

COMPONENT FOR A HEARING AID AND A METHOD OF MAKING A COMPONENT FOR A HEARING AID

FIELD OF THE INVENTION

The present invention relates to components for hearing aids. The invention further
5 relates to a method for manufacturing a component for a hearing aid.

BACKGROUND OF THE INVENTION

Hearing aids generally include a range of components such as housing, internal
electronic circuitry, lid, switches and buttons.

ITE hearings aids generally comprise a shell, which anatomically duplicates the
10 relevant part of the user's ear canal. A receiver is placed in the shell in communication
with an acoustic outlet port arranged at the proximal end, i.e. the end of the shell
adapted for being situated in the ear canal close to the tympanic membrane. The distal
end of the shell, i.e. the opposite end, intended to be oriented towards the surroundings,
is closed by a faceplate subassembly, connected to the receiver by leads. In one design,
15 the faceplate subassembly incorporates a microphone, electronics, a battery
compartment and a hinged lid. The microphone communicates with the exterior
through a port, which may covered by a grid.

Whereas an ITE hearing aid may be regarded as an earpiece integrating all parts of a
hearing aid, a BTE hearing aid comprises a housing adapted for resting over the pinna
20 of the user and an ear piece adapted for insertion into the ear canal of the user and
serving to convey the desired acoustic output into the ear canal. The earpiece is
connected to the BTE housing by a sound conduit or, in case it houses the receiver, by
electric leads. In either case it has an output port for conveying the sound output.

During normal use, a hearing aid is exposed to environmental factors such as wear,
25 moisture, sweat, ear wax, fungi, bacteria, dirt and water. Some of those factors may
have a corroding influence; others may cause development of an undesired biofilm or
of an otherwise irregular surface patina. Corrosion may be controlled by the selection

of durable materials. However the environmental factors may over time create an unsightly appearance.

WO-A1-00/03561 provides an in-the-ear hearing aid wherein the acoustic outlet port is protected against contamination by earwax by means of an earwax guard, which is inserted in port. An elastic hose connects the port to a receiver. The earwax guard comprises an essentially tubular element with a through-going cavity and an abutment collar in one end for sealing abutment against an edge of the hearing aid housing adjacent the port.

EP-A2-1432285 shows a method for hydrophobic coating of components for a hearing aid in areas of gaps, slits and apertures, such as for the battery lid, the battery compartment, the housing or a switch, for the purpose of ensuring entry of oxygen, which is needed for proper operation of Zn-air batteries, while controlling the entry of liquids. The coating comprises hydrophobic or oleophobic materials applied through immersion or spraying.

DE-A1-102004062279 shows an earwax guard for a hearing aid, which has been provided with an oleophobic or biofilm-inhibiting coating.

EP-A2-1458217 shows an acoustic filter of a hearing instrument, detachably placed nearby or at the opening for the acoustic output of the instrument. The filtering element is made of a polymer material, a synthetic, metallic or ceramic material or a fabric-like material.

EP-A2-1432285 provides a method for hydrophobic coating of a hearing aid for the purpose of preventing entry of moisture into crevices and openings of the housing.

US-3354022 provides a water-repellant surface having high and low portions with an average distance between high portions of not more than 1000 microns and an average height of high portions of at least 0.5 times the average distance between them; and having an air content of at least 60 %. The air content of the surface is determined by taking an imaginary plane parallel to the surface passing through the tops of the high portions of the surface and measuring at this plane the percentage of the total surface

area that is air. The surfaces may be coated with a solid having a water contact angle of greater than 90 degrees. These surfaces are highly water repellant.

WO-A1-0058415 provides a device for the loss-free transport or emptying of hydrophilic liquids, which device has raised areas and cavities on the side facing the liquid, the distance between the raised areas being between 0.1 and 200 microns and the height of said raised areas between 0.1 and 100 microns, and the raised areas being hydrophobic.

