

**SECURE AUTHENTICATION BASED ON IDENTITY DATA STORED IN A
CONTACTLESS CARD**

RELATED APPLICATIONS

[0001] This application claims priority to U.S. Patent Application Serial No. 16/726,385, titled “SECURE AUTHENTICATION BASED ON IDENTITY DATA STORED IN A CONTACTLESS CARD” filed on December 24, 2019. The contents of the aforementioned application are incorporated herein by reference in their entirety.

TECHNICAL FIELD

[0002] Embodiments herein generally relate to computing platforms, and more specifically, to using a contactless card storing identity data for secure authentication.

BACKGROUND

[0003] Identity verification is an important task for modern computing systems. Conventional approaches may require that users provide additional information, such as a one-time passcode (OTP), when attempting to access computing systems or perform electronic transactions. However, security vulnerabilities may exist in these solutions. For example, the OTP may be intercepted and used to gain unauthorized access. Furthermore, different systems may require different types of additional information for identity verification, making conventional solutions impractical for many users.

SUMMARY

[0004] Embodiments disclosed herein provide systems, methods, articles of manufacture, and computer-readable media for secure authentication based on identity data stored in a contactless card. In one example, an application may receive an indication specifying to perform an operation associated with an account. The

application may receive encrypted data from a contactless card associated with the account, the encrypted data based on a cryptographic algorithm, a customer identifier, and a private key for the contactless card. The application may receive, from an authentication server, an indication specifying that the authentication server verified the encrypted data based on the private key for the contactless card. The application may determine a type of authentication data required to authorize the operation. The application may receive, based on the determined type of authentication data, a first data element from the contactless card, the first data element comprising passport data or driver license data. The application may determine that the first data element satisfies at least one rule for authorizing the operation. The application may authorize performance of the operation based on the received indication specifying that the authentication server verified the encrypted data and the determination that the first data element satisfies the at least one rule for authorizing the operation.

BRIEF DESCRIPTION OF THE DRAWINGS

[0005] Figures 1A-1B illustrate embodiments of a system for secure authentication based on identity data stored in a contactless card.

[0006] Figures 2A-2C illustrate embodiments of tapping a contactless card to a computing device to provide secure authentication based on identity data stored in the contactless card.

[0008] Figures 4A-4B illustrate an example contactless card.

[0009] Figure 5 illustrates an embodiment of a first logic flow.

[0010] Figure 6 illustrates an embodiment of a second logic flow.

[0011] Figure 7 illustrates an embodiment of a third logic flow.

[0012] Figure 8 illustrates an embodiment of a computing system.

DETAILED DESCRIPTION

[0013] Embodiments disclosed herein provide techniques for secure authentication using identity data stored in a contactless card. Generally, a contactless card may store a plurality of different types of information for a user, such as driver's license information, passport information, social security number, and/or any other biographical information. The user may then attempt to perform an operation, such as making a purchase, transferring funds via an application executing on a mobile device, requesting a credit increase via the application, and the like. The application may determine a type of authentication data required to authorize the requested operation. For example, a rule may specify that transferring funds via the application requires authentication based on passport data stored in the contactless card. Therefore, the application may determine that passport data as the type of authentication data.

[0014] The user may then tap the contactless card to the mobile device to initiate the secure authentication process. Once tapped, the contactless card may generate and transmit encrypted data to the application. The encrypted data may be generated based on a cryptographic algorithm, a customer identifier, and an encryption key for the contactless card. The application may then transmit the encrypted data to an authentication server for authentication. The server may then decrypt the encrypted data using a local copy of the encryption key for the contactless card to yield the customer identifier, thereby authenticating the encrypted data. The server may then transmit an indication of the authentication of the encrypted data to the application.

[0015] The application may then process the passport data. In some embodiments, the passport data is sent by the contactless card to the application with the encrypted customer identifier. In other embodiments, the passport data is sent by the contactless card subsequent to another tap of the contactless card to the mobile device. To process the passport data, the application may perform any number of operations. For example, the passport data stored on the contactless card may include a passport image depicting

the user. In such an example, the application may instruct the user to capture an image depicting their face using the mobile device. Once captured, the application may compare the images to determine a similarity between the images. If the similarity exceeds a threshold level of similarity specified in a rule, the application may authenticate the user and/or validate the identity of the user. The application may then authorize the performance of the operation based on the received indication specifying that the authentication server verified the encrypted data and the determination that the similarity of the images exceeds the threshold level of similarity. For example, the user may be permitted to access an interface of the application to transfer funds from one account to another.

[0016] Advantageously, embodiments disclosed herein improve the security of all devices and associated data. For example, by requiring validation of encrypted data generated by the contactless card to access applications and/or data, the security of the applications and/or data are improved. As another example, by requiring validation of the encrypted data prior to performing operations (e.g., making purchases, extending credit, etc.), the security of such operations and associated assets is improved.

[0017] With general reference to notations and nomenclature used herein, one or more portions of the detailed description which follows may be presented in terms of program procedures executed on a computer or network of computers. These procedural descriptions and representations are used by those skilled in the art to most effectively convey the substances of their work to others skilled in the art. A procedure is here, and generally, conceived to be a self-consistent sequence of operations leading to a desired result. These operations are those requiring physical manipulations of physical quantities. Usually, though not necessarily, these quantities take the form of electrical, magnetic, or optical signals capable of being stored, transferred, combined, compared, and otherwise manipulated. It proves convenient at times, principally for reasons of common usage, to refer to these signals as bits, values, elements, symbols, characters, terms, numbers, or the like. It should be noted, however, that all of these and similar terms are to be associated with the appropriate physical quantities and are merely convenient labels applied to those quantities.

[0018] Further, these manipulations are often referred to in terms, such as adding or comparing, which are commonly associated with mental operations performed by a human operator. However, no such capability of a human operator is necessary, or desirable in most cases, in any of the operations described herein that form part of one or more embodiments. Rather, these operations are machine operations. Useful machines for performing operations of various embodiments include digital computers as selectively activated or configured by a computer program stored within that is written in accordance with the teachings herein, and/or include apparatus specially constructed for the required purpose or a digital computer. Various embodiments also relate to apparatus or systems for performing these operations. These apparatuses may be specially constructed for the required purpose. The required structure for a variety of these machines will be apparent from the description given.

[0019] Reference is now made to the drawings, wherein like reference numerals are used to refer to like elements throughout. In the following description, for the purpose of explanation, numerous specific details are set forth in order to provide a thorough understanding thereof. It may be evident, however, that the novel embodiments can be practiced without these specific details. In other instances, well-known structures and devices are shown in block diagram form in order to facilitate a description thereof. The intention is to cover all modification, equivalents, and alternatives within the scope of the claims.

[0020] Figure 1A depicts a schematic of an exemplary system 100, consistent with disclosed embodiments. As shown, the system 100 includes one or more contactless cards 101, one or more mobile computing devices 110, and an authentication server 120. The contactless cards 101 are representative of any type of payment cards, such as a credit card, debit card, ATM card, gift card, and the like. The contactless cards 101 may comprise one or more communications interfaces 133, such as a radio frequency identification (RFID) chip, configured to communicate with the computing devices 110 via NFC, the EMV standard, or other short-range protocols in wireless communication. Although NFC is used as an example communications protocol, the disclosure is equally applicable to other types of wireless communications, such as the EMV standard, Bluetooth, and/or Wi-Fi. The mobile devices 110 are representative of

any type of network-enabled computing devices, such as smartphones, tablet computers, wearable devices, laptops, portable gaming devices, and the like. The authentication server 120 is representative of any type of computing device, such as a server, workstation, compute cluster, cloud computing platform, virtualized computing system, and the like.

