed by video decoder 300. The units may be implemented as fixed-function circuits, programmable circuits, or a combination thereof. Similar to FIG. 3, fixed-function circuits refer to circuits that provide particular functionality, and are preset on the operations that can be performed. Programmable circuits refer to circuits that can be programmed to perform various tasks, and provide flexible functionality in the operations that can be performed. For instance, programmable circuits may execute software or firmware that cause the programmable circuits to operate in the manner defined by instructions of the software or firmware. Fixed-function circuits may execute software instructions (e.g., to receive parameters or output parameters), but the types of operations that the fixed-function circuits perform are generally immutable. In some examples, the one or more of the units may be distinct circuit blocks (fixed-function or programmable), and in some examples, the one or more units may be integrated circuits.

[0122] Video decoder 300 may include ALUs, EFUs, digital circuits, analog circuits, and/or programmable cores formed from programmable circuits. In examples where the operations of video decoder 300 are performed by software executing on the programmable circuits, on-chip or off-chip memory may store instructions (e.g., object code) of the software that video decoder 300 receives and executes.

[0123] Entropy decoding unit 302 may receive encoded video data from the CPB and may entropy decode the encoded video data to reproduce syntax elements. Prediction processing unit 304, inverse quantization unit 306, inverse transform processing unit 308, reconstruction unit 310, and filter unit 312 may generate decoded video data based on the syntax elements extracted from the bitstream.

[0124] In general, video decoder 300 reconstructs a picture on a block-by-block basis. Video decoder 300 may perform a reconstruction operation on each block individually

(where the block currently being reconstructed, i.e., decoded, may be referred to as a “current block”).

[0125] Entropy decoding unit 302 may entropy decode syntax elements defining quantized coefficients of a quantized coefficient block, as well as transform information, such as a quantization parameter (QP) and/or transform mode indication(s). Inverse quantization unit 306 may use the QP associated with the quantized coefficient block to determine a degree of quantization and, likewise, a degree of inverse quantization for inverse quantization unit 306 to apply. Inverse quantization unit 306 may, for example, perform a bitwise left-shift operation to inverse quantize the quantized coefficients. Inverse quantization unit 306 may thereby form a coefficient block including coefficients.

[0126] After inverse quantization unit 306 forms the coefficient block, inverse transform processing unit 308 may apply one or more inverse transforms to the coefficient block to generate a residual block associated with the current block. For example, inverse transform processing unit 308 may apply an inverse DCT, an inverse integer transform, an inverse Karhunen-Loeve transform (KLT), an inverse rotational transform, an inverse directional transform, or another inverse transform to the coefficient block. For blocks coded in a transform skip mode, inverse transform processing unit 308 may be viewed as a pass-through unit that does not alter the dequantized coefficient block.

[0127] Furthermore, prediction processing unit 304 generates a prediction block according to prediction information syntax elements that were entropy decoded by entropy decoding unit 302. For example, if the prediction information syntax elements indicate that the current block is inter-predicted, motion compensation unit 316 may generate the prediction block. In this case, the prediction information syntax elements may indicate a reference picture in DPB 314 from which to retrieve a reference block, as well as a motion vector identifying a location of the reference block in the reference picture relative to the location of the current block in the current picture. Motion compensation unit 316 may generally perform the inter-prediction process in a manner that is substantially similar to that described with respect to motion compensation unit 224 (FIG. 3).

[0128] As another example, if the prediction information syntax elements indicate that the current block is intra-predicted, intra-prediction unit 318 may generate the prediction block according to an intra-prediction mode indicated by the prediction

information syntax elements. Intra-prediction unit 318 may, for example, generate a prediction block using BDPCM and RDPCM as described above. Again, intra-prediction unit 318 may generally perform the intra-prediction process in a manner that is substantially similar to that described with respect to intra-prediction unit 226 (FIG. 3). Intra-prediction unit 318 may retrieve data of neighboring samples to the current block from DPB 314.

[0129] Reconstruction unit 310 may reconstruct the current block using the prediction block and the residual block. For example, reconstruction unit 310 may add samples of the residual block to corresponding samples of the prediction block to reconstruct the current block.

