AZABICYCLO (3.1.0) HEXANE DERIVATIVES USEFUL AS MODULATORS OF DOPAMINE D3 RECEPTORS

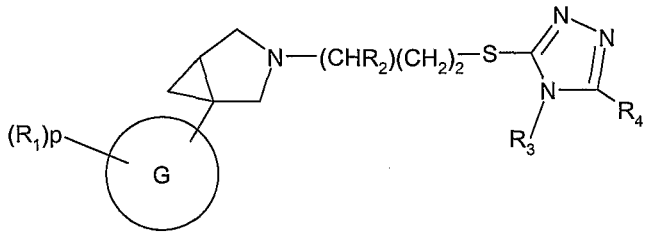

COMPOUNDS

The present invention relates to novel compounds, processes for their preparation, intermediates used in these processes, pharmaceutical compositions containing them and their use in therapy, as modulators of dopamine D_3 receptors.

WO 2002/40471 (SmithKline Beecham) discloses certain benzazepine compounds having activity at the dopamine D_3 receptor.

A new class of compounds which have affinity for dopamine receptors, in particular the dopamine D_3 receptor has been found. These compounds have potential in the treatment of conditions wherein modulation, especially antagonism/inhibition, of the D_3 receptor is beneficial, e.g. to treat drug dependency or as antipsychotic agents.

The present invention provides a compound of formula (I) or a salt thereof:

(I)

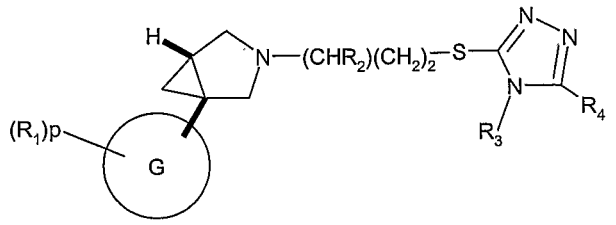

wherein

- G is selected from a group consisting of: phenyl, pyridyl, benzothiazolyl, indazolyl;
- p is an integer ranging from 0 to 5;
- R_1 is independently selected from a group consisting of: halogen, hydroxy, cyano, C_{1-4}alkyl, haloC_{1-4}alkyl, C_{1-4}alkoxy, haloC_{1-4}alkoxy, C_{1-4}alkanoyl; or corresponds to a group R_5;
- R_2 is hydrogen or C_{1-4}alkyl;
- R_3 is C_{1-4}alkyl;
- R_4 is hydrogen, or a phenyl group, a heterocyclyl group, a 5- or 6-membered heteroaromatic group, or a 8- to 11-membered bicyclic group, any of which groups is optionally substituted by 1, 2, 3 or 4 substituents selected from the group consisting of: halogen, cyano, C_{1-4}alkyl, haloC_{1-4}alkyl, C_{1-4}alkoxy, C_{1-4}alkanoyl;
- R_5 is a moiety selected from the group consisting of: isoxazolyl, -CH_2-N-pyrrolyl, 1,1-dioxido-2-isothiazolidinyl, thienyl, thiazolyl, pyridyl, 2-pyrrolidinonyl, and such a group is optionally substituted by one or two substituents selected from: halogen, cyano, C_{1-4}alkyl, haloC_{1-4}alkyl, C_{1-4}alkoxy, C_{1-4}alkanoyl;

and when R_1 is chlorine and p is 1, such R_1 is not present in the ortho position with respect to the linking bond to the rest of the molecule; and when R_1 corresponds to R_5, p is 1.

Because of the presence of the fused cyclopropane compounds of formula (I) are believed to have a "*cis*" disposition of the substituents (both groups linked to the bicyclic ring system are on the same face of this bicyclic ring system).

In another embodiment of the present invention compounds of formula (I)' are provided which correspond to the compounds of formula (I) having "cis" disposition, represented by the bold highlight of the bonds

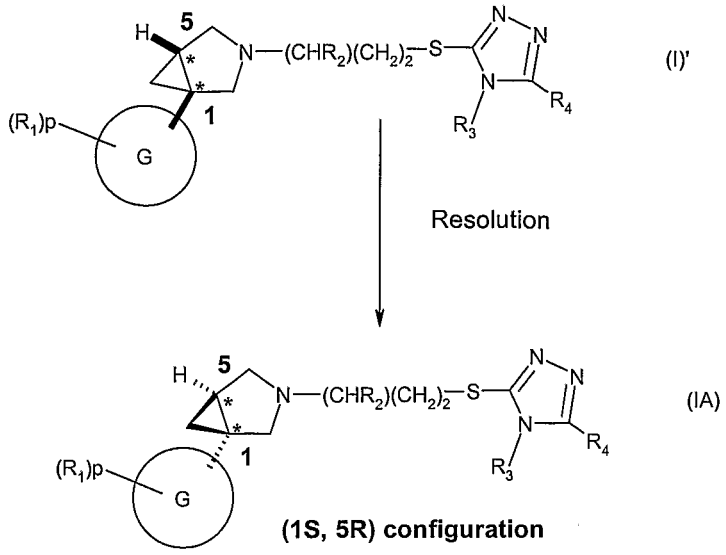

(I)'

wherein G, p, R_1, R_2, R_3, R_4, and R_5 are defined as above for compounds of formula (I).

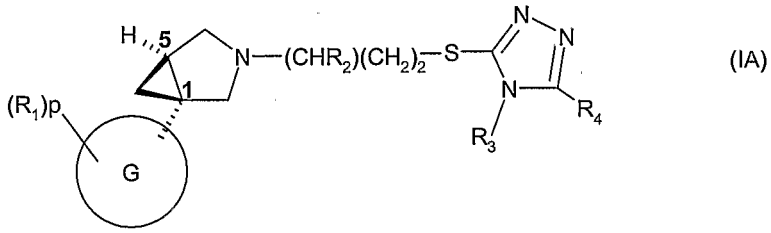

It will be appreciated that compounds of formula (I)' possess at least two chiral centres, namely at position 1 and 5 in the 3-azabicyclo[3.1.0]hexane portion of the molecule. Because of the fixed *cis* disposition, the compounds may exist in two stereoisomers which are enantiomers with respect to the chiral centres in the cyclopropane. It will also be appreciated, in common with most biologically active molecules that the level of biological activity may vary between the individual stereoisomers of a given molecule. It is intended that the scope of the invention includes all individual stereoisomers (diastereoisomers and enantiomers) and all mixtures thereof, including but not limited to racemic mixtures, which demonstrate appropriate biological activity with reference to the procedures described herein.

In compounds of formula (I)' there are at least two chiral centres, which are located in the cyclopropane portion, as depicted below (the bold highlight of the bonds means the "cis" configuration):

when G is a 2-pyridyl derivative the configuration becomes **(1R, 5R)** due to different Cahn-Ingold-Prelog nomenclature priorities

In a further embodiment of the present invention compounds of formula (IA) are provided that correspond to stereochemical isomers of compounds of formula (I)', enriched in configuration (1S,5R) or (1R,5R)

wherein G, p, R_1, R_2, R_3, R_4, and R_5 are defined as above for compounds of formula (I)' or a pharmaceutically acceptable salt thereof.

It is intended in the context of the present invention that stereochemical isomers enriched in configuration (1S,5R) or (1R,5R) of formula (IA) correspond in one embodiment to at least 90% e.e. In another embodiment the isomers correspond to at least 95% e.e. In another embodiment the isomers correspond to at least 99% e.e.

In another embodiment of the present invention the stereochemical isomers enriched in configuration (1R,5S) are provided:

The strategy for determining the absolute configuration of the compounds of the present invention comprised as a first step the preparation of the chiral intermediate, (1*S*,5*R*)-1-[4-(trifluoromethyl)phenyl]-3-azabicyclo[3.1.0]hexane,

(preparation 18), by using (S)-(+) acetyl mandelic acid as resolving agent.

In the literature the absolute configuration of a series of compounds similar to this chiral intermediate is known, see J. Med Chem 1981, 24(5), 481-90. For some compounds disclosed in the reference the absolute configuration was proved by single crystal X-ray analysis.

Among them, 1-(3,4-dichlorophenyl)-3-azabicyclo[3.1.0]hexane was disclosed.
The absolute configuration of the optical isomers of the compounds of the present invention was assigned using comparative VCD (vibrational circular dichroism) and OR (optical rotation) analyses.
The configuration of (1S,5R)-1-(3,4-dichlorophenyl)-3-azabicyclo[3.1.0]hexane was assigned by comparing its experimental VCD spectrum and observed specific rotation to ab initio derived calculated data for (1*S*,5*R*)-1-(3,4-dichlorophenyl)-3-azabicyclo[3.1.0]hexane (see Preparation 48) as the reference sample.