[0021] As shown, a memory 102 of the contactless card includes an applet 103, a counter 104, a master key 105, a diversified key 106, a unique customer identifier (ID) 107, passport data 108, driver's license data 109, and other user data 131. The applet 103 is executable code configured to perform the operations described herein. The counter 104, master key 105, diversified key 106, and customer ID 107 are used to provide security in the system 100 as described in greater detail below. The passport data 108 is representative of an electronic passport of a user associated with the contactless card 101. The passport data 108 may include any number and types of data. For example, the passport data 108 may include text data describing different attributes of the passport and/or user (e.g., name, date of birth, passport number, passport issue date, passport expiration date, issuing nation, etc.) as well as image data (e.g., one or more images of the passport itself, an image of the user included in the passport, etc.). The customer ID 107, passport data 108, driver's license data 109, and other user data 131 may collectively be referred to herein as "identity data."

[0022] The driver's license data 109 is representative of one or more driver's licenses held by the user associated with the contactless card. As with the passport data 108, the driver's license data 109 may include any number and types of data. For example, the driver's license data 109 may include a barcode (or other computer-readable marker) that encodes different attributes of the driver's license and/or user (e.g., name, date of birth, license number, license issue date, expiration date, issuing state, etc.), text data representing the attributes (and/or the barcode), and/or image data (e.g., one or more images of the driver's license, an image of the user included in the driver's license, etc.). The other user data 131 is representative of other data describing the user. For example, the other user data 131 may include social security numbers, images, data representing biometric identifiers of the user, other identification cards,

loyalty program information, and the like. In some embodiments, the passport data 108, driver's license data 109, and other user data 131 are encrypted.

[0023] As shown, a memory 111 of the mobile device 110 includes an instance of an operating system (OS) 112. Example operating systems 112 include the Android® OS, iOS®, macOS®, Linux®, and Windows® operating systems. As shown, the OS 112 includes an account application 113. The account application 113 allows users to perform various account-related operations, such as viewing account balances, purchasing items, processing payments, and the like. The account application 113 may further control access permissions to different functions provided by the account application 113 and/or the other applications 114. Generally, a user may authenticate using authentication credentials to access certain features of the account application 113. For example, the authentication credentials may include a username (or login) and password, biometric credentials (e.g., fingerprints, Face ID, etc.), and the like.

[0024] According to various embodiments, the user may request and/or attempt to perform an operation. The operation may include any type of operation, such as using the contactless card 101 to make a purchase, accessing certain features of the account application 113, performing various account-related operations using the account application 113, and/or accessing the other applications 114 (or any feature thereof). The other applications 114 are representative of any type of computing application, such as web browsers, messaging applications, word processing applications, social media applications, and the like. For example, the user may desire to transfer funds from their account to another account using the account application 113. The use of a specific operation as a reference example herein is not limiting of the disclosure, as the disclosure is equally applicable to any other type of operation.

[0025] To authorize the requested operation, (e.g., the previous example of transferring funds), the system 100 must authenticate and/or verify the identity of the user. To authenticate the identity of the user, embodiments disclosed herein may leverage the contactless card 101. More specifically, once the user requests to perform the operation (or otherwise access a restricted resource), the account application 113 may output a notification instructing the user to tap the contactless card 101 to the

device 110. Generally, once the contactless card 101 is brought within communications range of the communications interface 118 of the device 110, the applet 103 of the contactless card 101 may generate encrypted data, e.g., an encrypted customer ID 132 as part of the authentication process required to authorize the requested operation. To enable NFC data transfer between the contactless card 101 and the mobile device 110, the account application 113 may communicate with the contactless card 101 when the contactless card 101 is sufficiently close to the communications interface 118 of the mobile device 110. The communications interface 118 may be configured to read from and/or communicate with the communications interface 133 of the contactless card 101 (e.g., via NFC, Bluetooth, RFID, etc.). Therefore, example communications interfaces 118 include NFC communication modules, Bluetooth communication modules, and/or RFID communication modules.

[0026] As stated, the system 100 is configured to implement key diversification to secure data, which may be referred to as a key diversification technique herein. Generally, the server 120 (or another computing device) and the contactless card 101 may be provisioned with the same master key 105 (also referred to as a master symmetric key). More specifically, each contactless card 101 is programmed with a distinct master key 105 that has a corresponding pair in the server 120. For example, when a contactless card 101 is manufactured, a unique master key 105 may be programmed into the memory 102 of the contactless card 101. Similarly, the unique master key 105 may be stored in a record of a customer associated with the contactless card 101 in the account data 124 of the server 120 (and/or stored in a different secure location, such as the hardware security module (HSM) 125). The master key may be kept secret from all parties other than the contactless card 101 and server 120, thereby enhancing security of the system 100. In some embodiments, the applet 103 of the contactless card 101 may encrypt and/or decrypt data (e.g., the customer ID 107, passport data 108, driver's license data 109, and/or other user data 131) using the master key 105 and the data as input a cryptographic algorithm. For example, encrypting the customer ID 107 with the master key 105 may result in the encrypted customer ID 132. Similarly, the authentication server 120 may encrypt and/or decrypt data associated with the contactless card 101 using the corresponding master key 105.

[0027] In other embodiments, the master keys 105 of the contactless card 101 and server 120 may be used in conjunction with the counters 104 to enhance security using key diversification. The counters 104 comprise values that are synchronized between the contactless card 101 and server 120. The counter value 104 may comprise a number that changes each time data is exchanged between the contactless card 101 and the server 120 (and/or the contactless card 101 and the mobile device 110). When preparing to send data (e.g., to the server 120 and/or the mobile device 110), the contactless card 101 may increment the counter value 104. The contactless card 101 may then provide the master key 105 and counter value 104 as input to a cryptographic algorithm, which produces a diversified key 106 as output. The cryptographic algorithm may include encryption algorithms, hash-based message authentication code (HMAC) algorithms, cipher-based message authentication code (CMAC) algorithms, and the like. Non-limiting examples of the cryptographic algorithm may include a symmetric encryption algorithm such as 3DES or AES128; a symmetric HMAC algorithm, such as HMAC-SHA-256; and a symmetric CMAC algorithm such as AES-CMAC. Examples of key diversification techniques are described in greater detail in United States Patent Application 16/205,119, filed November 29, 2018. The aforementioned patent application is incorporated by reference herein in its entirety.

[0028] Continuing with the key diversification example, the contactless card 101 may then encrypt the data (e.g., the customer ID 107 and/or any other data, such as the passport data 108, driver's license data 109, and/or other user data 131) using the diversified key 106 and the data as input to the cryptographic algorithm. For example, encrypting the customer ID 107 with the diversified key 106 may result in the encrypted customer ID 132.

[0029] Regardless of the encryption technique used, the contactless card 101 may then transmit the encrypted data (e.g., the encrypted customer ID 132) to the account application 113 of the mobile device 110 (e.g., via an NFC connection, Bluetooth connection, etc.). The account application 113 of the mobile device 110 may then transmit the encrypted customer ID 132 to the server 120 via the network 130. In at least one embodiment, the contactless card 101 transmits the counter value 104 with

the encrypted data. In such embodiments, the contactless card 101 may transmit an encrypted counter value 104, or an unencrypted counter value 104.

[0030] Once received, the authentication application 123 may authenticate the encrypted customer ID 132. For example, the authentication application 123 may attempt to decrypt the encrypted customer ID 132 using a copy of the master key 105 stored in the memory 122 of the authentication server 120. In another example, the authentication application 123 may provide the master key 105 and counter value 104 as input to the cryptographic algorithm, which produces a diversified key 106 as output. The resulting diversified key 106 may correspond to the diversified key 106 of the contactless card 101, which may be used to decrypt the encrypted customer ID 132.

