

Description

This invention relates to a separator for classifying powder according to the preamble of claim 1.

When the powdery starting material flowing into a classification is fluidized in a whirl in said classification chamber, centrifugal force and air resistance force in the inward direction act on the respective particles of the powdery starting material, and the classification point is determined by the balance between the centrifugal force and the air resistance force.

Outside of the classification chamber, larger particles are whirled, while smaller particles whirl inside thereof. By providing powder discharging outlets respectively at the center and the outer peripheral at the lower portion of the classifying chamber, fine powder group and coarse powder group can be collected separately (classification).

In such a classifying separator, it is important that the starting powder should be sufficiently dispersed within the classifying chamber to become primary particles in enhancing the classification precision.

As this kind of classifying separator, litani system classifying separator or Kuracyclon has been proposed. However, in this type of classifying separator, it is very difficult to control the classification point, to involve such problems such as poor dispersion and poor classification precision at high dust concentration. In order to solve such problems, various proposals have been made. For example, there are proposals as disclosed in JP-A-5 448 378 or US-A-4 221 655. As a classifying separator practically applied, there may be mentioned a commercially available classifying separator sold under the name of DS separator. In this kind of classifying separator, although it has become possible to control the classification point, since powder is fed through a cyclon section into the classifying chamber, the powder is concentrated before entering the classifying chamber, whereby dispersion of the powder tended to become insufficient. Accordingly, lowering in, classification efficiency has been caused to occur. Referring now to Fig. 5 and Fig. 6 in the accompanying drawings, the prior art device is to be further explained.

Fig. 5 is a schematic view of the outer surface of a first embodiment of the prior art device, and Fig. 6 a schematic sectional view of said first embodiment of the prior art device.

In Fig. 5 and Fig. 6, the classifying separator has a main casing 1, a lower casing 2 connected to the lower portion of said casing 1, and a hopper 3 at the lower portion of the lower casing 2. Internally of the main body casing 1 is formed a classification chamber 4. At the upper portion of the main body casing 1 is standing a guide cylinder 10, and a feeding cylinder 9 is connected to the upper portion outer peripheral of said guide cylinder 10. At the bottom within the guide cylinder 10 is equipped a cone-shaped (umbrella-shaped) discharging guide plate 15 with high central portion, and an annular inlet 11 is formed at the lower brim outer peripheral of said discharging guide plate 15. At the bottom of the classifying chamber 4 is equipped a cone-shaped (umbrella-shaped) classifying plate 5 with high central portion, and an annular coarse powder discharging outlet 6 is formed at the lower outer periphery of the classifying plate 5, and a fine powder fraction discharging outlet 7 is formed at the central portion of the classifying plate 5. At the outer peripheral of the lower surrounding wall of the classifying chamber 4, there is a gas inflow inlet 8 equipped for inflowing air. The air inflow inlet 8 is constituted generally of the gaps between a plural number of blade-shaped louvers 14 (see Fig. 15A and 15B). The direction of the air introduced through the gas inflow inlet 8 is controlled by the classification louvers 14 so as to be jetted out in the whirling direction of the powder material which descends under whirling in the classifying chamber 4. Said air disperses the powder material, and also accelerates the whirling speed of the powder material.

Fig. 4B shows a cross sectional view seen along III-III in Fig. 5 and Fig. 6. In such gas current classifying separator, the starting powder pressure delivered by gas current from the feeding cylinder 9 to the guide cylinder 10 descends under whirling around the internal outer peripheral of the guide cylinder 10 to be inflowed under whirling through the annular feeding inlet 11 into the classifying chamber 4. Within the classifying chamber 4, the powder is separated into coarse powder group and fine powder group through the centrifugal force acting on the respective particles. However, in the first embodiment of the device of the prior art, since the starting powder is fed into the classifying chamber 4 while being concentrated at the inner wall of the guide cylinder, dispersion of the powder particles is insufficient, and the powder descends while drawing a spiral in band within the guide cylinder similarly as in cyclon, and therefore nonuniform in concentration fed into the classifying chamber depending on the place, whereby it has been difficult to obtain sufficient classification precision. When the fine powder forms an agglomerate, or when fine powder is attached on coarse powder, if dispersion is insufficient, fine powder increasingly tends to be mixed into the coarse powder group side. Further, if dispersion is insufficient, the dust concentration within the classifying chamber 4 becomes nonuniform, whereby the classification precision itself is worsened, thereby causing a problem that the classified product has a broad particle size distribution to occur. This tendency is more marked as the particle size of the starting powder is finer. Particularly, when the powder is 10 μm

or less, the tendency of lowering in classification precision becomes more marked.

According to a second arrangement representing a generic classifying separator, described in the US-A-4 221 655, the particles are already dispersed in the guide cylinder before they enter the classifying chamber, and subsequently led through the narrow ring-shaped supply openings. Thus, not only the classification efficiency, but also the treating capacity per unit time of this apparatus is unsatisfactory.

The present invention has solved various problems as described above.

The object of the present invention is to provide a separator for classifying powder by air current having a classification efficiency and a high treating capacity per unit time.

This object is achieved by the features defined in the characterizing part of claim 1. According to these features, a separator for classifying powder by air current is created, in which the gas feeding means is provided at said classifying chamber between the feeding inlet and the gas inflow inlet. Thus, the dispersion of the particles take place in the classifying chamber itself directly before they are classified. In this way, the possibility of a renewed agglomeration is prevented effectively and, besides, an additional turbulence enhancing the intensity of the separation is generated. Thereby, the classification efficiency is improved considerably, and the treating capacity per unit time is increased.

Preferable embodiments of the invention are defined in the subclaims.

In the following the invention is further illustrated by embodiments with reference to the enclosed figures.

Fig. 1, Fig. 8 and Fig. 10 shown schematic illustrations of the outer surface of the classifying separator; Fig. 2, Fig. 9, Fig. 11, Fig. 12, Fig. 13 and Fig. 14 show schematic longitudinal front views of the classifying separator;

Fig. 3 shows a schematic sectional view seen along I-I in the classifying separator shown in Fig. 1, Fig. 8 or Fig. 10, Fig. 4A a schematic sectional view seen along II-II and Fig. 4B a schematic sectional view seen along III-III in the classifying separator shown in Fig. 5;

Fig. 5 shows a schematic illustration of the outer surface of the first embodiment of the classifying separator according to the prior art example, Fig. 6 its longitudinal front view;

Fig. 7 is a flow chart of the pulverization-classification system in which the classifying separator is applied;

Fig. 15A shows a schematic plan view of a louver and Fig. 15B a schematic front view of the louver.

The separator for classifying powder by gas current is intended to improve dispersibility of the powder within the classifying chamber, thereby improving classification precision, by having a gas inflowing means for dispersing powder by whirling current to the upper part outer peripheral of the classifying chamber.