[0130] Filter unit 312 may perform one or more filter operations on reconstructed blocks. For example, filter unit 312 may perform deblocking operations to reduce blockiness artifacts along edges of the reconstructed blocks. Operations of filter unit 312 are not necessarily performed in all examples.

[0131] Video decoder 300 may store the reconstructed blocks in DPB 314. As discussed above, DPB 314 may provide reference information, such as samples of a current picture for intra-prediction and previously decoded pictures for subsequent motion compensation, to prediction processing unit 304. Moreover, video decoder 300 may output decoded pictures from DPB 314 for subsequent presentation on a display device, such as display device 118 of FIG. 1.

[0132] In this manner, video decoder 300 represents an example of a video decoding device that includes a memory configured to store video data and includes one or more processing units implemented in circuitry and configured to receive a syntax element indicating a maximum block size used for transform skip and determine a maximum size for a BDPCM or RDPCM mode based on the syntax element. In other examples, video decoder 300 may receive a second syntax element separate from the first syntax element and determine a maximum size for a BDPCM or RDPCM mode based on the second syntax element. In other examples, the maximum size for a BDPCM or RDPCM mode may be defined in a CODEC being executed by video decoder 300.

[0133] In this manner, video decoder 300 represents an example of a video decoding device that includes a memory configured to store video data and includes one or more processing units implemented in circuitry and configured to receive a syntax element indicating a maximum block size used for transform skip and process the syntax element in accordance with any technique described in this disclosure. Video decoder

300 may, for example, determine a maximum size for a BDPCM mode based on the syntax element. To determine the maximum size for the BDPCM mode based on the syntax element, video decoder 300 may, for instance, determine the maximum size for the BDPCM mode to be equal to the maximum block size used for transform skip. As part of determining the maximum size for the BDPCM mode based on the syntax element, video decoder 300 may receive a difference value and determine the maximum size for the BDPCM mode based on the maximum block size used for transform skip and the difference value. Video decoder 300 may, for example, receive the syntax element as part of an SPS, PPS, or slice header.

[0134] Video decoder 300 may additionally or alternatively be configured to determine a maximum size for an RDPCM mode based on the syntax element. To determine the maximum size for the RDPCM mode based on the syntax element, video decoder 300 may determine the maximum size for the RDPCM mode to be equal to the maximum block size used for transform skip. As part of determining the maximum size for the RDPCM mode based on the syntax element, video decoder 300 may, for example, receive a difference value and determine the maximum size for the RDPCM mode based on the maximum block size used for transform skip and the difference value.

[0135] In some instances, video decoder 300 may be configured to receive a second syntax element separate from the first syntax element and determine a maximum size for a BDPCM mode based on the second syntax element. In some instances, video decoder 300 may be configured to receive a second syntax element separate from the first syntax element and determine a maximum size for a RDPCM mode based on the second syntax element. Video decoder 300 may also be configured to set a maximum size for a BDPCM mode to a value defined in a CODEC and/or set a maximum size for a RDPCM mode to a value defined in a CODEC.

[0136] Video decoder 300 may also be configured to determine the maximum block size used for transform skip and, based on the maximum block size used for transform skip, determine whether a RDPCM mode flag is present in a bitstream that includes an encoded representation of the video data. Video decoder 300 may also be configured to determine the maximum block size used for transform skip and, based on the maximum block size used for transform skip, determine whether a BDPCM mode flag is present in a bitstream that includes an encoded representation of the video data. In some example, the BDPCM mode flag may specify a direction for the BDPCM mode. In other

examples, the BDPCM mode flag may additionally or alternatively specify whether BDPCM mode is used for a specific block.

[0137] FIG. 5 is a flowchart illustrating an example method for encoding a current block. The current block may comprise a current CU. Although described with respect to video encoder 200 (FIGS. 1 and 3), it should be understood that other devices may be configured to perform a method similar to that of FIG. 5.

[0138] In this example, video encoder 200 initially predicts the current block (350). For example, video encoder 200 may form a prediction block for the current block using BDPCM or RDPCM as discussed above. Video encoder 200 may then calculate a residual block for the current block (352). To calculate the residual block, video encoder 200 may calculate a difference between the original, unencoded block and the prediction block for the current block. Video encoder 200 may then transform and/or quantize coefficients of the residual block (354). Next, video encoder 200 may scan the quantized coefficients of the residual block (356). During the scan, or following the scan, video encoder 200 may entropy encode the coefficients (358). For example, video encoder 200 may encode the coefficients using CAVLC or CABAC. Video encoder 200 may then output the entropy encoded data of the block (360).