[0031] Regardless of the decryption technique used, the authentication application 123 may successfully decrypt the encrypted customer ID 132, thereby verifying the encrypted customer ID 132 (e.g., by comparing the resulting customer ID 107 to a customer ID stored in the account data 124, and/or based on an indication that the decryption using the key 105 and/or 106 was successful). Although the keys 105, 106 are depicted as being stored in the memory 122, the keys 105, 106 may be stored elsewhere, such as in a secure element and/or the HSM 125. In such embodiments, the secure element and/or the HSM 125 may decrypt the encrypted customer ID 132 using the keys 105 and/or 106 and a cryptographic function. Similarly, the secure element and/or HSM 125 may generate the diversified key 106 based on the master key 105 and counter value 104 as described above.

[0032] If, however, the authentication application 123 is unable to decrypt the encrypted customer ID 132 to yield the expected result (e.g., the customer ID 107 of the account associated with the contactless card 101), the authentication application 123 does not validate the encrypted customer ID 132. In such an example, the authentication application 123 transmits an indication of the failed verification to the account application 113. As such, the account application 113 may reject performance of the requested operation to preserve the security of the account.

[0033] Figure 1B illustrates an embodiment where the authentication application 123 has decrypted the encrypted customer ID 132, thereby verifying (or authenticating) the encrypted data. As shown, the authentication application 123 transmits a verification 134 to the mobile device 110, where the verification 134 indicates that the authentication application 123 successfully decrypted the encrypted customer ID 132. Responsive to receiving the verification 134, the account application 113 may reference the rules 115 to determine what, if any, additional authentication steps are required. The rules 115 may generally specify a plurality of different authentication rules and/or thresholds for different requested operations. The rules may be based on the type of requested operation. For example, for the transfer of funds, the rules 115 may require additional authentication based on additional data elements such as the passport data 108 and/or the driver's license data 109.

[0034] In the example where additional authentication is based on the passport data 108, the account application 113 may output an indication specifying that the user tap the contactless card 101 to the mobile device 110. The account application 113 may then instruct the contactless card 101 to transmit the passport data 108. In response, the contactless card 101 may transmit the passport data 108 to the account application 113. In some embodiments, the passport data 108 may be encrypted. In such embodiments, the account application 113 may transmit the encrypted passport data 108 to the server 120 for decryption (e.g., based on the keys 105 and/or 106), which then sends the decrypted passport data 108 to the account application 113. In another embodiment, the user may provide input to the account application 113 used to decrypt the encrypted passport data 108.

[0035] Furthermore, the account application 113 may instruct the user to capture an image depicting themselves using the camera 119. The account application 113 may then compare the captured image to a passport image in the passport data 108 to determine a similarity of the persons depicted in each image. If the account application 113 determines that the similarity of the persons depicted in the images exceeds a threshold similarity specified in the rules 115, the account application 113 may authorize the requested operation. The user may then proceed to complete the transfer of funds using the account application 113.

[0036] As stated, in another example, the rules 115 may require authentication based on the driver's license data 109. The account application 113 may then output an indication specifying that the user tap the contactless card 101 to the mobile device 110. The account application 113 may then instruct the contactless card 101 to transmit the driver's license data 109. In response, the contactless card 101 may transmit the driver's license data 109 to the account application 113. In some embodiments, the driver's license data 109 may be encrypted. Otherwise, the account application 113 may restrict performance of the operation (e.g., by restricting access to the graphical user interface (GUI) of the account application 113 used to transfer funds). In such embodiments, the account application 113 may transmit the encrypted driver's license data 109 to the server 120 for decryption, which then sends the decrypted driver's license data 109 to the account application 113.

[0037] As with the passport-based authentication, the account application 113 then may instruct the user to capture an image depicting themselves using the camera 119. The account application 113 may then compare the captured image to a driver's license image in the driver's license data 109 to determine a similarity of the persons depicted in each image. If the account application 113 determines that the similarity of the persons depicted in the images exceeds a threshold similarity specified in the rules 115, the account application 113 may authorize the requested operation. Otherwise, the account application 113 may restrict performance of the operation (e.g., by restricting access to the GUI of the account application 113 used to transfer funds). The user may then proceed to complete the transfer of funds using the account application 113.

[0038] Although image-based authentication is used as an example, other data elements may be used to authorize the requested operation. For example, the account application 113 may determine whether the name on the passport and/or driver's license matches a name on the account associated with the contactless card 101. As another example, the account application 113 may determine whether data encoded in the driver's license data 109 is readable. As yet another example, the account application 113 may determine whether a date of birth in passport and/or driver's license matches known a date of birth, e.g., a date of birth specified in the account data 124 for the account associated with the contactless card 101. In another example, a social security

number stored in the other user data 131 may be compared to a known social security number of the user associated with the account. If a matching name and/or social security number is found, the account application 113 may authorize the attempted operation. Otherwise, the account application 113 may reject the attempted operation.

[0039] In at least one embodiment, the applet 103 of the contactless card 101 may generate a digital signature (not pictured) for the passport data 108 and/or the driver's license data 109 using the keys 105 and/or 106. A respective digital signature may sign the passport data 108 and/or driver's license data 109. The contactless card 101 may then transmit the digital signatures with the passport data 108 and/or driver's license data 109 to the account application 113, which in turn transmits the digital signatures to the authentication server 120. The authentication application 123 may also verify the digital signature by decrypting the digital signature using a public key associated with the contactless card 101 and stored by the server 120. If the digital signature is verified, the authentication application 123 may transmit an indication of the successful verification to the account application 113, which may permit performance of the operation based on verification of the digital signature. If the digital signature is not verified, the account application 113 may restrict performance of the operation.

[0040] Although depicted in Figures 1A-1B as occurring in separate tap operations, in some embodiments, the passport data 108 and/or the driver's license data 109 may be transmitted with the encrypted customer ID 132 responsive to a single tap of the contactless card 101 to the mobile device 110.

[0041] Furthermore, in some embodiments, the user may obtain new and/or updated identification information, such as a passport, driver's license, etc. In such embodiments, the account application 113 may receive the new and/or updated versions of the passport data 108, driver's license data 109, and/or other user data 131, e.g., from the authentication server 120. In such embodiments, the account application 113 may transmit the data received from the server 120 to the contactless card 101, and the applet 103 may store the received data in the memory 102.

[0042] Figure 2A is a schematic 200 depicting an example embodiment of tapping the contactless card 101 to provide secure authentication based on identity data stored in the contactless card 101. As shown, the account application 113 may receive a request to perform an operation. Continuing with the previous example, the request may be to transfer funds from one account to another account. In response, the account application 113 may output an indication to tap the contactless card 101 to the device 110. Once the user taps the contactless card 101 to the mobile device 110, the applet 103 of the contactless card 101 generates the encrypted customer ID 132. The applet 103 may then transmit the encrypted customer ID 132 to the mobile device 110, e.g., via NFC. Once received, the account application 113 may transmit the encrypted customer ID 132 to the authentication application 123.

[0043] The authentication application 123 may then attempt to decrypt the encrypted customer ID 132 using the master key 105 and/or the diversified key 106 associated with the contactless card 101. If the authentication application 123 is unable to decrypt the encrypted customer ID 132 to yield an expected result (e.g., the customer ID 107 of the account, etc.), the authentication application 123 does not verify the encrypted customer ID 132 and informs the account application 113 of the failed verification. The account application 113 may then reject the request to initiate the transfer of funds. If the authentication application 123 successfully decrypts the encrypted customer ID 132 to yield an expected result (e.g., the customer ID 107 of the account, etc.), the authentication application 123 verifies the encrypted customer ID 132 and transmits an indication of the verification of the encrypted customer ID 132 to the account application 113.

