

Description

The present invention relates to an apparatus for holding a slider during the threading of a slide fastener chain through the slider in the manufacture of a slide fastener.

Most of slide fastener sliders include a slider body and a pull tab pivotally connected to the slider body and having an aperture. Various apparatus are known which automatically hold such a slider upside down for threading therethrough of a slide fastener chain in the manufacture of a slide fastener.

A prior art apparatus as disclosed in U.S. Pat. No. 3,902,235, issued September 2, 1975 includes a vertically movable holder body having at its upper end a slider seat with an upwardly opening slit and a spring-biased pivotable lever having a locking projection. To hold a slider, the holder body is moved upwardly toward the slider until the slider's pull tab is longitudinally received in the slit and then the slider body is supported on the slider seat, in response to which the lever is actuated to turn so that the locking projection projects into the slit for engagement with the edge of the aperture in the pull tab.

Another prior art apparatus as disclosed in U.S. Pat. No. 4,437,233, issued March 20, 1984 includes a holder body having at its upper end a slider seat and defining adjacent to the slider seat an upwardly opening space that is also opening toward a slider chute. A slider is fed from the chute horizontally to the apparatus until the slider body is supported on the slider seat, during which time the pull tab hanging from the slider body is introduced into the space and is then engaged by a locking projection of a spring-biased pivotable lever.

However, these prior art apparatus have the following disadvantages due to the fact that the pull tab is subject to objectionable vibration during operation: With the first-mentioned apparatus, the slider seat frequently fails to receive the pull tab in the slit, so that the slider can inevitably fall off the seat as the holder body is moved upwardly. With the second-mentioned apparatus, the locking projection of the lever tends to inadequately engage the edge of the aperture in the pull tab, and hence firm holding of the slider is difficult to achieve. As a result, the slider can be easily detached from the holder body during the threading of a slide fastener chain through the slider.

The present invention seeks to provide an apparatus which is simple in construction and can automatically hold a slider in position easily with adequate firmness.

According to a first aspect of the present invention, there is provided an apparatus for holding a slider in position during the threading of a slide fastener chain through the slider, the slider including a pull tab pivotally connected to a slider body and having an aperture, the slider being supplied toward said apparatus, said apparatus comprising: a holder body defining a space opening upwardly and rearwardly for receiving the pull tab as the slider is supplied to the apparatus; a slider support disposed across said space and having at an upper end a first seat for supporting thereon one half portion of

the slider body and also having a bore below said first seat; a supporting arm pivotally disposed in said space rearwardly of the slider support and having at one end a second seat for supporting thereon the other half portion of the slider body; a locking lever pivotally disposed in said space forwardly of the slider support and having a locking projection, said lever being normally urged by spring means in a direction in which said locking projection projects through said bore of the slider support; said supporting arm being angularly movable between an inclined position in which said second seat is positioned remotely from said first seat and the other end of the supporting arm presses said locking lever against the bias of the spring means such that said locking projection is retracted into the bore, and an upright position in which said second seat is positioned adjacent to and in horizontal alignment with said first seat for cooperating with the latter in supporting the slider body with the pull tab held between said slider support and supporting arm; and as said supporting arm is angularly moved from the inclined position to the upright position, said locking lever being allowed to turn under the bias of said spring means so that said locking projection projects into engagement with an edge of the aperture in the pull tab.

According to a second aspect of the present invention, there is provided an apparatus for holding a slider in position during the threading of a slide fastener chain through the slider, the slider including a pull tab pivotally connected to a slider body and having an aperture, the slider being supplied upside down toward said apparatus, said apparatus comprising: a holder body defining a space for receiving the pull tab as the slider is supplied to the apparatus; a pair of interconnected slider supports each having at its upper end a first seat for supporting thereon one half portion of the slider body and also having a bore below said first seat; a pair of horizontally oppositely directed supporting arms that is pivotally disposed in said space outwardly of the pair of the slider supports, each of said arms having at one end a second seat for supporting thereon the other half portion of the slider body; a pair of horizontally oppositely directed locking lever that is pivotally disposed in said space inwardly of the pair of the slider supports, each of said lever having a locking projection and being normally urged by spring means in a direction in which said locking projection projects through said bore of the corresponding slider support; each of said supporting arms being angularly movable between an inclined position in which said second seat is positioned remotely from the first seat of the corresponding slider support and the other end of the supporting arm presses the corresponding locking lever against the bias of the spring means so that the locking projection is retracted into said bore, and an upright position in which said second seat is positioned adjacent to and in horizontal alignment with said first seat of the corresponding slider support for cooperating with the latter in supporting the slider body with the pull tab held between said slider support and supporting arm; and as the supporting

arm is angularly moved from the inclined position to the upright position, the corresponding locking lever being allowed to turn under the bias of the spring means so that said locking projection projects into engagement with an edge of the aperture in the pull tab.