[0139] FIG. 6 is a flowchart illustrating an example method for decoding a current block of video data. The current block may comprise a current CU. Although described with respect to video decoder 300 (FIGS. 1 and 4), it should be understood that other devices may be configured to perform a method similar to that of FIG. 6.

[0140] Video decoder 300 may receive entropy encoded data for the current block, such as entropy encoded prediction information and entropy encoded data for coefficients of a residual block corresponding to the current block (370). Video decoder 300 may entropy decode the entropy encoded data to determine prediction information for the current block and to reproduce coefficients of the residual block (372). Video decoder 300 may predict the current block (374), e.g., using an intra- or inter-prediction mode as indicated by the prediction information for the current block, to calculate a prediction block for the current block. Video decoder 300 may, for example, predict the block using BDPCM or RDPCM as discussed above. Video decoder 300 may then inverse scan the reproduced coefficients (376), to create a block of quantized coefficients. Video decoder 300 may then inverse quantize and/or inverse transform the coefficients to produce a residual block (378). Video decoder 300 may ultimately decode the current block by combining the prediction block and the residual block (380).

[0141] FIG. 7 is a flowchart illustrating an example method for encoding a current block. The current block may comprise a current CU. Although described with respect to video encoder 200 (FIGS. 1 and 3), it should be understood that other devices may be configured to perform a method similar to that of FIG. 7.

[0142] Video encoder 200 determines a maximum block size used for a transform skip mode (402). Video encoder 200 determines a maximum block size for a BDPCM mode based on the maximum block size used for the transform skip mode (404). To determine the maximum block size for the BDPCM mode, video encoder 200 may, for example, determine the maximum block size for the BDPCM mode to be equal to the maximum block size used for the transform skip mode. The BDPCM mode may, for example, be an RDPCM mode or other type of BDPCM mode. The value for the maximum block size for the BDPCM mode may, for example, be one or both of a maximum block width for a block coded in the BDPCM mode or a maximum block height for a block coded in the BDPCM mode.

[0143] Video encoder 200 encodes a block of video data based on the determined maximum block size for the BDPCM mode (406). As part of encoding the block of video data, video encoder 200 may generate a syntax element (e.g., $\log_2_transform_skip_max_size_minus2$), for inclusion in a sequence parameter set syntax structure of the video data, that indicates the maximum block size used for the transform skip mode. The syntax element may for example have a value equal to X , with X being an integer value in a range of 0 to 3, inclusive. The maximum block size for the BDPCM mode may be equal to $1 \ll (X + 2)$, with $\ll$ representing a left shift operation.

[0144] As part of encoding the block of video data, video encoder 200 may also determine whether to include a BDPCM mode flag, for the block, in a bitstream of the encoded video data based on the maximum block size for the transform skip mode. Video encoder 200 may, for example, include the BDPCM mode flag in the bitstream of encoded video data in response to a size for the block of video data being less than or equal to the maximum block size for the BDPCM mode. Video encoder 200 may also output, for storage or for transmission, the bitstream of encoded video data.

[0145] FIG. 8 is a flowchart illustrating an example method for decoding a current block of video data. The current block may comprise a current CU. Although described with respect to video decoder 300 (FIGS. 1 and 4), it should be understood that other devices may be configured to perform a method similar to that of FIG. 8.

Video decoder 300 receives a syntax element (e.g., `log2_transform_skip_max_size_minus2`) indicating a maximum block size for a transform skip mode (410). The syntax element may, for example, be part of an SPS.

[0146] Video decoder 300 determines a maximum block size for a BDPCM mode based on the syntax element (412). The BDPCM mode may, for example, be an RDPCM mode or other type of BDPCM mode. The value for the maximum block size for the BDPCM mode may, for example, be one or both of a maximum block width for a block coded in the BDPCM mode or a maximum block height for a block coded in the BDPCM mode.

