

CERAMIC ANION EXCHANGE MATERIALS**RELATED APPLICATIONS**

This application claims priority under 35 U.S.C. § 119(e) to United States
5 Provisional Application Serial No. 62/857,227, filed June 4, 2019, and entitled
“CERAMIC ANION EXCHANGE MATERIALS,” which is incorporated herein by
reference in its entirety for all purposes.

TECHNICAL FIELD

10 Ion exchange membranes and materials, and associated methods, are generally
described.

BACKGROUND

Anion exchange membranes and materials are used in a variety of industrial
15 applications where the selective transport of negatively charged ions is desired. In the
case of anion exchange membranes, negatively charged ions can be selectively
transported through the membrane cross-section. One type of anion exchange membrane
is a hydroxide ion exchange membrane, though anion exchange membranes capable of
the selective transport of other types of negatively charged ions exist. Certain
20 embodiments of the present disclosure are directed to inventive compositions,
membranes, and materials, and related methods, for improving the performance and/or
properties of anion exchange membranes and materials.

SUMMARY

25 Anion exchange membranes and materials including silica-based ceramics, and
associated methods, are generally described. The subject matter of the present invention
involves, in some cases, interrelated products, alternative solutions to a particular
problem, and/or a plurality of different uses of one or more systems and/or articles.

In one aspect, anion exchange membranes are provided. In some embodiments,
30 the anion exchange membrane comprises a porous support membrane and a silica-based
ceramic that coats at least a portion of the porous support membrane. The silica-based
ceramic comprises quaternary ammonium groups covalently bound to the silica-based

– 2 –

ceramic. The silica-based ceramic has an average pore diameter of less than or equal to 10 nm.

In some embodiments, the anion exchange membrane comprises a porous support membrane and a silica-based ceramic that forms a coating on and/or within the porous support membrane. The silica-based ceramic comprises quaternary ammonium groups covalently bound to the silica-based ceramic. The anion exchange membrane has a chloride ion conductivity of greater than or equal to 0.00001 S/cm.

In some embodiments, the anion exchange membrane comprises a silica-based ceramic, and the anion exchange membrane has a water uptake of greater than or equal to 10 wt% and a linear expansion of less than or equal to 10%.

In some embodiments, the anion exchange membrane comprises a porous support membrane and a silica-based ceramic that forms a coating on and/or within the porous support membrane. The silica-based ceramic comprises quaternary ammonium groups covalently bound to the silica-based ceramic. The quaternary ammonium groups are directly adjacent to a surface of the porous support membrane.

In some embodiments, the anion exchange membrane comprises a porous support membrane and a silica-based ceramic that coats at least a portion of the porous support membrane. The silica-based ceramic comprises quaternary ammonium groups covalently bound to the silica-based ceramic. Greater than or equal to 50% of the pore volume of the porous support membrane is filled by the silica-based ceramic.

In some embodiments, the anion exchange membrane comprises a porous support membrane and a silica-based ceramic that forms a coating on and/or within the porous support membrane. The silica-based ceramic comprises quaternary ammonium groups covalently bound to the silica-based ceramic. The anion exchange membrane has an anion exchange capacity of greater than or equal to 0.01 meq/g.

In some embodiments, the anion exchange membrane comprises a porous support membrane and a silica-based ceramic that coats at least a portion of the porous support membrane. The silica-based ceramic comprises quaternary ammonium groups covalently bound to the silica-based ceramic. The quaternary ammonium groups are present in the anion exchange membrane in an amount of greater than or equal to 0.01 mmol per gram of the anion exchange membrane.

In some embodiments, an anion exchange material is provided. The anion exchange material comprises a silica-based ceramic that comprises quaternary

– 3 –

ammonium groups covalently bound to the silica-based ceramic. The silica-based ceramic comprises Si in an amount greater than or equal to 6 wt% of the silica-based ceramic. The anion exchange material has an anion exchange capacity of greater than or equal to 0.01 meq/g. The silica-based ceramic has an average pore diameter of less than
5 10 nm.

In some embodiments, an anion exchange membrane is provided. In some embodiments, the anion exchange membrane comprises a silica-based ceramic comprising Si in an amount greater than or equal to 6 wt% of the silica-based ceramic. The anion exchange membrane has an anion exchange capacity of greater than or equal
10 to 0.01 meq/g.

In some embodiments, the anion exchange membrane comprises a silica-based ceramic. The anion exchange membrane has an anion exchange capacity of greater than or equal to 0.01 meq/g and a linear expansion of less than or equal to 10%.

In some embodiments, an anion exchange membrane is provided. The anion
15 exchange membrane comprises a silica-based ceramic comprising Si in an amount greater than or equal to 6 wt% of the silica-based ceramic. The anion exchange membrane has an anion permselectivity of greater than or equal to 65%.

In some embodiments, an anion exchange membrane is provided. The anion exchange membrane comprises a silica-based ceramic comprising Si in an amount
20 greater than or equal to 6 wt% of the silica-based ceramic. The anion exchange membrane has a chloride ion conductivity of greater than or equal to 0.00001 S/cm.

In some embodiments, the anion exchange membrane has a silica-based ceramic and a chloride ion conductivity of greater than or equal to 0.00001 S/cm and a linear expansion of less than or equal to 10%.

25 In some embodiments, an anion exchange membrane is provided. The anion exchange membrane comprises a silica-based ceramic comprising Si in an amount greater than or equal to 6 wt% of the silica-based ceramic. The anion exchange membrane has an osmotic water permeance of less than or equal to 100 mL/(hr·bar·m²).

30 In some embodiments, the anion exchange membrane comprises a silica-based ceramic comprising Si in an amount greater than or equal to 6 wt% of the silica-based ceramic. The silica-based ceramic comprises pores, wherein an average diameter of the pores of the silica-based ceramic is larger when the anion exchange membrane is in a

– 4 –

hydrated state than when the anion exchange membrane is in a dry state by a factor of greater than or equal to 1.1.

In some embodiments, the anion exchange membrane comprises a silica-based ceramic comprising Si in an amount greater than or equal to 6 wt% of the silica-based ceramic. When the anion exchange membrane is in a dry state, the pores of the silica-based ceramic fit a model of small angle scattering spectra with intensity (I) as a function of a scattering vector, q , as follows:

$$I(q) = \frac{1}{a+c_1q^2+c_2q^4} + bck,$$

wherein a , c_1 , and c_2 are adjustable parameters and bck is background scattering; and when the anion exchange membrane is in a hydrated state the pores of the silica-based ceramic fit a core-shell model of small angle scattering spectra with intensity (I) as a function of a scattering vector, q , as follows:

$$I(q) = P(q)S(q) + bck,$$

$$S(q) = 1 + \frac{D_f \Gamma(D_f - 1)}{[1 + 1/(q\xi)^2]^{(D_f - 1)/2}} \frac{\sin[(D_f - 1)\tan^{-1}(q\xi)]}{(qR_0)^{D_f}},$$

$$P(q) = \frac{scale}{V_s} \left[3V_c(\rho_c - \rho_s) \frac{[\sin(qr_c) - qr_c \cos(qr_c)]}{(qr_c)^3} + 3V_s(\rho_s - \rho_{block}) \frac{[\sin(qr_s) - qr_s \cos(qr_s)]}{(qr_s)^3} \right]^2 + bck,$$

wherein R_0 is a radius of the building blocks (pores), $\rho_{solvent}$ is a scattering length density of the silica-based ceramic, D_f is a fractal dimension, ξ is a correlation length, Γ is the standard mathematical gamma function, $scale$ is a volume fraction of building blocks of the measured silica-based ceramic, V_c is a volume of the core, V_s is a volume of the shell, ρ_c is a scattering length density of the core, ρ_s is a scattering length density of the shell, ρ_{block} is a scattering length density of the pores, r_c is a radius of the core, r_s is a radius of the shell, and bck is background scattering.

In some embodiments, a method of forming an anion exchange membrane is described. In some embodiments, the method comprises exposing a porous support membrane, at least a portion of which is coated with a silica-based ceramic, to an amine. The silica-based ceramic comprises a moiety comprising a leaving group covalently bound to the silica-based ceramic. The silica-based ceramic comprises Si in an amount greater than or equal to 6 wt% of the silica-based ceramic. The method comprises

– 5 –

reacting the amine with the moiety to release the leaving group and form a quaternary ammonium group covalently bound to the silica-based ceramic.

In some embodiments, a method of forming an anion exchange material is described. In some embodiments, the method comprises exposing a resin comprising a silica-based ceramic, to an amine. The silica-based ceramic comprises a moiety comprising a leaving group covalently bound to the silica-based ceramic. The silica-based ceramic comprises Si in an amount greater than or equal to 6 wt% of the silica-based ceramic. The method comprises reacting the amine with the moiety to release the leaving group and form a quaternary ammonium group covalently bound to the silica-based ceramic.

In some embodiments, a method for using an anion exchange membrane described herein in an electrochemical application is provided. The method comprises contacting the anion exchange membrane with an electrolyte. The method comprises passing current through an electrode in electrical communication with the electrolyte.

In some embodiments, a method for using an anion exchange material described herein in an electrochemical application is provided. The method comprises contacting the anion exchange material with an electrolyte. The method comprises passing current through an electrode in electrical communication with the electrolyte.

In some embodiments, a method for using an anion exchange membrane described herein as an adsorbent material is provided. In some embodiments, the method comprises flowing a fluid through the anion exchange membrane. The method comprises adsorbing a component of the fluid.

In some embodiments, a method for using an anion exchange material described herein as an adsorbent material is provided. The method comprises flowing a fluid through the anion exchange material. The method comprises adsorbing a component of the fluid.

In some embodiments, a method for using an anion exchange membrane described herein in a separation application is provided. The method comprises applying a transmembrane pressure to the anion exchange membrane.

Other advantages and novel features of the present invention will become apparent from the following detailed description of various non-limiting embodiments of the invention when considered in conjunction with the accompanying figures. In cases

– 6 –

where the present specification and a document incorporated by reference include conflicting and/or inconsistent disclosure, the present specification shall control.

BRIEF DESCRIPTION OF THE DRAWINGS

- 5 Non-limiting embodiments of the present invention will be described by way of example with reference to the accompanying figures, which are schematic and are not intended to be drawn to scale. In the figures, each identical or nearly identical component illustrated is typically represented by a single numeral. For purposes of clarity, not every component is labeled in every figure, nor is every component of each
- 10 embodiment of the invention shown where illustration is not necessary to allow those of ordinary skill in the art to understand the invention. In the figures:
- FIG. 1A is a schematic cross-sectional illustration of an exemplary anion exchange membrane comprising a silica-based ceramic, according to some embodiments;
- FIG. 1B is a schematic cross-sectional illustration of an exemplary anion
- 15 exchange membrane comprising a silica-based ceramic, and an inset showing a zoomed in view of pores of the silica-based ceramic, according to some embodiments;
- FIG. 2A is a schematic top-down illustration of an exemplary anion exchange membrane comprising a silica-based ceramic and a porous support membrane, according to some embodiments;
- 20 FIG. 2B is a schematic cross-sectional illustration of an exemplary silica-based ceramic coating on a portion of a porous support membrane component, according to some embodiments;
- FIG. 3 is a schematic illustration of quaternary ammonium groups covalently bound to silica-based ceramic, according to some embodiments;
- 25 FIG. 4A is a schematic cross-sectional illustration of an exemplary silica-based ceramic coating on a portion of a porous support membrane component, where the coating comprises quaternary ammonium groups that are substantially homogeneously distributed within the silica-based ceramic across a thickness of the coating, according to some embodiments;
- 30 FIG. 4B is a schematic cross-sectional illustration of an exemplary silica-based ceramic coating on a portion of a porous support membrane component, where the coating comprises quaternary ammonium that are not substantially homogeneously

– 7 –

distributed within the silica-based ceramic across a thickness of the coating, according to some embodiments;

FIG. 5 is a schematic top-down illustration of an exemplary anion exchange membrane comprising a silica-based ceramic and a compressible edging material,

5 according to some embodiments;

FIG. 6 is a flow diagram showing steps of an exemplary procedure for fabricating a ceramic anion exchange membrane, according to some embodiments;

FIG. 7 is a schematic cross-sectional illustration of an anion exchange material comprising a silica-based ceramic, where the anion exchange material comprises
10 quaternary ammonium groups covalently bound to the silica-based ceramic, according to some embodiments;

FIGS. 8A-8D show anion permselectivity, osmotic water permeance chloride ion conductivity, and small angle X-ray scattering data and fitting results for exemplary anion exchange membranes, according to some embodiments;

15 FIG. 9A shows small angle X-ray scattering data and fitting results for an exemplary anion exchange membrane, according to certain embodiments;

FIGS. 9B-9D show pore radius, volumetric porosity, and anion exchange capacity data for exemplary anion exchange membranes as a function of TEOS:TMAPS mole ratio, according to some embodiments;

20 FIGS. 10A-10B show permselectivity and chloride ion conductivity data for exemplary anion exchange membranes at different porous support membrane thicknesses, according to some embodiments;

FIGS. 11A-11B show permselectivity and chloride ion conductivity data for exemplary anion exchange membranes as a function of number of coatings, time exposed
25 to silicon-containing precursor sols, and drying conditions, according to some embodiments; and

FIG. 11C shows a cross-sectional SEM image of an exemplary anion exchange membrane, according to some embodiments.

30

DETAILED DESCRIPTION

Anion exchange membranes and materials including silica-based ceramics, and associated methods, are provided. In some aspects, anion exchange membranes that include a silica-based ceramic that forms a coating on and/or within a porous support

– 8 –

membrane are described. The anion exchange membranes and materials may have certain structural or chemical attributes (e.g., pore size/distribution, chemical functionalization) that, alone or in combination, can result in advantageous performance characteristics in any of a variety of applications for which selective transport of negatively charged ions through membranes/materials is desired. For example, the anion exchange membranes or materials described herein may display relatively high anion exchange capacity, anion permselectivity, and/or mechanical burst strength, while in some cases also undergoing relatively low dimensional swelling (e.g., when in contact with water). In some embodiments, the silica-based ceramic contains relatively small pores (e.g., substantially spherical nanopores) that may contribute to some such advantageous properties.

In some embodiments, the anion exchange membrane or material includes quaternary ammonium groups covalently bound to the silica-based ceramic. In some such cases, the quaternary ammonium groups are present in relatively high loadings compared to certain existing anion exchange materials. In some embodiments, the quaternary ammonium groups are substantially homogeneously distributed within the silica-based ceramic across a thickness of a coating formed by the silica-based ceramic, which can, in some cases, lead to benefits over certain existing membranes that may be functionalized only at or near the surface.

In some embodiments, the anion exchange membranes and materials described herein can be produced via sol-gel techniques, such as via the co-condensation of certain silanes on porous support membranes. The anion exchange membranes and materials may be useful in a number of applications, such as electrochemical (e.g., redox flow battery) and purification (e.g., desalination, gas/liquid separation) processes.

Certain existing anion exchange membranes that are commercially available are made from hydrocarbon- or perfluorocarbon-based polymers containing covalently bound quaternary ammonium moieties. As a result, these anion exchange membranes have nanostructures characterized by a mixture of interconnected worm-like hydrophilic domains in a hydrophobic matrix. In the presence of water (e.g., when certain existing anion exchange membranes are in use), these hydrophilic domains tend to swell (e.g., undergo dimensional swelling such as linear expansion). Swelling of anion exchange membranes can be problematic in certain applications, because the swelling can cause tensile forces that can lead to tearing of the membrane and device failure. While certain

techniques such as chemical cross-linking and/or mechanical reinforcement of the membrane can sometimes reduce swelling, improved compositions and architectures that can more effectively reduce swelling while preserving or even enhancing the performance of anion exchange membranes and materials are needed.

5 It has been observed that anion exchange membranes that include rigid structures such as ceramics can undergo less swelling than hydrocarbon- or perfluorocarbon-based membranes. However, certain existing ceramics have been considered too brittle to be used in standalone ceramic-based membranes. Therefore, previous attempts at introducing ceramics into anion exchange membranes have typically involved
10 incorporation of ceramic nanoparticles into, for example, polymer matrices. In the context of the present disclosure, it has been unexpectedly observed that it is possible to achieve anion exchange membranes and materials that include silica-based ceramics without needing to resort to using nanoparticles incorporated into polymeric matrices. For example, it has been observed that anion exchange membranes containing silica-
15 based ceramics comprising functional groups such as quaternary ammonium group that are covalently bound to the silica-based ceramic are achievable. In some embodiments, such functionalized silica-based ceramic compositions can have ordered, nanoporous structures. In some embodiments, the resulting anion exchange membranes display unexpectedly beneficial performance characteristics (e.g., relatively high anion exchange
20 capacity, relatively high chloride ion conductivity, relatively high permselectivity, high mechanical burst strength), while displaying relatively low dimensional swelling. Such anion exchange membranes and materials, and methods for making and using them, are described herein.

 In one aspect, anion exchange membranes are generally described. FIG. 1A is a
25 schematic cross-sectional illustration of an exemplary anion exchange membrane 100. In some embodiments, the anion exchange membrane can realize any of a variety of advantageous properties and performance characteristics reported in the present disclosure. For example, anion exchange membrane 100 may display a relatively high anion exchange capacity, relatively high anion permselectivity, relatively high chloride
30 ion conductivity, relatively low osmotic water permeance, and/or relatively low dimensional swelling (e.g., relatively low linear expansion), the details of which are provided in greater detail below. As mentioned above, the anion exchange membrane

– 10 –

may be suitable for use in any of a variety of applications, described in more detail below.

Referring again to FIG. 1A, exemplary anion exchange membrane 100 comprises silica-based ceramic 150. In some embodiments, the silica-based ceramic is a ceramic comprising or formed of a network of silica (SiO_2), though the silica-based ceramic can include groups (e.g., terminal moieties) not encompassed by the SiO_2 formula. In some embodiments, the silica-based ceramic is porous (e.g., nanoporous). FIG. 1B is a schematic cross-sectional illustration of an exemplary anion exchange membrane 100 comprising an exemplary silica-based ceramic 150 that is porous (e.g., nanoporous), according to some embodiments. FIG. 1B shows an inset depicting a zoomed-in view of silica-based ceramic 150 showing exemplary pores, including an exemplary pore 152. The porosity (e.g., nanoporosity) of the silica-based ceramic may contribute, at least in part, to the performance characteristics of the anion exchange membrane. The silica-based ceramic is described in more detail below. It should be understood that the figures shown herein are for illustrative purposes, and may not necessarily be drawn to scale.

In some embodiments, the anion exchange membrane comprises a porous support membrane. For example, in some embodiments, anion exchange membrane 100 comprises a porous support membrane. The porous support membrane may provide for mechanical support for the overall anion exchange membrane. FIG. 2A shows a schematic top-down illustration of an exemplary anion exchange membrane 100 comprising a silica-based ceramic 150 and a porous support membrane 130 hidden by silica-based ceramic 150, according to some embodiments. For illustrative purposes, FIG. 2A shows porous support membrane 130 without a silica-based ceramic 150 present to the left of the arrow, while anion exchange membrane 100 to the right side of the arrow includes silica-based ceramic 150 present, which hides porous support membrane from view. It should be understood that FIG. 2A is illustrative for a non-limiting embodiment, and in some embodiments, the coating formed by the silica-based ceramic does not completely cover the porous support membrane. For example, in some such embodiments, portions of porous support membrane 130 may not be hidden by silica-based ceramic 150.

In some embodiments, the anion exchange membrane comprises a silica-based ceramic that coats at least a portion of the porous support membrane. Referring again to FIG. 2A, anion exchange membrane 100 comprises silica-based ceramic 150, which

– 11 –

coats porous support membrane 130 (hidden from view in anion exchange membrane 100 to the right of the arrow). In some such embodiments, the silica-based ceramic forms a coating on and/or within the porous support membrane. For example, the porous support membrane may be impregnated or encapsulated in the silica-based ceramic. In
5 some embodiments, the silica-based ceramic coats a portion, but not all, of the porous support membrane. In such embodiments, the porous support membrane may be substantially coated with the silica-based ceramic.

FIG. 2B shows a schematic cross-sectional view of an exemplary coating 140 formed by silica-based ceramic 150, according to some embodiments. As shown
10 illustratively in this figure, coating 140 of silica-based ceramic 150 is on a surface of porous support membrane component 135 (e.g., a single fiber on or within a porous support membrane), a cross-section of which is shown in FIG. 2B, in accordance with some embodiments. This exemplary embodiment (e.g., a coated fiber) may be a part of a anion exchange membrane in which a silica-based ceramic coats the porous support
15 membrane completely, or coats a porous support membrane partially.

It should be understood that when a portion (e.g., layer, coating,) is “on”, “adjacent”, “in contact with”, or “supported by” another portion, it can be directly on the portion, or an intervening portion (e.g., layer, coating) also may be present. A portion that is “directly on”, “directly adjacent”, “in direct contact with”, or “directly supported
20 by” another portion means that no intervening portion is present. It should also be understood that when a portion is referred to as being “on”, “adjacent”, “in contact with”, or “supported by” another portion, it may cover the entire portion or a part of the portion.