SUMMARY OF THE INVENTION

According to one aspect, there is provided a method of manufacturing a component for a hearing aid, comprising providing a slab, processing the surface of the slab with a laser to provide a microstructured surface, which surface comprises peaks and troughs and has an air content of at least 50%, and treating the microstructured surface with a moisture repellent matter.

The disclosure, in another aspect, provides a component for a hearing aid manufactured according to the method of the first aspect.

This provides a component for a hearing aid that has enhanced repellency to moisture and bodily fluids. Components on which this surface would be advantageous comprise housings, casings, shells, faceplates, grids, hooks, lids, battery drawers, buttons and manipulators etc. Suitable substances for the coatings are silanes such as perfluoroalkylsilanes or alkylsilanes. The silanes are chemically attached to the surface by reaction between hydroxy groups on the silane and on the surface, forming a self assembled monolayer (SAM).

According to an embodiment, the component comprises a slab with an exterior surface that has been microstructured. The inventors have discovered that microstructuring of the surface enhances the water repellant properties. The term exterior surface is here used to designate a surface intended for generally facing the environment exterior to the hearing aid, as opposed to a surface intended to face inner parts of the hearing aid.

Further advantageous features appear from the dependent components claims.

The disclosure, in another embodiment, provides a method as recited in claim 7.

This provides a method for manufacturing of components with superior properties with respect to repellency to water and bodily fluids. Components on which this method is

of advantage include housings, casings, shells, faceplates, grids, hooks, lids, battery drawers, buttons and manipulators, etc.

Within the present context surfaces exhibiting a contact angle to water exceeding 120° are termed super-hydrophobic. Suitable surfaces may be produced by selecting appropriate materials and providing a micro-surface structure with high air content.

Still other features and advantages of the present disclosure will become apparent to those skilled in the art from the following description wherein the invention will be explained in greater detail.

BRIEF DESCRIPTION OF THE DRAWINGS

By way of example, there is shown and described a preferred embodiment of this invention. As will be realized, the invention is capable of other different embodiments, and its several details are capable of modification in various, obvious aspects all without departing from the invention. Accordingly, the drawings and descriptions will be regarded as illustrative in nature and not as restrictive. In the drawings:

- Fig. 1 shows an ITE hearing aid;
- Fig. 2 shows a BTE hearing aid according to a first embodiment, in perspective;
- Fig. 3 shows a BTE hearing aid according to a second embodiment;
- Fig. 4 shows the BTE hearing aid of Fig. 3 in rear view;
- Fig. 5 shows a section of a droplet on a surface exhibiting a small contact angle;
- Fig. 6 shows a section of a droplet on a surface exhibiting a large contact angle;
- Fig. 7 shows a plan view of a slab for a component according to an embodiment of the invention; and
- Fig. 8 shows a section in a slab for a component according to another embodiment of the invention.

DETAILED DESCRIPTION

Reference is first made to fig. 1, which illustrates an ITE hearing aid 1, generally comprising a shell 2, a faceplate 3, a lid 5, a sound inlet port 6 and a sound output port 7. The hearing aid 1 is adapted to be positioned in the auditory canal of a user with the sound output port 7 facing the user's tympanic membrane. Fig. 1 also shows a push button 4 arranged in the lid. The push button serves to allow the user to input commands, e.g. stepping through different programs to enter a selected one.

Fig. 2 shows a BTE hearing aid 19 according to a first embodiment, this embodiment being essentially styled with hook and casing in one integral piece. This embodiment also has battery drawer 15 with battery drawer protrusion 16, and battery drawer nose 17. The Fig. 2 embodiment features a lock gripping portion 18, which is a manipulator that must be engaged by the tip of a nail or a pencil to permit opening the drawer for removal of the battery. For further details about these details reference may be had to WO-A1-2004073351.

Reference is now made to Fig. 3 and Fig. 4 for an explanation of a BTE hearing aid according to a second embodiment according to the invention.