[0147] To determine the maximum block size for the BDPCM mode based on the syntax element, video decoder 300 may, for example, determine the maximum block size for the BDPCM mode to be equal to the maximum block size used for the transform skip mode. To determine the maximum block size for the BDPCM mode based on the syntax element, video decoder 300 may, for example, determine the maximum block size for the BDPCM mode based on the syntax element by setting a value for the maximum block size for the BDPCM mode equal to $1 \ll (X + 2)$, with $\ll$ representing a left shift operation and X representing an integer value in a range of 0 to 3 inclusive.

[0148] Video decoder 300 decodes a block of video data based on the determined maximum block size for the BDPCM mode (414). As part of decoding the block of video data, video decoder 300 may, for example, determine the maximum block size for the transform skip mode based on the syntax element and, based on the maximum block size for the transform skip mode, determine whether a BDPCM mode flag is present in a bitstream that includes an encoded representation of the video data. For instance, video decoder 300 may determine the BDPCM mode flag is present for the block of video data in response to a size for the block of video data being less than or equal to the maximum block size for the BDPCM mode.

[0149] It is to be recognized that depending on the example, certain acts or events of any of the techniques described herein can be performed in a different sequence, may be added, merged, or left out altogether (e.g., not all described acts or events are necessary for the practice of the techniques). Moreover, in certain examples, acts or events may be performed concurrently, e.g., through multi-threaded processing, interrupt processing, or multiple processors, rather than sequentially.

[0150] In one or more examples, the functions described may be implemented in hardware, software, firmware, or any combination thereof. If implemented in software, the functions may be stored on or transmitted over as one or more instructions or code on a computer-readable medium and executed by a hardware-based processing unit. Computer-readable media may include computer-readable storage media, which corresponds to a tangible medium such as data storage media, or communication media including any medium that facilitates transfer of a computer program from one place to another, e.g., according to a communication protocol. In this manner, computer-readable media generally may correspond to (1) tangible computer-readable storage media which is non-transitory or (2) a communication medium such as a signal or carrier wave. Data storage media may be any available media that can be accessed by one or more computers or one or more processors to retrieve instructions, code and/or data structures for implementation of the techniques described in this disclosure. A computer program product may include a computer-readable medium.

[0151] By way of example, and not limitation, such computer-readable storage media can comprise RAM, ROM, EEPROM, CD-ROM or other optical disk storage, magnetic disk storage, or other magnetic storage devices, flash memory, or any other medium that can be used to store desired program code in the form of instructions or data structures and that can be accessed by a computer. Also, any connection is properly termed a computer-readable medium. For example, if instructions are transmitted from a website, server, or other remote source using a coaxial cable, fiber optic cable, twisted pair, digital subscriber line (DSL), or wireless technologies such as infrared, radio, and microwave, then the coaxial cable, fiber optic cable, twisted pair, DSL, or wireless technologies such as infrared, radio, and microwave are included in the definition of medium. It should be understood, however, that computer-readable storage media and data storage media do not include connections, carrier waves, signals, or other transitory media, but are instead directed to non-transitory, tangible storage media. Disk and disc, as used herein, includes compact disc (CD), laser disc, optical disc, digital versatile disc (DVD), floppy disk and Blu-ray disc, where disks usually reproduce data magnetically, while discs reproduce data optically with lasers. Combinations of the above should also be included within the scope of computer-readable media.

[0152] Instructions may be executed by one or more processors, such as one or more digital signal processors (DSPs), general purpose microprocessors, application specific integrated circuits (ASICs), field programmable gate arrays (FPGAs), or other

equivalent integrated or discrete logic circuitry. Accordingly, the terms “processor” and “processing circuitry,” as used herein may refer to any of the foregoing structures or any other structure suitable for implementation of the techniques described herein. In addition, in some aspects, the functionality described herein may be provided within dedicated hardware and/or software modules configured for encoding and decoding, or incorporated in a combined codec. Also, the techniques could be fully implemented in one or more circuits or logic elements.

[0153] The techniques of this disclosure may be implemented in a wide variety of devices or apparatuses, including a wireless handset, an integrated circuit (IC) or a set of ICs (e.g., a chip set). Various components, modules, or units are described in this disclosure to emphasize functional aspects of devices configured to perform the disclosed techniques, but do not necessarily require realization by different hardware units. Rather, as described above, various units may be combined in a codec hardware unit or provided by a collection of interoperative hardware units, including one or more processors as described above, in conjunction with suitable software and/or firmware.