The assignment of the absolute configuration of the title compound was confirmed by a single crystal X-ray structure obtained from a crystal of (1*S*,5*R*)-1-[4-(trifluoromethyl)phenyl]-3-azabicyclo[3.1.0]hexane, (*S*)-(+)-mandelic acid salt. Both the analysis based on the known configuration of the (S)-(+)–mandelic acid and on the basis of anomalous dispersion effects confirmed the assignment of the title compound as being (1S,5R)-1-[4-(trifluoromethyl)phenyl]-3-azabicyclo[3.1.0]hexane.

For those compounds which were subjected to detailed analysis (VCD; OR included in the experimental details) a common trend was recognised between absolute configuration of the 3-azabicyclo[3.1.0]hexane moiety and measured binding activity at the dopamine D3 receptor for each pair of enantiomers. For the remainder of the compounds of the present invention, where stereoisomers were evaluated separately, absolute configuration was assigned based on a reasonable assumption by a skilled person in the art, i.e. absolute configuration was then assigned based on measured binding activity at the dopamine D3 receptor for both enantiomers and comparison with the data of those compounds which were subjected to detailed analysis.

Chiral molecules exhibit vibrational circular dichroism (VCD). Vibrational circular dichroism (VCD) is the differential interaction of a chiral molecule with left and right circularly polarized infrared radiation during vibrational excitation.

The VCD spectrum of a chiral molecule is dependent on its three-dimensional structure. Most importantly, the VCD spectrum of a chiral molecule is a sensitive function of its absolute configuration and, in the case of flexible molecules, of its conformation. In principle, therefore, VCD permits the determination of the structure of a chiral molecule. VCD spectra were first measured in the 1970s. Subsequently, VCD instrumentation has developed enormously in spectral range and in sensitivity. Currently, VCD spectra of liquids and solutions can be measured over the majority of the fundamental infrared (IR) spectral range ($\nu \geq 650$ cm−1) with high sensitivity at acceptable resolution (1–5 cm−1) using both dispersive and Fourier Transform (FT) VCD instrumentation. Very recently, commercial FT VCD instrumentation has become available, greatly enhancing the accessibility of VCD spectra.

The use of VCD as a reliable method for the determination of absolute configuration of chiral molecules is now well established (see for example Shah RD, et al., Curr Opin Drug Disc Dev 2001;4:764–774; Freedman TB, et al., Helv Chim Acta 2002; 85:1160–1165; Dyatkin AB, et al. Chirality 2002;14:215–219; Solladie´-Cavallo A, Balaz Met al., Tetrahedron Assym 2001;12:2605–2611; Nafie LA, et al. Circular dichroism, principles and applications, 2nd ed. New York: John Wiley & Sons; 2000. p 97–131; Nafie LA, et al. in: Yan B, Gremlish H-U, editors. Infrared and Raman spectroscopy of biological materials. New York: Marcel Dekker; 2001. p 15–54; Polavarapu PL, et al., J Anal Chem 2000;366:727–734; Stephens PJ, et al., Chirality 2000;12:172–179; Solladie´ -Cavallo A, et al., Eur J Org Chem 2002: 1788–1796).

The method entails comparison of observed IR and VCD spectra with calculations of the spectra for a specific configuration and provides information both on the absolute configuration and on the solution conformation.

Given an experimental spectrum of a chiral molecule whose absolute configuration and/or conformation are unknown and to be determined, the general procedure is as follows:
1) all possible structures are defined; 2) the spectra of these structures are predicted; and 3) predicted spectra are compared to the experimental spectrum. The correct structure will give a spectrum in agreement with experiment; incorrect structures will give spectra in disagreement with experiment.

VCD spectra are always measured simultaneously with vibrational unpolarized absorption spectra ("infrared (IR) spectra") and the two vibrational spectra together provide more information than does the VCD spectrum alone. In addition, vibrational unpolarized absorption spectra are automatically predicted simultaneously with VCD spectra.

For ab initio assignments, VCD and unpolarized IR spectra were calculated using the Gaussian 98 software package.

When chiral organic molecules are synthesized (or, if natural products, isolated) their optical rotations are routinely measured at one frequency or at a small number of discrete frequencies in the visible–near ultraviolet spectral region. Most commonly, the specific rotation at one frequency, that of the sodium D line, $[\alpha]_D$, is measured. The frequencies used lie below the threshold for electronic absorption, i.e., they are in the "transparent" spectral region. Optical rotation is a reflection of the enantiomeric excess (ee) of the sample and of the absolute configuration (AC) of the predominant enantiomer.

When the optical rotation at a given frequency for 100% ee is available, the measured optical rotation at the same frequency enables the sample ee to be determined.
The determination of ee is the predominant application of discrete frequency, transparent spectral region optical rotations. In principle, the AC of the predominant enantiomer, if unknown, can also be determined. However, the determination of AC from optical rotation requires an algorithm which reliably predicts the optical rotations of molecules of known AC and a number of methodologies have been proposed for predicting discrete frequency, transparent spectral region optical rotations (Eliel EL, Wilen SH. Stereochemistry of organic compounds. New York: John Wiley & Sons; 1994. Chapter 13).

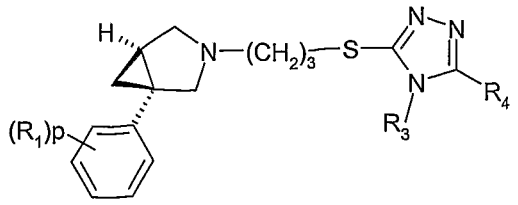

Very recently, developments in ab initio Density Functional Theory (DFT) have radically improved the accuracy of optical rotation calculation. As a result, for the first time it has become possible to routinely obtain ACs from optical rotations.

For ab initio OR assignments, the Dalton Quantum Chemistry Program was used.

Further embodiments of the present invention are compounds of formula (IB)', (IC)', (ID)', and (IF)' which, respectively, correspond to the stereochemical isomers of compounds of formula (IB), (IC), (ID) and (IF) as defined above enriched in configuration (1S, 5R).

Certain of the compounds of the invention may form acid addition salts with one or more equivalents of the acid. The present invention includes within its scope all possible stoichiometric and non-stoichiometric forms.

Pharmaceutical acceptable salts may also be prepared from other salts, including other pharmaceutically acceptable salts, of the compound of formula (I) using conventional methods.

Those skilled in the art of organic chemistry will appreciate that many organic compounds can form complexes with solvents in which they are reacted or from which they are precipitated or crystallized. These complexes are known as "solvates". For example, a complex with water is known as a "hydrate". Solvates of the compound of the invention are within the scope of the invention. The compounds of formula (I) may readily be isolated in association with solvent molecules by crystallisation or evaporation of an appropriate solvent to give the corresponding solvates.

In addition, prodrugs are also included within the context of this invention. As used herein, the term "prodrug" means a compound which is converted within the body, e.g. by hydrolysis in the blood, into its active form that has medical effects. Pharmaceutically acceptable prodrugs are described in T. Higuchi and V. Stella, Prodrugs as Novel Delivery Systems, Vol. 14 of the A.C.S. Symposium Series, Edward B. Roche, ed., Bioreversible Carriers in Drug Design, American Pharmaceutical Association and Pergamon Press, 1987, and in D. Fleisher, S. Ramon and H. Barbra "Improved oral drug delivery: solubility limitations overcome by the use of prodrugs", Advanced Drug Delivery Reviews (1996) 19(2) 115-130, each of which are incorporated herein by reference.

Prodrugs are any covalently bonded carriers that release a compound of structure (I) in vivo when such prodrug is administered to a patient. Prodrugs are generally prepared by modifying functional groups in a way such that the modification is cleaved, either by routine manipulation or in vivo, yielding the parent compound. Prodrugs include, for example, compounds of this invention wherein hydroxy, amine or sulfhydryl groups are bonded to any group that, when administered to a patient, cleaves to form the hydroxy, amine or sulfhydryl groups. Thus, representative examples of prodrugs include (but are not limited to) acetate, formate and benzoate derivatives of alcohol, sulfhydryl and amine functional groups of the compounds of structure (I). Further, in the case of a carboxylic acid (-COOH), esters may be employed, such as methyl esters, ethyl esters, and the like. Esters may be active in their own right and /or be hydrolysable under *in vivo* conditions in the human body. Suitable pharmaceutically acceptable *in vivo* hydrolysable ester groups include those which break down readily in the human body to leave the parent acid or its salt.

Furthermore, some of the crystalline forms of the compounds of structure (I) may exist as polymorphs, which are included in the present invention.