As an example of the classifying separator, one of the system shown in Fig. 1 (schematic view showing the outer surface of the device) and Fig. 2 (schematic view showing longitudinal front view of the device) can be exemplified.

In Fig. 1 and Fig. 2, the classifying separator has a main body casing 1, a lower casing 2 connected to the lower portion of said casing 1, and a hopper 3 at lower portion of the lower casing 2, with a classifying chamber 4 being formed internally of the main body casing 1. At the upper part of the main body casing 1 is standing an introducing means comprising a guide cylinder 10, and a feeding cylinder 9 which is connected to the upper outer peripheral of said guide cylinder 10. The guide cylinder 10 has a discharging guide plate 15 shaped in cone (shaped in umbrella) with high central portion at the internal bottom thereof, and an annular powder feeding inlet 11 is formed at the lower outer periphery of the discharging guide plate 15. At the bottom of the classifying chamber 4, a classifying plate 5 shaped in cone (shaped in umbrella) with high central portion is equipped, and an annular coarse powder fraction discharging outlet 6 for discharging coarse powder group is formed at the lower outer periphery of the classifying plate 5, and a fine powder fraction discharging outlet 7 for discharging fine powder fraction is formed at the central portion of the classifying plate 5. At the upper surrounding wall outer peripheral of the classifying chamber 4, a gas feeding means 12 is provided as the gas inflowing means for permitting a gas such as gas to inflow into the chamber. The means constituting said gas feeding means 12 may include, as a preferable example, one constituted of the gaps of a plural number of blade-shaped dispersing louvers 13. Fig. 3 shows a sectional view seen along I-I in Fig. 1 and Fig. 2. As shown in Fig. 3, the direction of the air 16 introduced through the gas feeding means 12 is controlled by the dispersing louvers 13 so that the air may descend while whirling around the inner peripheral of the guide cylinder 10 to be jetted out in the whirling direction of the powder material inflowing under whirling into the classifying chamber 4 through the annular feeding inlet 11. The gas inflowing means formed of the dispersing louvers 13 plays a role of making smaller the agglomerate of powder by dispersing positively the powder immediately after inflow into the classifying chamber 4, and further accelerating the powder. By this means, the classifying precision of powder is improved to great extent.

At the lower surrounding wall peripheral of the classifying chamber 4, a gas inflow inlet 8 for inflowing air is equipped. The gas inflow inlet 8 is constituted of the gaps of a plural number of blade-shaped classifying louvers 14 as shown in Fig. 4A. The direction of the air 17 introduced through the gas inflow inlet 8 is controlled by the classifying louvers 14 so that it may be jetted out in the whirling direction of the powder material descending through the classifying chamber 4 under whirling, so as to dispersing again the powder material and accelerate the whirling speed.

The intervals between the classifying louvers 14 and the intervals between the dispersing louvers 13 are controllable, and the heights of the classifying louvers 14 and the dispersing louvers 13 can be also set suitably.

According to the constitution of the present invention, the powder material concentrated by centrifugal force against the inner wall of the guide cylinder 10 and inflowed through the annular feeding inlet 11 under whirling into the classifying chamber 4 is dispersed by the air 16 inflowed through the gas feeding means 12, and also accelerated in whirling force to be fallen under whirling onto the lower portion of the classifying chamber, and at the bottom of the classifying chamber, the whirling force is further accelerated by the air 17 inflowed through the gas inflow inlet 8, whereby the powder is classified with good efficiency into coarse powder group and fine powder fraction. The dispersed state of the starting powder in the classifying chamber 4 affects very greatly the classification performance. In classifying separator, such dispersion was insufficient, while in the present invention, this problem is dissolved by providing a gas feeding means 12 at the upper portion of the classifying chamber. The gas feeding means 12 provided at the upper portion of the classifying chamber should be preferably provided at a level higher than one-half of the total height of the classifying chamber 4, and preferably provided below the annular feeding inlet 11 (formed substantially of the outer brim portion of the discharging guide plate 15 and the inner wall of the main body casing). The wind velocity of the air 16 inflowing through the gas feeding means 12 should be preferably controlled so as to be substantially equal to or slower than the wind velocity of the air 17 inflowing through the gas inflow inlet 8 at the lower portion of the classifying chamber. This is based on the technical thought that the air 16 inflowing through the gas feeding means 12 is primarily intended to disperse the particles constituting the powder, while the air 17 inflowing through the gas inflow inlet 8 is introduced for giving strong whirling force to the particles and classifying the powder into coarse powder fraction and fine powder fraction through the difference in centrifugal force.

When the total sum of the opening area of the gas feeding means 12 is made A (cm²) and the total sum of the opening area of the inflow inlet 8 is made B (cm²), it is preferable for improvement of performance to control the opening areas so that A and B may satisfy the following formula: $1 \leq A/B \leq 20$. The specific feature of the present invention resides in providing an inflow inlet of a gas such as air at the upper portion of the classifying chamber, and the constitution of the bottom of said gas feeding means as shown in Fig. 1 and Fig. 2 can be changed within the range which does not impair the technical thought of the present invention.

As another example of the gas current classifying separator of the present invention, one having a shape shown in Fig. 8 (outer surface view) and Fig. 9 (longitudinal front view) can be exemplified. In Fig. 8 and Fig. 9, the classifying separator has a main body casing 101, a lower casing 102 connected to the lower portion of said casing 101 and a hopper 103 at the lower portion of the casing 102, and a classifying chamber 104 is formed internally of the main body casing 101. At the upper portion of the main casing 101 is standing a guide cylinder 110, and to the upper peripheral surface of said guide cylinder 110 is connected a feeding cylinder 109. At the lower portion within the guide cylinder 110 is mounted a guide plate 115 having a slanted shape with high central portion, and an annular feeding inlet 111 is formed at the lower brim outer peripheral guiding plate 115. The diameter of the guide plate 115 is made larger than the inner diameter of the guide cylinder 101, whereby the powder feeding inlet 111 is formed of the outer peripheral portion of the guide plate 115, the inner wall of the main body casing 101 and the outermost peripheral portion of the classifying chamber 104.

At the bottom of the classifying chamber 104 is provided a slanted classifying plate 105 with high central portion, and an annular coarse powder fraction discharging outlet 106 is formed at the lower brim outer peripheral of the classifying plate 105, and a fine powder fraction discharging outlet 107 is formed at the central portion of the classifying plate 105.

At the outer peripheral of the lower surrounding wall of the classifying chamber 104 is equipped an air inflow inlet 8, and the air inflow inlet 8 is generally composed of the gap of a plural number of the blade-shaped classifying louvers 14 shown in Fig. 4. The current of the air introduced through the air inflow inlet 8 is controlled by the classifying louvers 14 so as to be jetted out in the whirling direction of the powder material descending under whirling in the classifying chamber 104 to disperse the powder material, and also accelerate the whirling speed.