[0044] Responsive to receiving the verification from the authentication application 123, the account application 113 may reference the rules 115 to determine which type of data is required to authorize the requested transfer of funds. For example, the rules 115 may specify that fund transfers require verification of the encrypted customer ID 132 and verification based on the passport data 108. In at least one embodiment, the type of data specified by the rules 115 is based on the type of requested operation (e.g., the transfer of funds). Generally, the rules 115 may specify different levels of security for different types of transaction (e.g., requiring verification of passport data 108 for

higher risk operations, while not requiring verification of the passport data 108 for lower risk operations).

[0045] The account application 113 may output another indication to tap the contactless card 101 to the device 110. The account application 113 may instruct the contactless card 101 to transmit the passport data 108. The applet 103 may then transmit the passport data 108 to the mobile device 110, e.g., via NFC.

[0046] As shown in the schematic 210 of Figure 2B, the account application 113 may then output an indication instructing the user to capture an image depicting their face. The user may then capture an image depicting their face using the camera 119. The account application 113 may then compare the captured image to a passport image in the passport data 108 to determine a similarity of the persons depicted in each image. If the account application 113 determines that the similarity of the persons depicted in the images exceeds a threshold similarity specified in the rules 115, the account application 113 may authorize the requested fund transfer operation. Otherwise, the account application 113 may reject the requested fund transfer operation and restrict access to the GUI of the account application 113 to perform fund transfers. In the example depicted in Figure 2B, the similarity exceeds the threshold, and the account application 113 permits performance of the requested transfer. The user may then proceed to complete the transfer of funds using a corresponding GUI of the account application 113.

[0047] Figure 3A is a schematic 300 illustrating an example embodiment of tapping the contactless card 101 to provide secure authentication based on identity data stored in the contactless card 101. As stated, the contactless card 101 may be used as a form of payment for a purchase and the system 100 may use identity data stored in the contactless card to provide secure authentication when processing the payment. While an in-person transaction is depicted as a reference example, the disclosure is equally applicable to online transactions.

[0048] As shown, a merchant device 301 display 302 outputs an indication specifying that an age-restricted item has been identified as part of the requested

purchase and the age of the customer must be provided to complete the requested purchase. The merchant device 301 is representative of any type of device that can process payments, such as card reader devices, smartphones, tablet computers, desktop computers, point of sale (POS) terminals, servers, workstations, laptop computers, and the like. The merchant device 301 includes a communications interface 303 configured to communicate via one or more of NFC, Bluetooth, RFID, and/or Wi-Fi. Therefore, the merchant device 301 may communicate with the contactless card 101 and/or the mobile device 110. In some embodiments, the communications interface 118 of the mobile device 110 operates in NFC card-emulation mode to emulate the contactless card 101 and pay for a transaction via the merchant device 301.

[0049] Therefore, the account application 113 may receive an indication from the merchant device 301 specifying that verification of the customer's age is needed. The account application 113 may then output an indication specifying to tap the contactless card 101 to the device 110. Once the customer taps the contactless card 101 to the mobile device 110, the applet 103 of the contactless card 101 generates the encrypted customer ID 132. The applet 103 may then transmit the encrypted customer ID 132 to the mobile device 110, e.g., via NFC. In the embodiment depicted in Figures 3A-3C, the contactless card 101 also encrypts and transmits the driver's license data 109 to the mobile device 110 with the encrypted customer ID 132. Once received, the account application 113 may transmit the encrypted customer ID 132 and the driver's license data to the authentication application 123. The authentication application 123 may then decrypt the encrypted customer ID 132, thereby verifying the encrypted customer ID 132. The authentication application 123 may further decrypt the driver's license data 109.

[0050] Figure 3B illustrates an embodiment where the account application 113 receives an indication from the authentication application 123 that the encrypted customer ID 132 was validated. The account application 113 may further receive the decrypted driver's license data 109 from the authentication application 123. The account application 113 (and/or the authentication application 123) may read the driver's license data 109 to determine the customer's age (e.g., based on a difference between a current date and a date of birth specified in the driver's license data 109). If

the determined age exceeds the minimum age for purchasing the age-restricted item, the account application 113 transmits an indication of verification 310 to the merchant device 301. In some embodiments, the account application 113 transmits the relevant driver's license data 109 (e.g., date of birth) to the merchant device 301. Doing so allows the merchant device 301 to independently verify that the customer is of the requisite age to purchase the age-restricted item.

[0051] Figure 3C illustrates an embodiment where the account application 113 instructs the user to tap the contactless card 101 to the mobile device 110 to complete the payment for the purchase based on the verification of the encrypted customer ID 132 by the authentication application 123 and the verification of the customer's age. The communications interface 118 of the mobile device 110, acting in NFC card-emulation mode, may cause the applet 103 of the contactless card 101 to transmit payment information (e.g., a card number, expiration date, and/or card verification value (CVV)) to the account application 113. In some embodiments, the payment information includes an encrypted customer ID 132, which is transmitted by the account application 113 to the server 120 for verification. Once verified, the account application 113 transmits the received payment information to the merchant device 301 as payment data 311. The merchant device 301 may then process the transaction using the received payment data 311.

[0052] Figure 4A illustrates a contactless card 101, which may comprise a payment card, such as a credit card, debit card, and/or a gift card. As shown, the contactless card 101 may be issued by a service provider 405 displayed on the front or back of the card 101. In some examples, the contactless card 101 is not related to a payment card, and may comprise, without limitation, an identification card. In some examples, the payment card may comprise a dual interface contactless payment card. The contactless card 101 may comprise a substrate 410, which may include a single layer or one or more laminated layers composed of plastics, metals, and other materials. Exemplary substrate materials include polyvinyl chloride, polyvinyl chloride acetate, acrylonitrile butadiene styrene, polycarbonate, polyesters, anodized titanium, palladium, gold, carbon, paper, and biodegradable materials. In some examples, the contactless card 101 may have physical characteristics compliant with the ID-1 format of the ISO/IEC 7810

standard, and the contactless card may otherwise be compliant with the ISO/IEC 14443 standard. However, it is understood that the contactless card 101 according to the present disclosure may have different characteristics, and the present disclosure does not require a contactless card to be implemented in a payment card.

[0053] The contactless card 101 may also include identification information 415 displayed on the front and/or back of the card, and a contact pad 420. The contact pad 420 may be configured to establish contact with another communication device, such as the mobile devices 40, a user device, smart phone, laptop, desktop, or tablet computer. The contactless card 101 may also include processing circuitry, antenna and other components not shown in FIG. 4A. These components may be located behind the contact pad 420 or elsewhere on the substrate 410. The contactless card 101 may also include a magnetic strip or tape, which may be located on the back of the card (not shown in FIG. 4A).

[0054] As illustrated in FIG. 4B, the contact pad 420 of contactless card 101 may include processing circuitry 425 for storing and processing information, including a microprocessor 430 and the memory 102. It is understood that the processing circuitry 425 may contain additional components, including processors, memories, error and parity/CRC checkers, data encoders, anti-collision algorithms, controllers, command decoders, security primitives and tamper proofing hardware, as necessary to perform the functions described herein.

[0055] The memory 102 may be a read-only memory, write-once read-multiple memory or read/write memory, e.g., RAM, ROM, and EEPROM, and the contactless card 101 may include one or more of these memories. A read-only memory may be factory programmable as read-only or one-time programmable. One-time programmability provides the opportunity to write once then read many times. A write once/read-multiple memory may be programmed at a point in time after the memory chip has left the factory. Once the memory is programmed, it may not be rewritten, but it may be read many times. A read/write memory may be programmed and re-programmed many times after leaving the factory. A read/write memory may also be read many times after leaving the factory.