Those skilled in the art will appreciate that in the preparation of the compound of the invention or a solvate thereof it may be necessary and/or desirable to protect one or more sensitive groups in the molecule to prevent undesirable side reactions. Suitable protecting groups for use according to the present invention are well known to those skilled in the art and may be used in a conventional manner. See, for example, "Protective groups in organic synthesis" by T.W. Greene and P.G.M. Wuts (John Wiley & sons 1991) or "Protecting Groups" by P.J. Kocienski (Georg Thieme Verlag 1994). Examples of suitable amino protecting groups include acyl type protecting groups (e.g. formyl, trifluoroacetyl, acetyl), aromatic urethane type protecting groups (e.g. benzyloxycarbonyl (Cbz) and substituted Cbz), aliphatic urethane protecting groups (e.g. 9-fluorenylmethoxycarbonyl (Fmoc), t-butyloxycarbonyl (Boc), isopropyloxycarbonyl, cyclohexyloxycarbonyl) and alkyl type protecting groups (e.g. benzyl, trityl, chlorotrityl). Examples of suitable oxygen protecting groups may include for example alky silyl groups, such as trimethylsilyl or tert-butyldimethylsilyl; alkyl ethers such as tetrahydropyranyl or tert-butyl; or esters such as acetate

When a specific enantiomer of a compound of general formula (I) is required, this may be obtained for example by resolution of a corresponding enantiomeric mixture of a compound of formula (I) using conventional methods. Thus the required enantiomer may be obtained from the racemic compound of formula (I) by use of chiral HPLC procedure.

The subject invention also includes isotopically-labelled compounds, which are identical to those recited in formula (I) and following, but for the fact that one or more atoms are replaced by an atom having an atomic mass or mass number different from the atomic mass or mass number usually found in nature. Examples of isotopes that can be incorporated into compounds of the invention and pharmaceutically acceptable salts thereof include isotopes of hydrogen, carbon, nitrogen, oxygen, phosphorous, sulphur, fluorine, iodine, and chlorine, such as ^{2}H, ^{3}H, ^{11}C, ^{13}C, ^{14}C, ^{15}N, ^{17}O, ^{18}O, ^{31}P, ^{32}P, ^{35}S, ^{18}F, ^{36}Cl, ^{123}I and ^{125}I.

Compounds of the present invention and pharmaceutically acceptable salts of said compounds that contain the aforementioned isotopes and/or other isotopes of other atoms are within the scope of the present invention. Isotopically-labelled compounds of the present invention, for example those into which radioactive isotopes such as ^{3}H, ^{14}C are incorporated, are useful in drug and/or substrate tissue distribution assays. Tritiated, i.e., ^{3}H, and carbon-14, i.e., ^{14}C, isotopes are particularly preferred for their ease of preparation and detectability. ^{11}C and ^{18}F isotopes are particularly useful in PET (positron emission tomography), and ^{125}I isotopes are particularly useful in SPECT (single photon emission computerized tomography), all useful in brain imaging. Further, substitution with heavier isotopes such as deuterium, i.e., ^{2}H, can afford certain therapeutic advantages resulting from greater metabolic stability, for example increased *in vivo* half-life or reduced dosage requirements and, hence, may be preferred in some circumstances. Isotopically labelled compounds of formula I and following of this

invention can generally be prepared by carrying out the procedures disclosed in the Schemes and/or in the Examples below, by substituting a readily available isotopically labelled reagent for a non-isotopically labelled reagent.

Certain groups/substituents included in the present invention may be present as isomers. The present invention includes within its scope all such isomers, including racemates, enantiomers, tautomers and mixtures thereof. Certain of the substituted heteroaromatic groups included in compounds of formula (I) may exist in one or more tautomeric forms. The present invention includes within its scope all such tautomeric forms, including mixtures.

In one embodiment of the present invention compounds are provided e a molecular weight of 800 or less. In another embodiment compounds are provided having a molecular weight of 600 or less. Generally, and without being limited thereto, such compounds may have higher oral bioavailability, and sometimes higher solubility and/or brain penetrancy. Molecular weight here refers to that of the unsolvated free base compound, excluding any molecular weight contributed by addition salts, solvent (e.g. water) molecules, prodrug molecular parts cleaved off *in vivo*, etc.

In general, the compounds or salts of the invention should be interpreted as excluding those compounds (if any) which are so chemically unstable, either per se or in water, that they are clearly unsuitable for pharmaceutical use through all administration routes, whether oral, parenteral or otherwise. Such compounds are known to the skilled chemist. Prodrugs or compounds which are stable *ex vivo* and which are convertable in the mammalian (e.g. human) body to the inventive compounds are however included.

The present invention also provides a process for preparing a compound of formula (I) or a salt thereof as defined above.

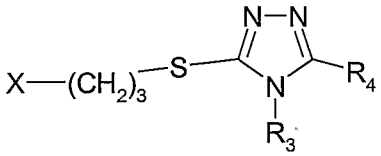

The process of the present invention for preparing compounds of formula (I) in which G is a phenyl derivative, comprises the steps of:

(a) reacting a compound of formula (II):

(II)

wherein R_1 and p are as defined for formula (I), with a compound of formula (III):

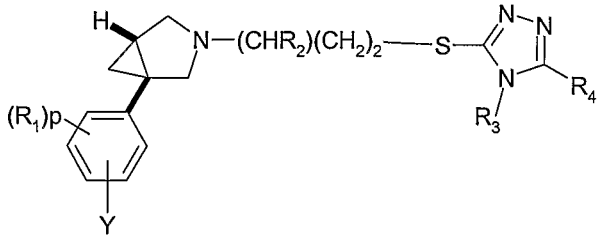

(III)

wherein R_2, R_3 and R_4 are as defined for formula (I) and X is a leaving group,

or

(b) for a compound of formula (I) wherein p is 1 or 2, reacting a compound of formula (IV):

(IV)

wherein R_1, R_2, R_3, and R_4 are as defined for formula (I) , p is 0 or 1 and Y is halogen, a perfluoroalkylsulfonyloxy group (e.g. trifluoromethylsulfonyloxy), or Y is a group M selected from a boron derivative (e.g. a boronic acid function $B(OH)_2$) or a metal function such as trialkylstannyl (e.g. $SnBu_3$), zinc halide or magnesium halide; with a compound R1-Y1, wherein Y1 is halogen when Y is a group M; or when Y is halogen or a perfluoroalkylsulfonyloxy group Y1 is a group M as defined above or hydrogen that can be activated by a suitable base (e.g. Cs_2CO_3) in the presence of a suitable transition metal (e.g. Pd); "leaving group" is as understood by a skilled chemist, i.e. a group which can be displaced by a nucleophile in e.g. a S_N2, S_N1 or S_NAr type reaction;

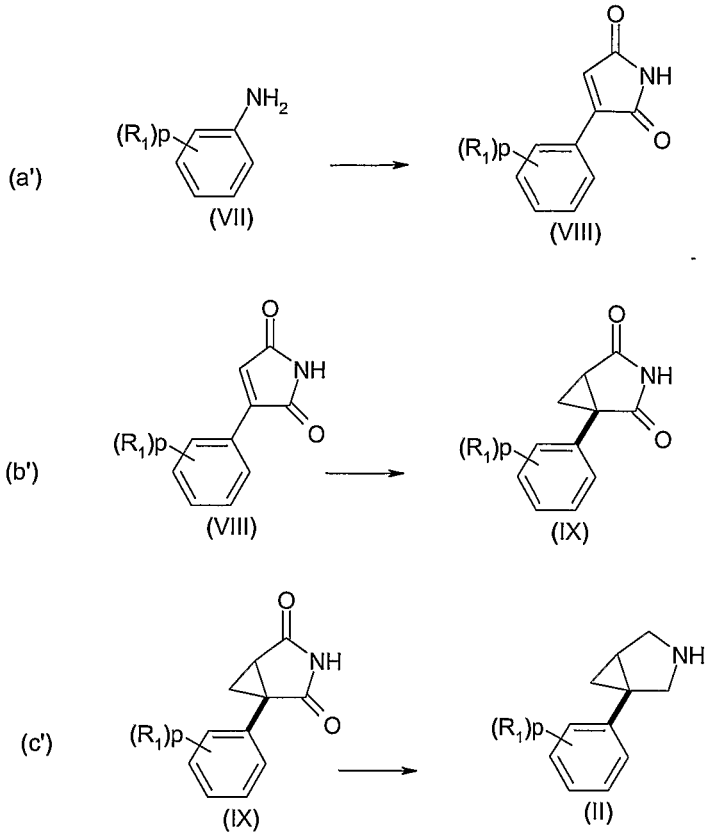

and thereafter optionally for process (a) or process (b):
(i) removing any protecting group(s); and/or
(ii) forming a salt; and/or
(iii) converting a compound of formula (I) or a salt thereof to another compound of formula (I) or a salt thereof.