According to the constitution of the present invention, by enlarging the diameter of the guide plate larger, the diameter of the annular feeding inlet 111 can be enlarged to make the distance to the fine powder fraction discharging outlet 107 larger, and therefore mixing of coarse powder into fine powder discharged through the fine powder fraction discharging outlet 107 can be prevented to make the average particle size of the separated fine powder smaller. At the same time, the powder material concentrated by centrifugal force at the guide plate inner wall and inflowing under whirling through the annular feeding inlet 111 into the classifying chamber 104 can be dispersed by the gas current inflowing through the air feeding means 12 at the upper portion of the classifying chamber, and by accelerating the whirling force, fallen under whirling to the lower part of the classifying chamber, and at the lower portion of the classifying chamber, the whirling speed is further accelerated by the air inflowing through the gas inflow inlet 8, whereby the powder can be classified with good efficiency to coarse powder and fine powder. In the classifying separator of the present invention shown in Fig. 9, by providing a gas feeding means 12 at the upper portion of the classifying chamber and increasing the whirling speed within the classifying chamber 104, the separated particle size can be made remarkably smaller along with the effect by the large guide plate as mentioned above.

Further, in the classifying separator of the present invention, by enlarging the diameter of the inflow inlet by enlarging the diameter of the guide plate; by providing an air feeding means for dispersing the powder material by whirling current to the outer peripheral of the upper portion of the classifying chamber; further in addition to the above means, by making the orifice diameter of the fine powder discharging outlet 10% to 25% (more preferably 20% to 25%) relative to the outer diameter of the classifying plate (as 100%); and/or making the slanted angle of the classifying plate relative to the vertical direction of the classifying chamber 30° to 60° (more preferably 40° to 50°), classification with small separated particle size can be performed with good precision.

More specifically, one having a shape shown in Fig. 10 (outer surface view) and Fig. 11 (longitudinal front view), Fig. 12, Fig. 13 or Fig. 14 can be exemplified.

In the drawings, the classifying separator has a main body casing 201, a lower casing 202 connected to the lower portion of said casing 201, and a hopper 203 at the lower portion thereof, and a classifying chamber 204 is formed within the main body casing 201. At the upper portion of the main body casing 201 is standing a guide cylinder 210, and to the upper outer peripheral surface of the guide cylinder 210 is connected a feeding cylinder 209. At the internal bottom of the guide cylinder 210 is mounted a slanted guide plate 215 with high central portion, and an annular feeding inlet 211 is formed at the lower brim outer peripheral of the guide plate 215.

The diameter of the guide plate 215 is enlarged, whereby the feeding inlet 211 is formed of the outer peripheral portion of the guide plate 215, the inner wall of the main body casing 201 and the outermost peripheral portion of the classifying chamber 204.

At the bottom of the classifying chamber 204 is provided a slanted classifying plate 205 with high central portion, and an annular coarse powder fraction discharging outlet 206 is formed at the lower outer periphery of the classifying plate 205, and a fine powder fraction discharging outlet 207 is formed at the central portion of the classifying plate 205.

At the outer peripheral of the surrounding wall at the lower portion of the classifying chamber 204 is equipped a gas inflow inlet 8, and the gas inflow inlet 8 is generally composed of the gaps between a plural number of blade-shaped classifying louvers 14 as shown in Fig. 14.

Further, at the outer peripheral of the surrounding wall at the upper portion of the classifying 204 is equipped a gas feeding means 12.

Further by making the orifice diameter of the fine powder fraction discharging outlet 207 narrower than the inner diameter of the fine powder discharging pipe 216, 10% to 25% relative to the outer diameter of the classifying plate 205, the distance from the outer peripheral of the classifying plate 205 to the fine powder fraction discharging outlet 207 can be enlarged to prevent mixing of coarse powder into the separated fine powder to further extent, thereby making the average particle size of the classified powder further smaller and also its particle size distribution more precise.

The orifice diameter of the fine powder fraction discharging outlet 207 should preferably be made 20% to 25% relative to the outer diameter of the classifying plate 205. With a diameter less than 20%, the pressure loss becomes greater to reduce the amount of air passing through the fine powder discharging pipe 216, whereby the air causing dispersion and whirling inflowed through the gas inflow inlet 8 and the gas feeding means 12 is undesirably reduced.

Also, by making the slanted angle of the classifying plate 205 30° to 60°, the distance from the outer peripheral of the classifying plate 205 to the fine powder fraction discharging outlet 207 can be enlarged, whereby the same effect as obtained when making the orifice of the fine powder fraction discharging outlet

207 smaller can be obtained.

In the classifying separator of the present invention, there is an extremely high tendency that the respective particles are sufficiently dispersed to primary particles within the classifying chamber, and therefore classifying efficiency is good, whereby the particle groups classified by the classifying separator of the present invention have precise particle size distributions and also the classification efficiency is better as compared with the gas current classifying separator of the prior art. In the classifying separator of the present invention, it is also possible to make the desired separated particle size diameter smaller than that in the classifying separator of the prior art.

The classifying separator of the present invention can be also effectively used by connecting to a pulverizer as shown in the flow chart in Fig. 7. In this case, the pulverized starting material is fed into the classifying separator of the present invention, and coarse powder with a certain defined particle size or more is introduced into the pulverizer and, after pulverization, is again circulated to the classifying separator. The particles pulverized to a defined particle size or less are taken out from the classifying separator by means of a suitable take-out means. In such pulverization-classification system, in the classifying separator of the prior art system, dispersion of the powder within the classifying chamber is insufficient, and therefore it is difficult to separate or loosen the agglomerate constituted of very fine particles or fine particles attached to coarse powder. Such agglomerate was mixed to the coarse powder group side during classification, and circulated again into the pulverizer to cause excessive pulverization, thereby tending to bring about lowering in pulverization efficiency. To cope with such problems, in the classifying separator of the present invention, since dispersion of the powder within the classifying chamber is sufficiently effected, such agglomerate can be well loosened to be prevented from mixing into the coarse powder fraction and the fine powder particles are removed as fine powder, whereby pulverization efficiency can be further improved.

The classifying separator of the present invention has more marked effect as the particle size of the powder is smaller, and as the dust concentration in the classifying chamber is higher. Particularly, it is effective for the region with particle sizes of 10 μm or less, and may be more effective in the manner of use wherein it is bound with a pulverizer.

The classifying separator of the present invention is suitable for classification and preparation of a powder such as toner for development of electrostatic charges, powdery paint, magnetic material, polymeric material, etc. of which the final product is demanded to be fine particles. Particularly, it is suitable as the classifying separator to be used for preparation of a toner for development of electrostatic charges which is liable to bear electrostatic force to be readily agglomerated.

The toner for development of electrostatic charges has the final product form of fine particles, and is demanded to have a precise particle size distribution from which a fraction of particles with a defined particle size or less has been removed. For removing a fraction of particles with a defined particle size or less, in the classifying separator of the prior art classification precision was not yet satisfactory, and the product obtained tended to have a broad particle size distribution.