[0056] The memory 102 may be configured to store one or more applets 103, the counter 104, master key 105, the diversified key 106, one or more customer (or user) IDs 107, the passport data 108, the driver's license data 109, and the other user data 131. The one or more applets 103 may comprise one or more software applications configured to execute on one or more contactless cards, such as a Java® Card applet. However, it is understood that applets 103 are not limited to Java Card applets, and instead may be any software application operable on contactless cards or other devices having limited memory. The customer ID 107 may comprise a unique alphanumeric identifier assigned to a user of the contactless card 101, and the identifier may distinguish the user of the contactless card from other contactless card users. In some examples, the customer ID 107 may identify both a customer and an account assigned to that customer and may further identify the contactless card associated with the customer's account. In some embodiments, the applet 103 may use the customer ID 107 as input to a cryptographic algorithm with the keys 105 and/or 106 to generate the encrypted customer ID 132.

[0057] The processor and memory elements of the foregoing exemplary embodiments are described with reference to the contact pad, but the present disclosure is not limited thereto. It is understood that these elements may be implemented outside of the pad 420 or entirely separate from it, or as further elements in addition to processor 430 and memory 102 elements located within the contact pad 420.

[0058] In some examples, the contactless card 101 may comprise one or more antennas 455. The one or more antennas 455 may be placed within the contactless card 101 and around the processing circuitry 425 of the contact pad 420. For example, the one or more antennas 455 may be integral with the processing circuitry 425 and the one or more antennas 455 may be used with an external booster coil. As another example, the one or more antennas 455 may be external to the contact pad 420 and the processing circuitry 425.

[0059] In an embodiment, the coil of contactless card 101 may act as the secondary of an air core transformer. The terminal may communicate with the contactless card 101 by cutting power or amplitude modulation. The contactless card 101 may infer the

data transmitted from the terminal using the gaps in the contactless card's power connection, which may be functionally maintained through one or more capacitors. The contactless card 101 may communicate back by switching a load on the contactless card's coil or load modulation. Load modulation may be detected in the terminal's coil through interference. More generally, using the antennas 455, processing circuitry 425, and/or the memory 102, the contactless card 101 provides a communications interface to communicate via NFC, Bluetooth, and/or Wi-Fi communications.

[0060] As explained above, contactless cards 101 may be built on a software platform operable on smart cards or other devices having limited memory, such as JavaCard, and one or more or more applications or applets may be securely executed. Applets may be added to contactless cards to provide a one-time password (OTP) for multifactor authentication (MFA) in various mobile application-based use cases. Applets may be configured to respond to one or more requests, such as near field data exchange requests, from a reader, such as a mobile NFC reader (e.g., the communications interface 118 of the device 110), and produce an NDEF message that comprises a cryptographically secure OTP encoded as an NDEF text tag.

[0061] Operations for the disclosed embodiments may be further described with reference to the following figures. Some of the figures may include a logic flow. Although such figures presented herein may include a particular logic flow, it can be appreciated that the logic flow merely provides an example of how the general functionality as described herein can be implemented. Further, a given logic flow does not necessarily have to be executed in the order presented unless otherwise indicated. In addition, the given logic flow may be implemented by a hardware element, a software element executed by a processor, or any combination thereof. The embodiments are not limited in this context.

[0062] Figure 5 illustrates an embodiment of a logic flow 500. The logic flow 500 may be representative of some or all of the operations executed by one or more embodiments described herein. For example, the logic flow 500 may include some or all of the operations to use the contactless card 101 to provide secure authentication

based on identity data stored in the contactless card 101. Embodiments are not limited in this context.

[0063] As shown, the logic flow 500 begins at block 505, where the account application 113 receives a request to perform an operation. As stated, the requested operation may be received based on input from a user of the account application 113, an external source (e.g., the merchant device 301), one of the other applications 114, or any other source. The request may be related to, for example and without limitation, use of the account application 113, use of the other applications 114, operations related to the account associated with the contactless card 101, and/or a transaction. More generally, the request may be received subsequent to a user providing authentication credentials required to access the account in the account application 113. At block 510, a user taps the contactless card 101 to the mobile device 110 to cause the applet 103 of the contactless card 101 to generate and transmit the encrypted customer ID 132 to the mobile device 110.

[0064] At block 515, the account application 113 may receive the encrypted customer ID 132 from the contactless card 101. The account application 113 may then transmit the encrypted customer ID 132 received from the contactless card 101 to the authentication server 120. The server 120 may attempt to decrypt the encrypted customer ID 132 as described herein. At block 520, the account application 113 receives an indication from the server 120 that the encrypted customer ID 132 was verified by decrypting the encrypted customer ID 132.

[0065] At block 525, the account application 113 determines a type of the request. At block 530, the account application 113 determines a type of verification data specified in the rules 115 required to authorize the type of operation. For example, the passport data 108 may be specified as the verification data required by the rules 115. At block 530, the user taps the contactless card 101 to the mobile device 110. Doing so instructs the applet 103 of the contactless card 101 to transmit the passport data 108 to the mobile device 110. The account application 113 may receive the additional data (e.g., the passport data 108) from the contactless card 101 at block 535.

[0066] At block 540, the account application 113 may receive the additional data from the contactless card 101. At block 545, the account application 113 may process the data received at block 540. For example, the account application 113 may perform any age-verification, account verification, and/or identify verification specified by the rules 115. As another example, the account application 113 and/or the authentication server 120 may verify a digital signature of the received data. At block 550, the account application 113 determines that the processed data satisfies the rules 115. At block 555, the account application 113 permits performance of the requested operation based on the verification of the encrypted customer ID 132 by the server 120 and the determination that the processed data received at block 535 satisfies the rules 115. At block 560, the requested operation may be performed, e.g., by the user and/or by the account application 113.

[0067] Figure 6 illustrates an embodiment of a logic flow 600. The logic flow 600 may be representative of some or all of the operations executed by one or more embodiments described herein. For example, the logic flow 600 may include some or all of the operations to provide authentication based on the passport data 108 stored in the contactless card 101. Embodiments are not limited in this context.

[0068] As shown, the logic flow 600 begins at block 610, where the account application 113 determines that the rules 115 require passport-based verification based on the type of the requested operation. At block 620, the account application 113 outputs an instruction to the user to capture an image depicting at least the face of the user. At block 630, the account application 113 receives the image captured by the camera 119 of the mobile device 110. At block 640, the account application 113 compares the captured image received at block 630 to one or more images associated with the passport in the passport data 108 and determines that a similarity of the persons depicted in each image exceeds a threshold level of similarity specified by the rules 115. At block 650, the account application 113 determines, based on the determination at block 640, that the user depicted in the captured image matches the person depicted in the passport image of the passport data 108. At block 660, the account application 113 permits performance of the requested operation based at least in part on the determinations that the user depicted in the captured image matches the person depicted

in the passport image of the passport data 108 and/or that the determined similarity exceeds the threshold specified by the rules 115.

[0069] Although the logic flow 600 relates to an image in the passport data 108, the logic flow 600 is equally applicable to image-based verification using an image of the user in the driver's license data 109. Therefore, the account application 113 may determine whether the user in the captured image matches a user depicted in the driver's license data 109. Embodiments are not limited in these contexts.

[0070] Figure 7 illustrates an embodiment of a logic flow 700. The logic flow 700 may be representative of some or all of the operations executed by one or more embodiments described herein. For example, the logic flow 700 may include some or all of the operations to provide authentication based on the driver's license data 109 stored in the contactless card 101. Embodiments are not limited in this context.