In some embodiments, the coating of the silica-based ceramic (e.g., coating 140) is present on (e.g., directly on) the surface of the porous support membrane. In some
25 embodiments, the coating is present on the surface of the porous support membrane while the interior of the porous support membrane is not substantially coated. However, in other embodiments, the coating of the silica-based ceramic is present within at least a portion of the interior of the porous support membrane (i.e., through the thickness of the porous support membrane). As one example, the coating of the silica-based ceramic is
30 formed on components in the interior of the porous support membrane accessible via, for example, pores or voids. In some such cases, the coating fills at least a portion or all of the pores of the porous support membrane. In some embodiments, at least a portion of

– 12 –

the interior of the porous support membrane is coated, while the surface of the porous support membrane is not substantially coated.

As described in more detail below, the porous support membrane may include support components such as fibers that provide structural support to the membrane. In some embodiments, substantially all of the support components of the porous support membrane are coated with the silica-based ceramic. As one example, in some embodiments, the porous support membrane comprises a non-woven fabric of fibers. In some such cases, substantially all of the fibers, including fibers in the interior of the porous support membrane, are coated with the silica-based ceramic. However, in other embodiments, not all of the support components of the porous support membrane are coated with the silica-based ceramic. For example, in some embodiments in which the porous support membrane comprises fibers as support components, not all fibers are coated with a silica-based ceramic. The extent of the coating may vary. In some cases, the coating of the silica-based ceramic covers the entire porous support membrane (e.g., as shown with anion exchange membrane 100 to the right of the arrow in FIG. 2A), though in other cases, the coating of the silica-based ceramic covers only a portion of the porous support membrane (e.g., only a subset of the area of the porous support membrane is coated, or only a portion of the support components are coated).

In some embodiments in which the silica-based ceramic forms a coating on and/or within the porous support membrane, the silica-based ceramic fills substantially all of the pores of the porous support membrane. For example, referring again to FIG. 2A, in some embodiments, when the silica-based ceramic coats porous support membrane 130, all of the pores of porous support membrane 130, including pore 132, are completely filled by the silica-based ceramic. In such embodiments, the porosity of the resulting overall anion exchange membrane would correspond to the porosity of the silica-based ceramic material. In other embodiments in which the silica-based ceramic forms a coating on and/or within the porous support membrane, the silica-based ceramic does not completely fill the pores of the porous support membrane, but reduces the pore size (e.g., average pore diameter) of the porous support membrane. In such embodiments, the overall porosity of the resulting overall anion exchange membrane would be different than the porosity of the silica-based ceramic material itself. The resulting overall exchange membrane in this case will have a porosity that is different than the porosity of the silica-based ceramic coating because both the reduced-in-size

– 13 –

pores of the porous support membrane and the pores corresponding to the silica-based ceramic will be present. In such embodiments, the silica-based ceramic coating may have a porosity in one or more of the ranges described herein, and the overall anion exchange membrane may have a porosity in one or more of the ranges described herein.

5 In some, but not necessarily all embodiments, the anion exchange membrane comprises one or more additional layers or coatings on the coating comprising the silica-based ceramic (e.g., on top of the silica-based ceramic coating). However, in some embodiments, no other layers or coatings are present on the coating comprising the silica-based ceramic (e.g., the silica-based coating forms the outer-most surface of the
10 anion exchange membrane). In some embodiments, the silica-based ceramic forms a single layer on the porous support membrane.

 The formation of a coating of the silica-based ceramic on and/or within at least a portion of the porous support membrane can be accomplished using any of a variety of suitable techniques. In some embodiments, the coating of the silica-based ceramic (e.g.,
15 coating 140) is formed using sol-gel techniques. For example, referring back to FIG. 2A, in some embodiments, porous support membrane 130 (shown to the left of the arrow) is coated using sol-gel techniques, thereby resulting in anion exchange membrane 100 comprising a silica-based ceramic 150 coated on and/or within at least a portion of porous support membrane 130 (shown to the right of the arrow). In some cases, sol-gel
20 techniques such as those described herein can provide for a relatively rapid and inexpensive formation of anion exchange membranes comprising silica-based ceramics. In some such cases, relatively mild conditions can be used to form the coating of the silica-based ceramic using sol-gel techniques, and the resulting silica-based ceramics may possess certain structural properties (e.g., ordered nanopores) that can in some cases
25 provide for advantageous performance. Exemplary sol-gel techniques are described in more detail below.

 In some embodiments, the silica-based ceramic comprises one or more functional groups covalently bound to the silica-based ceramic. The presence of functional groups covalently bound to the silica-based ceramic may contribute at least in part to the
30 performance of the anion exchange membrane. For example, in some embodiments, the silica-based ceramic comprises functional groups capable of associating and disassociating cations. In some embodiments, the functional groups covalently bound to the silica-based ceramic are positively-charged functional groups. For example, in some

– 14 –

embodiments, the functional groups covalently bound to the silica-based ceramic are quaternary ammonium groups. In some embodiments, the functional groups covalently bound to the silica-based ceramic are imidazole groups. In some embodiments, the functional groups covalently bound to the silica-based ceramic are weak base groups such as amine groups (e.g., tertiary amine groups). The functional groups may be bound to Si in the silica-based ceramic via a linking group (e.g., an organic linking group). For example, the nitrogen of the quaternary ammonium groups may be covalently bound to Si in the silica-based ceramic via an organic linker such as a linker chosen from optionally-substituted C₁₋₁₈ alkylene and arylene (or C₁₋₈ alkylene and arylene, or C₁₋₄ alkylene and arylene). It should be understood that in the present disclosure, any description of an item being “chosen from” a list of items can be replaced with a description of an item being selected from a “group consisting of” those items. For example, in some embodiments, the nitrogen of the quaternary ammonium groups may be covalently bound to Si in the silica-based ceramic via an organic linker such as a linker selected from the group consisting of optionally-substituted C₁₋₁₈ alkylene and arylene.

The functional group may be able to associate and dissociate cations such as protons or certain metal ions. As an example, quaternary ammonium groups bound to the silica-based ceramic may be able to associate and disassociate anions such as hydroxide or halides. Exemplary anions that may be able to associate and dissociate with the functional groups (e.g., quaternary ammonium groups) include F⁻, Cl⁻, Br⁻, I⁻, OH⁻, SO₃⁻, CO₃⁻, PO₄³⁻, BO₃⁻, NO₃⁻, NO₂⁻, and ClO₃⁻.

FIG. 3 is a schematic illustration of quaternary ammonium groups covalently bound to a silica-based ceramic 150, according to some embodiments. As shown illustratively in this figure, the quaternary ammonium groups are covalently attached to the interior portions of the silica-based ceramic material. In some embodiments, the functional groups (e.g., quaternary ammonium groups) are exposed at an exterior surface of the silica-based ceramic (e.g., the exterior of a coating of the silica-based ceramic). In some cases, the functional groups covalently bound to the silica-based ceramic groups (e.g., quaternary ammonium groups) are exposed at surfaces of pores in the silica-based ceramic. For example, in FIG. 3, quaternary ammonium groups covalently bound to silica-based ceramic 150 are shown exposed at a surface of a pore 152 of the silica-based ceramic. Having functional groups such as quaternary ammonium groups present at the

– 15 –

surface of pores of the silica-based ceramic may, in some embodiments, allow for relatively efficient transport of anions through the anion exchange membrane, and/or relatively high anion exchange capacity for the anion exchange membrane.

One of ordinary skill in the art would understand that the relative amount of the conjugate acid of a functional group covalently bound to the silica-based ceramic compared to the amount of conjugate base of the functional group present at any given time will depend on the conditions and environment of the anion exchange membrane or material. For example, in embodiments where the functional group is an imidazole or an amine (e.g., a tertiary amine), the relative number of imidazolium vs. imidazole or ammonium vs. amine groups will depend at least in part on the pH of any solution with which the membrane or material is in contact, the pK_a of other functional groups if present, and/or the concentration of anions in any solution for which the membrane or material is in contact.

In some embodiments, the silica-based ceramic comprises quaternary ammonium groups covalently bound to silica-based ceramic, and the quaternary ammonium groups are substantially homogeneously distributed within the silica-based ceramic across a thickness of the coating. A thickness of the coating refers to a thickness in a direction going from a surface of the component of the porous support membrane coated by the coating (e.g., the surface of a single fiber of the porous support membrane) to the closest exposed surface of the silica-based ceramic coating. An exposed surface of the silica-based ceramic coating refers to any surface of the silica-based ceramic that interfaces with the exterior of the anion exchange membrane, another layer or domain of material, or an unfilled pore or void of the porous support membrane. For example, in one embodiment, an exposed surface may be exposed to air or another environment different from the silica-based ceramic coating itself. FIG. 4A is a schematic cross-sectional illustration of an exemplary coating 140 of a silica-based ceramic 150 on a portion of a porous support membrane component 135 (e.g., a fiber on or within a porous support membrane), according to some embodiments. In some embodiments, coating 140 in FIG. 4A comprises quaternary ammonium groups that are substantially homogeneously distributed within silica-based ceramic 150 across a thickness 160 of coating 140. Having functional groups such as quaternary ammonium groups substantially homogeneously distributed within the silica-based ceramic across a thickness of the coating may, in some cases, result in a number of advantages. One advantage may be

– 16 –

that a substantially homogeneous distribution of functional groups in the silica-based ceramic can allow for a relatively high loading of the functional groups for a given amount of silica-based ceramic, which can lead to high anion exchange capacities per unit mass, and beneficial performance characteristics. Another possible advantage is that

5 a substantially homogeneous distribution of functional groups in the silica-based ceramic can result in relatively small distances between functional groups within the membrane, as opposed to certain existing membranes where functional groups (e.g., quaternary ammonium groups) are relatively localized (e.g., near a surface), which can result in regions of the membrane having a relatively low amount of the functional groups and

10 can limit anion conductivity. A substantially homogeneous distribution of functional groups (e.g., quaternary ammonium groups) can be achieved, for example, using certain sol-gel techniques, as described in more detail below.

FIG. 4B is a schematic cross-sectional illustration of an exemplary coating 240 comprising a silica-based ceramic 250 on a portion of a porous support membrane component 135 (e.g., a fiber on or within a porous support membrane), according to

15 some embodiments. In FIG. 4B, coating 240 comprises quaternary ammonium groups that are not substantially homogeneously distributed within silica-based ceramic 250 across a thickness 260 of coating 240. Rather, in FIG. 4B, the quaternary ammonium groups are localized at or near the surface of coating 240, leaving a region 245 of the

20 coating without quaternary ammonium groups.

Such a distribution of quaternary ammonium groups that is not substantially homogeneously distributed may result from coating techniques that use surface functionalization, rather than the certain sol-gel techniques described herein. For example, a coating comprising a silica-based ceramic comprising quaternary ammonium

25 groups that are not substantially homogeneously distributed may result from fabrication techniques where a support (e.g., porous support membrane) is first coated with a material (e.g., with a ceramic such as a silica-based ceramic) that does not comprise quaternary ammonium groups (or a relatively low amount of quaternary ammonium groups). Then, following the first coating step, a second coating step is performed where

30 a material that does comprise quaternary ammonium groups (or comprises a relatively higher amount of quaternary ammonium groups) is coated on the first coating. Having a silica-based ceramic coating that does not have a substantially homogeneous distribution of quaternary ammonium groups may result in relatively poor performance of the

– 17 –

resulting anion exchange membrane. For example, in some embodiments, the anion exchange membranes may have a relatively lower loading of quaternary ammonium groups compared to anion exchange membranes having coatings that have a substantially homogeneous distribution of quaternary ammonium groups. Additionally, in some cases, such coatings that do not have a substantially homogeneous distribution of quaternary ammonium groups and consequently have regions having a relatively low abundance of quaternary ammonium groups (e.g., region 245) may have relatively lower anion conductivity due to such regions.

In some embodiments in which the quaternary ammonium groups are substantially homogeneously distributed within the silica-based ceramic across a thickness of the coating, the amount of quaternary ammonium groups does not vary by more than 50% at any given point within a cross-section of thickness of the coating compared to an average amount of the quaternary ammonium groups in the silica-based ceramic. For example, referring again to FIG. 4A, the amount of quaternary ammonium groups at an arbitrary point A, or at an arbitrary point B, of cross-section 143 of coating 140 does not vary by more than 50% compared to the average amount of quaternary ammonium groups in coating 140. In some embodiments in which the quaternary ammonium groups are substantially homogeneously distributed within the silica-based ceramic across a thickness of the coating, the amount of quaternary ammonium groups is distributed within the silica-based ceramic such that any given point within a cross-section of thickness of the coating is within greater than or equal to 50%, greater than or equal to 60%, greater than or equal to 70%, greater than or equal to 75%, greater than or equal to 80%, greater than or equal to 90%, greater than equal to 95%, or greater than or equal to 99% of the average amount of quaternary ammonium groups in the coating. In some embodiments, the amount of quaternary ammonium groups is distributed within the silica-based ceramic such that any given point within a cross-section of thickness of the coating is within less than or equal to 100%, less than or equal to 99%, less than or equal to 95%, less than or equal to 90%, less than or equal to 75%, less than or equal to 70%, less than or equal to 60%, or less of the average amount of quaternary ammonium groups within the coating. Combinations of these ranges are possible. For example, in some embodiments, the amount of quaternary ammonium groups is distributed within the silica-based ceramic such that any given point within a cross-section of thickness of the coating is within greater than or equal to 50% and less than or equal to 100% of the

– 18 –

total average amount of quaternary ammonium groups within the coating. As an exemplary calculation, if a silica-based ceramic were determined to have an average amount of quaternary ammonium groups of 5 weight percent (wt%) (as determined by scanning electron microscopy/energy-dispersive X-ray techniques (SEM/EDX)), and all
5 points within at least 5 cross-sections across the thickness of the silica-based ceramic (e.g., point A in FIG. 4A) are determined to have an amount of quaternary ammonium groups of greater than or equal to 2.5 wt% and less than or equal to 7.5 wt%, then that silica-based ceramic would be considered to have quaternary ammonium groups substantially homogeneously distributed across a thickness of the coating based on the
10 average amount of quaternary ammonium groups measured.

In contrast, in some cases in which the quaternary ammonium groups are not substantially homogeneously distributed within the silica-based ceramic across a thickness of the coating, the amount of quaternary ammonium groups are within less than 50% of the average amount of quaternary ammonium groups within the coating (in
15 other words, the amount of quaternary ammonium groups varies by more than 50% at any given point within a cross-section of thickness of the coating compared to an average total amount of the quaternary ammonium groups in the silica-based ceramic). For example, referring again to FIG. 4B, the amount of quaternary ammonium groups at an arbitrary point C, or at an arbitrary point D, of cross-section 243 of coating 240 varies by
20 more than 50% compared to the average amount of quaternary ammonium groups in coating 240. As an exemplary calculation, if a silica-based ceramic were determined to have an average amount of quaternary ammonium groups of 5 wt%, and any point within a cross-section across the thickness of the silica-based ceramic (e.g., point D in FIG. 4B) were determined to have an amount of quaternary ammonium groups of less than 2.5
25 wt% or greater than 7.5 wt%, then that silica-based ceramic would not be considered to have quaternary ammonium groups substantially homogeneously distributed across a thickness of the coating based on the average amount of quaternary ammonium groups measured.

In some embodiments in which the quaternary ammonium groups are
30 substantially homogeneously distributed within the silica-based ceramic across a thickness of the coating, the amount of quaternary ammonium groups does not vary by more than 75% at any given point within a cross-section of thickness of the coating compared to a maximum amount of the quaternary ammonium groups in the silica-based

– 19 –

ceramic. For example, referring again to FIG. 4A, the amount of quaternary ammonium groups at an arbitrary point A, or at an arbitrary point B, of cross-section 143 of coating 140 does not vary by more than 75% compared to the maximum amount of quaternary ammonium groups in coating 140. In some embodiments in which the quaternary ammonium groups are substantially homogeneously distributed within the silica-based ceramic across a thickness of the coating, the amount of quaternary ammonium groups is distributed within the silica-based ceramic such that any given point within a cross-section of thickness of the coating is greater than or equal to 25%, greater than or equal to 40%, greater than or equal to 50% greater than or equal to 60%, greater than or equal to 70%, greater than or equal to 75%, greater than or equal to 80%, greater than or equal to 90%, greater than equal to 95%, or greater than or equal to 99% of the maximum amount of quaternary ammonium groups in the coating. In some embodiments, the amount of quaternary ammonium groups is distributed within the silica-based ceramic such that any given point within a cross-section of thickness of the coating is less than or equal to 100%, less than or equal to 99%, less than or equal to 95%, less than or equal to 90%, less than or equal to 75%, less than or equal to 70%, less than or equal to 60%, or less of the maximum amount of quaternary ammonium groups within the coating. Combinations of these ranges are possible. For example, in some embodiments, the amount of quaternary ammonium groups is distributed within the silica-based ceramic such that any given point within a cross-section of thickness of the coating is greater than or equal to 25% and less than or equal to 100% of the total maximum amount of quaternary ammonium groups within the coating. As an exemplary calculation, if a silica-based ceramic were determined to have a maximum amount of quaternary ammonium groups of 10 wt% (as determined by scanning electron microscopy/energy-dispersive X-ray techniques (SEM/EDX)), and all points within at least 5 cross-sections across the thickness of the silica-based ceramic (e.g., point A in FIG. 4A) are determined to have an amount of quaternary ammonium groups of greater than or equal to 2.5 wt%, then that silica-based ceramic would be considered to have quaternary ammonium groups substantially homogeneously distributed across a thickness of the coating based on the maximum amount of quaternary ammonium groups measured. It should be understood that it is the relative amounts of quaternary ammonium groups that is important in the above calculation, and the units used to express the amounts measured from the SEM/EDX technique are not particularly important. While weight percent is

– 20 –

used in the above exemplary calculation, other units for expressing the amount of quaternary ammonium groups are readily obtainable from the SEM/EDX technique or can be derived from the weight percentage as well.

In contrast, in some cases in which the quaternary ammonium groups are not substantially homogeneously distributed within the silica-based ceramic across a thickness of the coating, the amount of quaternary ammonium groups at a point are less than 25% of the maximum amount of quaternary ammonium groups within the coating (in other words, the amount of quaternary ammonium groups varies by more than 75% at any given point within a cross-section of thickness of the coating compared to a maximum total amount of the quaternary ammonium groups in the silica-based ceramic). For example, referring again to FIG. 4B, the amount of quaternary ammonium groups at an arbitrary point C, or at an arbitrary point D, of cross-section 243 of coating 240 varies by more than 75% compared to the maximum amount of quaternary ammonium groups in coating 240. As an exemplary calculation, if a silica-based ceramic were determined to have a maximum amount of quaternary ammonium groups of 10 wt%, and any point within a cross-section across the thickness of the silica-based ceramic (e.g., point D in FIG. 4B) were determined to have an amount of quaternary ammonium groups of less than 2.5 wt%, then that silica-based ceramic would not be considered to have quaternary ammonium groups substantially homogeneously distributed across a thickness of the coating based on the maximum amount of quaternary ammonium groups measured.

The amount of quaternary ammonium groups within the coating and within an arbitrary cross-section of the coating may be determined using a combination of scanning electron microscopy (SEM) and energy-dispersive X-ray (EDX) techniques. For example, the following procedure can be performed. The anion exchange membrane is dried and a cross sectional sample is mounted on to an SEM stub. The sample is first imaged using secondary electron and/or backscatter detection, followed by imaging via EDX. The EDX data can be acquired as a line profile across the cross sectional sample or as a map of the whole sample. The EDX data can then be interpreted to determine the average amount or maximum amount (e.g., in wt%) of quaternary ammonium groups are present in the coating, as well as amounts of quaternary ammonium groups at points along arbitrary cross-sections using the line profiles from the SEM/EDX data. Three or more line profiles can be acquired to determine a statistically representative set of data.

– 21 –

In some embodiments, quaternary ammonium groups are directly adjacent to a surface of the porous support membrane. For example, referring again to FIG. 4A, coating 140 comprising silica-based ceramic 150 comprises quaternary ammonium groups, and the quaternary ammonium groups are directly adjacent to porous support
5 membrane component 135, thereby making it directly adjacent to the porous support membrane to which porous support membrane component 135 belongs, according to some embodiments. In some embodiments, no intervening layer is present between the silica-based ceramic comprising quaternary ammonium groups in the porous support membrane. For example, in some embodiments, there is no intervening layer between
10 silica-based ceramic 150 and porous support membrane component 135 in FIG. 4A.