Process (a) may be performed using conventional methods for the formation of a tertiary amine. The leaving group X can be halogen such as chlorine. Alternatively X can be a sulfonyloxy group such C_{1-4}alkylsulfonyloxy (e.g. methanesulfonyloxy), C_{1-4}alkylsulfonyloxy or haloC_{1-4}alkylsulfonyloxy (e.g. trifluoromethanesulfonyloxy); or arylsulfonyloxy wherein aryl is optionally substituted phenyl, an optionally substituted 5- or 6- membered heteroaromatic group, or an optionally substituted bicyclic group, for example optionally substituted phenyl, wherein in each case the optional substituents are one or more C_{1-2}alkyl groups; e.g. *para*-toluenesulfonyloxy. When X is a halogen the reaction may be carried out using a base such as potassium carbonate in the presence of a source of iodide such as sodium iodide in a solvent such as *N,N*-dimethylformamide at a suitable temperature, e.g. 60 °C.

Compounds of formula (II) may be prepared by methods well known in the art (e.g. *J. Med. Chem.* **1981**, *24*, 481-490). For typical conditions see Preparations 1-6 and 15-18 hereinafter. Interconversion of groups R_1 may be affected by methodology well known in the art (e.g. demethylation of a methoxy group resulting in a hydroxy group using a suitable Lewis acidic reagent such as boron tribromide in an inert solvent such as dichloromethane). Preparations 7-11 hereinafter give additional examples of such interconversions in the presence of a suitable protecting group for the secondary amine, such as *N*-trifluoroacetyl.

Reaction of a compound of formula (IV) with R1-Y1 according to process (b) may be effected in the presence of a transition metal e.g., palladium catalyst such as *bis*-triphenylphosphinepalladium dichloride, *tetrakis*-triphenylphosphinepalladium (0) or the complex formed *in situ* from tris(dibenzylideneacetone) dipalladium(0) and 4,5-bis(diphenylphosphino)-9,9-dimethylxanthene. When M is a boronic acid function such as $B(OH)_2$ the reaction may be carried out under basic conditions, for example using aqueous sodium carbonate in a suitable solvent such as dioxane. When M is trialkylstannyl the reaction may be carried out in an inert solvent, such as xylene or dioxane optionally in the presence of LiCl. When M is a zinc or magnesium halide the reaction may be effected in an aprotic solvent such as tetrahydrofuran. When M is hydrogen that can be activated by a suitable base (e.g. Cs_2CO_3) in the presence of a suitable transition metal (e.g. Pd) the reaction may be carried out in an inert solvent such as dioxane in the presence of a suitable base such as Cs_2CO_3. The substituent Y may be halogen such as bromine, or a sulfonyloxy group such as trifluoromethylsulfonyloxy; and Y1 is may be a group M, such as hydrogen that can be activated by a suitable base (e.g. Cs_2CO_3) in the presence of a suitable transition metal (e.g. Pd).

In one aspect of the present invention there is provided a synthetic process for the preparation of compounds of formula (II). The process may be conveniently performed also for preparing compounds of formula (IIa), in which the phenyl moiety is replaced by pyridine, useful for preparing compounds of formula (IE). This process comprises the following steps:

wherein:

step(a') means diazotation of an aniline (VII) followed by reaction with maleimide to give 3-arylmaleimide (VIII);

step (b') means cycloropanation of (VIII) to provide bicyclic imide (IX);

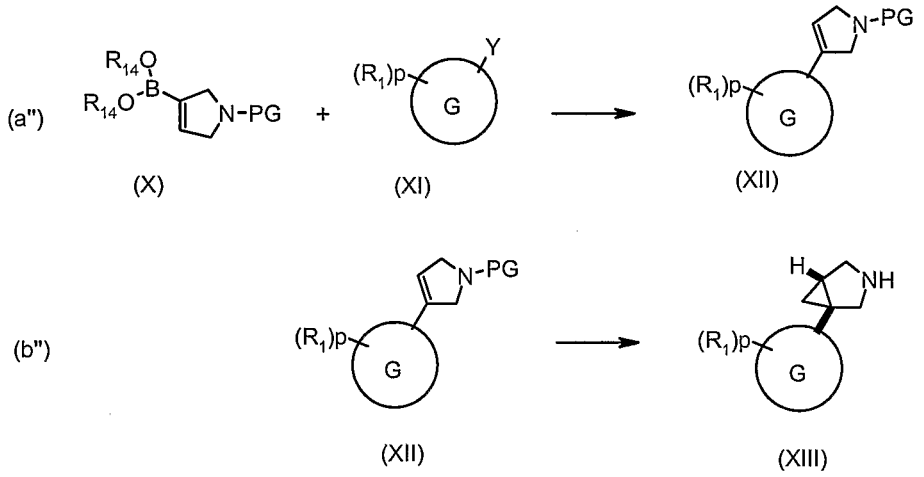

step (c') means reduction of imide (IX) to give compounds of formula (II).

Step (a') may be effected using conventional methods for the Meerwein reaction (*e.g. J. Am. Chem. Soc.* **1955**, *77*, 2313 describes the formation of arylmaleimides using this approach). Alternatively, in many cases this step is suitably performed applying a procedure where to a mixture of maleimide, an apropriate copper (II) salt such as anhydrous $CuCl_2$, and a suitable organonitrite, such as *tert*-butyl nitrite, in a compatible solvent, such as acetonitrile, is slowly added a solution of a compound of formula (VII). This is followed by allowing time to react as appropriate and a suitabe workup. Preparation 37 exemplifies this process.

Step (b') consists of slow addition of a solution of purified compound of formula (VIII), or mixtures containing a compound of formula (VIII), dissolved in a suitable solvent such as dimethylsulfoxide, to a solution of trimethylsulfoxonium iodide in a suitable solvent such as dimethylsulfoxide and a suitable base, such as sodium hydride. This is followed by allowing time to react as appropriate and a suitabe workup. Preparation 37 exemplifies this process.

Step (c') can be performed using a suitable reducing agent in a compatible solvent, such as borane in tetrahydrofuran or Red-Al® in toluene at an appropriate temperature, such as for example 65 °C in the case of borane as the reducing agent. This is followed by a suitabe workup. Preparation 38 exemplifies this process.

In another aspect of the present invention an alternative synthetic process for the preparation of compounds of formula (II), or generally of formula (XIII), is provided. This process comprises the following steps:

wherein:

R_1, p and G are as defined for formula (I), $R_{14}O$ is a suitable alkoxy group, PG is an appropriate protecting group and Y may be halogen such as bromine, or a sulfonyloxy group such as trifluoromethylsulfonyloxy and comprising the following steps:

step (a") means coupling reaction of a (2,5-dihydro-1H-pyrrol-3-yl)boronate (X) with the aromatic halogen or sulfonyloxy derivative (XI);

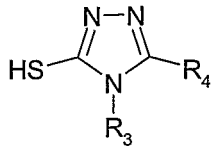

step (b") means cycloropanation of (XII) followed by, if appropriate, deprotection to provide bicyclic amine (XIII).

Step (a") may be effected using conventional methods for the Suzuki coupling, e.g. using tetrakis(triphenylphosphine)palladium(0) as the source of catalytic palladium(0) in the presence of cesium fluoride in an appropriate solvent such as tetrahydrofuran at a suitable temperature. $(R_{14}O)_2B$ may suitably be 4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-

yl and PG benzyl, representing a compound of structure (X) as reported in *Synlett* **2002,** *5*, 829-831. Preparation 50 exemplifies this process.

Step (b") consists of a cyclopropanation reaction effected for example using the reagent generated from trimethylsulfoxonium iodide and a suitable base such as sodium hydride, in a compatible solvent, for example dimethylsulfoxide. Preparation 52 exemplifies this process. This is followed by a deprotection reaction as exemplified in Preparation 54.

A compound of formula (III) may itself be prepared by reacting a compound of formula (V):

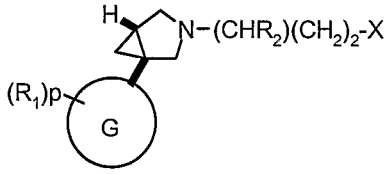

(V)

wherein R_3 and R_4 are as hereinbefore defined; with a compound of formula (VI):

$$L(CHR_2)(CH_2)_2\,X \quad (VI)$$

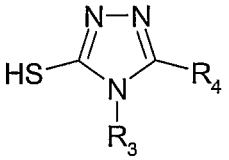

wherein X is defined as for formula (I) and L is a leaving group, e.g., a bromine atom. For typical reaction conditions, see Preparation 13 hereinafter.

