

ABSTRACT

APPARATUS AND METHOD FOR SELECTING DEVICES WITHIN AN INTERNET OF THINGS FOR CONNECTING AND DISCONNECTING

An apparatus and method for selecting devices within an Internet of Things (IoT) for connecting and disconnecting is disclosed. The method comprises selection of the one or more second devices by a user and providing selection input, for example by pushing the push button on the side of the watch. The user input is captured and a characteristic of the one or more second device is modified, which is transmitted as a signal of readiness for connecting to the first device. The signal is captured by the first device and the one or more selected second devices connect to the first device. Disconnection of the one or more second devices connected to the first device may be effected in a similar way by providing input, which modifies a characteristic of the second device. The modified characteristic is detectable by the first device to effect automatic disconnection.