[0071] As shown, the logic flow 700 begins at block 710, where the account application 113 receives an indication from a merchant device 301 specifying that age verification is required to purchase an age-restricted item. At block 720, the account application 113 receives the driver's license data 109 from the contactless card 101 based on a tap of the card 101 to the mobile device 110. At block 730, the account application 113 processes the driver's license data 109 to determine the age of the associated person, e.g., based on a date of birth included in the driver's license data.

[0072] At block 740, the account application 113 determines that the age of the person determined at block 730 exceeds a minimum age threshold. At block 750, the account application 113 transmits an indication that the person's age exceeds the threshold. Additionally and/or alternatively, the account application 113 may transmit the age and/or the driver's license data 109 to the merchant device 301 for processing and verification. At block 760, the account application 113 receives payment data from the contactless card 101 responsive to a tap of the contactless card 101 to the mobile device 110. At block 770, the account application 113 transmits the payment data to the merchant device 301. At block 780, the merchant device 301 may process the

transaction using the received payment data. In some embodiments, the merchant device 301 transmits a payment confirmation to the account application 113.

[0073] Figure 8 illustrates an embodiment of an exemplary computing architecture 800 comprising a computing system 802 that may be suitable for implementing various embodiments as previously described. In various embodiments, the computing architecture 800 may comprise or be implemented as part of an electronic device. In some embodiments, the computing architecture 800 may be representative, for example, of a system that implements one or more components of the system 100. In some embodiments, computing system 802 may be representative, for example, of the contactless card 101, mobile devices 110, and authentication server 120 of the system 100. The embodiments are not limited in this context. More generally, the computing architecture 800 is configured to implement all logic, applications, systems, methods, apparatuses, and functionality described herein with reference to Figures 1-7.

[0074] As used in this application, the terms “system” and “component” and “module” are intended to refer to a computer-related entity, either hardware, a combination of hardware and software, software, or software in execution, examples of which are provided by the exemplary computing architecture 800. For example, a component can be, but is not limited to being, a process running on a computer processor, a computer processor, a hard disk drive, multiple storage drives (of optical and/or magnetic storage medium), an object, an executable, a thread of execution, a program, and/or a computer. By way of illustration, both an application running on a server and the server can be a component. One or more components can reside within a process and/or thread of execution, and a component can be localized on one computer and/or distributed between two or more computers. Further, components may be communicatively coupled to each other by various types of communications media to coordinate operations. The coordination may involve the uni-directional or bi-directional exchange of information. For instance, the components may communicate information in the form of signals communicated over the communications media. The information can be implemented as signals allocated to various signal lines. In such allocations, each message is a signal. Further embodiments, however, may alternatively

employ data messages. Such data messages may be sent across various connections. Exemplary connections include parallel interfaces, serial interfaces, and bus interfaces.

[0075] The computing system 802 includes various common computing elements, such as one or more processors, multi-core processors, co-processors, memory units, chipsets, controllers, peripherals, interfaces, oscillators, timing devices, video cards, audio cards, multimedia input/output (I/O) components, power supplies, and so forth. The embodiments, however, are not limited to implementation by the computing system 802.

[0076] As shown in Figure 8, the computing system 802 comprises a processor 804, a system memory 806 and a system bus 808. The processor 804 can be any of various commercially available computer processors, including without limitation an AMD® Athlon®, Duron® and Opteron® processors; ARM® application, embedded and secure processors; IBM® and Motorola® DragonBall® and PowerPC® processors; IBM and Sony® Cell processors; Intel® Celeron®, Core®, Core (2) Duo®, Itanium®, Pentium®, Xeon®, and XScale® processors; and similar processors. Dual microprocessors, multi-core processors, and other multi processor architectures may also be employed as the processor 804.

[0077] The system bus 808 provides an interface for system components including, but not limited to, the system memory 806 to the processor 804. The system bus 808 can be any of several types of bus structure that may further interconnect to a memory bus (with or without a memory controller), a peripheral bus, and a local bus using any of a variety of commercially available bus architectures. Interface adapters may connect to the system bus 808 via a slot architecture. Example slot architectures may include without limitation Accelerated Graphics Port (AGP), Card Bus, (Extended) Industry Standard Architecture ((E)ISA), Micro Channel Architecture (MCA), NuBus, Peripheral Component Interconnect (Extended) (PCI(X)), PCI Express, Personal Computer Memory Card International Association (PCMCIA), and the like.

[0078] The system memory 806 may include various types of computer-readable storage media in the form of one or more higher speed memory units, such as read-only

memory (ROM), random-access memory (RAM), dynamic RAM (DRAM), Double-Data-Rate DRAM (DDRAM), synchronous DRAM (SDRAM), static RAM (SRAM), programmable ROM (PROM), erasable programmable ROM (EPROM), electrically erasable programmable ROM (EEPROM), flash memory (e.g., one or more flash arrays), polymer memory such as ferroelectric polymer memory, ovonic memory, phase change or ferroelectric memory, silicon-oxide-nitride-oxide-silicon (SONOS) memory, magnetic or optical cards, an array of devices such as Redundant Array of Independent Disks (RAID) drives, solid state memory devices (e.g., USB memory, solid state drives (SSD) and any other type of storage media suitable for storing information. In the illustrated embodiment shown in Figure 8, the system memory 806 can include non-volatile memory 810 and/or volatile memory 812. A basic input/output system (BIOS) can be stored in the non-volatile memory 810.

[0079] The computing system 802 may include various types of computer-readable storage media in the form of one or more lower speed memory units, including an internal (or external) hard disk drive (HDD) 814, a magnetic floppy disk drive (FDD) 816 to read from or write to a removable magnetic disk 818, and an optical disk drive 820 to read from or write to a removable optical disk 822 (e.g., a CD-ROM or DVD). The HDD 814, FDD 816 and optical disk drive 820 can be connected to the system bus 808 by a HDD interface 824, an FDD interface 826 and an optical drive interface 828, respectively. The HDD interface 824 for external drive implementations can include at least one or both of Universal Serial Bus (USB) and IEEE 1394 interface technologies. The computing system 802 is generally is configured to implement all logic, systems, methods, apparatuses, and functionality described herein with reference to Figures 1-7.

[0080] The drives and associated computer-readable media provide volatile and/or nonvolatile storage of data, data structures, computer-readable instructions, computer-executable instructions, and so forth. For example, a number of program modules can be stored in the drives and memory units 810, 812, including an operating system 830, one or more application programs 832, other program modules 834, and program data 836. In one embodiment, the one or more application programs 832, other program modules 834, and program data 836 can include, for example, the various applications and/or components of the system 100, e.g., the applet 103, counter 104, master key 105,

diversified key 106, customer ID 107, passport data 108, driver's license data 109, other user data 131, encrypted customer ID 132, operating system 112, account application 113, other applications 114, the authentication application 123, and/or the account data 124.

[0081] A user can enter commands and information into the computing system 802 through one or more wire/wireless input devices, for example, a keyboard 838 and a pointing device, such as a mouse 840. Other input devices may include microphones, infra-red (IR) remote controls, radio-frequency (RF) remote controls, game pads, stylus pens, card readers, dongles, finger print readers, gloves, graphics tablets, joysticks, keyboards, retina readers, touch screens (e.g., capacitive, resistive, etc.), trackballs, trackpads, sensors, styluses, and the like. These and other input devices are often connected to the processor 804 through an input device interface 842 that is coupled to the system bus 808, but can be connected by other interfaces such as a parallel port, IEEE 1394 serial port, a game port, a USB port, an IR interface, and so forth.

[0082] A monitor 844 or other type of display device is also connected to the system bus 808 via an interface, such as a video adaptor 846. The monitor 844 may be internal or external to the computing system 802. In addition to the monitor 844, a computer typically includes other peripheral output devices, such as speakers, printers, and so forth.