Compounds of formula (I) where R_1, R_2, R_3, R_4, G and p are as above defined may be prepared by reacting a compound of formula (XIV):

(XIV)

wherein R_1, R_2, G and p are as defined for formula (I) and X is a leaving group, with a compound of formula (V):

(V)

wherein R_3 and R_4 are as hereinbefore defined. For typical reaction conditions when X is chlorine see Example 35 or alternatively Examples 41-52.

A compound of formula (XIV) wherein R_1, G and p are as defined for formula (I), X is a leaving group and R_2 is H (hydrogen) can be prepared by alkylation of a compound of formula (XIII) in the presence of a suitable base such as a tertiary amine, for example

diisopropylethylamine, with a propyl derivative carrying two leaving groups of preferrably differential reactivity in positions 1 and 3, for example 1-bromo-3-chloropropane. Typical reaction conditions for this transformation are given in Preparation 40.

A compound of formula (XIV) wherein R_1, G and p are as defined for formula (I), X is a leaving group and R_2 is C_{1-4}alkyl can be prepared by the reaction between a beta-hydroxy ketone, for example 4-hydroxy-2-butanone if R_2 is methyl, with a compound of formula (XIII) in the presence of a suitable borohydride source such as $NaBH(OAc)_3$, followed by conversion of the hydroxyl group into a leaving group by methods known to the person skilled in the art, for example by the action of thionyl chloride. Typical reaction conditions for these transformations are given in Preparations 19 and 20.

Interconversion reactions between compounds of formula (I) and salts thereof may be performed using methods well known in the art. Examples include:
(i) converting one or more of R_1 from alkoxy (e.g.methoxy) to hydroxy,
(ii) converting one or more of R_1 from hydroxy to sulfonyloxy, such as alkylsulfonyloxy or haloalkylsulfonyloxy, e.g. methanesulfonyloxy or alkylsulfonyloxy or trifluoro-methanesulfonyloxy,
(iii) converting one or more of R_1 from halogen or perfluoroalkylsulfonyloxy to cyano;
and optionally thereafter forming a salt of formula (I).

Compounds of formula (I) have been found to exhibit affinity for dopamine receptors, in particular the D_3 receptor, and are expected to be useful in the treatment of disease states which require modulation of such receptors, such as psychotic conditions.
Such affinity is typically calculated from the IC_{50} as the concentration of a compound necessary to displace 50% of the radiolabeled ligand from the receptor, and is reported as a "K_i" value calculated by the following equation:

$$K_i = \frac{IC_{50}}{1 + L / K_D}$$

where L = radioligand and K_D = affinity of radioligand for receptor (Cheng and Prusoff, *Biochem. Pharmacol.* 22:3099, 1973).

In the context of the present invention pKi (corresponding to the antilogarithm of Ki) is used instead of Ki and the compounds of the present invention typically show pKi greater than 7. In one aspect the present invention provides compounds of formula (I) having a pKi comprised between 7 and 8. In another aspect the present invention provides compounds of formula (I) having a pKi comprised between 8 and 9. In a further aspect the present invention provides compounds of formula (I) having a pKi greater than 9.

Many of the compounds of formula (I) have also been found to have greater affinity for dopamine D_3 than for D_2 receptors. The therapeutic effect of currently available

antipsychotic agents (neuroleptics) is generally believed to be exerted via blockade of D_2 receptors; however this mechanism is also thought to be responsible for undesirable extrapyramidal side effects (eps) associated with many neuroleptic agents. It has been suggested that blockade of the recently characterised dopamine D_3 receptor may give rise to beneficial antipsychotic activity without significant eps. (see for example Sokoloff et al, Nature, 1990; 347: 146-151; and Schwartz et al, Clinical Neuropharmacology, Vol 16, No.4, 295-314, 1993). In one embodiment compounds of the present invention are provided which have higher (e.g. ≥10x or ≥100x higher) affinity for dopamine D_3 than dopamine D_2 receptors (such affinity can be measured using standard methodology for example using cloned dopamine receptors – see herein). Said compounds may suitably be used as selective modulators of D_3 receptors.

From the localisation of D_3 receptors, it could also be envisaged that the compounds could also have utility for the treatment of substance abuse where it has been suggested that D_3 receptors are involved (e.g. see Levant, 1997, Pharmacol. Rev., 49, 231-252). Examples of such substance abuse include alcohol, cocaine, heroin and nicotine abuse. Other conditions which may be treated by the compounds include dyskinetic disorders such as Parkinson's disease, neuroleptic-induced parkinsonism and tardive dyskinesias; depression; anxiety, cognitive impairment including memory disorders such as Alzheimers disease, eating disorders, sexual dysfunction, sleep disorders, emesis, movement disorders, obsessive-compulsive disorders, amnesia, aggression, autism, vertigo, dementia, circadian rhythm disorders and gastric motility disorders e.g. IBS.

Compounds of formula (I) may be used for treatment of all aspects of drug dependency including withdrawal symptoms from drugs of abuse such as alcohol, cocaine, opiates, nicotine, benzodiazepines and inhibition of tolerance induced by opioids. In addition, compounds of formula (I) and pharmaceutically acceptable salts and solvates thereof may be used to reduce craving and therefore will be useful in the treatment of drug craving. Drug craving can be defined as the incentive motivation to self-administer a psychoactive substance that was previously consumed. Three main factors are involved in the development and maintenance of drug craving: (1) Dysphoric states during drug withdrawal can function as a negative reinforcer leading to craving; (2) Environmental stimuli associated with drug effects can become progressively more powerful (sensitization) in controlling drug seeking or craving, and (3) A cognition (memory) of the ability of drugs to promote pleasurable effects and to alleviate a dysphoric state during withdrawal. Craving may account for the difficulty that individuals have in giving up drugs of abuse and therefore contributes significantly to the development and maintenance of drug dependence.

The compounds of formula (I) are of potential use as antipsychotic agents for example in the treatment of schizophrenia, schizo-affective disorders, psychotic depression, mania, paranoid and delusional disorders. Furthermore, they could have utility as adjunct therapy in Parkinsons Disease, particularly with compounds such as L-DOPA and possibly

dopaminergic agonists, to reduce the side effects experienced with these treatments on long term use (e.g. see Schwartz et al., Brain Res. Reviews, 1998, 26, 236-242).

Such conditions in particular include psychoses/psychotic conditions such as schizophrenia, and substance abuse.

The invention also provides the use of a compound of formula (I) or a pharmaceutically acceptable salt thereof in the manufacture of a medicament for the treatment of a condition in a mammal for which modulation (especially antagonism/inhibition) of dopamine receptors (especially dopamine D_3 receptors) is beneficial.

The invention also provides a compound of formula (I) or a pharmaceutically acceptable salt thereof for use in the treatment of a condition in a mammal for which modulation (especially antagonism/inhibition) of dopamine receptors (especially dopamine D_3 receptors) is beneficial.

In one embodiment, D_3 antagonists according to the present invention are used in the treatment of psychoses such as schizophrenia or in the treatment of substance abuse.

Thus, a still further aspect the invention provides a method of treating a psychotic condition (e.g. schizophrenia) or substance abuse which comprises administering to a mammal (e.g. human) in need thereof an effective amount of a compound of formula (I) as herein defined or a pharmaceutically acceptable salt thereof.

Also provided is the use of a compound of formula (I) or a pharmaceutically acceptable salt thereof in the manufacture of a medicament for the treatment of a psychotic condition (e.g. schizophrenia) or substance abuse in a mammal.

Also provided is a compound of formula (I) or a pharmaceutically acceptable salt thereof for use in the treatment of a psychotic condition (e.g. schizophrenia) or substance abuse in a mammal.

Also provided is a compound of formula (I) or a pharmaceutically acceptable salt thereof for use as an active therapeutic substance in a mammal, e.g. for use in the treatment of any of the conditions described herein.

"Treatment" includes prophylaxis, where this is appropriate for the relevant condition(s).

For use in medicine, the compounds of the present invention are usually administered as a standard pharmaceutical composition. The present invention therefore provides in a further aspect a pharmaceutical composition comprising a compound of formula (I) or a pharmaceutically (i.e physiologically) acceptable salt thereof and a pharmaceutically (i.e physiologically) acceptable carrier. The pharmaceutical composition can be for use in the treatment of any of the conditions described herein.

The compounds of formula (I) may be administered by any convenient method, for example by oral, parenteral (e.g. intravenous), buccal, sublingual, nasal, rectal or transdermal administration and the pharmaceutical compositions adapted accordingly.

The compounds of formula (I) and their pharmaceutically acceptable salts which are active when given orally can be formulated as liquids or solids, for example syrups, suspensions or emulsions, tablets, capsules and lozenges.

A liquid formulation will generally consist of a suspension or solution of the compound or pharmaceutically acceptable salt in a suitable liquid carrier(s) for example an aqueous solvent such as water, ethanol or glycerine, or a non-aqueous solvent, such as polyethylene glycol or an oil. The formulation may also contain a suspending agent, preservative, flavouring or colouring agent.