WHAT IS CLAIMED IS:

1. A method of decoding video data, the method comprising:
receiving a syntax element indicating a maximum block size for a transform skip mode;
determining a maximum block size for a block-based delta pulse code modulation (BDPCM) mode based on the syntax element; and
decoding a block of video data based on the determined maximum block size for the BDPCM mode.
2. The method of claim 1, wherein determining the maximum block size for the BDPCM mode based on the syntax element comprises determining the maximum block size for the BDPCM mode to be equal to the maximum block size used for the transform skip mode.
3. The method of claim 1, wherein receiving the syntax element comprises receiving the syntax element as part of a sequence parameter set syntax structure.
4. The method of claim 1, wherein the syntax element has a value equal to X, wherein X is an integer value in a range of 0 to 3 inclusive, and wherein the maximum block size for the BDPCM mode is equal to $1 \ll (X + 2)$, wherein $\ll$ represents a left shift operation.
5. The method of claim 4, wherein the maximum block size for the BDPCM mode comprises a maximum block width for the BDPCM mode.
6. The method of claim 4, wherein the maximum block size for the BDPCM mode comprises a maximum block height for the BDPCM mode.

7. The method of claim 1, further comprising:
 - determining the maximum block size for the transform skip mode based on the syntax element; and
 - based on the maximum block size for the transform skip mode, determining whether a BDPCM mode flag is present in a bitstream that includes an encoded representation of the video data.
8. The method of claim 7, wherein determining whether the BDPCM mode flag is present in the bitstream that includes the encoded representation of the video data comprises:
 - determining the BDPCM mode flag is present for the block of video data in response to a size for the block of video data being less than or equal to the maximum block size for the BDPCM mode.
9. The method of claim 1, wherein the BDPCM mode comprises a residual domain BDPCM (RDPCM) mode.
10. A method of encoding video data, the method comprising:
 - determining a maximum block size used for a transform skip mode;
 - determining a maximum block size for a block-based delta pulse code modulation (BDPCM) mode based on the maximum block size used for the transform skip mode; and
 - encoding a block of video data based on the determined maximum block size for the BDPCM mode.
11. The method of claim 10, wherein determining the maximum block size for the BDPCM mode comprises determining the maximum block size for the BDPCM mode to be equal to the maximum block size used for the transform skip mode.
12. The method of claim 10, further comprising:
 - generating, for inclusion in a sequence parameter set syntax structure of the video data, a syntax element indicating the maximum block size used for the transform skip mode.

13. The method of claim 12, wherein the syntax element has a value equal to X , wherein X is an integer value in a range of 0 to 3 inclusive, and wherein the maximum block size for the BDPCM mode is equal to $1 \ll (X + 2)$, wherein $\ll$ represents a left shift operation.
14. The method of claim 13, wherein the maximum block size for the BDPCM mode comprises a maximum block width for the BDPCM mode.
15. The method of claim 13, wherein the maximum block size for the BDPCM mode comprises a maximum block height for the BDPCM mode.
16. The method of claim 10, further comprising:
based on the maximum block size for the transform skip mode, determining whether to include a BDPCM mode flag in a bitstream of the encoded video data.
17. The method of claim 16, wherein determining whether to include the BDPCM mode flag in the bitstream of the encoded video data comprises:
including the BDPCM mode flag in the bitstream of encoded video data in response to a size for the block of video data being less than or equal to the maximum block size for the BDPCM mode.
18. The method of claim 10, wherein the BDPCM mode comprises a residual domain BDPCM (RDPCM) mode.
19. A device for decoding video data, the device comprising:
a memory configured to store video data; and
one or more processors configured to:
receive a syntax element indicating a maximum block size for a transform skip mode;
determine a maximum block size for a block-based delta pulse code modulation (BDPCM) mode based on the syntax element; and
decode a block of video data based on the determined maximum block size for the BDPCM mode.

20. The device of claim 19, wherein to determine the maximum block size for the BDPCM mode based on the syntax element, the one or more processors are further configured to determine the maximum block size for the BDPCM mode to be equal to the maximum block size used for the transform skip mode.

