

WASHING MACHINE

ABSTRACT

A washing machine of the present disclosure includes: a storage tub configured to store laundry; a foam generation unit provided on the storage tub, and configured to supply generated foam into the storage tub; a water supply path provided on the storage tub, and configured to supply washing liquid to the foam generation unit; a circulating water path provided on the storage tub, and configured to circulate the washing liquid in the storage tub around the storage tub; and a circulating pump configured to supply the washing liquid in the storage tub to the foam generation unit and the circulating water path. The water supply path and the circulating water path are arranged in a stacked manner in an axial direction of the storage tub. Thus, a washing machine with high detergency can be achieved without reducing an opening area of a loading port for putting in the laundry.