A composition in the form of a tablet can be prepared using any suitable pharmaceutical carrier(s) routinely used for preparing solid formulations. Examples of such carriers include magnesium stearate, starch, lactose, sucrose and cellulose.

A composition in the form of a capsule can be prepared using routine encapsulation procedures. For example, pellets containing the active ingredient can be prepared using standard carriers and then filled into a hard gelatin capsule; alternatively, a dispersion or suspension can be prepared using any suitable pharmaceutical carrier(s), for example aqueous gums, celluloses, silicates or oils and the dispersion or suspension then filled into a soft gelatin capsule.

Typical parenteral compositions consist of a solution or suspension of the compound or pharmaceutically acceptable salt in a sterile aqueous carrier or parenterally acceptable oil, for example polyethylene glycol, polyvinyl pyrrolidone, lecithin, arachis oil or sesame oil. Alternatively, the solution can be lyophilised and then reconstituted with a suitable solvent just prior to administration.

Compositions for nasal administration may conveniently be formulated as aerosols, drops, gels and powders. Aerosol formulations typically comprise a solution or fine suspension

of the active substance in a pharmaceutically acceptable aqueous or non-aqueous solvent and are usually presented in single or multidose quantities in sterile form in a sealed container, which can take the form of a cartridge or refill for use with an atomising device. Alternatively the sealed container may be a unitary dispensing device such as a single dose nasal inhaler or an aerosol dispenser fitted with a metering valve which is intended for disposal once the contents of the container have been exhausted. Where the dosage form comprises an aerosol dispenser, it will contain a propellant which can be a compressed gas such as compressed air or an organic propellant such as a fluoro-chlorohydrocarbon. The aerosol dosage forms can also take the form of a pump-atomiser.

Compositions suitable for buccal or sublingual administration include tablets, lozenges and pastilles, wherein the active ingredient is formulated with a carrier such as sugar and acacia, tragacanth, or gelatin and glycerin.

Compositions for rectal administration are conveniently in the form of suppositories containing a conventional suppository base such as cocoa butter.

Compositions suitable for transdermal administration include ointments, gels and patches.

In one embodiment, the composition is in unit dose form such as a tablet, capsule or ampoule.

Each dosage unit for oral administration contains for example from 1 to 250 mg (and for parenteral administration contains for example from 0.1 to 25 mg) of a compound of the formula (I) or a pharmaceutically acceptable salt thereof calculated as the free base.

The pharmaceutically acceptable compounds of the invention will normally be administered in a daily dosage regimen (for an adult patient) of, for example, an oral dose of between 1 mg and 500 mg, for example between 10 mg and 400 mg, e.g. between 10 and 250 mg or an intravenous, subcutaneous, or intramuscular dose of between 0.1 mg and 100 mg, for example between 0.1 mg and 50 mg, e.g. between 1 and 25 mg of the compound of the formula (I) or a pharmaceutically acceptable salt thereof calculated as the free base, the compound being administered 1 to 4 times per day. Suitably the compounds will be administered for a period of continuous therapy, for example for a week or more.

Biological Test Methods

Functional potency and intrinsic activity of compounds of this invention can be measured by the following GTPγS scintillation proximity assay (GTPγS-SPA). Cells used in the study are Chinese Hamster Ovary (CHO) Cells.

Cell Line
CHO_D2
CHO_D3

Cell membranes are prepared as follows. Cell pellets are resuspended in 10 volumes of 50mM HEPES, 1mM EDTA pH 7.4, using KOH. On the day the following proteases are added to the buffer just prior to giving the homogenisation buffer.

10^{-6}M Leupeptin (Sigma L2884) - 5000 x stock = 5 mg/ml in buffer
25ug/ml Bacitracin (Sigma B0125) - 1000 x stock = 25 mg/ml in buffer
1mM PMSF - 1000 x stock = 17 mg/ml in 100% ethanol
$2x10^{-6}$M Pepstain A - 1000 x stock = 2 mM in 100% DMSO

The cells are homogenised by 2 x 15 second bursts in a 1 litre Glass Waring blender in a class two biohazard cabinet. The resulting suspension is spun at 500g for 20 mins (Beckman T21 centrifuge: 1550 rpm). The supernatant is withdrawn with a 25 ml pipette, aliquotted into pre-chilled centrifuge tubes and spun at 48,000g to pellet membrane fragments (Beckman T1270: 23,000 rpm for 30mins). The final 48,000g pellet is resuspended in Homogenisation Buffer, (4 x the volume of the original cell pellet). The 48,000g pellet is resuspended by vortexing for 5 seconds and homogenized in a dounce homogenizer 10–15 stokes. The prep is distributed into appropriate sized aliquots, (200-1000ul), in polypropylene tubes and store at -80^0 C. Protein content in the membrane preparations is evaluated with the Bradford protein assay.

The final top concentration of test drug is 3uM in the assay and 11 points serial dilution curves 1:4 in 100% DMSO are carried out using a Biomek FX. The test drug at 1% total assay volume (TAV) is added to a solid, white, 384 well assay plate. 50%TAV of precoupled (for 90 mins at 4°C) membranes, 5µg/well, and Wheatgerm Agglutinin Polystyrene Scintillation Proximity Assay beads (RPNQ0260, Amersham), 0.25mg/well, in 20mM HEPES pH 7.4, 100mM NaCl, 10mM $MgCl_2$, 60µg/ml saponin and 30µM GDP is added. The third addition was a 20% TAV addition of either buffer, (agonist format) or EC_{80} final assay concentration of agonist, Quinelorane, prepared in assay buffer (antagonist format). The assay was started by the addition of 29%TAV of GTPγ[^{35}S] 0.38nM final (37MBq/ml, 1160Ci/mmol, Amersham). After all additions assay plates are spun down for 1 min at 1,000rpm. Assay plates are counted on a Viewlux, 613/55 filter, for 5 min., between 2-6 hours after the final addition.

The effect of the test drug over the basal generates EC_{50} value by an iterative least squares curve fitting programme, expressed in the table as pEC_{50} (i.e. $-logEC_{50}$). The ratio between the maximal effect of the test drug and the maximal effect of full agonist, Quinelorane, generates the Intrinsic Activity (IA) value (i.e. IA = 1 full agonist, IA < 1 partial agonist). fpKi values of test drug are calculated from the IC_{50} generated by

"antagonist format" experiment, using Cheng & Prusoff equation: fKi = IC_{50} / 1+([A] / EC_{50}) where: [A] is the concentration of the agonist 5-HT in the assay and EC_{50} is the 5-HT EC_{50} value obtained in the same experiment. fpKi is defined as -logfKi.

The compounds of the invention listed above have pKi values within the range of 7.0-10.5 at the dopamine D3 receptor. pKi results are only estimated to be accurate to about ±0.3-0.5.

The compounds of the invention listed above have a selectivity over D2 greater than 30.

Examples

The invention is further illustrated by the following non-limiting examples. Preparations 1 to 5 were carried out in analogy to the synthetic route described in *J.Med.Chem.* 1981, *24*, 481-490.

All temperatures refer to °C. Infrared spectra were measured on a FT-IR instrument. Compounds were analysed by direct infusion of the sample dissolved in acetonitrile into a mass spectra operated in positive electro spray (ES+) ionisation mode. Proton Magnetic Resonance (^{1}H-NMR) spectra were recorded at 400 MHz, chemical shifts are reported in ppm downfield (d) from Me_4Si, used as internal standard, and are assigned as singlets (s), broad singlets (bs), doublets (d), doublets of doublets (dd), triplets (t), quartets (q) or multiplets (m).

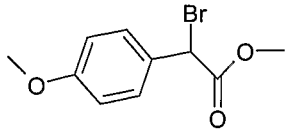

Experimental vibrational circular dichroism (VCD) spectra were measured using a ChiralIRTM VCD spectrometer operating in the 2000-800 cm-1 frequency range. Spectra were measured at room temperature (23o C) using a sealed transmission cell with barium fluoride windows and a path length of 100 microns. (Scan times varied from 60 to 120 minutes per isomer.) Sample solutions were typically prepared by dissolving 10 milligrams of each enantiomer in 100 microliters of deutero-chloroform ($CDCl_3$). For ab initio assignments, VCD and unpolarized IR spectra were calculated using the Gaussian 98 software package.1.

Optical rotations were measured using a (Perkin Elmer Model 241) polarimeter operating at 589 nm (Sodium source). Measurements were made using a 1 decimeter microcell thermostated at 23o C. Concentrations were typically 10 mg/ml (c=0.01). For ab initio OR assignments, the Dalton Quantum Chemistry Program was used.