Many other objects, advantages and additional features of the present invention will become manifest to those versed in the art upon making reference to the detailed description and the accompanying sheets of drawings in which preferred structural embodiments incorporating the principles of the present invention are shown by way of illustrative example.

Figure 1 is a perspective view, with parts broken away, of an apparatus according to the present invention;

Figures 2 and 3 are side elevational views, with parts in cross section, of the apparatus, illustrating the manner in which a slider is held on the apparatus;

Figure 4 is a plan view of the apparatus, showing the manner in which a slide fastener chain is threaded through the slider held on the apparatus;

Figure 5 is a side elevational view, with parts in cross section, of a modified apparatus according to the invention; and

Figure 6 is a plan view of a pair of stringers of a slide fastener chain threaded through two sliders by the modified apparatus shown in Figure 5.

Figure 1 shows an apparatus 30 for holding a slider S in position during the threading of a slide fastener chain F (Figures 3, 4 and 6) through the slider S. The slider S includes a slider body 20 having on its upper wing a lug 20a, and a pull tab 21 pivotally connected to the lug 20a. The pull tab 21 has an aperture 21a. The slider S is supplied upside down from a slider chute C to the apparatus 30 along a horizontal feed path, with the pull tab 21 hanging from the lug 20a.

The apparatus 30 generally comprises a holder body 1, a supporting arm 6, and a locking lever 15.

The holder body 1 includes a pair of confronting vertical walls 1a, 1a spaced transversely of the slider feed path so as to define a space 2 opening upwardly and rearwardly (toward the chute C) for receiving the pull tab 21 as the slider S is supplied to the apparatus 30. The holder body 1 has a slider support 5 secured at opposite sides to upper inner surfaces of the vertical walls 1a, 1a and extending across the space 2, the slider support 5 having an upper portion projecting upwardly beyond the walls 1a, 1a.

At the upper end of the slider support 5, a first seat 4 is provided which includes a pair of side ledges 4a, 4a (only one shown in Figure 1) spaced from each other transversely of the slider feed path, and a recess 4b between the ledges 4a, 4a. The slider support 5 also has a vertical rear surface 5a engageable with one (front) surface of the slider pull tab 21, and an elongated vertical bore 5b below the recess 4b for a purpose hereinafter described.

The supporting arm 6 is disposed in the space 2 rearwardly of the slider support 5 and is pivotally

connected at one end to the vertical walls 1a, 1a by a first pin 7 located below the slider support 5. The arm 6 is also connected to an actuator bar 8 by a second pin 9 slightly spaced from the first pin 7 toward the other end of the arm 6. The actuator bar 8 is disposed between the vertical walls 1a, 1a and is operatively connected to a piston rod 10a of an air cylinder 10 for longitudinal movement along the walls 1a, 1a. The arm 6 is thus angularly movable about the first pin 7 between an inclined position of Figures 1 and 2 and an upright position of Figure 3. The one end of the arm 6 has a cam surface 6a.

At the other end of the supporting arm 6, a second seat 12 is provided which includes a substantially U-shaped (as viewed from the right in Figure 1) ledge 12a and a recess 12b defined by the ledge 12a. The arm 6 also has a front (upper in Figure 1) surface 6b and a transverse slot 6c between the front surface 6b and the ledge 12a.

The locking lever 15 is disposed in the space 2 forwardly of the slider support 5 and is pivotally connected at an enlarged central portion to the vertical walls 1a, 1a by a third pin 16 located below the first pin 7. The cam surface 6a of the supporting arm 6 is slidably engageable with a rear surface of the lever 15 above the third pin 16. At the upper end of the lever 15, there is defined a rearwardly directed locking projection 17. A compression spring 18 acts between the lower end of the lever 15 and a central post 1b of the holder body 1 to normally urge the lever 15 clockwise (Figures 2 and 3) or in a direction in which the projection 17 projects through the bore 5b of the slider support 5 into the space 2.

The operation of the apparatus 30 will now be described with reference to Figures 2 through 4.