In some embodiments, the quaternary ammonium groups are relatively close to a surface of the porous support membrane (e.g., the surface of the support components that make up the porous support membrane). For example, in some embodiments, at least some of the quaternary ammonium groups are within 1 μm , within 500 nm, within 100
15 nm, within 50 nm, within 10 nm, within 5 nm, within 1 nm, or less of a surface of the porous support membrane. In some embodiments, at least some of the quaternary ammonium groups are within 1-10 μm of a surface of the porous support membrane. In some embodiments, the quaternary ammonium groups are in contact (e.g., direct contact) with the surface of the porous support membrane. The distance between the porous
20 support membrane and a quaternary ammonium group can be determined, for example, using an analytical electron microscope equipped with a transmission electron microscope (TEM) and an X-ray spectrometer.

As mentioned above, in some embodiments, the anion exchange membrane or material has a relatively high loading of functional groups. For example, in some
25 embodiments, the anion exchange membrane or material has a relatively high loading of quaternary ammonium groups. Having a relatively high loading of functional group such as quaternary ammonium groups may at least in part lead to beneficial performance characteristics of the anion exchange membrane or material. For example, a high loading of quaternary ammonium groups may contribute to a relatively high anion
30 exchange capacity, anion permselectivity, and/or anion conductivity (e.g., chloride ion conductivity, hydroxide conductivity). Certain methods described herein, such as certain sol-gel techniques involving co-condensation of functionalized and non-functionalized

– 22 –

silanes, may provide loadings of quaternary ammonium groups that are otherwise challenging to achieve using certain existing techniques.

In some embodiments, quaternary ammonium groups are present in the anion exchange membrane or material in an amount of greater than or equal to 0.01 mmol, greater than or equal to 0.05 mmol, greater than or equal 0.1 mmol, greater than or equal to 0.3 mmol, greater than or equal to 0.5 mmol, greater than or equal to 0.7 mmol, greater than or equal to 1 mmol, greater than or equal to 2 mmol, greater than or equal to 3 mmol or more per gram of the anion exchange membrane or material. In some embodiments, quaternary ammonium groups are present in the anion exchange membrane or material in an amount of less than or equal to 10 mmol, less than or equal to 5 mmol, or less per gram of the anion exchange membrane or material. Combinations of these ranges are possible. For example, in some embodiments, quaternary ammonium groups are present in the anion exchange membrane or material in an amount of greater than or equal to 0.01 mmol in less than or equal to 10 mmol, or greater than or equal to 0.1 mmol and less than or equal to 10 mmol per gram of the anion exchange membrane or material. It should be understood that the loadings described herein refer to the total sum of quaternary ammonium cations (i.e., a charged group) and quaternary ammonium salts (i.e., neutral groups comprising quaternary ammonium groups associated with anions). For example, if the anion exchange membrane or material included 0.1 mmol of free quaternary ammonium cations and 0.3 mmol of quaternary ammonium groups associated with anions per gram of the anion exchange membrane or material, the quaternary ammonium groups would be present in the anion exchange membrane or material in an amount of 0.4 mmol per gram of the anion exchange membrane or material. The loading of quaternary ammonium groups within the anion exchange membrane or material can be determined by performing the measurement of the anion exchange capacity of the anion exchange membrane as described below, and taking the number of chloride ions measured in solution (as determined by the titration) as being equal to the number of quaternary ammonium groups in the anion exchange membrane. The loading can then be determined using that number of quaternary ammonium groups (in mmol) and dividing by the weight of the dried anion exchange membrane (in g) . It should be understood that the above quantities and measurements for the loading of quaternary ammonium groups refers to accessible quaternary ammonium groups, and not to quaternary ammonium groups that are inaccessible to solvent and ions (e.g.,

– 23 –

quaternary ammonium groups trapped in enclosed pores that cannot be contacted by solvent or anions).

As described above, the silica-based ceramic (e.g., the silica-based ceramic 150), may be a ceramic comprising predominantly a network of silica (SiO_2), though the silica-based ceramic can include groups (e.g., terminal moieties) not described by the SiO_2 formula. For example, in some embodiments, the silica-based ceramic comprises a network a silica comprising terminal hydroxy groups, terminal organic groups, and/or terminal functional groups (e.g., quaternary ammonium groups). In some embodiments, a relatively high percentage of the Si atoms in the silica-based ceramic are in a tetrahedral environment and are bound to either an oxygen, a hydroxy group, or a functional group (e.g., quaternary ammonium group. For example, in some embodiments, a relative high percentage of the silica-based ceramic can be described using the following structure (I):

15

wherein each R group can independently be hydroxy, $-\text{OSiR}_3$, or a moiety containing a functional group such as a quaternary ammonium group. For example, in some cases, R can be an trialkylammoniumalkane acid group such as N,N,N-trimethylammoniumpropane. As can be seen from this structure, the silica-based ceramic can contain an extended (though not necessarily single-crystalline) ceramic structure comprising functional groups such as quaternary ammonium groups covalently bound to the silica-based ceramic. For example, in some embodiments, the silica-based ceramic can contain an extended ceramic structure that can be described using the following structure (II):

25

– 24 –

wherein each R group can independently be hydroxy, $-\text{OSiR}_3$, or a moiety containing a functional group such as a quaternary ammonium group.

In some embodiments, the silica-based ceramic can contain a structure that can be described using the following structure (III):

wherein each R group can independently be hydroxy, $-\text{OSiR}_3$, or a moiety containing a functional group such as a quaternary ammonium group, and R' can independently be optionally-substituted alkyl, cyclyl, or aryl.

The silica-based ceramic of the anion exchange membrane may have one or more properties of ceramics known in the art. For example, the silica-based ceramic may be relatively brittle, have a relatively high density, have a relatively high hardness, and/or have a relatively high melting point. In some embodiments, the silica-based ceramic is polycrystalline. The silica-based ceramic described herein stands in contrast to anion exchange membranes comprising particles (e.g., nanoparticles) of silica (e.g., functionalized silica nanoparticles) suspended in a non-silica-based matrix (e.g., a polymer matrix such as a carbon-based polymer matrix).

In some embodiments, Si is present in a relatively high amount in the silica-based ceramic. Si may be present in a relatively high amount in the silica-based ceramic due to the silica-based ceramic being predominantly silica-based, rather than having a relatively high percentage of other components, such as a polymer matrix. In some embodiments, the silica-based ceramic comprises Si in an amount of greater than or equal to 6 weight percent (wt%), greater than or equal to 10 wt%, greater than equal to 12 wt%, greater than or equal to 15 wt%, greater than or equal to 17 wt%, greater than or equal to 20 wt%, greater than or equal to 24 wt%, greater than or equal to 30 wt%, greater than or equal to 40 wt%, or more in the silica-based ceramic. In some embodiments, the silica-

based ceramic comprises Si in an amount less than or equal to 60 wt%, less than or equal to 50 wt%, less than or equal to 47 wt%, less than or equal to 40 wt%, less than or equal to 30 wt%, less than or equal to 28 wt%, less than or equal to 26 wt%, less than or equal to 24 wt%, less than or equal to 22 wt%, less than or equal to 20 wt%, less than or equal to 17 wt%, or less in the silica-based ceramic. Combinations of these ranges are possible. For example, in some embodiments, the silica-based ceramic comprises Si in an amount greater than or equal to 6 wt% and less than or equal to 60 wt%, or greater than or equal to 11 wt% and less than or equal to 26 wt% in the silica-based ceramic.

In some embodiments, the silica-based ceramic comprises Si in an amount of greater than or equal to 1.5 mole percent (mol%), greater than or equal to 3 mol%, greater than or equal to 5 mol%, greater than or equal to 8 mol%, greater than or equal to 10 mol%, greater than or equal to 12 mol%, greater than or equal to 15 mol%, greater than or equal to 18 mol%, greater than or equal to 20 mol%, or more in the silica-based ceramic. In some embodiments, the silica-based ceramic comprises Si in an amount less than or equal to 33.4 mol%, to 30 mol%, less than or equal to 28 mol%, less than or equal to 26 mol%, less than or equal to 24 mol%, less than or equal to 22 mol%, less than or equal to 20 mol%, less than or equal to 18 mol%, or less in the silica-based ceramic. Combinations of these ranges are possible. For example, in some embodiments, the silica-based ceramic comprises Si in an amount greater than or equal to 1.5 mol% and less than or equal to 33.4 mol%, greater than or equal to 8 mol% and less than or equal to 20 mol%, greater than or equal to 2.8 mol% and less than or equal to 18 mol%, or greater than or equal to 12 mol% and less than or equal to 18 mol% in the silica-based ceramic.

In some embodiments in which the silica-based ceramic comprises a nitrogen-containing functional group such as a quaternary ammonium group, the molar ratio of Si to nitrogen in the silica-based ceramic depends on the loading of the nitrogen-containing functional groups in the silica-based ceramic. In some embodiments, the silica-based ceramic has a silicon-to-nitrogen molar ratio of greater than or equal to 1:1, greater than or equal to 1.5:1, greater than or equal to 2:1, greater than or equal to 3:1, greater than or equal to 4:1, greater than or equal to 5:1, greater than or equal to 10:1, greater than or equal to 25:1, or more. In some embodiments, the silica-based ceramic has a silicon-to-nitrogen molar ratio of less than or equal to 120:1, less than or equal to 75:1, less than or equal to 50:1, less than or equal to 25:1, less than or equal to 10:1, less than or equal to

– 26 –

4:1, or less. Combinations of these ranges are possible. For example, in some embodiments, the silica-based ceramic has a silicon-to-nitrogen molar ratio of greater than or equal to 1:1 and less than or equal to 120:1, greater than or equal to 1:1 and less than or equal to 10:1, or greater than or equal to 1:1 and less than or equal to 4:1.

5 In some embodiments, the molar ratio of Si to carbon in the silica-based ceramic depends on the loading of carbon containing groups within the silica-based ceramic, such as organic moieties (e.g., organic functional groups). In some embodiments, the silica-based ceramic has a silicon-to-carbon (Si:C) molar ratio of greater than or equal to 1:100, greater than or equal to 1:75, greater than or equal to 1:50, greater than or equal to 1:40, 10 greater than or equal to 1:25, greater than or equal to 1:16, greater than or equal to 1:10, greater than or equal to 1:5, or greater than or equal to 1:3, greater than or equal to 1:1, or greater. In some embodiments, the silica-based ceramic has a silicon-to-carbon molar ratio of less than or equal to 3,000:1, less than or equal to 2,000:1, less than or equal to 1,000:1, less than or equal to 500:1, less than or equal to 200:1, less than or equal to 15 100:1, less than or equal to 75:1, less than or equal to 50:1, less than or equal to 25:1, less than or equal to 10:1, less than or equal to 2:1, less than or equal to 1:1, or less. Combinations of these ranges are possible. For example, in some embodiments, the silica-based ceramic has silicon-to-carbon molar ratio of greater than or equal to 1:100 and less than or equal to 3,00:1, greater than or equal to 1:100 and less than or equal to 20 100:1, greater than or equal to 1:40 and less than or equal to 10:1, or greater than or equal to 1:3 and less than or equal to 2:1.

 The weight percentage and mole percentage and molar ratios in the silica-based ceramic described above can be determined by removing the silica-based ceramic from the rest of the anion exchange membrane or material (e.g., porous support membrane, 25 compressible edging material etc.) and performing an elemental analysis, such as inductively coupled plasma mass spectrometry (ICP-MS) or nuclear magnetic resonance (NMR) .

 As mentioned above, in some embodiments, sol-gel techniques can be used to form the silica-based ceramic. As such, in some cases, the silica-based ceramic is sol-gel 30 derived. In some embodiments, the sol used in the sol-gel techniques is a silicon-containing precursor sol (i.e., the silica-based ceramic is derived from a silicon-containing precursor sol). During fabrication of the anion exchange membrane, for example, one or more components of the anion exchange membrane, such as a porous

– 27 –

support membrane described herein, may be coated with the silicon-containing precursor sol during at least one step of the fabrication process. The silicon-containing precursor sol may comprise any of a variety of suitable silicon-containing precursor components, such as silica colloidal particles, siloxanes, silicate esters, silanols, silanes, alkoxy silanes, tetraalkyl orthosilicates, halosilanes, or combinations thereof. In some embodiments, the silica-based ceramic is derived from a silicon-containing precursor sol containing two or more different silicon-containing precursor components. In some such cases, the silica-based ceramic is formed via a co-condensation of two or more silicon-containing precursor components (e.g., two or more different silanes or substituted silanes).

In some embodiments, the silicon-containing precursor sol from which the silica-based ceramic is derived comprises a silicon-containing precursor comprising an ammonium group or a moiety comprising a leaving group (e.g., a halo group). In some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising a silane (e.g., a substituted alkoxy silane) containing nitrogen (e.g., an ammonium). In some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising a compound having structure (IV):

wherein R^1 , R^2 , and R^3 are independently chosen from optionally-substituted, C_{1-18} alkoxy and halo, L is chosen from optionally-substituted C_{1-18} alkylene and arylene, and X is a leaving group. In some embodiments, each of R^1 , R^2 , and R^3 is independently chosen from optionally-substituted C_{1-8} alkoxy and halo, L is chosen from optionally-substituted C_{1-8} alkylene and arylene, and X is a leaving group. In some embodiments, each of R^1 , R^2 , and R^3 are independently chosen from optionally-substituted C_{1-4} alkoxy and halo, L is chosen from optionally-substituted C_{1-4} alkylene and arylene, and X is a leaving group. In some embodiments, X is chosen from chloro, bromo, iodo, tosyl, and trifluoromethanesulfonyl.

In some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising a compound having structure (V):

- 28 -

wherein each A^1 is independently chosen from hydrogen, methyl, ethyl, propyl, or butyl, n is greater than or equal to 1 and less than or equal to 18, and X is a leaving group (e.g., a leaving group chosen from chloro, bromo, iodo, tosyl, and trifluoromethanesulfonyl).

As one example, in some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising (3-chloropropyl)triethoxysilane (3CPTES). The resulting silica-based ceramic derived from the above-mentioned leaving group-containing compounds may, in some cases, be reacted with an amine to form a quaternary ammonium group, as described in more detail below.

In some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising a compound having structure (VI):

wherein R^4 , R^5 , and R^6 are independently chosen from optionally-substituted C_{1-18} alkoxy and halo, L is chosen from optionally-substituted C_{1-18} alkylene and arylene, and R^7 , R^8 , and R^9 are independently chosen from optionally-substituted C_{1-18} alkyl, cyclyl, and aryl. In some embodiments, each of R^4 , R^5 , and R^6 is independently chosen from optionally-substituted C_{1-8} alkoxy and halo, L is chosen from optionally-substituted C_{1-8} alkylene and arylene, and each of R^7 , R^8 , and R^9 is independently chosen from optionally-substituted C_{1-4} alkyl, cyclyl, and aryl. In some embodiments, each of R^4 , R^5 , and R^6 is independently chosen from optionally-substituted C_{1-4} alkoxy and halo, L is

– 29 –

chosen from optionally-substituted C₁₋₄ alkylene and arylene, and each of R⁷, R⁸, and R⁹ is independently chosen from optionally-substituted C₁₋₄ alkyl, cyclyl, and aryl.

In some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) containing a compound having structure (VII):

where A² is independently chosen from hydrogen, methyl, ethyl, propyl, or butyl, n is greater than or equal to 1 and less than or equal to 18, and R¹⁰, R¹¹, and R¹² are independently chosen from methyl, ethyl, propyl, butyl, cyclohexyl, and benzyl.

As one example, in some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising trimethoxysilylpropyl-N,N,N-trimethylammonium (TMAPS). As another example, in some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising triethoxysilylpropyl-N,N,N-trimethylammonium (TEAPS).

In some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising a compound having structure (VIII):

wherein each R¹³ is independently chosen from hydrogen or optionally-substituted C₁₋₁₈ alkyl. In some embodiments, each R¹³ is independently chosen from hydrogen or optionally-substituted C₁₋₈ alkyl. In some embodiments, each R¹³ is independently chosen from hydrogen or optionally-substituted C₁₋₄ alkyl. In some embodiments, each R⁷ is independently chosen from methyl, ethyl, propyl and butyl.

In some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising tetraethyl orthosilicate (TEOS) and/or tetraethyl orthosiloxane. In some embodiments, the silica-based ceramic is derived from

– 30 –

a single-phase mixture (e.g., a single-phase silicon-containing precursor sol) comprising both a compound having structure (VIII) (e.g., TEOS) and a compound having structure (IV) (e.g., (3-chloropropyl)triethoxysilane). In some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising a compound having structure (VIII), a compound having structure (IV), and water in a structure (VIII):structure(IV):water molar ratio of 1 : 0.01-20 : 1-30, a molar ratio of 1 : 0.1-10 : 16, or a molar ratio of 1 : 0.25-1 : 2-4. In some embodiments, the silica-based ceramic is derived from a single-phase mixture (e.g., a single-phase silicon-containing precursor sol) comprising both a compound having structure (VIII) (e.g., TEOS) and a compound having structure (VI) (e.g., trimethoxysilylpropyl-N,N,N-trimethylammonium). In some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising a compound having structure (VIII), a compound having structure (VI), and water in a structure (VIII):structure(VI):water molar ratio of 1 : 0.01-10 : 1-30, a molar ratio of 1 : 0.1-10 : 2-20, or a molar ratio of 1 : 0.20-1 : 2-15.

In some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising two or more precursors. For instance, in some embodiments, the silica-based ceramic is derived from a mixture comprising a compound having structure (VIII) (e.g., TEOS) and a compound having structure (IV) (e.g., (3-chloropropyl)triethoxysilane) in a structure (VIII):structure(IV) mass ratio of less than or equal to 99:1, less than or equal to 95:5, less than or equal to 90:10, less than or equal to 85:15, less than or equal to 80:20, less than or equal to 75:25, less than or equal to 70:30, less than or equal to 65:35, less than or equal to 60:40, or less. In some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising a compound having structure (VIII) (e.g., TEOS) and a compound having structure (IV) (e.g., (3-chloropropyl)triethoxysilane) in a structure (VIII):structure(IV) mass ratio of greater than or equal to 50:50, greater than or equal to 55:45, greater than or equal to 60:40, greater than or equal to 65:35, greater than or equal to 70:30, or greater. Combinations of these ranges are possible (e.g., greater than or equal to 50:50 and less than or equal to 99:1, greater than or equal to 60:40 and less than or equal to 90:10, or greater than or equal to 70:30 and less than or equal to 80:20).

– 31 –

In some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising a compound having structure (VIII) (e.g., TEOS) and a compound having structure (VI) (e.g., trimethoxysilylpropyl-N,N,N-trimethylammonium) in a structure (VIII):structure(VI) mass ratio of less than or equal to 99:1, less than or equal to 95:5, less than or equal to 90:10, less than or equal to 85:15, less than or equal to 80:20, less than or equal to 75:25, less than or equal to 70:30, less than or equal to 65:35, less than or equal to 60:40, or less. In some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising a compound having structure (VIII) (e.g., TEOS) and a compound having structure (VI) (e.g., trimethoxysilylpropyl-N,N,N-trimethylammonium) in a structure (VIII):structure(VI) mass ratio of greater than or equal to 40:60, greater than or equal to 45:55, greater than or equal to 50:50, greater than or equal to 55:45, greater than or equal to 60:40, greater than or equal to 65:35, greater than or equal to 70:30, or greater. Combinations of these ranges are possible (e.g., greater than or equal to 40:60 and less than or equal to 99:1, greater than or equal to 60:40 and less than or equal to 90:10, or greater than or equal to 70:30 and less than or equal to 80:20).

In some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising an aqueous solution having a certain pH, depending on the desired chemistry to be used. In some embodiments, the aqueous solution may have a pH of greater than or equal to -1, greater than or equal to 0, greater than or equal to 1, greater than or equal to 2, greater than or equal to 3, greater than or equal to 4, greater than or equal to 5, greater than the 6, greater than or equal to 7, greater than or equal to 8, greater than or equal to 9, or higher. In some embodiments, the aqueous solution may have a pH of less than or equal to 14, less than or equal to 13, less than or equal to 12, less than or equal to 11, less than or equal to 10, less than or equal to 9, less than or equal to 8, less than or equal to 7, less than or equal to 6, less than or equal to 5, less than or equal to 4, less than or equal to 3, or less. Combinations of these ranges are possible. For example, in some embodiments, the aqueous solution has a pH of greater than or equal to -1 and less than or equal to 14, greater than or equal to 0 and less than or equal to 7, or greater than or equal to 1 and less than or equal to 3. In some cases, having a relatively acidic pH (e.g., a pH of between 1-3) may allow for certain condensation and hydrolysis reactions to occur during fabrication of the anion exchange membrane involving the conversion of a sol-gel into a silica-based ceramic. In some

– 32 –

embodiments, the silica-based ceramic is derived from a mixture described above (e.g. a silicon-containing precursor sol) containing one or more acids such as, but not limited to, HCl, H₃PO₄, H₂SO₄, or HNO₃.