21. The device of claim 19, wherein to receive the syntax element, the one or more processors are further configured to receive the syntax element as part of a sequence parameter set syntax structure.

22. The device of claim 19, wherein the syntax element has a value equal to X , wherein X is an integer value in a range of 0 to 3 inclusive, and wherein the maximum block size for the BDPCM mode is equal to $1 \ll (X + 2)$, wherein $\ll$ represents a left shift operation.

23. The device of claim 22, wherein the maximum block size for the BDPCM mode comprises a maximum block width for the BDPCM mode.

24. The device of claim 22, wherein the maximum block size for the BDPCM mode comprises a maximum block height for the BDPCM mode.

25. The device of claim 19, wherein the one or more processors are further configured to:

determine the maximum block size for the transform skip mode based on the syntax element; and

based on the maximum block size for the transform skip mode, determine whether a BDPCM mode flag is present in a bitstream that includes an encoded representation of the video data.

26. The device of claim 25, wherein to determine whether the BDPCM mode flag is present in the bitstream that includes the encoded representation of the video data, the one or more processors are further configured to:

determine the BDPCM mode flag is present for the block of video data in response to a size for the block of video data being less than or equal to the maximum block size for the BDPCM mode.

27. The device of claim 19, wherein the BDPCM mode comprises a residual domain BDPCM (RDPCM) mode.

28. The device of claim 19, wherein the device comprises a wireless communication device, further comprising at least one of a receiver configured to receive an encoded representation of the video data or a display configured to display the decoded block of video data.

29. The device of claim 28, wherein the wireless communication device comprises a telephone handset and wherein the receiver is configured to demodulate, according to a wireless communication standard, a signal comprising the encoded representation of the video data.

30. A device for encoding video data, the device comprising:
a memory configured to store video data; and
one or more processors configured to:
 determine a maximum block size used for a transform skip mode;
 determine a maximum block size for a block-based delta pulse code modulation (BDPCM) mode based on the maximum block size used for the transform skip mode;
and
 encode a block of video data based on the determined maximum block size for the BDPCM mode.

31. The device of claim 30, wherein to determine the maximum block size for the BDPCM mode, the one or more processors are further configured to determine the maximum block size for the BDPCM mode to be equal to the maximum block size used for the transform skip mode.

32. The device of claim 30, wherein the one or more processors are further configured to:
- generate, for inclusion in a sequence parameter set syntax structure of the video data, a syntax element indicating the maximum block size used for the transform skip mode.
33. The device of claim 32, wherein the syntax element has a value equal to X , wherein X is an integer value in a range of 0 to 3 inclusive, and wherein the maximum block size for the BDPCM mode is equal to $1 \ll (X + 2)$, wherein $\ll$ represents a left shift operation.
34. The device of claim 33, wherein the maximum block size for the BDPCM mode comprises a maximum block width for the BDPCM mode.
35. The device of claim 33, wherein the maximum block size for the BDPCM mode comprises a maximum block height for the BDPCM mode.
36. The device of claim 30, wherein the one or more processors are further configured to:
- based on the maximum block size for the transform skip mode, determine whether to include a BDPCM mode flag in a bitstream of the encoded video data.
37. The device of claim 36, wherein to determine whether to include the BDPCM mode flag in the bitstream of the encoded video data, the one or more processors are further configured to:
- include the BDPCM mode flag in the bitstream of encoded video data in response to a size for the block of video data being less than or equal to the maximum block size for the BDPCM mode.
38. The device of claim 30, wherein the BDPCM mode comprises a residual domain BDPCM (RDPCM) mode.
39. The device of claim 30, further comprising:
- a camera configured to capture the video data.

40. A computer-readable storage medium storing instructions that when executed by one or more processors cause the one or more processor to:

receive a syntax element indicating a maximum block size for a transform skip mode;

determine a maximum block size for a block-based delta pulse code modulation (BDPCM) mode based on the syntax element; and

decode a block of video data based on the determined maximum block size for the BDPCM mode.

41. An apparatus for decoding video data, the apparatus comprising:

means for receiving a syntax element indicating a maximum block size for a transform skip mode;

means for determining a maximum block size for a block-based delta pulse code modulation (BDPCM) mode based on the syntax element; and

means for decoding a block of video data based on the determined maximum block size for the BDPCM mode.