The slider S is fed along the feed path to the apparatus 30 until one (front) half portion of the slider body 20 is supported on the first seat 4 with one half portion of the lug 20a received in the recess 4b, as shown in Figure 2, during which time the pull tab 21 hanging from the slider body 20 is introduced through the space 2 to abut against the vertical rear surface 5a of the slider support 5 with the aperture 21a communicating with the bore 5b. At that time, the slider supporting arm 6 is in the inclined position in which the second seat 12 is positioned remotely from the first seat 4 of the slider support 5, and the cam surface 6a presses the locking lever 15 against the bias of the spring 18 so that the projection 17 is retracted into the bore 5b. Then, the piston rod 10a of the air cylinder 10 is extended to move the actuating bar 8 upwardly, thereby causing the arm 6 to angularly move about the first pin 7 toward the upright position (Figure 3) in which the second seat 12 is positioned adjacent to and in horizontal alignment with the first seat 4. As a result, the other half portion of the slider body 20 is supported on the second seat 12 with the other half portion of the lug 20a received in the recess 12c. The slider body 20 is supported on the first and second seats 4, 12, with the pull tab 21 held against oscillations between the rear surface 5a of the slider support 5 and the front surface 6a of the supporting arm 6. As the supporting arm 6 is angularly moved from the inclined position to the upright position, the lever 15 is

allowed to turn clockwise under the bias of the spring 18 so that the locking projection 17 projects through the bore 5b into engagement with the edge of the aperture 21a of the slider pull tab 21, thus causing the tip of the locking projection 17 to be received in the transverse slot 6c of the supporting arm 6. The slider S is thus firmly held on the apparatus 30 in position for threading therethrough of the slide fastener chain F, as shown in Figure 4.

Figure 5 shows a modified apparatus 40 which is different from the apparatus 30 of Figures 1 through 3 in that for holding two sliders S, S at a time, it includes a pair of interconnected slider supports 5, 5 each having at its upper end a first seat 4. The apparatus 40 also has a pair of horizontally oppositely directed supporting arms 6, 6 disposed outwardly of the pair of the slider supports 5, 5, each of said arms 6, 6 having at one end a second seat 12. Further, a pair of horizontally oppositely directed locking levers 15, 15 is disposed inwardly of the pair of the slider supports 5, 5. Thus the individual double parts are disposed in a mirror-image relationship.

Figure 6 shows a pair of stringers of a slide fastener chain F, to which two sliders S, S are mounted by the apparatus 40 to provide a bidirectionally openable slide fastener that is suitably used such as in a suitcase.

With the apparatus described above, because the slider pull tab is locked without fail during the angular movement of the supporting arm from the inclined position to the upright position, a slider can be held in position easily with adequate firmness so as not to be detached from the apparatus during threading therethrough of a slide fastener chain.

Claims

1. An apparatus for holding a slider in position during the threading of a slide fastener chain (F) through the slider (S), the slider (S) including a pull tab (21) pivotally connected to a slider body (20) and having an aperture (21a), the slider (S) being supplied toward said apparatus, said apparatus comprising: a holder body (30) defining a space (2) opening upwardly and rearwardly for receiving the pull tab (21) as the slider (S) is supplied to the apparatus; a slider support (5) disposed across said space (2) and having at an upper end a first seat (4) for supporting thereon one half portion of the slider body (20) and also having a bore (5b) below said first seat (4); and a locking lever (15) pivotally disposed in said space (2) forwardly of the slider support (5) and having a locking projection (17), said lever (15) being normally urged by spring means (18) in a direction in which said locking projection (17) projects through said bore (5b) of the slider support (5), characterized in that said apparatus further comprises a supporting arm (6) pivotally disposed in said space (2) rearwardly of the slider support (5) and having at one end a second seat (12) for supporting thereon the other half portion of the slider body (20); said supporting arm (6) being angularly movable between an inclined position in which said second seat (12) is positioned remotely from said

first seat (4) and the other end of the supporting arm (6) presses said locking lever (15) against the spring means (18) such that said locking projection (17) is retracted into the bore (5b), and an upright position in which said second seat (12) is positioned adjacent to and in horizontal alignment with said first seat (4) for cooperating with the latter in supporting the slider body (20) with the pull tab (21) held between said slider support (5) and supporting arm (6); and as said supporting arm (6) is angularly moved from the inclined position to the upright position, said locking lever (15) being allowed to turn under the bias of said spring means (18) so that said locking projection (17) projects into engagement with an edge of the aperture (21a) in the pull tab (21).

2. An apparatus according to claim 1, characterized in that said other end of said supporting arm (6) has a cam surface (6a).