Even when a product with a precise particle size distribution may be obtained in a classifying separator of the prior art, lowering in classification efficiency is caused to result in increased cost. In contrast, by use of the classifying separator of the present invention, dispersion of the powder within the classifying chamber is effected sufficiently, and the coarse powder can be separated efficiently from the fine powder, whereby a classified product with precise particle distribution (for example, used as toner) can be formed without lowering yield.

The present invention is described in detail below by referring to Examples.

Example 1

Styrene-acrylate ester type resin (weight average molecular weight about 300,000)	100 wt. parts
Magnetic ferrite (particle size 0.2 μm)	60 wt. parts
Low molecular weight polyethylene	2 wt. parts
Negatively chargeable controller	2 wt. parts

A toner starting material comprising a mixture of the above recipe was melted and kneaded at about 180 °C for about 1.0 hour, then solidified by cooling, coarsely pulverized by a hammer mill into particles of 100 to 1000 μ , and subsequently pulverized by a sonication jet mill manufactured by Nippon Pneumatic Kogyo K.K. to obtain a pulverized product (powder starting material) with a weight average particle size of

10.5 μm (containing 1 wt.% or less of particles with particle sizes of 20.2 μm or more and 9.3 wt.% of particles with particle sizes of 5.04 μm or less). The pulverized product was introduced into the classifying separator shown in Fig. 1 and Fig. 2 for classification. In the classifying separator, the pulverized product was aspirated with a wind amount of 5 $\text{m}^3/\text{min.}$, and the gas feeding means 12 for inflowing air 16 had 20 openings of 2 cm x 0.6 cm (total opening area $2 \times 0.6 \times 20 = 24 \text{ cm}^2$) set by dispersing louvers 13. The gas inflow inlet 8 for inflowing gas 17 at the lower portion of the classifying chamber had 20 openings of 2 cm x 0.2 cm (total opening area $2 \times 0.2 \times 20 = 8 \text{ cm}^2$) set by classifying louvers 14, and the height of the classifying chamber was made 14 cm. The flow velocity of the gas 17 inflowed through the gas inflow inlet 8 was faster by about 2-fold than the gas 16 inflowed through the gas feeding means 12. As the result of classification of the pulverized product, a classified product preferable as toner with an average particle size of 11.5 μm (containing 0.3 wt.% of particles with sizes of 5.04 μm or less) was obtained as a classified product from which fine powder was removed with a classification yield of 81%. Here, the classification yield refers to the ratio of the weight of the classified product finally obtained to the total weight of the starting pulverized product supplied. The particle size data are measurement results obtained by Coulter Counter manufactured by Coulter Electronics.

Comparative example 1

The pulverized product obtained in the same manner as in Example 1 was introduced into a classifying separator of the system shown in Fig. 5 and Fig. 6 for classification. The gas current classifying separator aspirated the powder with a wind amount of 5 $\text{m}^3/\text{min.}$, with the gas inflow inlet at the bottom of the classifying chamber having 20 openings of 2 cm x 0.2 cm and the height of the classifying chamber being made 10 cm. As the result of classification of the pulverized product, the product with a weight average particle size of 11.2 μm (containing 0.9 wt.% of particles with sizes of 5.04 μm or less) was obtained as the classified product from which fine powder was removed with a classification yield of 72%. The classification yield was inferior to that of Example 1, and further as the result of examination of the product, it was found that agglomerates of 5 μm or more with very fine particles being agglomerated existed in spots.

The results of Example 1 and Comparative example 1 are shown below in Table 1

Table 1

	Classification yield (wt.%)	Weight average particle size (μm)	Particle size distribution	
			Content of particles of 5.04 μm or less	Content of particles of 20.2 μm or more
Example 1	81	11.5	0.3 wt.%	1.0 wt.% or less
Comparative example 1	72	11.2	0.9	1.0 or less

The principal parts of the classifying separator used in Example 1 had the dimensions shown below.

The guide cylinder 10 had an inner diameter of about 29 cm, the discharging guide plate 15 an outer diameter of about 26 cm, the gas feeding means 12 and the gas inflow inlet 8 were apart by about 6 cm, the classifying plate 5 had an outer diameter of about 37 cm, the lower casing 2 opposed to the classifying plate 5 an inner diameter of about 42 cm, and the fine powder fraction discharging outlet 7 of the classifying plate 5 an inner diameter of about 100 cm.

Example 2

Styrene-acrylate ester type resin (weight average molecular weight about 300,000)	100 wt. parts
Magnetic ferrite (particle size 0.2 μm)	60 wt. parts
Low molecular weight polyethylene	2 wt. parts
Negatively chargeable controller	2 wt. parts

A toner starting material comprising a mixture of the above recipe was melted and kneaded at about 180 °C for about 1.0 hour, then solidified by cooling, coarsely pulverized by a hammer mill into particles of

100 to 1000 μ , and subsequently pulverized by a sonication jet mill manufactured by Nippon Pneumatic Kogyo K.K. to obtain a pulverized product with a weight average particle size of 7.0 μ m (containing 1 wt.% or less of particles with particle sizes of 16 μ m or more and 8.0 wt.% of particles with particle sizes of 4.0 μ m or less). The pulverized product was introduced into the classifying separator shown in Fig. 1 and Fig. 2 for classification. In the classifying separator, the pulverized product was aspirated with a wind amount of 5 m³/min., and the gas feeding means 12 had 20 openings of 2 cm x 0.2 cm (total opening area 2 x 0.2 x 20 = 8 cm²) set by dispersing louvers 13. The gas inflowing inlet 8 at the bottom of the classifying chamber had 20 openings of 2 cm x 0.1 cm (total opening area 2 x 0.1 x 20 = 4 cm²) set by classifying louvers 14, and the height of the classifying chamber was made 16 cm. As the result of classification of the pulverized product, a classified product with an average particle size of 7.5 μ m (containing 2.0 wt.% of particles with sizes of 4.0 μ m or less) was obtained as a classified product from which fine powder was removed with a classification yield of 78%.

Comparative example 2

The pulverized product obtained in the same manner as in Example 2 was introduced into a classifying separator shown in Fig. 5 and Fig. 6 for classification. The classifying separator aspirated the powder with a wind amount of 5 m³/min., with the gas inflow inlet at the lower part of the classifying chamber having 20 openings of 2 cm x 0.1 cm and the height of the classifying chamber being made 12 cm. As the result of classification of the pulverized product, the product with a weight average particle size of 7.3 μ m (containing 4.1 wt.% of particles with sizes of 4.0 μ m or less) was obtained as the classified product from which fine powder was removed with a classification yield of 70%. The classification yield was inferior to that of Example 2, and further as the result of examination of the product, it was found that agglomerates of 3 μ m or more with very fine particles being agglomerated existed in spots.