5 In some, but not necessarily all embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising one or more other solvents in addition to water. For example, in some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising an alcohol. In some such cases, the presence of an alcohol in the mixture can enhance the miscibility of the components of the mixture. Exemplary alcohols that can be present
10 include, but are not limited to, methanol, ethanol, isopropanol, butanol, or combinations thereof. In some embodiments, for example, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising methanol (e.g., in some cases in which TMAPS is used as a precursor). In some embodiments, the silica-based ceramic is derived from a mixture (e.g., a silicon-containing precursor sol) comprising
15 one or more solvents that may be able to mitigate problems (e.g., cracking) that can occur during, for example, drying of a coating comprising the mixture to form the silica-based ceramic. Exemplary solvents that, in some embodiments, may mitigate such problems include, but are not limiting to, formamide and aromatics (e.g., toluene, xylene).

20 As mentioned above, in some embodiments, the silica-based ceramic is porous. In some such embodiments, the silica-based ceramic is nanoporous (having pores with an average (mean) diameter of less than or equal to 10 nm). The presence of relatively small pores in the silica-based ceramic may, in some cases, be advantageous in a number of applications such as electrochemical applications and separation applications. In
25 some embodiments, the presence of relatively small pores in the silica-based membrane ceramic can contribute to a relatively high selectivity of the anion exchange membrane (e.g., due to size exclusion). Relatively small pores may also contribute relatively high permselectivity and a useful balance between anion conductivity (e.g., chloride ion conductivity) and water transport. In some embodiments, the silica-based ceramic has an
30 average pore diameter of less than or equal to 1 μm (e.g., less than or equal to 500 nm, less than or equal to 100 nm, or less than or equal to 50 nm). In some cases, the silica-based ceramic has an average pore diameter of less than or equal to 10 nm, less than or equal to 8 nm, less than or equal to 6 nm, less than or equal to 5 nm, less than or equal to

– 33 –

3 nm, less than or equal to 2 nm, or less. In some embodiments, the silica-based ceramic has an average pore diameter of greater than or equal to 0.25 nm, greater than or equal to 0.4 nm, greater than or equal to 0.6 nm, or greater than or equal to 1 nm. Combinations of these ranges are possible. For example, in some embodiments, the silica-based ceramic has an average pore diameter of greater than or equal to 0.25 nm and less than or equal to 1 μm , greater than or equal to 0.25 nm and less than or equal to 10 nm, greater than or equal to 0.4 nanometers and less than or equal to 10 nm, greater than or equal to 0.6 nm and less than or equal to 5 nm, or greater than or equal to 0.6 nm and less than or equal to 2.5 nm.

10 The average pore diameter of the silica-based ceramic may be determined using a small angle X-ray scattering (SAXS) technique. In a suitable SAXS technique, a collimated X-ray beam is focused onto a membrane comprising the silica-based ceramic for at least 15 minutes, and the scattering intensity as a function of scattering angle is collected on an image plate. The scattering intensity is integrated to generate a 1-
15 dimensional scattering profile that plots the scattering intensity as a function of the q-vector. Scattering of the membrane can be fit with a sphere-based form factor (e.g., solid or core-shell). In some cases, the sphere-based form factor can include a structure factor (e.g., fractal or hard-sphere interactions). Fitting can be performed in the freely available SASView software. A log-normal distribution on pore size polydispersity is assumed. A
20 1-D SAXS profile is assumed to be well-fit if the residual between the model and data set (χ^2) is less than or equal to 10, less than or equal to 1, less than or equal 0.5, or less. Certain parameters are held constant during fitting, including $\text{SLD}_{\text{solvent}} = 18.8 \times 10^{-6} \text{ \AA}^{-2}$ and $\text{SLD}_{\text{sphere}} = 0 \text{ \AA}^{-2}$, where SLD is the scattering length density. SAXS fitting can be used to determine the volume fraction of porosity, pore size (e.g., average pore
25 diameter), and polydispersity index of the pore size distribution. Suitable SAXS procedures are described in more detail, for example, in Pedersen, J. S., Analysis of small-angle scattering data from colloids and polymer solutions: modeling and least-squares fitting. Advances in Colloid and Interface Science 1997, 70, 171-210, and in Zemb., T.; Lindner, P., Neutron, X-Rays and Light. Scattering Methods Applies to Soft
30 Condensed Matter. North Holland: 2002, which are incorporated herein by reference in their entirety. The average pore diameter may also be determined using other small angle scattering techniques, such as small angle neutron scattering (SANS).

– 34 –

In some embodiments, the anion exchange membrane or material has a relatively large volumetric porosity. The volumetric porosity may depend on the porosity of the silica-based ceramic. Having a relatively high volumetric porosity may contribute to certain beneficial performance characteristics of the anion exchange membrane, such as

5 an anion exchange capacity and water uptake. In some embodiments, the anion exchange membrane or material has a volumetric porosity of greater than or equal to 1%, greater than or equal to 3%, greater than or equal to 5%, greater than or equal to 10%, greater than or equal to 20%, greater than or equal to 30%, greater than or equal to 40%, or more. In some embodiments, the anion exchange membrane or material has a

10 volumetric porosity of less than or equal to 70%, less than or equal to 60%, less than or equal to 50%, less than or equal to 45%, less than or equal to 40%, less than or equal to 35%, less than or equal to 30%, less than or equal to 25%, less than or equal to 15%, or less. Combinations of these ranges are possible. For example, in some embodiments, the anion exchange membrane or material has a volumetric porosity of greater than or

15 equal to 1% and less than or equal to 70%, greater than or equal to 5% and less than or equal to 50%, greater than or equal to 10% and less than or equal to 50%, or greater than or equal to 30% and less than or equal to 50%. As mentioned above, these volumetric porosities of the anion exchange membrane or material are determined via fitting of SAXS data of the anion exchange membrane or material.

20 In some embodiments, the pores of the silica-based ceramic have a relatively small aspect ratio (length:width). Aspect ratio of the pores of the silica-based membrane can be determined by fitting SAXS data to an ellipsoid model to determine an average first radius and an average second radius of the pores of the silica-based membrane, and taking the ratio of the average first and the average second radius. In some

25 embodiments, the pores of the silica-based membrane have an aspect ratio of less than or equal to 40:1, less than or equal to 20:1, less than or equal to 10:1, less than or equal to 5:1, or less.

In some embodiments, the pores of the silica-based ceramic have an ordered structure. Such an ordered structure may, in some cases, contrast with the pores of

30 certain existing anion exchange membrane such as those made from hydrocarbon- or perfluorocarbon-based polymers, which can have worm-like, disordered pores (e.g., with a high polydispersity). Having a silica-based ceramic with regular, ordered pores over a relatively large size scale can, in some cases, correspond to improved performance

– 35 –

characteristics in anion exchange applications. The pores of the silica-based ceramic have an ordered structure if the scattering data from a SAXS experiment on a membrane or material containing the silica-based ceramic can be fit to a mathematical model, such as a fractal aggregate model, with a χ^2/N value of less than or equal to 10, less than or equal to 5, less than or equal to 1, less or equal to 0.5, or less, where χ^2 is a squared sum of an intensity difference between the mathematical model and the small angle scattering spectra data, and N is the number of points small-angle scattering data points over a model fitting range. An exemplary fractal aggregate model using SAXS data of intensity (I) as a function of a scattering vector, q , is as follows:

$$I(q) = P(q)S(q) + bck$$

$S(q)$ is a network or fractal structure that defines an organization or configuration of building blocks of the network of pores of the silica-based ceramic. In other words, in some embodiments, the building blocks are the pores of the silica-based ceramic. bck defines background scattering, such as from a scattering particle source and/or inelastic scattering of scattering particles off of the silica-based ceramic. In some embodiments, $S(q)$ is defined by the following equation:

$$S(q) = 1 + \frac{D_f \Gamma(D_f - 1)}{[1 + 1/q\xi^2]^{(D_f-1)/2}} \frac{\sin[(D_f - 1)\tan^{-1}(q\xi)]}{(qR_0)^{D_f}}$$

where

R_0 is a radius of the building blocks (pores), ρ_{solvent} is a scattering length density of a solvent (the silica-based ceramic), ρ_{block} is a scattering length density of the building blocks (assumed to be the scattering length density of air at ambient conditions if the membrane is dry), D_f is a fractal dimension, ξ is a correlation length, and Γ is the standard mathematical gamma function.

$P(q)$ is a form factor that defines a structure of the building blocks of the network of pores of the silica-based ceramic as a function of q . Such form factors may take on a variety of shapes, such as simple geometric shapes like spheres, ellipsoids, cubes, ovals, and the like.

In some embodiments, the building blocks (pores) are defined as homogeneous building blocks, such as homogeneous spheres. In that regard, in some embodiments, $P(q)$ is defined by the following equation:

– 36 –

$$P(q) = scale \times V(\rho_{block} - \rho_{solvent})^2 F(qR_0)^2,$$

where

$$F(x) = \frac{3[\sin(x) - x \cos(x)]}{x^3},$$

$$V = \frac{4}{3}\pi R_0^3,$$

5 and *scale* is a volume fraction of building blocks of the measured silica-based ceramic.

In some embodiments, the form factor defines a spherical core-shell building block (pore). In some such embodiments, regard, $P(q)$ is defined by the following formula:

$$10 \quad P(q) = \frac{scale}{V_s} \left[3V_c(\rho_c - \rho_s) \frac{[\sin(qr_c) - qr_c \cos(qr_c)]}{(qr_c)^3} + 3V_s(\rho_s - \rho_{block}) \frac{[\sin(qr_s) - qr \cos(qr_s)]}{(qr_s)^3} \right]^2 + bkg$$

where

scale is a volume fraction of building blocks of the measured silica-based ceramic, V_c is a volume of the core, V_s is a volume of the shell, ρ_c is a scattering length density of the core, ρ_s is a scattering length density of the shell (e.g., shell of functional groups), ρ_{block} is a scattering length density of the building blocks (pores), r_c is a radius of the core, r_s is a radius of the shell, and *bck* is background scattering.

In some embodiments, one or more surfaces of the silica-based ceramic are coated with an additional coating. A core-shell model, such as the core-shell fractal aggregate model may be suitable to characterize core-shell particle building blocks. In some cases, a core-shell model is suitable even in the absence of an additional coating process. For example, in some embodiments, the method used to form the silica-based ceramic (e.g., a sol-gel based method) produces phase segregated regions that can be modeled using a core-shell model.

25 As above, various embodiments of the form factors, $P(q)$, of the fractal aggregate models used to characterize small-angle scattering spectra can include a factor that accounts for differences between scattering length densities.

In some embodiments, scattering length densities in the above equations are defined by the materials that make up the components of the silica-based ceramic membranes. Generally, larger differences between scattering length densities of scattering sources, such as pores, and surrounding ceramic materials provide larger scattering contrast. Accordingly, in some embodiments, small-angle scattering data is generated from silica-based ceramics that have been dried to remove solvent or other liquid from the pores, thus providing a greater difference in scattering length densities compared to a silica-based ceramic with pores filled with a liquid solvent.

In some embodiments, the scattering length densities are defined in units of $\text{\AA}^{-2}$ (inverse angstroms squared). The scattering length density is defined as the sum of the bound coherent scattering length of each atom normalized by the molecular volume. For example, the X-ray scattering length density of air is roughly $0 \text{ \AA}^{-2}$ while x-ray scattering length density of amorphous silica is roughly $18.8 \times 10^{-6} \text{ \AA}^{-2}$.

In some embodiments, small-angle scattering data is generated from silica-based ceramic that have been rinsed to remove residual ions, chemical reactants, and the like.

In some embodiments, fitting small-angle scattering spectra to a fractal aggregate model includes fitting the small-angle scattering spectra over a range of q values that exceeds an order of magnitude, such as over an order of magnitude where q is in units of $\text{\AA}^{-1}$. Such a relatively wide fitting range may ensure that the data is fit to the fractal aggregate model over a range of sizes commensurate in scope with, for example, a size scale of pores of the silica-based ceramic, in addition to providing data sufficient to fit with the fractal aggregate model. In some embodiments, fitting small-angle scattering spectra to a fractal aggregate model includes fitting the small-angle scattering spectra over a range of q values in a range of about $0.01 \text{ \AA}^{-1}$ to about $1 \text{ \AA}^{-1}$. In some embodiments, fitting small-angle scattering spectra to a fractal aggregate model includes fitting the small-angle scattering spectra over a range of q values in a range of about $0.02 \text{ \AA}^{-1}$ to about $0.8 \text{ \AA}^{-1}$.

As above, *scale* corresponds to a volume fraction of pores in the silica-based ceramic. In some embodiments, *scale* corresponds to membrane porosity when the small-angle scattering spectra are in intensity units of $1/\text{cm}$ and the *scale* is less than 0.7. In this regard, the *scale* corresponds to a number of pores, normalized by a size of the sample. In some embodiments, the silica-based ceramic has a porosity volume fraction in a range of

– 38 –

about 0.01 to about 0.7. In some embodiments, the silica-based ceramic has a porosity volume fraction in a range of about 0.15 to about 0.35. It should be understood that the above-mentioned ranges correspond to cases in which the scattering length density refers to that of air at ambient conditions for the pores and amorphous silica for the silica-based ceramic, respectively.

In some embodiments, D_f is a fractal dimension of the fractal aggregate models described herein. In some embodiments, D_f corresponds to a shape and/or configuration of pores within the silica-based ceramic. Generally, D_f is in a range of about 1 to about 3. Where D_f is close to or at 1, the pores may be generally characterized as 1-dimensional tunnels. Where D_f is close to or at 3, the pores may be generally characterized as open spheres.

In some embodiments, it is advantageous to have a silica-based ceramic defining pores having a tortuous or indirect route through the silica-based ceramic. For an ion or other particle in fluid communication with a tortuous pore, it is less likely that the ion or other particle will traverse the membrane as a size of the ion or other particle approaches that of the tortuous pore than compared to a less tortuous pore. In that regard, such silica-based ceramics defining tortuous pores may, in some cases, be suitable to provide, for example, more selective anion exchange than, for example, silica-based ceramics defining pores of the same size, but that provide a more direct path through the silica-based ceramic. In this regard, in some, but not necessarily all embodiments D_f is in a range of 2.0-4.0. Such D_f ranges describe or characterize silica-based ceramics having relatively tortuous pores having a form factor somewhere between a straight line and an open sphere.

In some embodiments, the fractal aggregate model is constrained to have pore sizes within a particular range. As above, the porous support defines pores with an average pore diameter within the ranges described above. Likewise, the methods described in the present disclosure are suitable to make such silica-based ceramics defining pores in such a size range. Accordingly, by constraining fractal aggregate models used to fit small-angle scattering data, a good fit between the fractal silica-based ceramic and the fractal aggregate model can be obtained.

As above, the correlation length, ξ , is a length over which the fractal pattern of the silica-based ceramic repeats itself. In some cases, silica-based ceramics will repeat the fractal pattern over a relatively large size scale. In this regard, such silica-based ceramics

– 39 –

define regular, ordered pores over a relatively large size scale, which may, in some cases, correspond to improved functional properties, such as filtration, ion exchange, and the like. Analogously, a fractal pattern generally cannot extend to size scales smaller than a size scale of building blocks of the silica-based ceramic, such as smaller than molecules or
 5 atoms. Accordingly, in some embodiments, the correlation length, ξ , is constrained to a value of greater than 1 nm. In some embodiments, the correlation length, ξ , is constrained to a value of greater than 50 nm. In some embodiments, the correlation length, ξ , is constrained to a value of greater than 100 nm. In some embodiments, the correlation length, ξ , is constrained to a value of about a thickness of the silica-based ceramic. In
 10 some embodiments, the silica-based ceramics have a correlation length, ξ , greater than 1 nm, such as greater than 50 nm or greater than 100 nm.

The fractal aggregate models used to characterize the silica-based ceramic may include terms to account for variability in sizes of scattering sources, such as the pores of the silica-based ceramic. In that regard, in some embodiments, the fractal aggregate model
 15 includes a polydispersity index in a radius parameter. Accordingly, in some embodiments a radius of a building block, R_0 , is a weighted average rather than a constant. The weighted average may be according to a number of mathematical functions, such a Gaussian function, a log-normal function, a rectangular distribution, and the like. In some embodiments, the polydispersity index is Gaussian and according to the equation:

$$20 \quad f(x) = \frac{1}{Norm} \exp\left(-\frac{(x - x_{mean})^2}{2\sigma^2}\right)$$

where x_{mean} is a mean value of the distribution (average radius), $Norm$ is a normalization factor determined during numerical calculation, and the polydispersity index is the ratio of σ/x_{mean} .

In some embodiments, the polydispersity ratio is log-normal and according to the
 25 equation:

$$f(x) = \frac{1}{Norm} \frac{1}{xp} \exp\left(-\frac{(\ln(x) - \mu)^2}{2p^2}\right)$$

where p is the polydispersity index, $\mu = \ln(x_{med})$, x_{med} is a median value of the distribution, and $Norm$ is a normalization factor determined during numerical calculation.

– 40 –

In some embodiments, log-normal distributions are advantageous as they are generally not symmetric about x_{med} . In this regard, as the polydispersity ratio increases, the lower tail may not fall into ranges that are aphysical, such as those which would define a pore size smaller than, for example, atoms, etc. that physically define the pores.

5 In some embodiments, the pores of the silica-based ceramic have a relatively low log-normal polydispersity index of pore radius. Having a relatively low log-normal polydispersity index of pore radius generally corresponds to the pores having relatively similar radii, which may be indicative of a regular, ordered structure to the pores of the silica-based ceramic. In some embodiments, the pores of the silica-based ceramic have a
10 log-normal polydispersity index of pore radius of less than or equal to 0.8, less than or equal to 0.7, less than or equal to 0.5, less than or equal to 0.3, or less. In some embodiments, the pores of the silica-based ceramic have a log-normal polydispersity index of greater than or equal to 0 and less than or equal to 0.8, greater than or equal to 0 and less than or equal to 0.7, greater than or equal to 0 and less than or equal to 0.5, in
15 greater than or equal to 0 and less than or equal to 0.3.

In some embodiments, the pores of the silica-based ceramic fit a Teubner-Strey model. The Teubner-Strey model was originally developed to describe the scattering patterns and microstructure of microemulsions (e.g., mixtures of water, oil, and amphiphiles). Small angle scattering experiments such as small angle neutron scattering
20 (SANS) experiments have revealed herein that, unexpectedly, in embodiments, ion exchange membranes or materials have a silica-based ceramic pore structure that fits such a Teubner-Strey model. A Teubner-Strey ordering is more commonly associated with packed micellar structures where the micelles enforce well-defined pore structures and pore-pore distances, rather than in ceramic-based structures observed herein.

25 When the pores of the silica-based ceramic fit a Teubner-Strey model of small angle scattering spectra, the intensity (I) as a function of a scattering vector, q , fits the following equation:

$$I(q) = \frac{1}{a + c_1 q^2 + c_2 q^4} + bck$$

where a , c_1 , and c_2 are adjustable parameters and bck is background scattering. The
30 pores of the silica-based ceramic may fit a Teubner-Strey model if the scattering data from a small angle scattering experiment (e.g., small angle neutron scattering, SANS) on a membrane or material containing the silica-based ceramic can be fit to a Teubner-Strey

– 41 –

model with a Chi^2/N value of less than or equal to 10, less than or equal to 5, less than or equal to 1, less or equal to 0.5, or less, where Chi^2 is a squared sum of an intensity difference between the mathematical model and the small angle scattering spectra data, and N is the number of points small-angle scattering data points over a model fitting range. N may be, for example, at least 30, at least 50, at least 100, at least 200, at least 500, and/or up to 1,000, up to 2,000 or more points over a model fitting range. In some embodiments, the model fitting range for q is from $0.01 \text{ \AA}^{-1}$ to $1 \text{ \AA}^{-1}$, or from $0.07 \text{ \AA}^{-1}$ to $0.7 \text{ \AA}^{-1}$.

A Teubner-Strey fitting of small angle scattering of pores of the silica-based ceramic may also afford measurements of the domain size, d , (periodicity) and correlation length, ξ , according to the following equations:

$$I(q) = \frac{(8\pi)/\xi \langle \eta^2 \rangle c_2}{a + c_1 q^2 + c_2 q^4}$$

$$\gamma(r) = \frac{\sin kr}{kr} e^{-r/\xi}$$

$$\xi = \left[\frac{1}{2} \left(\frac{a}{c_1} \right)^{\frac{1}{2}} + \left(\frac{c_1}{4c_2} \right) \right]^{-\frac{1}{2}}$$

$$\frac{d}{2\pi} = \left[\frac{1}{2} \left(\frac{a}{c_1} \right)^{\frac{1}{2}} - \left(\frac{c_1}{4c_2} \right) \right]^{-\frac{1}{2}}$$

where $\langle \eta^2 \rangle$ is the mean square to the fluctuation in scattering density of the media, $\gamma(r)$ is the real-space correlation function corresponding to $I(q)$, and $k = 2\pi/d$. In the context of the anion exchange membranes or materials, ξ is equivalent to the radius of the pores of the silica-based ceramic, and d is equivalent to the pore-pore distance measured from the center of two separate nearest-neighbor pores of the silica-based ceramic. Further description of the Teubner-Strey model and its application to small angle scattering measurements can be found in Schubert, K. V., Strey, R., Kline, S. R., & Kaler, E. W. (1994). Small angle neutron scattering near Lifshitz lines: Transition from weakly structured mixtures to microemulsions. *The Journal of Chemical Physics*, 101(6), 5343-5355., and Teubner, M., & Strey, R. (1987). Origin of the scattering peak in microemulsions. *The Journal of Chemical Physics*, 87(5), 3195-3200, each of which is incorporated herein by reference in its entirety for all purposes.