3. An apparatus according to claim 1, characterized in that said supporting arm (6) is connected with an actuator bar (8) connected to a piston rod (10a) of an air cylinder (10).

4. An apparatus according to claim 1, characterized in that said slider support comprises a pair of interconnected slider supports (5, 5) each having at its upper end a first seat (4) for supporting thereon one half portion of the slider body (S) and cooperation with a pair of horizontally oppositely directed supporting arms (6, 6), and a pair of horizontally oppositely directed locking lever (15, 15).

5. An apparatus according to claim 4, characterized in that said other end of each of the supporting arm (6) has a cam surface (6a).

Patentansprüche

1. Vorrichtung zum Festhalten eines Reißverschlußschiebers während des Hindurchziehens einer Reißverschlußkette (F) durch den Schieber (S), wobei der Schieber (S) einen Griff (21) umfaßt, der mit einem Schieberkörper (20) schwenkbar verbunden ist und eine Öffnung (21a) aufweist, wobei der Schieber (S) der Vorrichtung zugeführt wird, wobei diese Vorrichtung umfaßt: einen Halterkörper (30), der einen nach oben und nach hinten offenen Hohlraum (2) begrenzt zur Aufnahme des Griffs (21), wenn der Schieber (S) der Vorrichtung zugeführt wird; eine Schieberabstützung (5), die quer zu dem Hohlraum (2) angeordnet ist und an einem oberen Ende einen ersten Sitz (4) zum Abstützen der einen Hälfte des Schieberkörpers (20) und ferner eine Bohrung (5b) unter dem ersten Sitz (4) aufweist; und einen Sperrhebel (15), der vor der Schieberabstützung (5) in dem Hohlraum (2) schwenkbar angeordnet ist und einen Sperrvorsprung (17) aufweist, wobei dieser Hebel (15) durch Federmittel (18) normalerweise in einer Richtung vorgespannt ist, in der der Verriegelungsvorsprung (17) durch die Bohrung (5b) der Schieberabstützung (5) hindurchragt, dadurch gekennzeichnet, daß die Vorrichtung ferner einen Stützarm (6) umfaßt, der in dem Hohlraum (2) hinter der Schieberabstützung (5) schwenkbar angeordnet ist und an einem Ende einen zweiten Sitz (12) zum Abstützen der anderen Hälfte des Schieberkörpers (20) aufweist; wobei der Stützarm (6)

allowed to turn clockwise under the bias of the spring 18 so that the locking projection 17 projects through the bore 5b into engagement with the edge of the aperture 21a of the slider pull tab 21, thus causing the tip of the locking projection 17 to be received in the transverse slot 6c of the supporting arm 6. The slider S is thus firmly held on the apparatus 30 in position for threading therethrough of the slide fastener chain F, as shown in Figure 4.

Figure 5 shows a modified apparatus 40 which is different from the apparatus 30 of Figures 1 through 3 in that for holding two sliders S, S at a time, it includes a pair of interconnected slider supports 5, 5 each having at its upper end a first seat 4. The apparatus 40 also has a pair of horizontally oppositely directed supporting arms 6, 6 disposed outwardly of the pair of the slider supports 5, 5, each of said arms 6, 6 having at one end a second seat 12. Further, a pair of horizontally oppositely directed locking levers 15, 15 is disposed inwardly of the pair of the slider supports 5, 5. Thus the individual double parts are disposed in a mirror-image relationship.

Figure 6 shows a pair of stringers of a slide fastener chain F, to which two sliders S, S are mounted by the apparatus 40 to provide a bidirectionally openable slide fastener that is suitably used such as in a suitcase.

With the apparatus described above, because the slider pull tab is locked without fail during the angular movement of the supporting arm from the inclined position to the upright position, a slider can be held in position easily with adequate firmness so as not to be detached from the apparatus during threading therethrough of a slide fastener chain.