The results of Example 2 and Comparative example 2 are shown below in Table 2

Table 2

	Classification yield (wt.%)	Weight average particle size (μ m)	Particle size distribution	
			Content of particles of 4.0 μ m or less	Content of particles of 16 μ m or more
Example 2	78	7.5	2.0wt.%	1.0 wt.% or less
Comparative example 2	70	7.3	4.1	1.0 or less

Example 3

Styrene-acrylate ester type resin (weight average molecular weight about 300,000)	100 wt. parts
Magnetic ferrite (particle size 0.2 μ m)	60 wt. parts
Low molecular weight polyethylene	2 wt. parts
Negatively chargeable controller	2 wt. parts

A toner starting material comprising a mixture of the above recipe was melted and kneaded at about 180 °C for about 1.0 hour, then solidified by cooling, coarsely pulverized by a hammer mill into particles of 100 to 1000 μ , and subsequently pulverized by ACM pulverizer manufactured by Hosokawa Micron K.K. to obtain a pulverized product with a weight average particle size of 30 μ m. The pulverized product was introduced into the classifying separator for classification shown in Fig. 1 and Fig. 2, and micropulverization and classification were performed based on the flow chart shown in Fig. 7. As the pulverizing machine, a sonication jet mill I-5 Model manufactured by Nippon Pneumatic was employed, and in the classifying separator, the pulverized product was aspirated with a wind amount of 5 m³/min., and the gas inflowing inlet had 20 openings of 2 cm x 0.2 cm (total opening area 2 x 0.2 x 20 = 8 cm²) set. The gas inflowing inlet at the lower portion of the classifying chamber had 20 openings of 2 cm x 0.2 cm (total opening area 2 x 0.2 x 20 = 8 cm²) set, and the height of the classifying chamber was made 12 cm. The

starting material (pulverized product) was fed at a rate of 40 kg/hour, and the product pulverized to the defined particle size or lower was taken out as fine powder.

The fine powder obtained was found to have a weight average particle size of 11.2 μm , 5.0 wt.% of particles with particle sizes of 5.04 μm or less and 0.5 wt.% of particles with particle sizes of 20.2 μm or more. From this fact, it can be seen that the coarse powder was precisely classified.

Comparative example 3

The pulverized product obtained in the same manner as in Example 3 was introduced into a classifying separator shown in Fig. 5 and Fig. 6, and fine pulverization and classification were performed based on the flow chart shown in Fig. 7. As the pulverizer, a sonication jet mill I-5 Model manufactured by Nippon Pneumatic Kogyo K.K. was employed, and gas current classifying separator aspirated with a wind amount of 5 $\text{m}^3/\text{min.}$, with the gas inflow inlet at the bottom of the classifying chamber having 20 openings of 2 cm x 0.2 cm and the height of the classifying chamber being made 8 cm.

The starting material (pulverized product) was fed at a rate of 30 kg/hour, and the product pulverized to the defined particle size or lower was taken out as fine powder. The fine powder obtained was found to have a weight average particle size of 11.5 μm , 9.1 wt.% of particles with particle sizes of 5.04 μm or less and 5.1 wt.% of particles with particle sizes of 20.2 μm or more, thus being widely distributed on the coarse powder side.

The results of Example 3 and Comparative example 3 are shown below in Table 3

Table 3

	Amount treated (Kg/hour)	Weight average particle size (μm)	Particle size distribution	
			Content of particles of 5.04 μm or less	Content of particles of 20.2 μm or more
Example 3	40	11.2	5.0 wt. %	0.5 wt. %
Comparative example 3	30	11.5	9.1	5.1

As can be clearly seen from the treated amounts in the above Table, the classifying separator of the present invention used in Example 3 was also excellent in treating capacity as compared with the classifying separator used in Comparative example 3.

Example 4

Except for using the classifying separator shown in Fig. 8 and Fig. 9 as the classifying separator, in the same manner as in Example 3, fine powder with defined particle size (weight average particle size about 7.4 to 7.5 μm) was obtained as the classified product from the pulverized product. The results are shown below in Table 4. For reference, the results obtained when utilizing the system of Example 3 are shown together as Example 3A.

Table 4

	Amount treated (Kg/hour)	Weight average particle size (μm)	Particle size distribution	
			Content of particles of 4.0 μm or less	Content of particles of 16 μm or more
Example 4	25	7.5	2.1 wt. %	0.1 wt. % or less
Example 3A	20	7.4	3.5	0.1

It can be seen that the classifying performance is improved by making the outer diameter of the guide plate 115 larger than the guide cylinder 101.

Example 5

Styrene-acrylate ester type resin	100 wt. parts
Magnetic material	60 wt. parts
Charge controller	2 wt. parts
Low molecular weight polypropylene	4 wt. parts

A toner material comprising the above formulation was kneaded by heating, cooled and then coarsely pulverized by a hammer mill. The starting powder obtained was charged into a classifying separator shown in Fig. 10 and Fig. 11 (orifice diameter ratio of fine powder discharging outlet 207 to classifying plate 205: about 24%, slanted angle of classifying plate: 60°), and the separated coarse powder was permitted to inflow into a sonication jet mill I-10 Model (manufactured by Nippon Pneumatic Kogyo K.K.) connected to said classifying separator to effect fine pulverization (jet air pressure for pulverization: 6 kgf/cm²), and the fine material micropulverized was again charged together with the powder material obtained by coarse pulverization into said classifying separator to obtain the separated fine powder as the micropulverized product (see the pulverization-classification system in Fig. 7).

As the result, a fine pulverized product with a weight average particle size of 14.3 μm and a content of particles with particle sizes of 20 μm or more of 6.2 wt.% was obtained.

Example 6

In the same manner as in Example 5, the powder material was charged into the classifying separator shown in Fig. 12, and a finely micropulverized product was obtained under a jet air pressure for pulverization of 6 kgf/cm².

As the result, a fine pulverized product with a weight average particle size of 12.6 μm and a content of particles with particle sizes of 20 μm or more of 1.8 wt.% was obtained.

The classifying separator shown in Fig. 12 has the fine powder discharging orifice shown in Fig. 11 which has an orifice diameter made 20% relative to the outer diameter of the classifying plate.

Example 7

In the same manner as in Example 5, the powder material was charged into the classifying separator shown in Fig. 13, and a finely micropulverized product was obtained under a jet air pressure for pulverization of 6 kgf/cm².

As the result, a fine pulverized product with a weight average particle size of 12.1 μm and a content of particles with particle sizes of 20 μm or more of 1.5 wt.% was obtained.

The classifying separator shown in Fig. 13 has the classifying plate shown in Fig. 11 which is slanted at an angle of 50°.

Example 8

In the same manner as in Example 5, the powder material was charged into the classifying separator shown in Fig. 14, and a finely micropulverized product was obtained under a jet air pressure for pulverization of 6 kgf/cm².

As the result, a fine pulverized product with a weight average particle size of 10.4 μm and a content of particles with particle sizes of 20 μm or more of 0 wt.% was obtained.