Fig. 3 illustrates a BTE hearing aid 8 according to the second embodiment, in side view. This hearing aid 8 comprises BTE housing 9, generally consisting of casing 10, hook 11, sound tube 12 and ear piece 13. The hearing aid has various details such as microphone grid 20, rocker button 14, battery drawer 15, battery drawer protrusion 16, and battery drawer nose 17. The rocker button is used for permitting the user to turn up or down the volume. The battery drawer may be partially opened by engaging the protrusion 16 for switching off the hearing aid, and closed to switch on the hearing aid again. The battery drawer may also be fully opened for removing the battery by engaging the nose 17. For a further explanation about these details reference may be had to WO-A1-2004073351.

Fig. 4 shows the BTE hearing aid of Fig. 3 in rear view. Reference may be had to the explanation given in relation to Fig. 3.

According to the invention components of the hearing aids may be treated to achieve enhanced surface properties. Components where this can be used to advantage comprise housings, casings, shells, faceplates, grids, hooks, lids, battery drawers, buttons and manipulators. In the present context the expression enhanced surface
5 properties towards aqueous and oily substances signifies an improved ability of the surface to repel such substances. Generally, the ability of a solid surface to repel a liquid substance can be determined in terms of wetting.

One quantitative measure of the wetting of a solid by a liquid is the contact angle, which is defined geometrically as the internal angle formed by a liquid at the three-
10 phase boundary where the liquid, gas and solid intersect. This is illustrated in fig. 5, where θ_n denotes the contact angle of a water droplet on a normal untreated surface and in fig. 6, where θ_m denotes the contact angle of a water droplet on a modified surface.

Contact angle values below 90° indicate that the liquid spreads out over the solid surface in which case the liquid is said to wet the solid. If the contact angle is greater
15 than 90° the liquid instead tends to form droplets on the solid surface and is said to exhibit a non-wetting behavior.

In this terminology it follows that the larger the contact angle, the better the ability of a surface to repel a respective substance. As indicated in fig. 5, for untreated surfaces the contact angle is normally less than 90° . It is well known in the art to coat a solid with a
20 hydrophobic layer in order to increase the contact angle and thereby obtain a moisture repellent surface. Such a surface coating may typically increase the contact angle of water to around $115-120^\circ$.

The inventors have discovered that a structural modification of the surface of certain materials will improve the ability of the material to repel aqueous and oily substances.
25 The inventors have further discovered that the combination of structural modification and coating significantly improves barrier properties of the surface. Fig. 6 shows a water droplet on a surface, which has been modified according to the invention. The increased contact angle largely exceeds 90° . In fact, as documented below, when the surface is modified by a combination of a structuring and a coating, the contact angle of

water exceeds 145° for a variety of materials. The obtained surface characteristics may be termed super-hydrophobic. In addition to the super-hydrophobic surface characteristics, the modified materials obtained super-oleophobic surface characteristics, as will also become clear in the following.

5 The component surface modification will now be described in more detail beginning with the surface structuring. Fig. 7 shows an example of a laser structured surface of a slab for a component according to the invention as seen through a microscope. This slab may represent a part of a component of a hearing aid, e.g. a part of a housing, a casing, a shell, a faceplate, a grid, a hook, a lid, a battery drawer, a button, or a
10 manipulator, etc.

The surface structuring is preferably realized on lateral scales that are much larger than characteristic sizes for atoms and molecules as well as for grains or other sub-nanometer structures, but not larger than 1000 microns. This is referred to as a microstructure.

15 The structuring and/or coating can be applied to the entire component surface or it can be applied to a part of it. A controlled structuring of at least a part of the surface in the immediate vicinity of the pores is particularly advantageous.

The applied structure can be periodic, quasi-periodic or random within a certain spatial bandwidth. The spatial bandwidth is defined as the range of reciprocal wave numbers
20 of the lateral scales of the structure, the wave number being defined as the reciprocal value of the lateral wavelength of a periodic structure. The structure is applied to at least a part of the component surface. The average pitch in the surface structure should be 1000 microns or lower. The aspect ratio is typically about 1:1 or larger. Good results have been obtained with samples over a broad pitch range, including pitch at 40
25 microns, 10 microns and 5 microns.