– 42 –

In some, but not necessarily all embodiments, the structure of the pores of the silica-based ceramic depends on a state of the anion exchange membrane or material. For example, whether the anion exchange is in a dry state or a hydrated state can in some instances affect the pore structure of the silica-based ceramic. The pores of a silica-based ceramic may fit a first mathematical model of small angle scattering spectra when the anion exchange membrane or material is in a first state (e.g., a dry state), and the pores of a silica-based ceramic may fit a second, different mathematical model of small angle scattering spectra when the anion exchange membrane or material is in a second, different state (e.g., a hydrated state). In this context, an anion exchange membrane or material is considered to be in a dry state when it has been heated in an oven at 100 °C and 0% relative humidity for 2 hours, and an anion exchange membrane or material is considered to be in a hydrated state when it is submerged in H₂O or D₂O at room temperature for 24 hours in a vacuum environment having a reduced pressure to pull air out of the pores but that is not low so low as to cause the H₂O or D₂O to boil.

As another example, in some but not necessarily all embodiments, the average pore diameter of the silica-based ceramic is larger when the anion exchange membrane or material is in a hydrated state as compared to when the anion exchange membrane or material is in a dry state. It has been observed that having an average pore diameter in a hydrated state that is greater than an average pore diameter in a dry state can result in a percolation of hydrated domains in the silica-based ceramic. Such percolation can result in improved anion transport properties (e.g., chloride ion conductivity). In some embodiments, the silica-based ceramic has an average pore diameter that is larger when the anion exchange membrane is in a hydrated state than when the anion exchange membrane is in a dry state by a factor of greater than or equal to 1.1, greater than or equal to 1.2, greater than or equal to 1.3, greater than or equal to 1.4, greater than or equal to 1.5, greater than or equal to 1.6, greater than or equal to 1.8, greater than or equal to 2, or greater. In some embodiments, the silica-based ceramic has an average pore diameter that is larger when the anion exchange membrane is in a hydrated state than when the anion exchange membrane is in a dry state by a factor of less than or equal to 5, less than or equal to 4.5, less than or equal to 4, less than or equal to 3.5, less than or equal to 3, less than or equal to 2.8, less than or equal to 2.6, less than or equal to 2.5, less than or equal to 2.4, less than or equal to 2.3, less than or equal to 2.2, less than or equal to 2.1, less than or equal to 2, or less. Combinations of these ranges are possible.

– 43 –

For example, in some embodiments, the silica-based ceramic has an average pore diameter that is larger when the anion exchange membrane is in a hydrated state than when the anion exchange membrane is in a dry state by a factor of greater than or equal to 1.1 and less than or equal to 5, or greater than or equal to 1.3 and less than or equal to 3.

As another example, in some but not necessarily all embodiments, the pores of a silica-based ceramic fit a Teubner-Strey model of small angle scattering spectra as described above when the anion exchange membrane or material is in a dry state, and the pores of a silica-based ceramic fit a core-shell model of small angle scattering spectra as described above when the anion exchange membrane or material is in a hydrated state. It has been observed that in some embodiments, having a Teubner-Strey ordering in a dry state and a core-shell structure in a hydrated state is associated with structural changes upon water-intake that impart beneficial performance properties (e.g., anion exchange capacity, anion conductivity, permselectivity, etc.).

In some embodiments, the pore structure of a silica-based membrane depends on a state of the anion exchange membrane or material can depend on the composition of the silica-based membrane or material and/or the conditions under which the anion exchange membrane or material was made. For example, the dependence of the pore structure on a state of the anion exchange membrane or material (e.g., when dry vs. when hydrated) may depend on an amount of functional groups (e.g., quaternary ammonium groups) present in the silica-based ceramic. The amount of functional groups present may in turn depend on ratios of silicon-containing precursors in, for example, a silicon-containing precursor sol during fabrication of the anion exchange membrane or material. In some embodiments, anion exchange membranes derived from silicon-containing precursor sols having relatively low amounts (e.g., less than or equal to 5 mol%, less than or equal to 1 mol%, or less) of silicon-containing precursors comprising functional groups (e.g., having structure IV or VI) have a pore structure (e.g., average pore diameter, small angle scattering model fit) that is relatively similar whether the anion exchange membrane or material is in a dry state or in a hydrated state. For example, in some such instances the average pore diameter in a hydrated state is within 10%, within 5%, or within 2% of the average pore diameter in the dry state. However, in some embodiments, anion exchange membranes derived from silicon-containing precursor sols having relatively high amounts (e.g., greater than or equal to 15 mol%, greater than or

– 44 –

equal to 20 mol%, greater than or equal to 25 mol%, greater than or equal to 30 mol%, greater than or equal to 35 mol%, greater than or equal to 40 mol%, or greater) of silicon-containing precursors comprising functional groups (e.g., having structure IV or VI) have a pore structure (e.g., average pore diameter, small angle scattering model fit) that is substantially different (e.g., pore diameters in a hydrated state greater than pore diameters in a dry state by a factor of greater than or equal to 1.1, greater than or equal to 1.2, greater than or equal to 1.3, greater than or equal to 1.4, greater than or equal to 2, or greater) when the anion exchange membrane or material is in a dry state versus when it is in a hydrated state.

As mentioned above, in some embodiments, the anion exchange membrane comprises a porous support membrane. The porous membrane (e.g., porous support membrane 130) may comprise any of a variety of suitable materials and may be in any of a variety of forms.

In some embodiments, the porous support membrane comprises relatively large pores in the absence of the silica-based ceramic, such as prior to being coated with the silica-based ceramic. For example, referring back to FIG. 2A, porous support membrane 130 comprises pores that include pore 132, which is relatively large. Having relatively large pores may, in some embodiments, allow for sufficient overall permeability across the membrane as well as sufficient space for the silica-based ceramic to be present in cases in which a coating formed by the silica-based ceramic is located at least partially within the porous membrane support. In some embodiments, the porous support membrane comprises pores having an average (mean) pore diameter, in the absence of the silica-based ceramic, such as prior to being coated with the silica-based ceramic, of greater than or equal to 50 nm, greater than or equal to 75 nm, greater than or equal to 100 nm, greater than or equal to 200 nm, greater than or equal to 500 nm, greater than or equal to 1 μ m, greater than or equal to 2 μ m, greater than or equal to 5 μ m, greater than or equal to 10 μ m, greater than or equal to 15 μ m, greater than or equal to 20 μ m, greater than or equal to 30 μ m, greater than or equal to 40 μ m, or more. However, in some embodiments, the porous support membrane does not comprise pores that are so large as to cause deleterious effects on the performance or properties of the anion exchange membrane (e.g., poor mechanical burst strength, low retention of coating, etc.). In some embodiments, the porous support membrane comprises pores having an average pore diameter, in the absence of the silica-based ceramic, such as prior to being coated with

– 45 –

the silica-based ceramic, of less than or equal to 50 μm , less than or equal to 25 μm , less than or equal to 10 μm , less than or equal to 5 μm , less than or equal to 2 μm , less than or equal to 1 μm , less than or equal to 500 nm or less. Combinations of these ranges are possible. For example, in some embodiments, the porous support membrane comprises
5 pores having an average diameter, in the absence of the silica-based ceramic, such as prior to being coated with the silica-based ceramic, of greater than or equal to 50 nm and less than or equal to 50 μm , greater than or equal to 500 nm and less than or equal to 10 μm , or greater than or equal to 1 μm and less than or equal to 5 μm . The average pore diameter of the porous support membrane in the anion exchange membrane can be
10 determined by Brunauer-Emmett-Teller (BET) gas sorption techniques or mercury intrusion porosimetry.

It should be understood that in some embodiments, the silica-based ceramic, when present fills at least a portion (or all) of the pores of the porous support membrane. In such cases, the average pore diameter of the porous support membrane in the final
15 anion exchange membrane will be smaller than the average pore diameter of the porous support membrane prior to being coated by the silica-based ceramic. Additionally and as mentioned above, in some embodiments, the silica-based ceramic itself is porous (e.g., nanoporous). As such, in some embodiments, the anion exchange membrane has a bimodal distribution of pores. For example, in some embodiments the anion exchange
20 membrane has a bimodal distribution of pores comprising relatively small pores that correspond to the pores of the silica-based ceramic and relatively large pores that correspond to the partially-filled (e.g., 70%-filled) pores of the porous support membrane. In these embodiments, the bimodal distribution can be determined by measuring the relatively small pores using the SAXS techniques described above (e.g., to
25 measure the pores that correspond to the silica-based ceramic), and measuring the relatively large pores using the BET gas sorption or mercury intrusion porosimetry techniques described above (e.g., to measure the pores that correspond to partially-filled pores of the porous support membrane).

In some embodiments, the relatively small pores of the bimodal distribution (e.g.,
30 that correspond to the pores silica-based ceramic) have an average pore diameter of less than or equal to 1 μm (e.g., less than or equal to 500 nm, less than or equal to 100 nm, or less than or equal to 50 nm). In some cases, the relatively small pores of the bimodal distribution (e.g., that correspond to the pores silica-based ceramic) have an average pore

– 46 –

diameter of less than or equal to 10 nm, less than or equal to 8 nm, less than or equal to 6 nm, less than or equal to 5 nm, less than or equal to 3 nm, less than or equal to 2 nm, or less. In some embodiments, the relatively small pores of the bimodal distribution (e.g., that correspond to the pores silica-based ceramic) have an average pore diameter of
5 greater than or equal to 0.25 nm, greater than or equal to 0.4 nm, greater than or equal to 0.6 nm, or greater than or equal to 1 nm. Combinations of these ranges are possible. For example, in some embodiments, the relatively small pores of the bimodal distribution (e.g., that correspond to the pores silica-based ceramic) have an average pore diameter of
10 0.25 nm and less than or equal to 10 nm, greater than or equal to 0.4 nanometers and less than or equal to 10 nm, greater than or equal to 0.6 nm and less than or equal to 5 nm, or greater than or equal to 0.6 nm and less than or equal to 2.5 nm.

In some embodiments, the relatively large pores of the bimodal distribution (e.g., that correspond to the partially-filled pores of the porous support membrane) have an
15 average pore diameter of greater than or equal to 50 nm, greater than or equal to 75 nm, greater than or equal to 100 nm, greater than or equal to 200 nm, greater than or equal to 500 nm, greater than or equal to 1 μ m, greater than or equal to 2 μ m, greater than or equal to 5 μ m, greater than or equal to 10 μ m, greater than or equal to 15 μ m, greater than or equal to 20 μ m, greater than or equal to 30 μ m, greater than or equal to 40 μ m, or
20 more. In some embodiments, the relatively large pores of the bimodal distribution (e.g., that correspond to the partially-filled pores of the porous support membrane) have an average pore diameter of less than or equal to 50 μ m, less than or equal to 25 μ m, less than or equal to 10 μ m, less than or equal to 5 μ m, less than or equal to 2 μ m, less than or equal to 1 μ m, less than or equal to 500 nm or less. Combinations of these ranges are
25 possible. For example, in some embodiments, the relatively large pores of the bimodal distribution (e.g., that correspond to the partially-filled pores of the porous support membrane) have an average pore diameter of greater than or equal to 50 nm and less than or equal to 50 μ m, greater than or equal to 500 nm and less than or equal to 10 μ m, or greater than or equal to 1 μ m and less than or equal to 5 μ m.

30 In some embodiments, the porous support membrane has a relatively high volumetric porosity in the absence of the silica-based ceramic, such as prior to being coated with the silica-based ceramic. Having a relatively high volumetric porosity may, in some cases, allow for sufficient overall permeability as well as sufficient space for the

silica-based ceramic to be present in cases in which a coating formed by the silica-based ceramic is located at least partially within the porous membrane support. In some embodiments, the porous support membrane, in the absence of the silica-based ceramic, such as prior to being coated with the silica-based ceramic, has a volumetric porosity of greater than or equal to 10%, greater than or equal to 15%, greater than or equal to 20%, greater than or equal to 30%, greater than or equal to 40, greater than or equal to 50%, greater than or equal to 60%, greater than or equal to 70%, greater than or equal to 80%, greater than or equal to 90%, or higher. In some embodiments, the porous support membrane has a volumetric porosity, in the absence of the silica-based ceramic, such as prior to being coated with the silica-based ceramic, of less than or equal to 99%, less than or equal to 95%, less than or equal to 90%, less than or equal to 80%, less than or equal to 70%, less than or equal to 60%, less than or equal to 50%, less than or equal to 40%, less than or equal to 30%, or less. Combinations of these ranges are possible. For example, in some embodiments, the porous support membrane, in the absence of the silica-based ceramic, such as prior to being coated with the silica-based ceramic, has a volumetric porosity of greater than or equal to 10% and less than or equal to 99%, greater than or equal to 50% and less than or equal to 99%, greater than or equal to 80% and less than or equal to 99%, or greater than or equal to 60% and less than or equal to 80%. It should be understood that in some embodiments, the silica-based ceramic fills at least a portion of the pores of the porous support membrane. Therefore, in some embodiments, the overall anion exchange membrane may have a volumetric porosity that is different than the volumetric porosity of the porous support membrane in the absence of the silica-based ceramic. The volumetric porosity of the porous support membrane in the anion exchange membrane can be determined by BET gas sorption techniques or mercury intrusion porosimetry.

The porous support membrane may have any suitable cross-sectional thickness. Having a suitable cross-sectional thickness can, in some cases, allow for the porous support membrane and ultimately the anion exchange membrane to have suitable mechanical properties (e.g., mechanical burst strength) and performance characteristics (e.g., by having an appropriate permeability and ion transport rate). In some embodiments, the porous support membrane has a cross-sectional thickness of greater than or equal to 3 μm , greater than or equal to 5 μm , greater than or equal to 10 μm , greater than or equal to 25 μm , greater than or equal to 50 μm , greater than or equal to 75

– 48 –

μm, greater than or equal to 100 μm, greater than or equal to 150 μm, greater than or equal to 200 μm, greater than or equal to 300 μm, greater than or equal to 400 μm, greater than or equal to 500 μm, or more. In some embodiments, the porous support membrane has a cross-sectional thickness of less than or equal to 1,000 μm, less than or equal to 500 μm, less than or equal to 300 μm, less than or equal to 100 μm, or less. Combinations of these ranges are possible. For example, in some embodiments, the porous support membrane has a cross-sectional thickness of greater than or equal to 3 μm and less than or equal to 1,000 μm, or greater than or equal to 25 μm and less than or equal to 300 μm. The cross-sectional thickness of the porous support membrane in the anion exchange membrane can be determined using SEM/EDX techniques on the anion exchange membrane. In some embodiments, the EDX component of the technique can be used to distinguish between the porous support membrane and other components of the anion exchange membrane, such as the silica-based ceramic.

The porous support membrane can be in the any of a variety of suitable forms. It should therefore be understood that the depiction of porous support membrane 130 in FIG. 2A is non-limiting and exemplary, and that porous support membrane 130 can be in the form of any suitable structure. In some embodiments, the porous support membrane may be in the form of a macroporous structure. For example, in some embodiments, the porous support membrane is in the form of a non-woven fabric or a non-woven mesh. In some embodiments, the porous support membrane is in the form of a veil. In some embodiments, the porous support membrane is in the form of a knit fabric. In some cases, the porous support membrane is in the form of a woven fabric or mesh. In some embodiments, the porous support membrane is in the form of an open-cell structure, such as an open-cell foam. In some embodiments, the porous support membrane is in the form of a fibril and node structure. In some cases, the porous support membrane includes combinations of multiple types of microporous structures. For example, in some embodiments, the porous support membrane includes combinations of the exemplary structures described above (e.g., non-woven fabric, open-cell foam, etc.).

The porous support membrane may be formed by any suitable method. In some embodiments, the porous support membrane is a wet-laid structure or a non-wet-laid structure (e.g., an airlaid structure, a carded structure, a meltblown structure, a meltspun structure (e.g., spunbond), a centrifugal spun web, a solvent spun web, an electroblown web, a gel spun web).

– 49 –

As mentioned above, in some embodiments, the porous support membrane comprises support components. The support components of the porous support membrane generally refer to the components of the porous support membrane that contribute to the overall structure and mechanical properties of the porous support
5 membrane. For example, in some embodiments in which the porous support membrane is in the form of a non-woven fabric, the support components of the non-woven fabric may include the fibers and/or filaments from which the non-woven fabric is formed. As another example, in some embodiments in which the porous support membrane is in the form of a mesh, the support components of the mesh may include the strands of which
10 the mesh is formed. Examples of support components include, but are not limited to, fibers, strands, and wires. Referring again to FIG. 2A, porous support membrane 130 comprises an exemplary porous support component 135, according to some embodiments.

In some embodiments, the support components have a relatively large number
15 average diameter. In some cases, having support components have a relatively large diameter can contribute to the porous support membrane having relatively beneficial mechanical properties (e.g., relatively high mechanical burst strength). In some embodiments, the porous support membrane has a number average support component diameter (e.g., fiber diameter, cell diameter) of greater than or equal to 10 nm, greater
20 than or equal to 25 nm, greater than or equal to 50 nm, greater than or equal to 100 nm, greater than or equal to 200 nm, greater than or equal to 500 nm, greater than or equal to 1 μm , greater than or equal to 2 μm , greater than or equal to 5 μm , greater than or equal to 10 μm , greater than or equal to 20 μm , or more. In some embodiments, the support components of the porous support membrane are not so large as to contribute to
25 deleterious effects in the overall anion exchange membrane, such as insufficient porosity or permeability. In some embodiments, the porous support membrane has a number average support component diameter (e.g., fiber diameter, cell diameter) of less than or equal to 50 μm , less than or equal to 20 μm , less than or equal to 10 μm , less than or equal to 5 μm , less than or equal to 2 μm , less than or equal to 1 μm , less than or equal to
30 500 nm, less than or equal to 100 nm, or less. Combinations of these ranges are possible. For example, in some embodiments, the porous support membrane has a number average support component diameter of greater than or equal to 10 nm and less than or equal to 50 μm , greater than or equal to 10 nm and less than or equal to 20 μm , greater than or

– 50 –

equal to 100 nm and less than or equal to 1 μ m, or greater than or equal to 100 nm and less than or equal to 500 nm.

The porous support membrane may comprise any of a variety of suitable materials (e.g., organic materials, inorganic materials, or combinations thereof). In some
5 embodiments, the porous support membrane comprises a polymeric material. In some such cases, greater than or equal to 20 wt%, greater than or equal to 30 wt%, greater than or equal to 40 wt%, greater than or equal to 50 wt%, greater than or equal to 60 wt%, greater than or equal to 70 wt%, greater than or equal to 75 wt%, greater than or equal to 80 wt%, greater than or equal to 90 wt%, greater than equal to 95 wt%, or more by
10 weight of the porous support membrane is composed of one or more polymers. In some embodiments, less than or equal to 100 wt%, less than or equal to 99 wt%, less than or equal to 95 wt%, less than or equal to 90 wt%, less than or equal to 80 wt%, less than or equal to 50 wt%, less than or equal to 30 wt%, or less by weight of the porous support membrane is composed of one or more polymers. Combinations of these ranges are
15 possible. For example, in some embodiments, greater than or equal to 20 wt% and less than or equal to 100 wt%, or greater than or equal to 50 wt% and less than or equal to 99 wt% by weight of the porous support membrane is composed of one or more polymers. Exemplary polymers that the porous support membrane can comprise include, but are not limited to, polyethylene, polyvinyl chloride, polypropylene, polystyrene, polyamide,
20 polyimide, polyacetonitrile, polyvinylacetate, polyethylene glycol, poly ether ether ketone, polysulfone, polyacrylamide, polydimethylsiloxane, polyvinylidene fluoride, polyacrylic acid, polyvinyl alcohol, polyphenylene sulfide, polytetrafluoroethylene, cellulose, microfibrillated cellulose, nanofibrillated cellulose, or combinations or derivatives thereof.