Preparation 14: 3-[(3-Chloropropyl)thio]-4-methyl-5-(4-methyl-1,3-oxazol-5-yl)-4*H*-1,2,4-triazole

Ethyl-2-chloroacetoacetate (1 wt; 1 eq., 1000 g) was aged with formamide (0.68 vol; *ca.* 2.8 eq.) and the resulting solution was heated to 120 °C. After 5 hours the mixture was allowed to cool to room temperature and allowed to age under nitrogen over night. The mixture was treated with NaOH (3 M, 6 vol, reaction moderately exothermic) and stirred at room temperature for 4 hours. Ethyl acetate (6 vol) was added and the phases allowed to

separae. The organic layer was discarded while the aqueous was acidified with conc. (32%) aqueous HCl to pH 2 (*ca.* 2.0 vol). A precipitate started to form. The suspension was treated with AcOEt (8 vol) and vigorously stirred until the bulk of the precipitate had dissolved. The aqueous phase was further extracted with AcOEt twice (6 vol each) and the combined organic layers distilled to low volume (again a suspension was observed at low volume). Fresh AcOEt (8 vol) was added and the mixture evaporated to dryness. The collected solid was placed in the oven at 40 °C over night under reduced pressure to give 4-methyl-1,3-oxazole-5-carboxylic acid (498 g, 64.5%).

This material (498 g, 1 wt) was dissolved in dry tetrahydrofuran (5 vol), under nitrogen, cooled to 0 °C. DCC (1.62 wt, 1 eq) was added portionwise followed by HOBt (1.07 wt, 1 eq). The mixture was warmed to 25±2 °C and stirred for 30 min. 4-Methyl-3-thiosemicarbazide (0.83 wt, 1 eq) was then added and the mixture further stirred for 2 h at 25±2°C. The mixture was filtered and the cake was washed with fresh tetrahydrofuran (1 vol) and dried on the filter for a few hours. The cake was suspended in 1 M aqueous NaOH (13 vol) and heated to 70 °C for 30 min. After this time, the mixture was cooled to 25±2 °C and a solid was removed by filtration. The cake was washed with 1 M aqueous NaOH (10 vol). The combined mother liquors were cooled to 0 °C and acidified to ca. pH 5 with HCl (aqueous, 16%; NOTE: keep temperature while adding HCl below +10 °C). The suspended product was isolated by filtration washing with water (2x3 vol). The cake was dried at 40 °C for 18 h in high vacuum to obtain 4-methyl-5-(4-methyl-1,3-oxazol-5-yl)-2,4-dihydro-3*H*-1,2,4-triazole-3-thione (respectively a tautomeric form thereof; 290 g, 37%).

NaOEt (21% solution in EtOH, 2.08 vol, 1.1 eq) was added to EtOH (20 vol) under nitrogen atmosphere. 4-Methyl-5-(4-methyl-1,3-oxazol-5-yl)-2,4-dihydro-3*H*-1,2,4-triazole-3-thione (respectively a tautomeric form thereof; 290 g, 1 wt) was added in one portion and the resulting mixture stirred at 25±2°C until a clear solution was obtained. Then 1-bromo-3-chloropropane (0.54 vol, 1.1 eq) was added and the solution stirred at 40 'C for 24 h then cooled to 25 'C. After filtration water (20 vol) was added and the ethanolic phase was removed by vacuum distillation (internal temperature ~40 'C). The mixture was extracted with EtOAc (41 vol). The aqueous layer was removed and the organic phase was evaporated to dryness. Dichloromethane (4 vol) was added. The organic solution is purified through a short silica gel column (18 wt of silica), eluting with EtOAc (200 vol) to give the title compound as a solid foam (267.64 g, 66%).

NMR (^{1}H, $CDCl_3$): δ 7.90 (s, 1H), 3.70 (s, 5H), 3.40 (t, 2H), 2.52 (s, 3H), 2.30 (m, 2H).

Preparation 15: 3-[4-(Trifluoromethyl)phenyl]-1*H*-pyrrole-2,5-dione

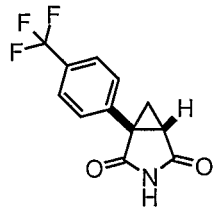

A mixture of hydrochloric acid (37%, 285 mL) and water (190 mL) was added to 4-(trifluoromethyl)aniline (150 g, 116 mL) at room temperature with vigorous stirring and the formed precipitate was allowed to stir for further 30 minutes. Temperature was reduced to 0 °C and sodium nitrite (70.6 g) in 180 mL of water was added dropwise to the stirred suspension. At the end of diazotisation, a clear yellow solution was obtained. Maleimide (180 g) in acetone (1.1 l) was added dropwise at 0 °C and then the pH of the solution was adjusted to 3-3.5 by adding sodium acetate. Copper (II) chloride (18.8 g) was added to the vigorously stirred mixture. After a few minutes a gas started to develop (conspicuous foaming). The reaction mixture was allowed to stir at 0 °C for 1 h and overnight at room temperature.

Acetone was removed *in vacuo*, the residue was filtered and dried overnight *in vacuo* to give the title compound (155 g) as a light brown solid (y = 63%).

Milled sodium hydroxide (40 g) was added in small portions to a stirred solution of trimethylsulfoxonium iodide (219 g) in DMSO (anhydrous, 2 l). The resulting mixture was allowed to stir at room temperature for 1.5 h.

3-[4-(Trifluoromethyl)phenyl]-1*H*-pyrrole-2,5-dione (Preparation 15, 120 g) dissolved in DMSO (anhydrous, 0.5 l) was then added dropwise and the resulting mixture was allowed to stir at room temperature for 20 minutes. Temperature was then reduced to 0 °C and NH_4Cl (aqueous saturated solution, 2 l) was slowly added, followed by Et_2O (1 l). After separation of the two phases, the aqueous layer was repeatedly extracted with Et_2O (3 x 1 l). Combined organic layers were washed with brine (2 x 1 l) and then dried over Na_2SO_4. Evaporation of the solvent gave a light brown solid which was suspended in 1 l of dichloromethane and 1 l of cyclohexane. Preparation 32: (*1S,5R*)-1-(4-Bromophenyl)-3-azabicyclo[3.1.0]hexane

(S)(+)–Acetyl mandelic acid (3.22 g) was added in portions to a stirred solution of (1*R*,5*S*/1*S*,5*R*)-1-[4-bromophenyl]-3-azabicyclo[3.1.0]hexane (Preparation 6, 3.96 g) in 80 mL of IPA. The resulting mixture was stirred at room temperature for 2 h until a white precipitate was formed. The mixture was then warmed up to reflux temperature, stirred for 45 minutes and then slowly allowed to cool to room temperature. The white solid was collected by filtration and dried *in vacuo*. This material was recrystallised 4 times from IPA (10 volumes) to give 2.3 g of a white solid.

This material was then suspended in sodium hydroxide (1M aqueous solution, 400 mL) and Et_2O (400 mL) and allowed to stir at room temperature until complete dissolution. After separation of the two phases, the aqueous layer was extracted again with Et_2O (3 x 250 mL). Combined organic layers were washed with sodium hydroxide (1M solution, 3 x 200 mL) and then dried over Na_2SO_4. Evaporation of solvent *in vacuo* gave the title compound (1.24 g) as white solid.

The absolute configuration of the optical isomers was assigned as described for Preparation 18.

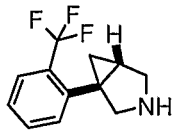

The assignment of the absolute configuration of the title compound was confirmed by a single crystal X-ray structure obtained from a crystal of (1*S*,5*R*)-1-(4-bromophenyl)-3-azabicyclo[3.1.0]hexane, (*S*)-(+)-*O*-acetyl mandelic acid salt. Both, analysis based on the known configuration of the (S)(+)–acetyl mandelic acid and on the basis of anomalous dispersion effects confirmed the assignment of the title compound as being (1S,5R)-1-(4-bromophenyl)-3-azabicyclo[3.1.0]hexane.

NMR (^{1}H, CD_3OD): δ 8.37 (s, 1H), 7.8 (d, 2H), 7.43 (d, 2H), 6.55 (s, 1H), 4.16/3.88 (2d, 2H), 3.78 (s, 3H), 3.7 (m, 2H), 3.48-3.4 (2t, 4H), 2.48 (s, 3H), 2.45 (s, 3H), 2.29 (m, 3H), 1.51/1.37 (2t, 2H). **MS (*m/z*):** 477.2[MH]$^+$.