[0083] The computing system 802 may operate in a networked environment using logical connections via wire and/or wireless communications to one or more remote computers, such as a remote computer 848. The remote computer 848 can be a workstation, a server computer, a router, a personal computer, portable computer, microprocessor-based entertainment appliance, a peer device or other common network node, and typically includes many or all of the elements described relative to the computing system 802, although, for purposes of brevity, only a memory/storage device 850 is illustrated. The logical connections depicted include wire/wireless connectivity to a local area network (LAN) 852 and/or larger networks, for example, a wide area network (WAN) 854. Such LAN and WAN networking environments are commonplace in offices and companies, and facilitate enterprise-wide computer

networks, such as intranets, all of which may connect to a global communications network, for example, the Internet. In embodiments, the network 130 of Figure 1 is one or more of the LAN 852 and the WAN 854.

[0084] When used in a LAN networking environment, the computing system 802 is connected to the LAN 852 through a wire and/or wireless communication network interface or adaptor 856. The adaptor 856 can facilitate wire and/or wireless communications to the LAN 852, which may also include a wireless access point disposed thereon for communicating with the wireless functionality of the adaptor 856.

[0085] When used in a WAN networking environment, the computing system 802 can include a modem 858, or is connected to a communications server on the WAN 854, or has other means for establishing communications over the WAN 854, such as by way of the Internet. The modem 858, which can be internal or external and a wire and/or wireless device, connects to the system bus 808 via the input device interface 842. In a networked environment, program modules depicted relative to the computing system 802, or portions thereof, can be stored in the remote memory/storage device 850. It will be appreciated that the network connections shown are exemplary and other means of establishing a communications link between the computers can be used.

[0086] The computing system 802 is operable to communicate with wired and wireless devices or entities using the IEEE 802 family of standards, such as wireless devices operatively disposed in wireless communication (e.g., IEEE 802.16 over-the-air modulation techniques). This includes at least Wi-Fi (or Wireless Fidelity), WiMax, and Bluetooth™ wireless technologies, among others. Thus, the communication can be a predefined structure as with a conventional network or simply an ad hoc communication between at least two devices. Wi-Fi networks use radio technologies called IEEE 802.11x (a, b, g, n, etc.) to provide secure, reliable, fast wireless connectivity. A Wi-Fi network can be used to connect computers to each other, to the Internet, and to wire networks (which use IEEE 802.3-related media and functions).

[0087] Various embodiments may be implemented using hardware elements, software elements, or a combination of both. Examples of hardware elements may

include processors, microprocessors, circuits, circuit elements (e.g., transistors, resistors, capacitors, inductors, and so forth), integrated circuits, application specific integrated circuits (ASIC), programmable logic devices (PLD), digital signal processors (DSP), field programmable gate array (FPGA), logic gates, registers, semiconductor device, chips, microchips, chip sets, and so forth. Examples of software may include software components, programs, applications, computer programs, application programs, system programs, machine programs, operating system software, middleware, firmware, software modules, routines, subroutines, functions, methods, procedures, software interfaces, application program interfaces (API), instruction sets, computing code, computer code, code segments, computer code segments, words, values, symbols, or any combination thereof. Determining whether an embodiment is implemented using hardware elements and/or software elements may vary in accordance with any number of factors, such as desired computational rate, power levels, heat tolerances, processing cycle budget, input data rates, output data rates, memory resources, data bus speeds and other design or performance constraints.

[0088] One or more aspects of at least one embodiment may be implemented by representative instructions stored on a machine-readable medium which represents various logic within the processor, which when read by a machine causes the machine to fabricate logic to perform the techniques described herein. Such representations, known as “IP cores” may be stored on a tangible, machine readable medium and supplied to various customers or manufacturing facilities to load into the fabrication machines that make the logic or processor. Some embodiments may be implemented, for example, using a machine-readable medium or article which may store an instruction or a set of instructions that, if executed by a machine, may cause the machine to perform a method and/or operations in accordance with the embodiments. Such a machine may include, for example, any suitable processing platform, computing platform, computing device, processing device, computing system, processing system, computer, processor, or the like, and may be implemented using any suitable combination of hardware and/or software. The machine-readable medium or article may include, for example, any suitable type of memory unit, memory device, memory article, memory medium, storage device, storage article, storage medium and/or storage

unit, for example, memory, removable or non-removable media, erasable or non-erasable media, writeable or re-writeable media, digital or analog media, hard disk, floppy disk, Compact Disk Read Only Memory (CD-ROM), Compact Disk Recordable (CD-R), Compact Disk Rewriteable (CD-RW), optical disk, magnetic media, magneto-optical media, removable memory cards or disks, various types of Digital Versatile Disk (DVD), a tape, a cassette, or the like. The instructions may include any suitable type of code, such as source code, compiled code, interpreted code, executable code, static code, dynamic code, encrypted code, and the like, implemented using any suitable high-level, low-level, object-oriented, visual, compiled and/or interpreted programming language.

[0089] The foregoing description of example embodiments has been presented for the purposes of illustration and description. It is not intended to be exhaustive or to limit the present disclosure to the precise forms disclosed. Many modifications and variations are possible in light of this disclosure. It is intended that the scope of the present disclosure be limited not by this detailed description, but rather by the claims appended hereto. Future filed applications claiming priority to this application may claim the disclosed subject matter in a different manner, and may generally include any set of one or more limitations as variously disclosed or otherwise demonstrated herein.

CLAIMS

What is claimed is:

1. A system, comprising:
 - a processor; and
 - a memory storing instructions which when executed by the processor cause the processor to:
 - receive, by an application executing on the processor, an indication specifying to perform an operation associated with an account;
 - receive, by the application, encrypted data from a contactless card associated with the account, the encrypted data based on a cryptographic algorithm, a customer identifier, and a private key for the contactless card;
 - receive, by the application from an authentication server, an indication specifying that the authentication server verified the encrypted data based on the private key for the contactless card;
 - determine, by the application, a type of authentication data required to authorize the operation;
 - receive, by the application based on the determined type of authentication data, a first data element from the contactless card, the first data element comprising passport data or driver license data;
 - determine, by the application, that the first data element satisfies at least one rule for authorizing the operation; and
 - authorize performance of the operation by the application based on the received indication specifying that the authentication server verified the encrypted data and the determination that the first data element satisfies the at least one rule for authorizing the operation.
2. The system of claim 1, the memory storing instructions which when executed by the processor cause the processor to:

determine that a digital signature of the first data element received from the contactless card is a valid digital signature based on a public key associated with an entity providing the digital signature; and
determine the type of authentication data based on a type of the operation.

3. The system of claim 2, the first data element comprising a passport image, the memory storing instructions which when executed by the processor cause the processor to:

receive a first image depicting a person;
compare the first image to the passport image; and
determine, based on the comparison, that a similarity of a person depicted in the passport image and the person depicted in the first image exceeds a similarity threshold, wherein the determination the first data element satisfies the at least one rule is based on the similarity of the person depicted in the passport image and the person depicted in the first image exceeding the similarity threshold.

4. The system of claim 3, the memory storing instructions which when executed by the processor cause the processor to:

output, by the application, an indication specifying to capture the first image to authorize the operation; and
capture the first image by an image capture device of the system.

5. The system of claim 4, the memory storing instructions which when executed by the processor cause the processor to:

receive authentication credentials associated with the account, the authentication credentials comprising one or more of a login, a password, or biometric credentials; and
determine, based on the similarity of the person depicted in the passport image and the person depicted in the first image exceeding the similarity threshold, that the person depicted in the first image associated with the account, wherein the type of the operation comprises one or more of: (i) viewing attributes of the account, (ii)

modifying the attributes of the account, (iii) accessing a page of the application, or (iv) processing a transaction using the contactless card.