25 In some embodiments, the porous support membrane comprises a ceramic or glass material. In some such cases, greater than or equal to 20 wt%, greater than or equal to 30 wt%, greater than or equal to 40 wt%, greater than or equal to 50 wt%, greater than or equal to 60 wt%, greater than or equal to 70 wt%, greater than or equal to 75 wt%, greater than or equal to 80 wt%, greater than or equal to 90 wt%, greater than equal to 95
30 wt%, or more by weight of the porous support membrane is composed of one or more ceramic or glass materials. In some embodiments, less than or equal to 100 wt%, less than or equal to 99 wt%, less than or equal to 95 wt%, less than or equal to 90 wt%, less than or equal to 80 wt%, less than or equal to 50 wt%, less than or equal to 30 wt%, or

– 51 –

less by weight of the porous support membrane is composed of one or more one or more ceramic or glass materials. Combinations of these ranges are possible. For example, in some embodiments, greater than or equal to 20 wt% and less than or equal to 100 wt%, or greater than or equal to 50 wt% and less than or equal to 99 wt% by weight of the porous support membrane is composed of one or more one or more ceramic or glass materials. Exemplary ceramics that the porous support membrane can comprise include, but are not limited to, borosilicate glass, silica, titania, zirconia, alumina, silicon carbide, silicon nitride, boron nitride, lithium silicate, potassium silicate, tin oxide, iron oxide, or combinations thereof.

10 In some embodiments, the porous support membrane comprises a metal and/or metal alloy. In some such cases, greater than or equal to 20 wt%, greater than or equal to 30 wt%, greater than or equal to 40 wt%, greater than or equal to 50 wt%, greater than or equal to 60 wt%, greater than or equal to 70 wt%, greater than or equal to 75 wt%, greater than or equal to 80 wt%, greater than or equal to 90 wt%, greater than equal to 95
15 wt%, or more by weight of the porous support membrane is composed of one or more metals and/or metal alloys. In some embodiments, less than or equal to 100 wt%, less than or equal to 99 wt%, less than or equal to 95 wt%, less than or equal to 90 wt%, less than or equal to 80 wt%, less than or equal to 50 wt%, less than or equal to 30 wt%, or less by weight of the porous support membrane is composed of one or more metals
20 and/or metal alloys. Combinations of these ranges are possible. For example, in some embodiments, greater than or equal to 20 wt% and less than or equal to 100 wt%, or greater than or equal to 50 wt% and less than or equal to 99 wt% by weight of the porous support membrane is composed of one or more metals and/or metal alloys. Exemplary metals that the porous support membrane can comprise include, but are not limited to,
25 iron, nickel, copper, titanium, aluminum, or combinations thereof. One non-limiting example of a metal alloys that the porous support membrane can comprise is steel.

In some embodiments, the porous support membrane comprises a combination of the material described above. For example, in some embodiments, the porous support membrane comprises a combination of a polymeric material and a ceramic or glass
30 material (or a polymeric material and a metal and/or metal alloy, or a ceramic material and a metal and/or metal alloy). One non-limiting example is an embodiment in which the porous support membrane comprises a glass material (e.g. borosilicate glass)

– 52 –

containing one or more polymeric materials (e.g., one or more polymeric binders that may enhance mechanical properties of the porous support membrane).

In some, but not necessarily all embodiments, the porous support membrane comprises one or more amphiphilic molecules on a surface of the porous support membrane. Inclusion of one or more amphiphilic molecules on a surface of the porous support membrane may, in some cases, promote enhanced wetting of solutions used during fabrication of the anion exchange membrane. For example, in some cases, the anion exchange membrane is fabricated via application of a sol-gel solution to the porous support membrane. In some cases, such enhanced wetting may contribute to a reduction in cracking during certain fabrication steps, such in cases where drying steps are performed. In some such cases, having one or more amphiphilic molecules present on a surface of the porous support membrane may promote wetting of the sol-gel ceramic material on the porous support membrane. In some cases, an amphiphilic molecule is covalently bound to at least a portion of the porous support membrane (e.g., as a surface functional group). In some embodiments, the amphiphilic molecule is coated on or within the porous support membrane (e.g., prior to coating the porous support membrane with the sol-gel). Exemplary amphiphilic molecules include, but are not limited to, sodium alkyl sulfates (e.g., sodium dodecyl sulfate), dialkyl sulfosuccinate, and alkyltrimethylammonium bromide.

In some embodiments, the porous support membrane has a relatively high surface area (e.g., prior to being coated with a silica-based ceramic). Having a relatively high surface area of the porous support membrane can, in some cases, promote adhesion between the porous support membrane and the silica-based ceramic. One exemplary way in which a relatively high surface area of the porous support membrane may be achieved is by etching the porous support membrane prior to coating the porous support membrane with the silica-based ceramic. The porous support membrane can be etched, in some cases, with an appropriate solvent, acid, caustic, or oxidizer. In some embodiments, the porous support membrane has a specific surface area of greater than or equal to 0.0001 m²/g, greater than or equal to 0.0002 m²/g, greater than or equal to 0.0005 m²/g, greater than or equal to 0.001 m²/g, greater than or equal to 0.002 m²/g, greater than or equal to 0.005 m²/g, greater than or equal to 0.01 m²/g, greater than or equal to 0.02 m²/g, greater than or equal to 0.05 m²/g, greater than or equal to 0.1 m²/g, greater than or equal to 0.2 m²/g, greater than or equal to 0.5 m²/g, or greater prior to

being coated with a silica-based ceramic. In some embodiments, the porous support membrane has a specific surface area of less than or equal to $100 \text{ m}^2/\text{g}$, less than or equal to $50 \text{ m}^2/\text{g}$, less than or equal to $20 \text{ m}^2/\text{g}$, less than or equal to $10 \text{ m}^2/\text{g}$, less than or equal to $5 \text{ m}^2/\text{g}$, less than or equal to $2 \text{ m}^2/\text{g}$, less than or equal to $1 \text{ m}^2/\text{g}$, or less prior to being coated with a silica-based ceramic. Combinations of these ranges are possible. For example, in some embodiments, the porous support membrane has a specific surface area of greater than or equal to $0.0001 \text{ m}^2/\text{g}$ and less than or equal to $100 \text{ m}^2/\text{g}$, greater than or equal to $0.001 \text{ m}^2/\text{g}$ and less than or equal to $10 \text{ m}^2/\text{g}$, or greater than or equal to $0.01 \text{ m}^2/\text{g}$ and less than or equal to $1 \text{ m}^2/\text{g}$ prior to being coated with a silica-based ceramic.

10 The specific surface area of the porous support membrane prior to being coated with the silica-based ceramic can be determined using BET gas sorption techniques (either before the silica-based ceramic coating is formed, or by removing the silica-based ceramic from the anion exchange membrane).

In some embodiments, a relatively high percentage of the pore volume of the porous support membrane is filled by the silica-based ceramic that coats at least a portion of the porous support membrane. The percentage of the pore volume of the porous support membrane filled by the silica-based ceramic can be determined, for example, using SEM. Generally, several images are taken of both the top and cross-section of the anion exchange membrane at various magnifications from 200x for the top up to 2000x for the cross-section. These images can be compared to images of the porous support membrane at the same magnifications. To determine the extent to which the pore volume of the porous support membrane is filled with the silica-based ceramic, the cross-section of the anion exchange membrane is inspected. An anion exchange membrane in which the pore volume of the porous support membrane is well-filled with the silica-based ceramic will look dense with little to no obvious macropores or open areas. In some cases, if there are places that are less dense (e.g., cracks, smaller pores, etc.), it can be beneficial if they are not structured in such a way as to create a clear pathway for liquid to travel from one side of the anion exchange membrane to the other. Likewise, in some embodiments, it can be beneficial if the anion exchange membrane is such that images of the top of the membrane look smooth and uniform. In some embodiments, it is beneficial if the membranes have relatively little surface excess of silica-based ceramic. Surface excess of silica-based ceramic in the anion exchange membrane can be determined by inspecting the SEM for regions of the silica-based ceramic on the top or

– 54 –

bottom surface of the porous support membrane. In some embodiments, the surface excess of silica-based ceramic on top of the porous support membrane is less than or equal to 200 μm , less than or equal to 20 μm , less than or equal to 2 μm , or less, as determined by SEM.

- 5 In some embodiments, greater than or equal to 50%, greater than or equal to 60%, greater than or equal to 70%, greater than or equal to 75%, greater than or equal to 80%, greater than or equal to 90%, greater than or equal to 95%, greater than or equal to 96%, greater than or equal to 97%, greater than or equal to 98%, greater than or equal to 99%, greater than or equal to 99.9%, and/or up to 100% of the pore volume of the porous
- 10 support membrane is filled by the silica-based ceramic. In some embodiments, less than or equal to 100%, less than or equal to 99.9%, less than or equal to 99%, less than or equal to 98%, less than or equal to 97%, less than or equal to 96%, less than or equal to 95%, less than or equal to 90%, less than or equal to 80%, less than or equal to 75%, less than or equal to 70%, or less than or equal to 60% of the pore volume of the porous
- 15 support membrane is filled by the silica-based ceramic. Combinations of these ranges are possible. For example, in some embodiments, greater than or equal to 50% and less than or equal to 100%, greater than or equal to 75% and less than or equal to 100%, greater than or equal to 90% and less than or equal to 100%, or greater than or equal to 97% and less than or equal to 100% of the pore volume of the porous support membrane
- 20 is filled by the silica-based ceramic, as determined by SEM. For example, SEM images can be acquired for a representative number of cross-sections (e.g., at least three cross section) of different regions of the membrane sample. Image processing software (e.g., ImageJ) can then be used to highlight the contrast between the void regions (which typically appear black in the images) and filled regions (which typically appear gray in
- 25 the images) and divide the area of the void region by the total area probed. So long as you provide a sufficiently large sample size ($\sim 0.5 \text{ cm}^2$ in images) you could determine the total “void area” relative to the total area of the cross-section. It would be important to pull cross-sections from multiple regions of the membrane to try to get a somewhat representative sample.
- 30 The anion exchange membrane may have any suitable thickness. For example, referring to FIG. 1A, anion exchange membrane 100 has a thickness 154. The thickness of the anion exchange membrane may be selected based on, for example, the application for which the anion exchange membrane is intended or the geometry of a device into

– 55 –

which the anion exchange membrane is to be incorporated (e.g., an electrochemical device, a filtration device, etc.). In some embodiments, the anion exchange membrane has a thickness of greater than or equal to 1 μm , greater than or equal to 3 μm , greater than or equal to 5 μm , greater than or equal to 10 μm , greater than or equal to 25 μm ,
5 greater than or equal to 50 μm , greater than or equal to 100 μm , greater than or equal to 200 μm , greater than or equal to 300 μm , greater than or equal to 400 μm , greater than or equal to 500 μm , greater than or equal to 700 μm , greater than or equal to 1,000 μm , greater than or equal to 1,200 μm , or more. In some embodiments, the anion exchange membrane has a thickness of less than or equal to 1,500 μm , less than or equal to 1,000
10 μm , less than or equal to 500 μm , less than or equal to 300 μm , less than or equal to 100 μm , less than or equal to 75 μm , less than or equal to 50 μm , or less. Combinations of these ranges are possible. For example, in some embodiments, the porous support membrane has a cross-sectional thickness of greater than or equal to 1 μm and less than or equal to 1,500 μm , or greater than or equal to 25 μm and less than or equal to 300 μm .
15 The thickness of the porous support membrane in the anion exchange membrane can be determined by taking an SEM cross-section of the anion exchange membrane or by using calipers.

In some embodiments, the weight ratio of the silica-based ceramic to the porous support membrane in the anion exchange membrane is greater than or equal to 1:10,
20 greater than or equal to 1:5, greater than or equal to 1:2, greater than or equal to 1:1, greater than or equal to 2:1, greater than or equal to 5:1, greater than or equal to 10:1, greater than or equal to 20:1, greater than or equal to 35:1, greater than or equal to 50:1, greater than or equal to 75:1, greater than or equal to 100:1, or greater. In some embodiments, the weight ratio of the silica-based ceramic to the porous support
25 membrane in the anion exchange membrane is less than or equal to 300:1, less than or equal to 250:1, less than or equal to 220:1, less than or equal to 200:1, less than or equal to 150:1, less than or equal to 120:1, less than or equal to 100:1, less than or equal to 75:1, less than or equal to 50:1, less than or equal to 35:1, less than or equal to 20:1, less than or equal to 10:1, less than or equal to 5:1, less than or equal to 2:1, less than or equal
30 to 1:1, less than or equal to 1:2, less than or equal to 1:5, or less. Combinations of these ranges are possible. For example, in some embodiments, the weight ratio of the silica-based ceramic to the porous support membrane in the anion exchange membrane is

greater than or equal to 1:10 and less than or equal to 300:1, or greater than or equal to 1:2 and less than or equal to 220:1.

In some embodiments, the anion exchange membrane has a density of greater than or equal 0.8 g/cm³, greater than or equal 0.9 g/cm³, greater than or equal 1.0 g/cm³,
5 greater than or equal 1.2 g/cm³, greater than or equal 1.5 g/cm³, greater than or equal 1.8 g/cm³, or greater. In some embodiments, the anion exchange membrane has a density of less than or equal to 2.2 g/cm³, less than or equal to 2.1 g/cm³, less than or equal to 2.0 g/cm³, less than or equal to 1.9 g/cm³, less than or equal to 1.8 g/cm³, less than or equal to 1.7 g/cm³, less than or equal to 1.6 g/cm³, less than or equal to 1.5 g/cm³, less than or
10 equal to 1.2 g/cm³, or less. Combinations of these ranges are possible. For example, in some embodiments, the anion exchange membrane has a density of greater than or equal to 0.8 g/cm³ and less than or equal to 2.2 g/cm³, or greater than or equal to 1.0 and less than or equal to 2.0 g/cm³.

In some embodiments, the anion exchange membrane has a basis weight of
15 greater than or equal 320 g/m², greater than or equal 350 g/m², greater than or equal to 400 g/m², greater than or equal to 450 g/m², greater than or equal to 500 g/m², greater than or equal to 550 g/m², greater than or equal to 600 g/m² or greater. In some embodiments, the anion exchange membrane has a basis weight of less than or equal to 880 g/m², less than or equal to 850 g/m², less than or equal to 800 g/m², less than or
20 equal to 750 g/m², less than or equal to 700 g/m², less than or equal to 650 g/m², less than or equal to 600 g/m², less than or equal to 550 g/m², less than or equal to 500 g/m², or less. Combinations of these ranges are possible. For example, in some embodiments, the anion exchange membrane has a basis weight of greater than or equal to 320 g/m² and less than or equal to 800 g/m². The basis weight can be measured, for example, by
25 cutting a 0.1 m² portion of the anion exchange membrane into 10 samples and measuring the weight of each sample after drying at 80 °C in a 0% humidity chamber for 24 hours.

In some embodiments, the anion exchange membrane has a specific surface area of greater than or equal 50 m²/g, greater than or equal 75 m²/g, greater than or equal to 100 m²/g, greater than or equal to 150 m²/g, greater than or equal to 200 m²/g, greater
30 than or equal to 300 m²/g, greater than or equal to 400 m²/g, greater than or equal to 500 m²/g, or greater. In some embodiments, the anion exchange membrane has a specific surface area of less than or equal to 1,000 m²/g, less than or equal to 900 m²/g, less than or equal to 800 m²/g, less than or equal to 750 m²/g, less than or equal to 700 m²/g, less

– 57 –

than or equal to 650 m²/g, less than or equal to 600 m²/g, less than or equal to 550 m²/g, less than or equal to 500 m²/g, or less. Combinations of these ranges are possible. For example, in some embodiments, the anion exchange membrane has a specific surface area of greater than or equal to 500 g/m² and less than or equal to 1,000 g/m².

5 In some embodiments, the anion exchange membrane comprises a compressible edging material. Such a compressible edging may, in certain cases, serve as a gasket that can seal the membrane. Having a compressible edging material that can serve as a gasket may be useful in some cases in which the anion exchange membrane is incorporated into an electrochemical device (e.g., a battery, fuel cell, etc.). In some
10 cases, the compressible edging material is mechanically compressible. In some embodiments, the compressible edging material is resistant to heat and/or harsh chemical environments. FIG. 5 depicts an exemplary illustration of a non-limiting embodiment in which an anion exchange membrane 100 comprises an optional compressible edging material 180.

15 In some embodiments, the anion exchange membrane comprises a compressible edging material along at least a portion of an edge of the anion exchange membrane. In some embodiments, the compressible edging material infiltrates the porous support membrane by at least 1 μm. For example, referring again to FIG. 5, in some
20 embodiments anion exchange membrane 100 comprises a silica-containing ceramic 150, compressible edging material 180, and porous support membrane 130 hidden behind silica-based ceramic 130 and compressible edging material 180, according to some embodiments. In some such cases, compressible edging material 180 infiltrates porous support membrane 130 by at least 1 μm. In some embodiments, the compressible edging
25 is located along all edges of the anion exchange membrane, defining a gasket (e.g., as shown in FIG. 5). In some embodiments, the compressible edging material covers about 50% or less, 25% or less, 10% or less, or 5% or less of a surface of the anion exchange membrane. In some embodiments, the percentage of the external geometrical surface area of the anion exchange membrane not covered by the compressible edging material is greater than or equal to 50%, greater than or equal to 90%, greater than or equal to 95%,
30 or more. In some embodiments, the percentage of the external geometric surface area of the anion exchange membrane not covered by the compressible edging material is greater than or equal to 1 cm², greater than or equal to 10 cm², greater than or equal to 100 cm², greater than or equal to greater than or equal to 1,000 cm² and/or up to 1 m², up to 2 m²,

– 58 –

up to 5m², up to 10 m², or more. The compressible edging material may have a width. For example, compressible edging material 180 in FIG. 5 has width 182. In some embodiments, the compressible edging material is 1 mm or greater in width. In some embodiments the compressible edging material is 5 mm or greater in width. In some
5 embodiments, the edge portion is 1 cm or greater in width.

 The compressible edging material can be formed on the anion exchange membrane using any suitable method. For example, in some embodiments, the compressible edging material is formed on the porous support membrane prior to forming the silica-based ceramic coating on and/or within the porous support membrane.
10 In some cases, the compressible edging material is formed on the porous support membrane after forming the silica-based ceramic coating on and/or within the porous support membrane.

 In some embodiments, forming the compressible edging material includes a step of impregnating an edge portion of the porous support membrane with a polymeric
15 material, for example, impregnating regions at or near one or more or all edges of the porous support membrane with a compressible polymer, sufficient to form a gasket bordering the porous membrane support membrane (and ultimately the anion exchange membrane). In some embodiments, the compressible edging material is formed using ultrasonic welding, hot pressing, or UV curing. In some embodiments, impregnating the
20 edge portion of the porous support membrane with the compressible polymer comprises one or more techniques chosen from melting, solution deposition, or *in situ* reaction.

 In some embodiments, the compressible edging material comprises a polymeric material. In some embodiments, the polymeric material comprises an elastomeric polymer, such as a thermoplastic elastomeric polymer. Any suitable elastomeric
25 polymer can be used to form the compressible edging material of the anion exchange membranes disclosed herein. Exemplary polymeric materials that the compressible edging material can comprise include, but are not limited to silicone, epoxy, polyurethane, acrylic, silicone rubber, poly(styrene-isoprene-styrene), poly(styrene-isobutylene-styrene), polypropylene, polyethylene, polyvinyl chloride, polystyrene,
30 polyamide, polyimide, polyacetonitrile, polyvinylacetate, polyethylene glycol, poly ether ether ketone, polysulfone, polyacrylamide, polydimethylsiloxane, polyvinylidene fluoride, polyacrylic acid, polyvinyl alcohol, polyphenylene sulfide, polytetrafluoroethylene, cellulose, or combinations or derivatives thereof.

– 59 –

As mentioned above, in some cases, inventive features associated with the anion exchange membrane and materials described herein can contribute to any of a number of potentially advantageous performance characteristics.

In some embodiments, the anion exchange membrane or material (e.g., anion
5 exchange membrane 100) has a relatively high anion exchange capacity. Having a relatively high anion exchange capacity is generally associated with good performance characteristics for an anion exchange material. The anion exchange capacity of a material such as membrane can be measured using the following procedure. An anion exchange membrane is soaked in an aqueous solution of sodium chloride (2.0 M) for at
10 least 12 hours, with the sodium chloride solution being exchanged twice with fresh sodium chloride solution during this 12 hour time period. After soaking in the sodium chloride solution, the membrane is soaked in deionized water for at least 15 minutes, with the deionized water being exchanged twice with fresh deionized water during this 15 minute time period. After soaking in the deionized water, the membrane is soaked in
15 an aqueous solution containing 1.0 M sodium nitrate for at least 3 hours, with the 1.0 M sodium nitrate solution being exchanged twice with fresh 1.0 M sodium nitrate solution (1.0 M sodium nitrate in otherwise deionized water) during this 3 hour period. The anion exchange membrane is removed from the sodium nitrate solution and rinsed with deionized water. All of the sodium nitrate solutions as well as the rinse solutions are
20 then combined and titrated with an aqueous solution containing 0.010 M silver nitrate using potassium chromate (0.25 M in the solution) as an indicator. The titration ends when solution changes color from bright yellow to slightly yellow-brown. An autotitrator can be used to perform the titration without the use of an indicator such as potassium chromate, instead using, for example a silver sensing probe. A set of “blank”
25 sodium nitrate solutions that are not exposed to the anion exchange membrane are used and titrated to determine a baseline chloride ion background for the aqueous solutions. The membrane is rinsed with deionized water and dried in an oven overnight. The weight and of the membrane is recorded following drying step. The anion exchange capacity (AEC) is measured using:

$$AEC = \frac{V_{titrant} C_{titrant}}{w_{dry}}$$

30

– 60 –

where V_{titrant} is the volume of the silver nitrate titrant added during the titration, corrected for the baseline chloride concentration of the aqueous solutions ($V_{\text{titrant}} = V_{\text{titrant,membrane}} - V_{\text{titrant,blanks}}$), C_{titrant} is the concentration of the titrant (0.010 M in this case), and w_{dry} is the weight of the dried membrane in grams. In this disclosure, anion exchange capacity is reported in units of eq/g, which are equivalents (eq) per unit weight (g, grams). The number of equivalents in a solution refers to the numbers of moles of an ion (e.g., chloride ions) in solution multiplied by the valence of the ions. The same procedure described above can be used for any anion exchange materials and is not limited to just membranes.