The classifying separator shown in Fig. 14 has the fine powder discharging orifice shown in Fig. 11 which has an orifice diameter made 20% relative to the outer diameter of the classifying plate, and the classifying plate shown in Fig. 11 which is slanted by an angle of 50°.

Example 9

In the same manner as in Example 8 except for using the system having a sonication jet Kill I-5 Model (produced by Nippon Pneumatic Kogyo K.K.) connected to the classifying separator shown in Fig. 14, a fine pulverized product was obtained from the starting powder.

As the result, a fine pulverized product with a weight average particle size of 4.6 μm and a content of particles with particle sizes of 10 μm or more of 0.1 wt.% was obtained.

The classifying separator used here has the classifying chamber which has a diameter made 80% of that (about 42 cm) of the classifying chamber in the classifying separator used in Example 8.

5

Comparative example 4

In the same manner as in Example 5 except for using the classifying separator having no gas feeding means 12, a fine pulverized product was obtained. Said product was found to have a weight average particle size of 18.3 μm and a content of particles with particle sizes of 20 μm or more of 12.1 wt.%, thus being widely distributed on the coarse powder side. In the case of the same feeding amount as in Example 5, the particle size distribution was found to become broader.

10

Comparative example 5

15

When a fine pulverized product was obtained under a jet air pressure for pulverization of 6 kgf/cm² by charging the starting powder into a classifying separator as shown in Fig. 5 and Fig. 6 having the same classification chamber diameter as in Example 9, its particle size distribution was a weight average particle size of 5.8 μm and a content of the particles with particle sizes of 10.8 μm or more of 5.0 wt.%.

20

As described above, by enlarging the diameter of the feeding groove by enlarging the diameter of the guide plate, providing a gas feeding means for dispersing the powder material to the upper outer peripheral of the classifying chamber by whirling current, and further by making smaller the orifice diameter of the fine powder fraction discharging outlet and/or making slanting of the classifying plate steep gradient, a classified product with small separated particle size and precise distribution can be obtained with good efficiency.

25

Claims

30

1. A separator for classifying powder by gas current, comprising at least a classifying chamber (4, 104, 204) and an introducing means (9, 109, 209; 10, 110, 210) for introducing the powder into said classifying chamber (4, 104, 204), a powder feeding inlet (11, 111, 211) for feeding the powder formed at the upper portion of said classifying chamber (4, 104, 204), a cone-shaped classifying plate (5, 105, 205) with a high central portion formed at the lower portion of said classifying chamber (4, 104, 204), a coarse powder fraction discharging outlet (6, 106, 206) for discharging coarse powder fraction provided at the lower outer periphery of said classifying plate (5, 105, 205), a fine powder fraction discharging outlet (7, 107, 207) for discharging fine powder fraction provided at the central portion of said classifying plate (5, 105, 205), a gas feeding means (12) for dispersing the powder by whirling of gas before classifying the powder and a gas inflow inlet (8) for creating whirling current of gas for classifying the powder provided at said classifying chamber (4, 104, 204),

35

characterized in that

40

said gas feeding means (12) is provided at said classifying chamber (4, 104, 204) between said feeding inlet (11, 111, 211) and said gas inflow inlet (8).

45

2. A separator according to claim 1, characterized in that said gas feeding means (12) is provided at a level higher than one-half of the total height of the classifying chamber (4).

3. A separator according to claim 1, characterized in that the gas feeding means (12) is formed of louvers.

4. A separator according to claim 1, characterized in that said gas inflow inlet (8) is formed of louvers.

50

5. A separator according to claim 1, characterized in that when the total sum of the opening area of the gas inflow inlet of said gas feeding means (12) for introducing gas from the outside into the classifying chamber (4, 104, 204) at the upper portion of the classifying chamber (4, 104, 204) is represented by A and the total sum of the opening area of the gas inflow inlet (8) for inflowing gas from the outside for classifying powder at the lower portion of the classifying chamber (4, 104, 204) is represented by B, said total sum A and said total sum B satisfy the following formula:

55

$$1 \leq A/B \leq 20.$$

As the result, a fine pulverized product with a weight average particle size of 4.6 μm and a content of particles with particle sizes of 10 μm or more of 0.1 wt.% was obtained.

The classifying separator used here has the classifying chamber which has a diameter made 80% of that (about 42 cm) of the classifying chamber in the classifying separator used in Example 8.

5

Comparative example 4

In the same manner as in Example 5 except for using the classifying separator having no gas feeding means 12, a fine pulverized product was obtained. Said product was found to have a weight average particle size of 18.3 μm and a content of particles with particle sizes of 20 μm or more of 12.1 wt.%, thus being widely distributed on the coarse powder side. In the case of the same feeding amount as in Example 5, the particle size distribution was found to become broader.

Comparative example 5

15

When a fine pulverized product was obtained under a jet air pressure for pulverization of 6 kgf/cm^2 by charging the starting powder into a classifying separator as shown in Fig. 5 and Fig. 6 having the same classification chamber diameter as in Example 9, its particle size distribution was a weight average particle size of 5.8 μm and a content of the particles with particle sizes of 10.8 μm or more of 5.0 wt.%.

As described above, by enlarging the diameter of the feeding groove by enlarging the diameter of the guide plate, providing a gas feeding means for dispersing the powder material to the upper outer peripheral of the classifying chamber by whirling current, and further by making smaller the orifice diameter of the fine powder fraction discharging outlet and/or making slanting of the classifying plate steep gradient, a classified product with small separated particle size and precise distribution can be obtained with good efficiency.

25

Claims

1. A separator for classifying powder by gas current, comprising at least a classifying chamber (4, 104, 204) and an introducing means (9, 109, 209; 10, 110, 210) for introducing the powder into said classifying chamber (4, 104, 204), a powder feeding inlet (11, 111, 211) for feeding the powder formed at the upper portion of said classifying chamber (4, 104, 204), a cone-shaped classifying plate (5, 105, 205) with a high central portion formed at the lower portion of said classifying chamber (4, 104, 204), a coarse powder fraction discharging outlet (6, 106, 206) for discharging coarse powder fraction provided at the lower outer periphery of said classifying plate (5, 105, 205), a fine powder fraction discharging outlet (7, 107, 207) for discharging fine powder fraction provided at the central portion of said classifying plate (5, 105, 205), a gas feeding means (12) for dispersing the powder by whirling of gas before classifying the powder and a gas inflow inlet (8) for creating whirling current of gas for classifying the powder provided at said classifying chamber (4, 104, 204),
characterized in that
said gas feeding means (12) is provided at said classifying chamber (4, 104, 204) between said feeding inlet (11, 111, 211) and said gas inflow inlet (8).
2. A separator according to claim 1, characterized in that said gas feeding means (12) is provided at a level higher than one-half of the total height of the classifying chamber (4).
3. A separator according to claim 1, characterized in that the gas feeding means (12) is formed of louvers.
4. A separator according to claim 1, characterized in that said gas inflow inlet (8) is formed of louvers.
5. A separator according to claim 1, characterized in that when the total sum of the opening area of the gas inflow inlet of said gas feeding means (12) for introducing gas from the outside into the classifying chamber (4, 104, 204) at the upper portion of the classifying chamber (4, 104, 204) is represented by A and the total sum of the opening area of the gas inflow inlet (8) for inflowing gas from the outside for classifying powder at the lower portion of the classifying chamber (4, 104, 204) is represented by B, said total sum A and said total sum B satisfy the following formula:

$$1 \leq A/B \leq 20.$$

6. A separator according to claim 5, characterized in that the flow velocity of the gas (16) inflowing from said gas feeding means (12) at the upper portion of the classifying chamber (4, 104, 204) is substantially equal to or slower than the velocity of the gas (17) inflowing from said gas inflow inlet (8) at the lower portion of said classifying chamber (4, 104, 204).
7. A separator according to claim 1, characterized in that the classifying chamber (4, 104, 204) is formed internally of a main body casing (1, 101, 201), and a guide cylinder (10, 110, 210) for introducing powder to be classified into the classifying chamber (4, 104, 204) is provided at the upper portion of said main body casing (1, 101, 201).
8. A separator according to claim 7, characterized in that said classifying chamber (4, 104, 204) is formed between a guide plate (15, 115, 215) and said classifying plate (5, 105, 205).
9. A separator according to claim 8, characterized in that the outer diameter of said guide plate (115, 215) is larger than the inner diameter of said guide cylinder (110, 210), and an annular powder feeding inlet (111, 211) is defined by the outer brim portion of said guide plate (115, 215) and the inner wall of said main body casing (101, 201).
10. A separator according to claim 1, characterized in that said classifying plate (205) has a circular fine powder discharging outlet (207) having a diameter which is 10 to 25% of the outer diameter of said classifying plate (205).
11. A separator according to claim 1, characterized in that said classifying plate (205) has a circular fine powder discharging outlet (207) having a diameter which is 20 to 25% of the outer diameter of said classifying plate (205).
12. A separator according to claim 1, characterized in that said classifying plate (205) has a slanted angle of 30 to 60° relative to the vertical direction of said classifying chamber (204).
13. A separator according to claim 1, characterized in that said classifying plate (205) has a slanted angle of 40 to 50° relative to the vertical direction of said classifying chamber (204).
14. A separator according to claim 1, characterized in that air flows into said classifying chamber (4, 104, 204) through said gas feeding means (12) and air flows into said classifying chamber (4, 104, 204) through said gas inflow inlet (8).

Patentansprüche

1. Abscheider zum Klassieren von Pulver über einen Gasstrom mit mindestens einer Klassierkammer (4, 104, 204) und einer Einführungseinrichtung (9, 109, 209; 10, 110, 210) zum Einführen des Pulvers in die Klassierkammer (4, 104, 204), einem Pulvereinlaß (11, 111, 211) zum Zuführen des am oberen Abschnitt der Klassierkammer (4, 104, 204) gebildeten Pulvers, einer konischen Klassierplatte (5, 105, 205) mit einem am unteren Abschnitt der Klassierkammer (4, 104, 204) ausgebildeten hohen mittleren Abschnitt, einem Auslaß (6, 106, 206) für die grobe Pulverfraktion zum Abgeben der am unteren Außenumfang der Klassierplatte (5, 105, 205) vorgesehenen groben Pulverfraktion, einem Auslaß (7, 107, 207) für die feine Pulverfraktion zum Abgeben der am mittleren Abschnitt der Klassierplatte (5, 105, 205) vorgesehenen feinen Pulverfraktion, einer Gaszuführeinrichtung (12) zum Dispergieren des Pulvers durch Gasverwirbelung, bevor das Pulver klassiert wird, und einem Gaseinlaß (8) zur Erzeugung eines Gaswirbelstromes zum Klassieren des an der Klassierkammer (4, 104, 204) vorgesehenen Pulvers, dadurch gekennzeichnet, daß die Gaszuführeinrichtung (12) an der Klassierkammer (4, 104, 204) zwischen dem Pulvereinlaß (11, 111, 211) und dem Gaseinlaß (8) vorgesehen ist.
2. Abscheider nach Anspruch 1, dadurch gekennzeichnet, daß die Gaszuführeinrichtung (12) auf einem Niveau angeordnet ist, das höher liegt als eine Hälfte der Gesamthöhe der Klassierkammer (4).

3. Abscheider nach Anspruch 1, dadurch gekennzeichnet, daß die Gaszuführeinrichtung (12) durch Lamellen gebildet ist.
- 5 4. Abscheider nach Anspruch 1, dadurch gekennzeichnet, daß der Gaseinlaß (8) durch Lamellen gebildet ist.
5. Abscheider nach Anspruch 1, dadurch gekennzeichnet, daß die Gesamtsumme von A und die Gesamtsumme von B, wenn die Gesamtsumme des Öffnungsbereiches des Gaseinlasses der Gaszuführeinrichtung (12) zum Einführen von Gas von der Außenseite in die Klassierkammer (4, 104, 204) am oberen Abschnitt der Klassierkammer (4, 104, 204) mit A und die Gesamtsumme des Öffnungsbereiches des Gaseinlasses (8) für das von der Außenseite einströmende Gas zum Klassieren des Pulvers am unteren Abschnitt der Klassierkammer (4, 104, 204) mit B bezeichnet wird, die folgende Ungleichung erfüllen:
10 1 A/B 20.
6. Abscheider nach Anspruch 5, dadurch gekennzeichnet, daß die Fließgeschwindigkeit des von der Gaszuführeinrichtung (12) am oberen Abschnitt der Klassierkammer (4, 104, 204) einströmenden Gases im wesentlichen der Geschwindigkeit des Gases (17), das vom Gaseinlaß (8) am unteren Abschnitt der Klassierkammer (4, 104, 204) einströmt, entspricht oder langsamer als diese ist.
7. Abscheider nach Anspruch 1, dadurch gekennzeichnet, daß die Klassierkammer (4, 104, 204) im Inneren eines Hauptgehäuses (1, 101, 201) ausgebildet ist und daß ein Führungszylinder (10, 110, 210) zum Einführen von zu klassierendem Pulver in die Klassierkammer (4, 104, 204) am oberen Abschnitt des Hauptgehäuses (1, 101, 201) vorgesehen ist.
8. Abscheider nach Anspruch 7, dadurch gekennzeichnet, daß die Klassierkammer (4, 104, 204) zwischen einer Führungsplatte (15, 115, 215) und der Klassierplatte (5, 105, 205) ausgebildet ist.
9. Abscheider nach Anspruch 8, dadurch gekennzeichnet, daß der Außendurchmesser der Führungsplatte (115, 215) größer ist als der Innendurchmesser des Führungszylinders (110, 210) und daß ein ringförmiger Pulvereinlaß (111, 211) durch den Außenrandabschnitt der Führungsplatte (115, 215) und die Innenwand des Hauptgehäuses (101, 201) gebildet wird.
10. Abscheider nach Anspruch 1, dadurch gekennzeichnet, daß die Klassierplatte (205) einen kreisförmigen Feinpulverauslaß (207) mit einem Durchmesser besitzt, der 10 bis 25% des Außendurchmessers der Klassierplatte (205) beträgt.
11. Abscheider nach Anspruch 1, dadurch gekennzeichnet, daß die Klassierplatte (205) einen kreisförmigen Feinpulverauslaß (207) besitzt, der einen Durchmesser aufweist, der 20 bis 25% des Außendurchmessers der Klassierplatte (205) beträgt.
12. Abscheider nach Anspruch 1, dadurch gekennzeichnet, daß die Klassierplatte (205) einen schiefen Winkel von 30 bis 60° relativ zur Vertikalrichtung der Klassierkammer (204) aufweist.
13. Abscheider nach Anspruch 1, dadurch gekennzeichnet, daß die Klassierplatte (205) einen schiefen Winkel von 40 bis 50° relativ zur Vertikalrichtung der Klassierkammer (204) aufweist.
14. Abscheider nach Anspruch 1, dadurch gekennzeichnet, daß Luft durch die Gaszuführeinrichtung (12) und durch den Gaseinlaß (8) in die Klassierkammer (4, 104, 204) strömt.