Example 14: (1*S*,5*R*)-3-(3-{[4-Methyl-5-(4-methyl-1,3-oxazol-5-yl)-4*H*-1,2,4-triazol-3-yl]thio}propyl)-1-[4-(trifluoromethyl)phenyl]-3-azabicyclo[3.1.0]hexane

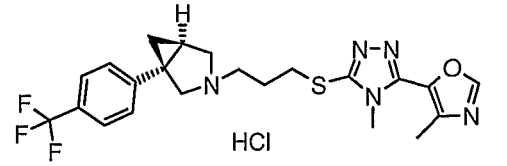

A mixture of (1*S*,5*R*)-1-[4-(trifluoromethyl)phenyl]-3-azabicyclo[3.1.0]hexane (Preparation 18, 10.4 g), 3-[(3-chloropropyl)thio]-4-methyl-5-(4-methyl-1,3-oxazol-5-yl)-4*H*-1,2,4-triazole (Preparation 14, 15.0 g), K_2CO_3 (7.5 g) and NaI (8.23 g) in DMF (anhydrous, 100 mL) were heated at 60 °C for 15 h. The mixture was then allowed to cool to room temperature, diluted with Et_2O (250 mL) and water (200 mL). After separation of the two phases, the aqueous layer was extracted again with Et_2O (2 x 200 mL). The combined organic layers were washed with water (2 x 150 mL) and then dried over Na_2SO_4. After evaporation of the solvent *in vacuo*, the crude product was purified by flash chromatography (dichloromethane to 10% MeOH in dichloromethane) to give 16.5 g of a yellow solid. The material thus obtained was triturated with Et_2O to provide the title compound (13 g) as white solid (y = 61%).

Assignment of the configuration of the title compound is based on two lines of evidence: The fact that it was prepared from (1*S*,5*R*)-1-[4-(trifluoromethyl)phenyl]-3-azabicyclo[3.1.0]hexane (of known configuration, see Preparation 14) and by comparison with the spectroscopic data obtained for (1S,5R)-1-[4-(trifluoromethyl)-phenyl]-3-azabicyclo[3.1.0]hexane: Bands in the VCD spectrum of the title compound are coincident with the corresponding bands in the spectrum of (1*S*,5*R*)-1-[4-(trifluoromethyl)phenyl]-3-azabicyclo[3.1.0]hexane, additionally the sign of the specific rotation is the same for both compounds.

Hydrochloric acid (1M solution in Et_2O, 19.4 mL) was added dropwise under N_2 to a solution of (1*S*,5*R*)-3-(3-{[4-methyl-5-(4-methyl-1,3-oxazol-5-yl)-4*H*-1,2,4-triazol-3-

yl]thio}propyl)-1-[4-(trifluoromethyl)phenyl]-3-azabicyclo[3.1.0]hexane (Example 14, 9 g) in Et_2O (anhydrous, 135 mL). The resulting suspension was allowed to stir at room temperature for 2 h. The solid was then filtered, washed with Et_2O and dried *in vacuo* overnight to provide the title compound (8.9 g) as off white solid (y = 92%).

After elimination of the solvent under *vacuo*, the residue was dissolved in ethyl acetate and the organic layer was washed with saturated aqueous $NaHCO_3$ and dried over Na_2SO_4. This solution was filtered and the filtrate was concentrated *in vacuo*. The crude was purified by flash chromatography (dichloromethane to 10% MeOH in dichloromethane) to give 940 mg of the free base of the title compound.

This free base (886 mg) was converted to the hydrochloride salt (847 mg) according to the method described in Example 1. The title compound was obtained as a white solid.

Analytical Chiral HPLC confirmed the product to be identical to Enantiomer 2 of Example 16.

NMR and MS data corresponded to those reported for Example 16.

The absolute configuration of the title compound was confirmed using comparative VCD and comparative OR analyses of the corresponding free base to be (1*S*,5*R*)-1-[2-fluoro-4-(trifluoromethyl)phenyl]-3-(3-{[4-methyl-5-(4-methyl-1,3-oxazol-5-yl)-4*H*-1,2,4-triazol-3-yl]thio}propyl)-3-azabicyclo[3.1.0]hexane. (1*S*,5*R*)-3-(3-{[4-Methyl-5-(4-methyl-1,3-oxazol-5-yl)-4*H*-1,2,4-triazol-3-yl]thio}propyl)-1-[4-(trifluoromethyl)phenyl]-3-azabicyclo[3.1.0]hexane (see Example 14) was used used as the reference.

Specific Optical Rotation of the corresponding free base: $[\alpha]_D$ = - 42 ° ($CDCl_3$, T = 25 °C, c ≅ 0.005 g/0.8 mL).

Examples 41-52:

To a solution of the respective 3-thio-5-aryl-1,2,4-triazole (prepared in analogy to the method described in Preparation 13, 0.131 mmol) in dry acetonitrile (2 mL) 2-*tert*-butylimino-2-diethylamino-1,3-dimethyl-perhydro-1,3,2-diaza-phosphorine on polystyrene (90 mg, 2.2 mmol/g) was added and the resulting mixture was shaken for 30 minutes at room temperature. (1*S*,5*R*)-3-(3-Chloropropyl)-1-[4-(trifluoromethyl)phenyl]-3-azabicyclo[3.1.0]hexane (40 mg) was added and the resulting mixture was shaken at 70 °C for three hours. After cooling the resin was removed by filtration, washed with methanol (2 mL), and then the solvent was removed under reduced pressure. Purifications were carried out using mass directed HPLC using a Waters XTerra Prep MS C18 10µm, 30x150 mm column using the following conditions:

Then solvent was removed under reduced pressure to give title compounds as formate salts.

In the case of **Examples 93** and **94** the isomers were separated by silica gel flash chromatography. The S-alkylated isomers were dissolved in dry diethyl ether and cooled at 0 °C. 1.2 eq of HCl (as 1.0 M solution in diethyl ether) were slowly added. The resulting precipitate was decanted, washed with pentane and filtered, yielding the products as the hydrochloride salts.

NMR (corresponding free base, ^{1}H, CD_3OD): δ 8.71 (s, 1H), 7.93 (s, 1H), 7.78 (dd, 1H), 7.15 (d, 1H), 3.72 (s, 3H), 3.41 (d, 1H), 3.36 (t, 2H), 3.13 (d, 1H), 2.8 (d, 1H), 2.68 (m, 2H), 2.54 (s, 3H), 2.48 (dd, 1H), 2.04 (m, 3H), 1.6 (m, 1H), 1.26 (dd, 1H). **MS (*m/z*):** 465 $[MH]^+$.

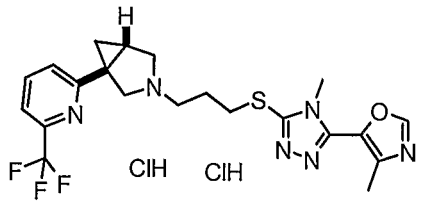

Example 96 was separated to give the separated enantiomers by semi-preparative HPLC using a chiral column Chirapak AD-H 5 µm, 250 x 4.6 mm, eluent A: n-hexane; B: Ethanol + 0.1% isopropylamine, gradient isocratic 30% B v/v, flow rate 6 mL/min, detection UV at 270 nm. Retention times given were obtained using a chiral column Chirapak AD-H 5 µm, 250 x 4.6 mm, eluent A: n-hexane; B: Ethanol, gradient isocratic 30% B v/v, flow rate 0.8 mL/min, detection UV at 200 - 400 nm.

Enantiomer 1 was recovered in 18 mg yield as a white solid, hydrochloride salt from the racemate (70 mg). **Rt.** = 19.09 min. Purity 100% a/a by UV

Enantiomer 2 was recovered in 18 mg yield as white solid, hydrochloride salt from the racemate (70 mg). **Rt.** = 21.6 min. Purity 99% a/a by UV.

Enantiomer 2 showed fpKi (D3) > 1 log-unit higher than Enantiomer 1.

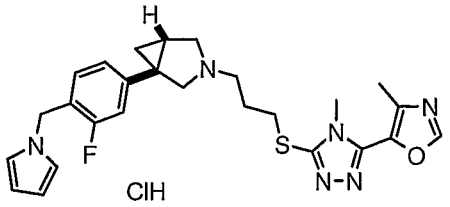

Example 97: 3-(3-{[4-methyl-5-(4-methyl-1,3-oxazol-5-yl)-4*H*-1,2,4-triazol-3-yl]thio}propyl)-(1*R*,5*R/1S,5S*)-1-[6-(trifluoromethyl)-2-pyridinyl]-3-azabicyclo[3.1.0]hexane dihydrochloride

3-(Phenylmethyl)-1-[5-(trifluoromethyl)-2-pyridinyl]-3-azabicyclo[3.1.0]hexane (0.19 mmol) was dissolved in 1,2-dichloroethane (1 mL) and 1-chloroethyl chloridocarbonate was added (0.21 mmol). After two microwave cycles (5 min at 120 °C and 10 min at 140 °C) the solvent was removed at reduced pressure.