10 In some embodiments, it has been observed that anion exchange membranes described herein having a relatively high loading of certain functional groups (e.g., quaternary ammonium groups) contributes at least in part to the relatively high anion exchange capacity as compared to certain existing anion exchange membranes. Additionally, it has been observed that the anion exchange capacity of anion exchange membranes and materials described herein may also depend at least in part on the composition of a silicon-containing precursor sol from which a silica-based ceramic of the anion exchange membrane is derived (e.g., water to silicon ratio, acid strength, ratio of silicon-containing precursors such as TEOS and TMAPS).

20 In some embodiments, the anion exchange membrane or material has an anion exchange capacity of greater than or equal to 0.01 milliequivalents per gram (meq/g). In some embodiments, the anion exchange membrane or material has an anion exchange capacity of greater than or equal to 0.1 meq/g, greater than or equal to 0.2 meq/g, greater than or equal to 0.3 meq/g, greater than or equal to 0.5 meq/g, greater than or equal to 0.7 meq/g, greater than or equal to 1 meq/g, greater than or equal to 1.2 meq/g, greater than or equal to 1.5 meq/g, greater than or equal to 1.7 meq/g, or greater. In some embodiments, the anion exchange membrane or material has an anion exchange capacity of less than or equal to 2.5 meq/g, less than or equal to 2.2 meq/g, 2 meq/g, less than or equal to 1.8 meq/g, less than or equal to 1.5 meq/g, less than or equal to 1.2 meq/g, less than or equal to 1 meq/g, less than or equal to 0.7 meq/g, or less. Combinations of these ranges are possible. For example, in some embodiments, the anion exchange membrane or material has an anion exchange capacity of greater than or equal to 0.01 meq/g and less than or equal to 2.5 meq/g, greater than or equal to 0.1 meq/g and less than or equal to 2.5 meq/g, greater than or equal to 0.5 meq and less than or equal to 2.5 meq/g, or

– 61 –

greater than or equal to 1 meq/g and less than or equal to 2.5 meq/g. In some embodiments, the anion exchange membrane or material has a relatively high anion exchange capacity while having a relatively high amount of Si present in the silica-based ceramic of the anion exchange membrane. For example, in some embodiments, the anion exchange membrane has an anion exchange capacity of greater than or equal to 0.01 meq/g, greater than or equal to 0.1 meq/g, greater than or equal to 0.2 meq/g, greater than or equal to 0.3 meq/g, greater than or equal to 0.5 meq/g, greater than or equal to 0.7 meq/g, greater than or equal to 1 meq/g and/or up to 1.2 meq/g, up to 1.5 meq/g, up to 1.8 meq/g, or up to 2 meq/g while having Si present in the silica-based ceramic in an amount of at least 6 wt%, at least 10 wt%, at least 12 wt%, at least 15 wt%, at least 17 wt%, at least 20 wt%, and/or up to 24 wt%, up to 26 wt%, up to 28 wt%, up to 30 wt%, up to 40 wt%, up to 47 wt%, up to 60 wt%, or more.

In some embodiments, the anion exchange membrane or material undergoes a relatively small amount of dimensional swelling (in the form of linear expansion), according to a dimensional swelling test described herein. As mentioned above, having a relatively small amount of dimensional swelling can, in some cases, be advantageous for an anion exchange membrane or material. It has been observed that anion exchange membranes and materials described herein, some of which comprise a silica-based ceramic, may undergo relatively less dimensional swelling (e.g., linear expansion) than certain existing anion exchange membrane or materials, such as those comprising predominantly polymeric components such as hydrocarbon or fluorocarbon polymers. Without wishing to be bound by any particular theory, it is believed that linear expansion can occur when a membrane's pore size or structure changes (e.g., swelling, de-swelling) based on the environment of the anion exchange membrane (e.g., temperature, humidity, salinity). When an anion exchange membrane is incorporated into devices where the edges of the membrane are fixed in place, for example, an electrochemical device (e.g., an electrochemical stack), the swelling/de-swelling can result in mechanical stresses that can cause membrane failure. Having a relatively low linear expansion can also make it easier to align membranes (e.g., via making alignment holes in the membrane) when positioning membranes in a device (e.g., a stack) during assembly. However, in some embodiments, it is beneficial to have some amount of linear expansion (e.g., via swelling) to allow for percolation of hydrated domains and beneficial performance characteristics (e.g., anion exchange capacity, chloride ion conductivity). The linear

– 62 –

expansion of an anion exchange membrane can be measured using the following dimensional swelling test. The dimensional swelling test is conducted using a modified version of ASTM D756 and ASTM D570. The membrane sample is cut into a 50 mm × 50 mm square and conditioned in a room maintained at 23°C and 50% relative humidity for 48 hours. After conditioning, the length and width of the membrane sample is measured. The sample is then soaked in either 23°C water or 100°C water for one hour. After the soaking, the membrane is removed from the water and wiped with a dry cloth. Immediately after the membrane is wiped with the cloth, the length of each side is recorded. The linear expansion for a given dimension (e.g., length or width) is determined by dividing the measured length of that dimension following the step of wiping the membrane with a dry cloth by the original 50 mm length, and is reported as a percentage change relative to the original 50 mm length. For example, a membrane for which a length of 55 mm is measured following the soaking and wiping with the cloth has a linear expansion of 10%, while a membrane for which a length of 60 mm is measured following the soaking and wiping with the cloth has a linear expansion of 20%. The linear expansion of an anion exchange membrane is determined by performing the above-mentioned dimensional swelling test on three identical samples and determining the number average of the three tests.

In some embodiments, the anion exchange membrane has a relatively small linear expansion, as mentioned above. In some embodiments, the anion exchange membrane has a linear expansion along at least one dimension of less than or equal to 10%, less than or equal to 8%, less than or equal to 6%, less than or equal to 5%, less than or equal to 2%, less than or equal to 1%, less than or equal to 0.5%, or less. In some embodiments, the anion exchange membrane has a linear expansion of as low as 0% along at least one dimension. In some embodiments, the anion exchange membrane has a linear expansion of greater than or equal to 0%, greater than or equal to 0.01%, or greater than or equal to 0.1% along at least one dimension. Combinations of these ranges are possible. For example, in some embodiments, the anion exchange membrane has a linear expansion of greater than or equal to 0% and less than or equal to 5%, greater than or equal to 0% and less than or equal to 2%, greater than or equal to 0% and less than or equal to 1%, or greater than or equal to 0% and less than or equal to 0.5% along at least one dimension.

– 63 –

In some embodiments, the anion exchange membrane has a relatively small linear expansion while having a relatively large anion exchange capacity. For example, in some embodiments, the anion exchange membrane has a linear expansion of less than or equal to 20%, less than or equal to 15%, less than or equal to 10%, less than or equal to 8%,
5 less than or equal to 6%, less than or equal to 5%, less than or equal to 2%, less or equal to 1%, less than or equal to 0.5%, or less along at least one dimension while having an anion exchange capacity of greater than or equal to 0.01 meq/g, greater than or equal to 0.2 meq/g, greater than or equal to 0.3 meq/g, greater than or equal to 0.5 meq/g, greater than or equal to 0.7 meq/g, greater than or equal to 1 meq/g, and/or up to 1.2 meq/g, up
10 to 1.5 meq/g, up to 1.8 meq/g, up to 2 meq/g, up to 2.5 meq/g, or more. Obtaining such high anion exchange capacities while undergoing such a small amount of dimensional swelling (e.g., linear expansion) when exposed to water may not be possible with certain existing anion exchange membranes or materials.

In some embodiments, the anion exchange membrane or material has a relatively
15 high anion permselectivity. Anion permselectivity generally refers to a metric quantifying an extent to which a membrane or material is more permeable to anions than cations. Selectivity toward anions relative to cations may, in certain applications, be an important characteristic of an anion exchange membrane. Herein, anion permselectivity is measured by comparing the permeability of the membrane or material to chloride
20 anions as compared to sodium anions. The permselectivity is measured in this case using an open circuit voltage method. The open circuit voltage method is well known in literature, being described, for example, in Sata, T., Properties, Characterization and Microstructure of Ion Exchange Membranes. In Ion Exchange Membranes: Preparation, Characterization, Modification and Application, Sata, T., Ed. The Royal Society of
25 Chemistry: 2004; pp 89-134 and in Kingsbury, R. S.; Flotron, S.; Zhu, S.; Call, D. F.; Coronell, O., Junction Potentials Bias Measurements of Ion Exchange Membrane Permselectivity. Environmental Science & Technology 2018, 52 (8), 4929-4936, both of which are incorporated herein by reference in their entirety. In the performance of the open circuit voltage method tests, the membrane is equilibrated in a 0.5 M NaCl aqueous
30 solution prior to testing. The membrane is then installed in a two-compartment cell. One compartment of the cell is filled with 100 mL of 0.5 M NaCl aqueous solution, while the other compartment is filled with 100 mL of 0.1 M NaCl aqueous solution. Each compartment of the two-compartment cell is stirred, and fresh solution is pumped

– 64 –

through each compartment at a rate of approximately 5 mL/min. AgCl wire electrodes and a multimeter (e.g., Fluke 116 True RMS) is used to make the voltage measurements. The AgCl wire electrodes are immersed in the respective compartments, and the multimeter is set to the dc voltage setting. The multimeter probes are connected to the respective AgCl wires, and a voltage reading is taken from the multimeter. The wires are allowed to equilibrate for 30 minutes before the final membrane potential is recorded. The anion permselectivity is then calculated using the Nernst equation. The offset potential of the AgCl wires is measured in the 0.5 M NaCl and 0.1 M NaCl solutions, and averaged to account for the reference potential in the final calculations.

10 In some embodiments, the anion exchange membrane or material has an anion permselectivity of greater than or equal 65%. In some embodiments, the anion exchange membrane has an anion permselectivity of greater than or equal to 70%, greater than or equal to 75%, greater than or equal to 80%, greater than or equal to 85%, greater than or equal to 90%, greater than or equal to 95%, greater than or equal to 97%, greater than or equal to 98%, or higher. In some embodiments, the anion exchange membrane has an anion permselectivity of less than or equal to 100%, less than or equal to 99%, less than or equal to 98%, less than or equal to 97%, less than or equal to 95%, less than or equal to 90%, less than or equal to 85%, less than or equal to 80%, or less. Combinations of these ranges are possible. For example, in some embodiments, the anion exchange membrane has an anion permselectivity of greater than or equal to 65% and less than or equal to 100%, greater than or equal to 85% and less than or equal to 100%, greater than or equal to 90% and less than or equal to 100% percent, greater than or equal to 95% and less than or equal to 100%, or greater than or equal to 98% and less than or equal to 100%.

25 In some embodiments, the anion exchange membrane has a relatively high chloride ion (Cl^-) conductivity (C_{Cl}). Chloride ion conductivity can be a useful metric in evaluating the conductivity of the anion exchange membrane with respect to anions such as chloride ions. Having a relatively high chloride ion conductivity may be important in certain applications, such as certain electrochemical applications (e.g., electrodialysis applications). For example, a relatively high chloride ion conductivity can, in some embodiments, promote energy efficiency in electrochemical systems. It has been observed that the anion exchange membranes described herein may have a relatively high chloride ion conductivity at least in part due to inventive characteristics of the anion

– 65 –

exchange membranes, such as relatively high loadings of functional groups (e.g., quaternary ammonium groups). The chloride ion conductivity may also be affected by the pore structure of the silica-based ceramic (e.g., pore diameter, pore-pore distance, pore ordering such as fractal aggregate vs. otherwise). It has been observed herein that ion conductivity is not necessarily correlated with other properties of an ion exchange membrane or material (e.g., anion exchange capacity), and that structural and compositional factors leading to relatively high chloride ion conductivity may differ from those affecting other properties. For example, if an anion exchange membrane comprises functional groups (e.g., quaternary ammonium groups) localized near exterior surfaces of the anion exchange membrane, the membrane could have a relatively high anion exchange capacity but a poor chloride ion conductivity because the functional groups would not be distributed through a thickness of the membrane. In contrast, an anion exchange membrane with an effective distribution (e.g., a substantially homogeneous distribution) of functional groups may have both a relatively high anion exchange capacity and a relatively high chloride ion conductivity. Factors affecting such a distribution can include choice of precursor materials (e.g., silicon-containing precursor materials), ratios of precursor materials (e.g., in a silicon-containing precursor sol), and choice of porous support membrane (if present).

As another example, certain existing anion exchange compositions having higher amounts of functional groups (e.g., quaternary ammonium groups) generally tend to experience greater linear expansion because the functional groups tend to adsorb water, leading to swelling. It has been realized herein that it is possible to achieve anion exchange membranes having relatively high chloride ion conductivity and relatively low linear expansion. One way to achieve such a result is by designing a pore structure of a silica-based ceramic such that the membrane swells enough upon hydration to achieve percolated pores, but not so much that the pores become too large and lack permselectivity while causing significant linear expansion. In some embodiments, percolated pores resulting from some swelling of the membrane can promote both relatively high chloride ion conductivity and relatively high anion exchange capacity.

The chloride ion conductivity of the anion exchange membrane can be measured using the following four-electrode electrical impedance spectroscopy (EIS) procedure. A four-electrode electrical impedance spectroscopy procedure is described in more detail in Galama, A. H.; Hoog, N. A.; Yntema, D. R., Method for determining ion exchange

– 66 –

membrane resistance for electrodialysis systems. Desalination 2016, 380, 1-11, which is incorporated herein by reference in its entirety. The membrane is equilibrated in a solution of 0.5 M NaCl prior to testing. The membrane is then incorporated into a two-compartment cell. Prior to incorporating the membrane into the two compartment cell, the two-compartment cell is first assembled and filled with the 0.5 M NaCl solution in order to measure a background resistance of the cell. The cell is then emptied, reassembled with the membrane and filled with the 0.5 NaCl solution, at which point another resistance measurement is acquired. A galvanostatic EIS measurement is used. A constant current of 5 mA is applied to working platinum electrodes and is swept from 10,000 Hz to 10 Hz with 15 points measured per decade. Ag/AgCl reference electrodes are used to measure the resulting voltage across membrane. The resistances for the blank cell and cell with the membrane incorporated are taken from the x-axis intercept of the resulting Nyquist plot, indicating the real component of the impedance, and the difference corresponds to the resistance of the membrane. The conductance is determined by taking the reciprocal of the resistance, and is normalized to the membrane surface area and thickness to determine the chloride ion conductivity.

In some embodiments, the anion exchange membrane or material has a chloride ion conductivity of greater than or equal to 0.00001 S/cm. In some embodiments, the anion exchange membrane or material has a chloride ion conductivity of greater than or equal to 0.00005 S/cm, greater than or equal to 0.0001 S/cm, greater than or equal to 0.0005 S/cm, greater than or equal to 0.001 S/cm, greater than or equal to 0.005 S/cm, greater than or equal to 0.01 S/cm, or greater. In some embodiments, the anion exchange membrane or material has a chloride ion conductivity of less than or equal to 0.3 S/cm, less than or equal to 0.2 S/cm, less than or equal to 0.1 S/cm, less than or equal to 0.05 S/cm, less than or equal to 0.02 S/cm, less than or equal to 0.01 S/cm, less than or equal to 0.005 S/cm, less than or equal to 0.001 S/cm, less than or equal to 0.0005 S/cm, or less. Combinations of these ranges are possible. For example, in some embodiments, the anion exchange membrane or material has a chloride ion conductivity of greater than or equal to 0.00001 S/cm and less than or equal to 0.3 S/cm, greater than or equal to 0.001 S/cm and less than or equal to 0.3 S/cm, or greater than or equal to 0.01 S/cm and less than or equal to 0.3 S/cm.

In some embodiments, the anion exchange membrane or material has a relatively high chloride ion conductivity and a relatively high anion exchange capacity. For

– 67 –

example, in some embodiments, the anion exchange membrane has a chloride ion conductivity of greater than or equal to 0.00001 S/cm, greater than or equal to 0.00005 S/cm, greater than or equal to 0.0001 S/cm, greater than or equal to 0.0005 S/cm, greater than or equal to 0.001 S/cm, greater than or equal to 0.005 S/cm, greater than or equal to 0.01 S/cm, and/or up to 0.02 S/cm, up to 0.05 S/cm, up to 0.1 S/cm, up to 0.2 S/cm, or up to 0.3 S/cm, while having an anion exchange capacity of greater than or equal to 0.01 meq/g, greater than or equal to 0.1 meq/g, greater than or equal to 0.2 meq/g, greater than or equal to 0.3 meq/g, greater than or equal to 0.5 meq/g, greater than or equal to 0.7 meq/g, greater than or equal to 1 meq/g and/or up to 1.2 meq/g, up to 1.5 meq/g, up to 1.8 meq/g, or up to 2 meq/g. Combinations of the above-referenced ranges as well as other ranges of chloride ion conductivity and/or anion exchange capacity described elsewhere herein are also possible.

In some embodiments, the anion exchange membrane or material has a relatively high chloride ion conductivity and a relatively low linear expansion. For example, in some embodiments, the anion exchange membrane has a chloride ion conductivity of greater than or equal to 0.00001 S/cm, greater than or equal to 0.00005 S/cm, greater than or equal to 0.0001 S/cm, greater than or equal to 0.0005 S/cm, greater than or equal to 0.001 S/cm, greater than or equal to 0.005 S/cm, greater than or equal to 0.01 S/cm, and/or up to 0.02 S/cm, up to 0.05 S/cm, up to 0.1 S/cm, up to 0.2 S/cm, or up to 0.3 S/cm, while having a linear expansion of less than or equal to 10%, less than or equal to 8%, less than or equal to 6%, less than or equal to 5%, less than or equal to 2%, less than or equal to 1%, less than or equal to 0.5%, or less. Combinations of the above-referenced ranges as well as other ranges of chloride ion conductivity and/or linear expansion described elsewhere herein are also possible.

In some embodiments, the anion exchange membrane has a relatively low osmotic water permeance. The osmotic water permeance of a membrane generally refers to the flux of water across the membrane due to osmotic pressure. Having a relatively low osmotic water permeance may be beneficial in certain applications, such as applications where the anion exchange membrane is used in electrochemical applications such as electrodialysis applications. Details of an exemplary test for determining the osmotic water permeance of the membrane are described by Kingsbury, Ryan; Zhu, Shan; Flotron, Sophie; Coronell, Orlando (2018): Microstructure determines water and salt permeation in commercial ion exchange membranes. ChemRxiv. Preprint and in

– 68 –

Kingsbury, R. S., Zhu, S., Flotron, S., & Coronell, O. (2018). Microstructure determines water and salt permeation in commercial ion-exchange membranes. *ACS applied materials & interfaces*, 10(46), 39745-39756, each of which is incorporated herein by reference in its entirety. The osmotic water permeance of the membranes described

5 herein can be determined using the following procedure. The membrane is incorporated into a two-compartment cell and the volumetric flow rate of water across the membrane is measured to determine the flux of water across the membrane due to osmotic pressure. One compartment of the two-compartment cell is filled with a 4 M NaCl aqueous solution prior to testing. To begin the test, the membrane is assembled into the two-

10 compartment cell and one compartment of the two-compartment cell is filled with a 2-4 M NaCl aqueous solution, and the other compartment of the two-compartment cell is filled with deionized water. Before recording any volume changes, the membrane is left exposed to the concentration gradient between the 2-4 M NaCl solution and the deionized water solution in their respective compartments for at least one hour to

15 establish a pseudo-steady state of water transported membrane. The cell is then emptied, and fresh 2-4 M NaCl and deionized water are used to refill the cell completely. The cell is sealed with a lid that is fit with a volumetric syringe that has 0.01 mL increments and the levels of the solution in the cell are adjusted to be approximately equal at the start of the test. The two compartments of the two-compartment cell are agitated via stirring

20 with stir bars for the duration the test. Once the levels are equal, a stopwatch is started and the volume changes over time are recorded until at least 0.05 mL of volume change is observed in each compartment.