6. The system of claim 3, the first data element comprising a barcode of the driver license, the memory storing instructions which when executed by the processor cause the processor to:

receive, by the application from a point of sale device, an indication specifying that the operation is to complete a transaction for an age-restricted item using the contactless card, the at least one rule comprising an age required to purchase the age-restricted item;

determine, by the application based on the barcode of the driver license, an age of a person associated with the driver license and the contactless card;

determine, by the application, that the age of the person associated with the driver license and the contactless card exceeds the age required to purchase the age-restricted item;

transmit, by the application to the point of sale device, an indication specifying that the age of the person associated with the driver license and the contactless card exceeds the age required to purchase the age-restricted item;

receive, by the application, payment data received from the contactless card; and

transmit, by the application to the point of sale device, the payment data to complete the transaction.

7. The system of claim 2, the memory storing instructions which when executed by the processor cause the processor to:

receive, by the application, an updated version of the first data element; and

transmit, by the application to the contactless card, the updated version of the first data element for storage in the contactless card.

8. A non-transitory computer-readable storage medium having computer-readable program code embodied therewith, the computer-readable program code executable by a processor to cause the processor to:

receive, by an application executing on the processor, an indication specifying to perform an operation associated with an account;

receive, by the application, encrypted data from a contactless card associated with the account, the encrypted data based on a cryptographic algorithm, a customer identifier, and a private key for the contactless card;

receive, by the application from an authentication server, an indication specifying that the authentication server verified the encrypted data based on the private key for the contactless card;

determine, by the application, a type of authentication data required to authorize the operation;

receive, by the application based on the determined type of authentication data, a first data element from the contactless card, the first data element comprising passport data or driver license data;

determine that the first data element satisfies at least one rule for authorizing the operation; and

authorize performance of the operation based on the received indication specifying that the authentication server verified the encrypted data and the determination that the first data element satisfies the at least one rule for authorizing the operation.

9. The non-transitory computer-readable storage medium of claim 8, further comprising computer-readable program code executable by the processor to cause the processor to:

determine that a digital signature of the first data element received from the contactless card is a valid digital signature based on a public key associated with an entity providing the digital signature; and

determine the type of authentication data based on a type of the operation.

10. The non-transitory computer-readable storage medium of claim 9, wherein the first data element comprises a passport image, further comprising computer-readable program code executable by the processor to cause the processor to:

receive a first image depicting a person;

compare the first image to the passport image; and

determine, based on the comparison, that a similarity of a person depicted in the passport image and the person depicted in the first image exceeds a similarity threshold, wherein the determination the first data element satisfies the at least one rule is based on the similarity of the person depicted in the passport image and the person depicted in the first image exceeding the similarity threshold.

11. The non-transitory computer-readable storage medium of claim 10, further comprising computer-readable program code executable by the processor to cause the processor to:

output, by the application, an indication specifying to capture the first image to authorize the operation; and

capture the first image by an image capture device of a device comprising the processor.

12. The non-transitory computer-readable storage medium of claim 11, further comprising computer-readable program code executable by the processor to cause the processor to:

receive authentication credentials associated with the account, the authentication credentials comprising one or more of a login, a password, or biometric credentials; and

determine, based on the similarity of the person depicted in the passport image and the person depicted in the first image exceeding the similarity threshold, that the person depicted in the first image associated with the account, wherein the type of the operation comprises one or more of: (i) viewing attributes of the account, (ii) modifying the attributes of the account, (iii) accessing a page of the application, or (iv) processing a transaction using the contactless card.

13. The non-transitory computer-readable storage medium of claim 9, the first data element comprising a barcode of the driver license, further comprising computer-readable program code executable by the processor to cause the processor to:

receive, by the application from a point of sale device, an indication specifying that the operation is to complete a transaction for an age-restricted item using the contactless card, the at least one rule comprising an age required to purchase the age-restricted item;

determine, by the application based on the barcode of the driver license, an age of a person associated with the driver license and the contactless card;

determine, by the application, that the age of the person associated with the driver license and the contactless card exceeds the age required to purchase the age-restricted item;

transmit, by the application to the point of sale device, an indication specifying that the age of the person associated with the driver license and the contactless card exceeds the age required to purchase the age-restricted item;

receive, by the application, payment data received from the contactless card;
and

transmit, by the application to the point of sale device, the payment data to complete the transaction.

14. The non-transitory computer-readable storage medium of claim 9,
receive, by the application, an updated version of the first data element; and
transmit, by the application to the contactless card, the updated version of the first data element for storage in a memory of the contactless card.

15. A method, comprising:
receiving, by an application executing on a processor, an indication specifying to perform an operation associated with an account;
receiving, by the application, encrypted data from a contactless card associated with the account, the encrypted data based on a cryptographic algorithm, a customer identifier, and a private key for the contactless card;
transmitting, by the application to an authentication server, the encrypted data received from the contactless card;

receiving, by the application from the authentication server, an indication specifying that the authentication server verified the encrypted data based on the private key for the contactless card;

determining, by the application, a type of authentication data required to authorize the operation;

receiving, by the application based on the determined type of authentication data, a first data element from the contactless card, the first data element comprising passport data or driver license data;

determining that the first data element satisfies at least one rule for authorizing the operation; and

authorizing performance of the operation based on the received indication specifying that the authentication server verified the encrypted data and the determination that the first data element satisfies the at least one rule for authorizing the operation.

16. The method of claim 15, further comprising:

determining that a digital signature of the first data element received from the contactless card is a valid digital signature based on a public key associated with an entity providing the digital signature; and

determining the type of authentication data based on a type of the operation.

17. The method of claim 16, wherein the first data element comprises a passport image, the method further comprising:

outputting, by the application, an indication specifying to capture an image to authorize the operation;

capturing a first image by an image capture device of a device comprising the processor;

receiving, by the application, the first image depicting a person;

comparing the first image to the passport image; and

determining, based on the comparison, that a similarity of a person depicted in the passport image and the person depicted in the first image exceeds a similarity threshold, wherein the determination the first data element satisfies the at least one

rule is based on the similarity of the person depicted in the passport image and the person depicted in the first image exceeding the similarity threshold.

18. The method of claim 17, further comprising:

receiving authentication credentials associated with the account, the authentication credentials comprising one or more of a login, a password, or biometric credentials; and

determining, based on the similarity of the person depicted in the passport image and the person depicted in the first image exceeding the similarity threshold, that the person depicted in the first image associated with the account, wherein the type of the operation comprises one or more of: (i) viewing attributes of the account, (ii) modifying the attributes of the account, (iii) accessing a page of the application, or (iv) processing a transaction using the contactless card.

19. The method of claim 16, the first data element comprising a barcode of the driver license, the method further comprising:

receiving, by the application from a point of sale device, an indication specifying that the operation is to complete a transaction for an age-restricted item using the contactless card, the at least one rule comprising an age required to purchase the age-restricted item;

determining, by the application based on the barcode of the driver license, an age of a person associated with the driver license and the contactless card;

determining, by the application, that the age of the person associated with the driver license and the contactless card exceeds the age required to purchase the age-restricted item;

transmitting, by the application to the point of sale device, an indication specifying that the age of the person associated with the driver license and the contactless card exceeds the age required to purchase the age-restricted item;

receiving, by the application, payment data received from the contactless card; and

transmitting, by the application to the point of sale device, the payment data to complete the transaction.

20. The method of claim 16, further comprising:
- receiving, by the application, an updated version of the first data element;
 - transmitting, by the application to the contactless card, the updated version of the first data element; and
 - storing, by an applet executing on a processor of the contactless card, the updated version of the first data element in a memory of the contactless card.