The surface structuring may be performed by a number of methods, for example by laser processing of the surface with thermal or non-thermal interactions. Non-limiting examples of lasers that can be used for surface structuring are CO₂ lasers, solid state

lasers, such as Nd:YAG, picosecond lasers and femtosecond lasers. Processes used in the fabrication of micro/nano-electronics or micro/nano-electromechanical systems as well as other etching or electrochemical processes can also be applied.

For a number of components of the hearing aid, e.g. housings, casings, shells,
5 faceplates, grids, hooks, lids, battery drawers, buttons and manipulators, it is generally preferred to manufacture them by injection molding. In this case structuring of the component surface may be achieved through suitable structuring of an inner surface of the die used, e.g. by laser drilling, etching, or spark treatment. In case of components manufactured by an SLA technique, sometimes referred to as a rapid prototyping
10 method, it is generally preferred to provide microstructuring of the component surface subsequent to the molding, e.g. by laser processing, etching or electrochemical processing.

The coating of the surface structured component will now be described. The coating may be applied using a gas phase nano-coating process. The process is based on
15 applying a hydrophobic coating to a surface using silanes such as perfluoroalkylsilanes or alkylsilanes. The silanes are chemically attached to the surface by reaction between hydroxy groups on the silane and on the surface, forming a self-assembled monolayer.

Firstly, the material to be coated is rendered active by treatment with a plasma, e.g. an oxygen plasma. The plasma treatment both acts as a cleaning of the surface and as a
20 way of making surface reactive by the introduction of hydroxy groups into the surface.

Preferably, an adhesion layer that further enhances the reactivity of the surface by creating even more hydroxy groups may then be deposited and, more preferred, a catalyst is added to promote deposition of the adhesion layer. This step is necessary for
non-metallic substrates and also for glasses and some metals in order to create stable
25 coatings.

In the last step, a silane is then reacted with the activated surface with or without adhesion layer. Preferably, a catalyst is added to promote deposition of the silane.

Both silane and adhesion layer are preferably deposited using a vapor phase reaction scheme. Preferably, the equipment is designed so as to have a reaction chamber and separate reservoirs containing the different chemistries used (silane, adhesion layer precursor and a catalyst) and a remote plasma source. From each reservoir, well-
5 defined amounts of the different chemistries are evaporated into a vaporization chamber, from where the vapor is injected into the reaction chamber once a specified pressure in the vaporization chamber is reached. The connections between each reservoir and the vaporization chamber and between the vaporization chamber and the reaction chamber are controlled by valves. The reservoirs and the transfer lines may be
10 heated if necessary in order to promote vaporization and to avoid condensation in the transfer lines. Also, the reaction chamber may be heated.

The system is initially pumped so as to keep a low pressure in the reaction chamber, transfer lines and vaporization chamber. Thereafter, the pumping action is halted and the compounds in the reservoirs are allowed to evaporate into the vaporization
15 chamber. Once the pre-set pressure in the vaporization chamber is reached the vapor is injected into the reaction chamber by action of the pressure difference between the vaporization chamber and the reaction chamber. Once a reaction step is completed the reaction chamber, transfer lines and vaporization chamber are pumped down after which a new reaction cycle can start.

20 Other gas phase deposition schemes may be used, but the setup described above has the advantage that plasma activation, deposition of adhesion layer and deposition of the silane are carried out in the same equipment in an automated fashion, providing no need for user intervention between the individual steps. Furthermore, the precise control over the injected amounts of chemical substances into the reaction chamber and
25 the control over the total pressure in the reaction chamber are advantageous in order to obtain a good quality of the coating both with respect to structure and surface binding.