Revendications

1. Séparateur pour classer de la poudre au moyen d'un courant de gaz, comprenant au moins une chambre de classification (4, 104, 204) et un moyen d'introduction (9, 109, 209; 10, 110, 210) pour introduire la poudre dans ladite chambre de classification (4, 104, 204), une entrée d'amenée de poudre (11, 111, 211) pour amener la poudre formée en partie haute de ladite chambre de classification (4, 104, 204), une plaque de classification (5, 105, 205) de forme conique, pourvue d'une partie

- centrale élevée formée en partie basse de ladite chambre de classification (4, 104, 204), une sortie d'évacuation de fraction de poudre grossière (6, 106, 206) pour évacuer une fraction de poudre grossière fournie sur la périphérie extérieure inférieure de ladite plaque de classification (5, 105, 205), une sortie d'évacuation de fraction de poudre fine (7, 107, 207) pour évacuer une fraction de poudre fine fournie sur la partie centrale de ladite plaque de classification (5, 105, 205), un moyen d'amenée de gaz (12) pour disperser la poudre au moyen d'un tourbillonnement de gaz, avant d'effectuer le classement de la poudre et une entrée d'admission de gaz (8), pour créer un courant tourbillonnant de gaz en vue de classer la poudre fournie dans ladite chambre de classification (4, 104, 204), caractérisé en ce que
- ledit moyen d'amenée de gaz (12) est prévu dans ladite chambre de classification (4, 104, 204) entre ladite entrée d'amenée (11, 111, 211) et ladite entrée d'admission de gaz (8).
2. Séparateur selon la revendication 1, caractérisé en ce que ledit moyen d'amenée de gaz (12) est prévu à un niveau supérieur à la moitié de la hauteur totale de la chambre de classification (4).
 3. Séparateur selon la revendication 1, caractérisé en ce que le moyen d'amenée de gaz (12) est constitué d'auvents.
 4. Séparateur selon la revendication 1, caractérisé en ce que ladite entrée d'admission de gaz (8) est constitué d'auvents.
 5. Séparateur selon la revendication 1, caractérisé en ce que lorsque la somme totale de l'aire d'ouverture de l'entrée d'admission de gaz dudit moyen d'amenée de gaz (12), pour introduire du gaz depuis l'extérieur dans la chambre de classification (4, 104, 204), en partie haute de la chambre de classification (4, 104, 204), est représentée par la lettre A et la somme totale de l'aire d'ouverture de l'entrée d'admission de gaz (8), pour permettre l'admission de gaz depuis l'extérieur, pour classer de la poudre en partie basse de la chambre de classification (4, 104, 204), est représentée par la lettre B, ladite somme totale A et ladite somme totale B satisfaisant à la formule ci-dessous:

$$1 \leq A/B \leq 20.$$
 6. Séparateur selon la revendication 5, caractérisé en ce que la vitesse d'écoulement du gaz (16) entrant en partie haute de la chambre de classification (4, 104, 204) par ledit moyen d'amenée de gaz (12) est sensiblement inférieure ou égale à la vitesse du gaz (17) entrant en partie basse de ladite chambre de classification (4, 104, 204) par ladite entrée d'admission de gaz (8).
 7. Séparateur selon la revendication 1, caractérisé en ce que la chambre de classification (4, 104, 204) est constituée intérieurement d'un carter de corps principal (1, 101, 201) et un cylindre de guidage (10, 110, 210) servant à introduire de la poudre à classer dans la chambre de classification (4, 104, 204) est prévu en partie haute dudit carter de corps principal (1, 101, 201).
 8. Séparateur selon la revendication 7, caractérisé en ce que ladite chambre de classification (4, 104, 204) est formée entre une plaque de guidage (15, 115, 215) et ladite plaque de classification (5, 105, 205).
 9. Séparateur selon la revendication 8, caractérisé en ce que le diamètre extérieur de ladite plaque de guidage (115, 215) est supérieur au diamètre intérieur dudit cylindre de guidage (110, 210) et une entrée d'amenée de poudre annulaire (111, 211) est définie par la partie de rebord extérieure de ladite plaque de guidage (115, 215) et la paroi intérieure dudit carter de corps principal (101, 201).
 10. Séparateur selon la revendication 1, caractérisé en ce que ladite plaque de classification (205) présente une sortie d'évacuation de poudre fine (207) circulaire, dotée d'un diamètre qui constitue 10 à 25 % du diamètre extérieur de ladite plaque de classification (205).
 11. Séparateur selon la revendication 1, caractérisé en ce que ladite plaque de classification (205) présente une sortie d'évacuation de poudre fine (207) circulaire, dotée d'un diamètre qui constitue 20 à 25 % du diamètre extérieur de ladite plaque de classification.

12. Séparateur selon la revendication 1, caractérisé en ce que ladite plaque de classification (205) présente un angle incliné de 30 à 60° par rapport à la direction verticale de ladite chambre de classification (204).
- 5 13. Séparateur selon la revendication 1, caractérisé en ce que ladite plaque de classification (205) présente un angle incliné de 40 à 50° par rapport à la direction verticale de ladite chambre de classification (204).
- 10 14. Séparateur selon la revendication 1, caractérisé en ce que de l'air s'écoule dans ladite chambre de classification (4, 104, 204), par l'intermédiaire dudit moyen d'amenée de gaz (12) et de l'air s'écoule dans ladite chambre de classification (4, 104, 204), par l'intermédiaire de ladite entrée d'admission de gaz (8).