Claims

1. An apparatus for holding a slider in position during the threading of a slide fastener chain (F) through the slider (S), the slider (S) including a pull tab (21) pivotally connected to a slider body (20) and having an aperture (21a), the slider (S) being supplied toward said apparatus, said apparatus comprising: a holder body (30) defining a space (2) opening upwardly and rearwardly for receiving the pull tab (21) as the slider (S) is supplied to the apparatus; a slider support (5) disposed across said space (2) and having at an upper end a first seat (4) for supporting thereon one half portion of the slider body (20) and also having a bore (5b) below said first seat (4); and a locking lever (15) pivotally disposed in said space (2) forwardly of the slider support (5) and having a locking projection (17), said lever (15) being normally urged by spring means (18) in a direction in which said locking projection (17) projects through said bore (5b) of the slider support (5), characterized in that said apparatus further comprises a supporting arm (6) pivotally disposed in said space (2) rearwardly of the slider support (5) and having at one end a second seat (12) for supporting thereon the other half portion of the slider body (20); said supporting arm (6) being angularly movable between an inclined position in which said second seat (12) is positioned remotely from said

first seat (4) and the other end of the supporting arm (6) presses said locking lever (15) against the spring means (18) such that said locking projection (17) is retracted into the bore (5b), and an upright position in which said second seat (12) is positioned adjacent to and in horizontal alignment with said first seat (4) for cooperating with the latter in supporting the slider body (20) with the pull tab (21) held between said slider support (5) and supporting arm (6); and as said supporting arm (6) is angularly moved from the inclined position to the upright position, said locking lever (15) being allowed to turn under the bias of said spring means (18) so that said locking projection (17) projects into engagement with an edge of the aperture (21a) in the pull tab (21).

2. An apparatus according to claim 1, characterized in that said other end of said supporting arm (6) has a cam surface (6a).

3. An apparatus according to claim 1, characterized in that said supporting arm (6) is connected with an actuator bar (8) connected to a piston rod (10a) of an air cylinder (10).

4. An apparatus according to claim 1, characterized in that said slider support comprises a pair of interconnected slider supports (5, 5) each having at its upper end a first seat (4) for supporting thereon one half portion of the slider body (S) and cooperation with a pair of horizontally oppositely directed supporting arms (6, 6), and a pair of horizontally oppositely directed locking lever (15, 15).

5. An apparatus according to claim 4, characterized in that said other end of each of the supporting arm (6) has a cam surface (6a).

Patentansprüche

1. Vorrichtung zum Festhalten eines Reißverschlußschiebers während des Hindurchziehens einer Reißverschlußkette (F) durch den Schieber (S), wobei der Schieber (S) einen Griff (21) umfaßt, der mit einem Schieberkörper (20) schwenkbar verbunden ist und eine Öffnung (21a) aufweist, wobei der Schieber (S) der Vorrichtung zugeführt wird, wobei diese Vorrichtung umfaßt: einen Halterkörper (30), der einen nach oben und nach hinten offenen Hohlraum (2) begrenzt zur Aufnahme des Griffs (21), wenn der Schieber (S) der Vorrichtung zugeführt wird; eine Schieberabstützung (5), die quer zu dem Hohlraum (2) angeordnet ist und an einem oberen Ende einen ersten Sitz (4) zum Abstützen der einen Hälfte des Schieberkörpers (20) und ferner eine Bohrung (5b) unter dem ersten Sitz (4) aufweist; und einen Sperrhebel (15), der vor der Schieberabstützung (5) in dem Hohlraum (2) schwenkbar angeordnet ist und einen Sperrvorsprung (17) aufweist, wobei dieser Hebel (15) durch Federmittel (18) normalerweise in einer Richtung vorgespannt ist, in der der Verriegelungsvorsprung (17) durch die Bohrung (5b) der Schieberabstützung (5) hindurchragt, dadurch gekennzeichnet, daß die Vorrichtung ferner einen Stützarm (6) umfaßt, der in dem Hohlraum (2) hinter der Schieberabstützung (5) schwenkbar angeordnet ist und an einem Ende einen zweiten Sitz (12) zum Abstützen der anderen Hälfte des Schieberkörpers (20) aufweist; wobei der Stützarm (6)

zwischen einer geneigten Stellung, in der der zweite Sitz (12) im Abstand von dem ersten Sitz (4) angeordnet ist und das andere Ende des Stützarmes (6) den Sperrhebel (15) gegen die Vorspannkraft der Federmittel (18) derart belastet, daß der Sperrvorsprung (17) in die Bohrung (5b) zurückgezogen wird, und einer aufrechten Stellung verschwenkbar ist, in der der zweite Sitz (12) neben dem ersten Sitz (4) und mit diesem horizontal fluchtend angeordnet ist, um gemeinsam mit diesem den Schieberkörper (20) abzustützen, wobei der Griff (21) zwischen der Schieberabstützung (5) und dem Stützarm (6) gehalten ist; und wobei beim Verschwenken des Stützarms (6) von der geneigten Stellung in die aufrechte Stellung sich der Sperrhebel (15) unter der Vorspannkraft der Federmittel (18) verdrehen kann, so daß der Sperrvorsprung (17) zum Eingriff mit einem Rand der Öffnung (21a) des Griffs (21) vorspringt.

2. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß das andere Ende des Stützarms (6) eine Steuerkurve (6a) aufweist.

3. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß der Stützarm (6) mit einer Betätigungsstange (8) verbunden ist, die mit der Kolbenstange (10a) eines Pneumatikzylinders (10) verbunden ist.

4. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß die Schieberabstützungen zwei miteinander verbundene Schieberabstützungen (5, 5) umfaßt, die jeweils an ihrem oberen Ende einen ersten Sitz (4) zum Abstützen einer Hälfte des Schieberkörpers (S) aufweisen und mit zwei horizontal gegenüberliegenden Stützarmen (6, 6) und mit zwei horizontal gegenüberliegenden Sperrhebeln (15, 15) zusammenwirken.

5. Vorrichtung nach Anspruch 4, dadurch gekennzeichnet, daß das andere Ende eines jeden Stützarms (6) eine Steuerkurve (6a) aufweist.

Revendications

1. Appareil destiné à maintenir un curseur en place pendant l'enfilage d'une chaîne (F) de fermeture à glissière dans le curseur (S) le curseur (S) comportant une tirette (21) reliée de façon pivotante au corps de curseur (20) et munie d'une ouverture (21a), le curseur (S) étant avancé en direction dudit appareil, ledit appareil comprenant: un corps de maintien (30) définissant un espace (2) ouvert vers le haut et vers l'arrière en vue de recevoir la tirette (21) lorsque le curseur (S) est défilé à l'appareil; un support (5) de curseur disposé en travers dudit espace (2) et comportant à son extrémité supérieure un premier siège (4) destiné à supporter une partie formant une moitié du corps (20) de curseur, et comportant également un trou (5b) en dessous dudit premier siège (4); et un levier de blocage (15) disposé de façon pivotante dans ledit espace (2) en avant du support (5) de curseur et muni d'une saillie (17) de verrouillage, ledit levier (15) étant normalement poussé par un moyen (18) formant ressort dans une direction dans laquelle ladite saillie (17) de verrouillage passe dans ledit trou (5b) du support (5) de curseur, caractérisé en ce que ledit appareil com-

prend en outre un bras de support (6) disposé de manière pivotante dans ledit espace (2) à l'arrière du support (5) de curseur et comportant à une de ses extrémités un second siège (12) destiné à servir de support à une partie formant l'autre moitié du curseur (20); ledit bras de support (6) pouvant se déplacer angulairement entre une position inclinée dans laquelle ledit second siège (12) est positionné à l'écart dudit premier siège (4) et dans laquelle l'autre extrémité du bras de support (6) pousse ledit levier (15) de verrouillage à l'encontre de la force du moyen de ressort (18) de façon telle que ladite saillie (17) de verrouillage est rappelée dans le trou (5b), et une position verticale dans laquelle ledit second siège (12) est positionné à proximité dudit premier siège (4) et en alignement horizontal avec celui-ci, en vue de coopérer avec ce dernier pour supporter le corps (20) de curseur, la tirette (21) étant maintenue entre ledit support (5) de curseur et ledit bras (6) de support; et lorsque ledit bras (6) de support est déplacé angulairement à partir de la position inclinée jusqu'à la position verticale, ledit levier (15) de verrouillage pouvant tourner sous la force dudit moyen de ressort (18) de façon telle que ladite saillie (17) de verrouillage soit avancée en prise avec un bord de l'ouverture (21a) de la tirette (21).

2. Appareil selon la revendication 1, caractérisé en ce que ladite autre extrémité dudit bras (6) de support comporte une surface (6a) de came.

3. Appareil selon la revendication 1, caractérisé en ce que ledit bras (6) de support est relié à une tige d'actionnement (8) elle-même reliée à une tige (10a) de piston d'un vérin pneumatique (10).

4. Appareil selon la revendication 1, caractérisé en ce que ledit support de curseur comprend une paire de supports (5, 5) reliés entre eux, chacun comportant à son extrémité supérieure un premier siège (4) en vue de supporter sur celui-ci une des parties formant la moitié du corps (S) de curseur et coopérant avec une paire de bras de support (6, 6) qui se font face horizontalement, ainsi qu'une paire de leviers (15, 15) de verrouillage qui se font face horizontalement.

5. Appareil selon la revendication 4, caractérisé en ce que ladite autre extrémité de chacun des bras (6) de support comporte une surface (6a) de came.