Alternatively, after plasma activation the process may be performed in liquid solution with the same deposition steps as previously described. The gas phase deposition is, however, the preferred technique, as the liquid phase deposition is more cumbersome
30 and demands several rinse steps.

Also, polymerization of the silane in the liquid phase produces by-products that may only be deposited onto the surface via physical adsorption and not chemical binding, resulting in both low-quality coatings and in irreproducible coating thicknesses.

Reference is made to fig. 8 for an illustration of a barrier 15 having an exterior surface 16, which is structured and coated according to an embodiment of the invention. The surface is characterized by a square-wave like profile having alternating peaks 28 and troughs 29 which can be described in terms of peak height 32, peak width 30 and trough width 31. A part of the surface is further provided with a coating 33.

The barrier performance has been tested for different materials with different surface structures. A hexagonal pattern of columns on polytetrafluoroethylene (Teflon[®]) was produced with a femtosecond laser. The column width at the bottom was approximately 40 microns and the spacing about 40 microns. Each column had a microstructure generated by the ablation process, which is non-thermal. This ensures that surface tension does not smooth the surface locally. Typical fill factors are below 50%. The fill factor is defined as the ratio of the amount of material left relative to the amount of material that is removed from the surface layer. The average laser power was 100 mW, the pulse repetition rate was 6 kHz, the optical wavelength was 775 nm, and the pulse width was 150 fs. An increase in contact angle from about 115 degrees to about 150 degrees was observed after the processing, which included the coating.

Equivalent experiments were performed with polyethylene (Stamylex[®], available from DEXPlastomers v.o.f., Heerlen, The Netherlands). The average laser power was 50 mW. An even more dramatic change in contact angle was observed. Experiments on stainless steel have also been performed with equivalent results. The average laser power was in this case 275 mW. Experiments on steel with random structures generated in conjunction with the formation of pores of a diameter of 80 microns have produced similar results.

Contact angles obtained for water and olive oil on different surfaces are displayed in the below tables 1 and 2. Olive oil can be regarded as a representative of liquid earwax.

The clean surfaces have undergone oxygen plasma treatment for 5 minutes. The structured surfaces were created by a femtosecond laser with a wavelength of 775 nm and obtained peak heights of 25 microns. The surfaces were coated by molecular vapor deposition.

5

Table 1. Contact angles for water

Substrate	Clean surface (°)	Laser structured surface (°)	Coated surface (°)	Laser structured and coated surface (°)
Steel	85 ± 5	55 ± 5	115 ± 5	155 ± 5
Glass	40 ± 5	10 ± 5	115 ± 5	150 ± 5
Polyamide	70 ± 5	< 15	115 ± 5	160 ± 5
PET	80 ± 5	125 ± 5	115 ± 5	150 ± 5
PE (Stamylex)	90 ± 5	125 ± 5	115 ± 5	160 ± 5
FEP (Teflon®-like)	120 ± 5	155 ± 5	115 ± 5	160 ± 5

Table 2. Contact angles for olive oil

Substrate	Cleaned surface (°)	Laser structured surface (°)	Coated surface (°)	Laser structured and coated surface (°)
Steel	-	-	80 ± 5	105 ± 5
PE (Stamylex)	-	-	80 ± 5	130 ± 5

The large relative increase in the contact angles for both water and olive oil indicates that the modified surfaces of the different materials have become super-hydrophobic as well as super-oleophobic.

10

Materials favored for components such as a housing, a housing, a casing, a shell, a faceplate, a grid, a hook, a lid, a battery drawer, a button, or a manipulator, comprise

ABS = Acrylonitrile Butadiene Styrene

15 ABS-PC = Blend of Acrylonitrile Butadiene Styrene and Polycarbonate

CAP/CP = Cellulosepropionate

MABS = Methyl Methacrylate Acrylonitrile Butadiene Styrene

PA = Polyamide

PBT = Thermoplastic polyester

PC = Polycarbonate

PMMA = Poly Methyl Methacrylate

POM = Polyoxymethylene, also known as Acetal plastic

A test program was conducted on samples of these materials. Slabs were injection
5 molded in polished and in spark-treated dies. The molded slabs subsequently had their
surfaces micro-structured by laser treatment and coated. For comparison, a set of slabs
injection molded in polished and spark-treated dies was included. The spark treatment
was done according to a specification Chamilles 24 as defined by a the company
Charmilles Technologies SA, 1217 Meyrin 1, Geneva, Switzerland. Specimens molded
10 in spark-treated dies thus have some microstructuring in the surface. Subsequent
structuring by laser treatment of the surfaces introduces a deeper structuring so as to get
a surface with an air content at or above 50 %, preferably at or above 60 %.

The comparison samples were not micro-structured and were not coated. Droplets of
water and olive oil were deposited, and the contact angles were measured.

15 Table 3 shows results of measurements of contact angles with drops of water. Table 4
shows results of tests measurements of contact angles with drops of olive oil, which
may be assumed to simulate the properties of liquid earwax.

The slabs were then subjected to an accelerated ageing process, where they were stored
for 24 hours in warm water mixed with NaCl and acetic acid. This ageing test emulates
20 the degrading influence of sweat. The measurements after ageing (only micro-
structured slabs) are given in tables 5 and 6, table 5 showing measurements with water,
and table 6 showing measurements with olive oil.

Table 3. Contact angles for water

PC	NA	NA	146	145
PMMA	NA	NA	143	122
POM	NA	NA	139	134

This was found to be a very satisfactory result. There is a significant enhancement of repellency to water and to olive oil. The enhanced properties are persistent after ageing.

CLAIMS

1. A method of manufacturing a component for a hearing aid, comprising providing a slab, processing the surface of the slab with a laser to provide a microstructured surface, which surface comprises peaks and troughs and has an air content of at least 50%, and treating the microstructured surface with a moisture repellent matter.
2. The method according to claim 1, wherein the slab is adapted to provide one of a housing, a casing, a shell, a faceplate, a grid, a hook, a lid, a battery drawer, a button, or a manipulator.
3. The method according to claim 1, wherein the step of providing the slab with the microstructured surface comprises injection molding in a die, which die has been microstructured at an inside.
4. The method according to claim 1, wherein the step of processing the surface of the slab with a laser comprises selecting the laser from the group comprising a CO₂ laser, a solid state laser, a picosecond laser and a femtosecond laser.
5. The method according to claim 1, wherein the step of providing the slab with the microstructured surface comprises manufacturing a blank by an SLA technique, and subsequently providing microstructuring of the blank surface.
6. The method according to claim 1, wherein the step of treating the microstructured surface with a moisture repellent matter comprises gas phase deposition using a silane, preferably a perfluoroalkylsilane or an alkylsilane.
7. The method according to any one of the preceding claims, comprising the steps of treating the microstructured surface with a plasma and depositing an adhesion layer adapted for enhancing the reactivity of the surface by creating hydroxy groups.
8. The method according to claim 7, wherein the steps of depositing the adhesion layer and treating the microstructured surface with a moisture repellent matter comprise vapor phase deposition.

9. The method according to claim 7 or 8, wherein the steps of plasma treatment, deposition of adhesion layer and treatment with a moisture repellent matter are carried out in an automated fashion.
- 5 10. The method according to any one of the preceding claims, wherein the microstructured surface comprises a microstructure with an average pitch in the range of 5 microns to 50 microns.
- 10 11. The method according to any one of the preceding claims, wherein the step of providing a slab includes providing a slab that comprises a material selected from the group consisting of acrylonitrile butadiene styrene, blend of acrylonitrile butadiene styrene and polycarbonate, cellulosepropionate, methyl methacrylate acrylonitrile butadiene styrene, polyamide, thermoplastic polyester, polycarbonate and polyoxymethylene.
12. A component for a hearing aid manufactured according to the method of any one of the preceding claims.