Water permeance (A [$\text{L}\cdot\text{m}^{-2}\cdot\text{h}^{-1}\cdot\text{bar}^{-1}$]) relates to the hydraulic flux (J_w [$\text{L}\cdot\text{m}^{-2}\cdot\text{h}^{-1}$]) of water across the membrane:

$$25 \quad J_w = A(\Delta P - \Delta\pi) = \frac{P_w}{L}(\Delta P - \Delta\pi)$$

where ΔP and $\Delta\pi$ [bar] are the differences in hydraulic and osmotic pressure across the membrane, respectively. The flux, J_w , can be calculated from the flow rate of water across the membrane (Q_w [$\text{L}\cdot\text{h}^{-1}$]) divided by the membrane area [m^2]:

$$J_w = \frac{Q_w}{A}$$

30 The flow rate can be determined by calculating the slope of the volume readings over time for each compartment and taking the average of the two sides (the slopes should be similar

– 69 –

in magnitude and opposite in sign). Since there is no external hydraulic pressure being applied to the membranes during the test ($\Delta P = 0$), the osmotic pressure is calculated from the composition of the solutions using the Gibbs equation to account for the non-ideality of the concentrated solution.

$$\Delta\pi = \pi_c - \pi_d = \pi_c = -\frac{RT}{V_w} \ln(a_w)$$

The water activity is calculated using the Pitzer activity model *via* the freely-available pyEQL software.

In some embodiments, the anion exchange membrane has an osmotic water permeance of less than or equal to 100 mL/(hr·bar·m²), less than or equal to 50 mL/(hr·bar·m²). In some embodiments, the anion exchange membrane has an osmotic water permeance of less than or equal to 45 mL/(hr·bar·m²), less than or equal to 40 mL/(hr·bar·m²), less than or equal to 35 mL/(hr·bar·m²), less than or equal to 30 mL/(hr·bar·m²), less than or equal to 20 mL/(hr·bar·m²), less than or equal to 15 mL/(hr·bar·m²), less than or equal to 10 mL/(hr·bar·m²), less than or equal to 5, less than or equal to 4, less than or equal to 3, less than or equal to 2.5, less than or equal to 2 mL/(hr·bar·m²), or less. In some embodiments, the anion exchange membrane has an osmotic water permeance of greater than or equal to 0 mL/(hr·bar·m²), greater than or equal to 0.1 mL/(hr·bar·m²), greater than or equal to 0.2 mL/(hr·bar·m²), greater than or equal to 0.3 mL/(hr·bar·m²), greater than or equal to 0.5 mL/(hr·bar·m²), greater than or equal to 0.8 mL/(hr·bar·m²), greater than or equal to 1 mL/(hr·bar·m²), greater than or equal to 1.2 mL/(hr·bar·m²), greater than or equal to 1.5 mL/(hr·bar·m²), greater than or equal to 2 mL/(hr·bar·m²), greater than or equal to 5 mL/(hr·bar·m²), or more. Combinations of these ranges are possible. For example, in some embodiments, the anion exchange membrane has an osmotic water permeance of greater than or equal to 0 mL/(hr·bar·m²) and less than or equal to 100 mL/(hr·bar·m²), greater than or equal to 0 mL/(hr·bar·m²) and less than or equal to 50 mL/(hr·bar·m²), greater than or equal to 0 mL/(hr·bar·m²) and less than or equal to 10 mL/(hr·bar·m²), greater than or equal to 0 mL/(hr·bar·m²) and less than or equal to 5 mL/(hr·bar·m²), or greater than or equal to 0 mL/(hr·bar·m²) and less than or equal to 2 mL/(hr·bar·m²).

In some embodiments, the anion exchange membrane has a relatively large water uptake. As used herein, the water uptake of the membrane refers to the amount of water

– 70 –

a membrane can absorb when soaked in water at 100°C. The water uptake of the membrane can be measured using the following procedure. The membrane is cut into a 50 mm x 50 mm square and dried in an oven set to a temperature of greater than 105°C for 24 hours. The weight of the membrane is measured after drying. The water uptake is then measured by immersing the membrane in boiling water at 100°C for one hour. The membrane is then removed from the boiling water bath and the surface water is wiped off with a dry cloth. The membrane is then weighed immediately after the step of wiping the membrane with the cloth. This procedure is performed separately on three identical membranes, and the number average for the change in weight of the membrane following the immersion in the boiling water is used to determine the water uptake of the membrane. It has been unexpectedly observed that, in some embodiments, anion exchange membranes described herein (e.g., anion exchange membranes comprising a silica-based ceramic comprising covalently bound functional group such as quaternary ammonium groups) are capable of relatively high water uptake while undergoing a relatively small amount of dimensional swelling (e.g., linear expansion) compared to certain existing anion exchange membranes. The water uptake can be represented as a percentage change in weight relative to the weight of the dried membrane.

In some embodiments, the anion exchange membrane has a water uptake greater than or equal to 1%, greater than or equal to 3%, of greater than or equal to 5%, greater than or equal to 8%, greater than or equal to 10%, greater than or equal to 15%, greater than or equal to 20%, greater than or equal to 25%, greater than or equal to 30%, greater than or equal to 35%, greater than or equal to 40%, greater than or equal to 45%, greater than or equal to 50%, greater than or equal to 60%, greater than or equal to 70%, or more. In some embodiments, the anion exchange membrane has water uptake of less than or equal to 100%, less than or equal to 90%, less than or equal to 85%, less than or equal to 80%, less than or equal to 75%, less than or equal to 70%, less than or equal to 65%, less than or equal to 60%, less than or equal to 50%, less than or equal to 40%, less than or equal to 35%, less than or equal to 25%, less than or equal to 15%, less than or equal to 10%, or less. Combinations of these ranges are possible. For example, in some embodiments, the anion exchange membrane has a water uptake of greater than or equal to 1% and less than or equal to 100%, greater than or equal to 5% and less than or equal to 50%, or greater than or equal to 10% and less than or equal to 25%.

– 71 –

In some embodiments, the anion exchange membrane has a relatively high water uptake and a relatively low linear expansion. In some embodiments, the anion exchange membrane has a water uptake of greater than or equal to 1%, greater than or equal to 3%, of greater than or equal to 5%, greater than or equal to 8%, greater than or equal to 10%,
5 greater than or equal to 15%, greater than or equal to 20%, greater than or equal to 25%, greater than or equal to 30%, greater than or equal to 35%, greater than or equal to 40%, greater than or equal to 45%, greater than or equal to 50%, or greater than or equal to 60%, greater than or equal to 70%, while having a linear expansion of less than or equal to 10%, less than or equal to 8%, less than or equal to 6%, less than or equal to 5%, less
10 than or equal to 2%, less than or equal to 1%, less than or equal to 0.5%, or less. Combinations of the above-referenced ranges as well as other ranges of water uptake and/or linear expansion described elsewhere herein are also possible.

In some embodiments, the anion exchange membrane has a relatively high mechanical burst pressure. Mechanical burst pressure of a membrane generally refers to
15 the amount of force that can be applied to the membrane prior to the membrane undergoing mechanical failure and bursting. Having a relatively high mechanical burst pressure can, in some instances, be advantageous for an anion exchange membrane. For example, in certain applications involving flowing solutions in contact with the anion exchange membrane (e.g., redox flow batteries) or applying a hydrostatic or hydraulic
20 pressure to the anion exchange membrane (e.g., reverse osmosis or nanofiltration), having a sufficient mechanical burst pressure can be important in avoiding failure of the membrane during operation. It has been observed that, in some embodiments, the anion exchange membranes described herein can possess good mechanical properties such as a high mechanical burst pressure while also possessing good performance characteristics
25 (e.g., anion exchange capacity, anion permselectivity). In certain cases, such a combination of good mechanical properties and good performance characteristics can be achieved by combining the silica-based ceramic (which may impart good anion exchange performance characteristics) with the porous support membrane (which may impart good mechanical performance).

30 The mechanical burst pressure of the anion exchange membrane can be determined using the following procedure. The procedure can be used to determine a burst pressure in units of Newtons (N). The procedure is carried out based on a modified version of ASTM D6797. A membrane having a circular shape with a diameter of 70

– 72 –

mm is kept hydrated in water prior to testing. The membrane is removed from the water, and excess water on the surface of the membrane is wiped off with a dry cloth. After the step of wiping the membrane with a dry cloth, the membrane is clamped in a fixture with a ring clamp having an internal diameter of 40 mm in the center of the membrane. A
5 polished steel ball having a diameter 25 mm is used to apply a force to the membrane. The polished steel ball is attached to the movable part of a tensile test machine of the constant rate of extension type. The tensile test machine is started by setting the moving rate to 305 mm/minute, and ball movement is maintained until the membrane bursts.

As mentioned above, in some embodiments, the anion exchange membrane has a
10 relatively high mechanical burst pressure, as measured using the procedure described above. In some embodiments, the anion exchange membrane has a mechanical burst pressure of at least 1.5 N, at least 1.7 N, at least 2.0 N, at least 5 N, at least 10 N, at least 25 N, or more. In some embodiments, the anion exchange membrane has a mechanical
15 burst pressure of less than or equal to 1,000 N, less than or equal to 900 N, less than or equal to 800 N, less than or equal to 700 N, less than or equal to 600 N, less than or equal to 500 N, less than or equal to 400 N, less than or equal to 250 N, less than or equal to 100 N, less than or equal to 75 N, less than or equal to 50 N, less than or equal to 25 N, or less. Combinations of these ranges are possible. For example, in some
20 embodiments, the anion exchange membrane has a mechanical burst pressure of at least 1.5 N and less than or equal to 1,000 N, or greater than or equal to 1.7 N and less than or equal to 400 N.

The mechanical burst pressure of the anion exchange membrane can also be determined in units of pressure. Such units provide a measure that is independent of dimensional properties of the anion exchange membrane (e.g., membrane area). The
25 mechanical burst pressure of the anion exchange membrane can be determined in units of pressure using the following procedure. The procedure is carried out based on a modified version of ASTM D3786 using a Cyeeoyo 302AQT burst tester. A membrane having a circular shape with a diameter of 40 mm is kept hydrated in water prior to testing. The membrane is removed from the water, and excess water on the surface of
30 the membrane is wiped off with a dry cloth. After the step of wiping the membrane with a dry cloth, the membrane is clamped in a fixture with a ring clamp having an internal diameter of 33 mm in the center of the membrane. During the test, the diaphragm of the burst tester below the sample is expanded upwards until the point of specimen rupture.

– 73 –

The burst point, indicated as the peak pressure value, can be read from display of the burst test. The burst point corresponds to the mechanical burst pressure.

As mentioned above, in some embodiments, the anion exchange membrane has a relatively high mechanical burst pressure, as measured in units of pressure using the procedure described above. In some embodiments, the anion exchange membrane has a mechanical burst pressure of at least 2.0 pounds per square inch (PSI), at least 2.1 PSI, at least 2.5 PSI, at least 3.0 PSI, at least 3.5 PSI, at least 4.0 PSI, at least 5.0 PSI, at least 6.0 PSI, at least 8.0 PSI, at least 10.0 PSI, at least 12.0 PSI, at least 15.0 PSI, at least 20.0 PSI, at least 25.0 PSI, at least 30.0 PSI, at least 40.0 PSI, at least 50.0 PSI, at least 60.0 PSI at least 75.0 PSI, at least 100.0 PSI, or more. In some embodiments, the anion exchange membrane has a mechanical burst pressure of less than or equal to 1,000 PSI, less than or equal to 900 PSI, less than or equal to 800 PSI, less than or equal to 700 PSI, less than or equal to 600 PSI, less than or equal to 500 PSI, less than or equal to 400 PSI, less than or equal to 250 PSI, less than or equal to 150 PSI, less than or equal to 100 PSI, less than or equal to 90 PSI, less than or equal to 80 PSI, less than or equal to 75 PSI, less than or equal to 70 PSI, less than or equal to 65 PSI, less than or equal to 60 PSI, less than or equal to 55 PSI, less than or equal to 50 PSI, less than or equal to 40 PSI, less than or equal to 30 PSI, less than or equal to 25 PSI, less than or equal to 10 PSI or less. Combinations of these ranges are possible. For example, in some embodiments, the anion exchange membrane has a mechanical burst pressure of at least 2.0 PSI and less than or equal to 1,000 PSI, greater than or equal to 5.0 PSI and less than or equal to 400 PSI, or greater than or equal to 20 PSI and less than or equal to 60 PSI.

In certain aspects, methods of fabricating the anion exchange membranes in materials described herein are provided. One exemplary method of fabricating the anion exchange membrane involves a sol-gel process.

FIG. 6 is a flow diagram illustrating one non-limiting method of fabricating an anion exchange membrane. In some embodiments, a porous support membrane, as described herein, is provided. For example, FIG. 6 shows a porous support membrane 130. In some cases, an optional step of applying a compressible edging material to the porous support membrane is performed. For example, as shown in step 1 in FIG. 6, a compressible edging material 180 is formed on porous support membrane 130.

In a non-limiting case, the optional compressible edging material is formed at least in part by adding a polymer to the top surface of the porous support membrane such

– 74 –

that the polymer infiltrates the entire thickness of the porous support membrane and forms a border having a width of at least 1 μm around the edge region of the porous support membrane. Such a compressible edging material may, in some cases, act as a gasket capable of contributing to sealing the anion exchange membrane (e.g., in a cell).

5 The method of forming the compressible edge material depends on the composition (e.g., polymeric material) used to form the compressible edging material. In some cases, the compressible edging material can be applied as a film and/or sheet using heating, solvent, or radiation. In some embodiments, the optional compressible edging material can be applied to the porous support membrane from a liquid phase as a solution or
10 dispersion using any of a variety of known coating techniques (e.g., dip, spray, drop, blade, screen, etc.). In some embodiments, the method of forming the compressible edging material can include a step of performing an in situ reaction after deposition of the precursor material. For example, in some cases, an in situ reaction takes place in which deposited monomeric units react to form a polymer within the porous support
15 membrane. In some embodiments, the percentage of the external geometrical surface area of the porous support membrane not covered by the compressible edging material is greater than or equal to 30%, greater than or equal to 40%, greater than or equal to 50%, greater than or equal to 70%, greater than or equal to 80%, greater than or equal to 90%, greater than or equal to 95%, greater than or equal to 99% or more. In some
20 embodiments, the area of the external geometric surface area of the porous support membrane not covered by the compressible edging material is greater than or equal to 1 cm^2 , greater than or equal to 10 cm^2 , greater than or equal to 100 cm^2 , greater than or equal to greater than or equal to 1,000 cm^2 and/or up to 1 m^2 , up to 2 m^2 , up to 5 m^2 10 m^2 , or more.

25 In some embodiments, a silicon-containing precursor sol is applied to the porous support membrane during the fabrication of the anion exchange membrane. For example, referring again to FIG. 6, in step 2, a silicon-containing precursor sol is applied to porous support membrane 130 (optionally comprising compressibility material 180) via solution 270. Exemplary compositions of the silicon-containing precursor sol are
30 described herein. In some embodiments, the silicon-containing precursor sol is applied to the porous support membrane such that the silicon-containing precursor sol wicks into the porous support membrane and coats at least a portion of the porous support membrane. In some embodiments, the sol wicks into the interior of the porous support

– 75 –

membrane and in some cases fills some or all of the porous volume of the porous support membrane. The silicon-containing precursor sol (e.g., solution 270) can be applied to the porous support membrane using one or more standard coating processes such as dip coating, spray coating, roll coating, blade coating, screen printing, or blowing with air (e.g., with an air knife) according to some embodiments. Excess silicon-containing precursor sol can be removed via any suitable method, such as scraping. The porous support membrane can be in any of a variety of orientations (e.g., vertical, horizontal) during the step of applying the silicon-containing precursor sol to the porous support membrane. In some embodiments, the silicon-containing precursor sol can be applied to the porous support membrane when the porous support membrane is flat and free standing. In some embodiments, the silicon-containing precursor sol can be applied to the porous support membrane when the porous support membrane is flat and contacting another surface. In some embodiments, the silicon-containing precursor sol can be applied to the porous support membrane when the porous support membrane is curved and free standing. In some embodiments, the silicon-containing precursor sol can be applied to the porous support membrane when the porous support membrane is curved and contacting another surface. As one example, in some cases, the porous support membrane can be arranged to be in a cylindrical or conical shape during the application of the silicon-containing precursor sol (e.g., solution 270 in FIG. 6). In some embodiments, the silicon-containing precursor sol can be applied to the porous support membrane when the membrane is held taut in at least one dimension.

In some embodiments, the silicon-containing precursor sol is a single phase sol prior to and/or during the step of applying the silicon-containing precursor sol to the porous support membrane. For example, in embodiments in which the silicon-containing precursor sol comprises two or more different types of silicon-based precursors (e.g., both a silane comprising a functional group such as a quaternary ammonium group and a silane that does not comprise such a functional group), the silicon-containing precursor sol is a homogeneous mixture comprising the two or more different types of silicon-based precursors. Applying a single phase sol can, in some cases, allow for the formation of a coating of the silica-based ceramic on the porous support membrane having a number of desirable properties, such as relatively high loading and/or substantially homogeneous distribution of functional groups (e.g., quaternary ammonium groups) in the coating.

– 76 –

In some embodiments, the silicon-containing precursor sol (e.g., solution 270 in FIG. 6) is aged prior to the step of applying the silicon-containing precursor sol to the porous support membrane. In some embodiments, the aging can occur for at least zero minutes, at least 30 minutes, at least two hours, or more, from the time the precursor materials are mixed together to form the sol. In some embodiments, the aging can occur for less than or equal to one week, less than or equal to 48 hours, less than or equal to 24 hours, or less. Combinations of these ranges are possible. For example, in some embodiments, the aging can occur for at least 0 minutes and less than or equal to one week, greater than or equal to 30 minutes and less than or equal to 48 hours, or greater than or equal to two hours and less than or equal to 24 hours. In some embodiments, the temperature of the silicon-containing precursor sol during the aging is at least 0°C, at least 20°C, at least 30°C, or more. In some embodiments, the temperature of the silicon-containing precursor sol during the aging is less than or equal to 80°C, less than or equal to 60°C, less than or equal to 50°C, or less. Combinations of these ranges are possible. For example, in some embodiments, the temperature of the silicon-containing precursor sol during aging is at least 0°C and less than or equal to 80°C, at least 20°C and less than or equal to 60°C, or at least 30°C and less than or equal to 50°C. In some cases, silicon-containing precursor sol is aged in an open atmosphere (e.g., open to ambient air), while in some embodiments the converting step is performed in a sealed atmosphere (e.g., in atmosphere fluidically isolated from ambient air). Aging in an open atmosphere can allow for at least partial evaporation during aging, which may be desirable in some but not necessarily all embodiments. Aging in an sealed atmosphere reduce or eliminate evaporation during aging, which may be desirable in some but not necessarily all embodiments.

In some embodiments, the porous support membrane, now comprising at least a portion of the silicon-containing precursor sol, is removed from the solution used to apply the silicon-containing precursor sol, and a step of converting the silicon-containing precursor sol to the silica-based ceramic is performed. For example, now referring to step 3 in FIG. 6, porous support membrane 130, at least a portion of which is now coated with at least a portion of the silicon-containing precursor sol of solution 270, is removed from solution 270. The silicon-containing precursor sol coated on and/or within at least a portion of the porous support membrane (e.g., coated membrane 280) is then converted to the silica-based ceramic, according to some embodiments. In some embodiments,

– 77 –

converting the silicon-containing precursor sol to the silica-based ceramic comprises performing a hydrolysis and condensation reaction. It has been observed in the context of the present disclosure that, in some such embodiments, the hydrolysis and condensation reaction results in a self-assembly of components of the silicon-containing precursor sol to form the silica-based ceramic (e.g., as an interconnected network structure that, in some cases, is nanoporous).

In some embodiments, the step of converting the silicon-containing precursor sol coating at least a portion of the porous support membrane into the silica-based ceramic (e.g., via a hydrolysis and condensation reaction) proceeds for at least one second, at least 1 minute, at least 30 minutes, at least 1 hour, at least 2 hours, at least 4 hours, or more. In some embodiments, the step of converting the silicon-containing precursor sol coating at least a portion of the porous support membrane into the silica-based ceramic proceeds for less than or equal to 2 weeks, less than or equal to 1 week, less than or equal to 96 hours, less than or equal to 48 hours, less than or equal to 24 hours, or less. Combinations of these ranges are possible. For example, in some embodiments, the step of converting proceeds for at least 1 second and less than or equal to 2 weeks, at least 2 hours and less than or equal to 48 hours, or at least 4 hours and less than or equal to 24 hours. The step of converting the silicon-containing precursor sol coating at least a portion of the porous support membrane into the silica-based ceramic (e.g., via a hydrolysis and condensation reaction) can be performed in any of a variety of conditions. In some cases, the converting step is performed in an open atmosphere (e.g., open to ambient air), while in some embodiments the converting step is performed in a sealed atmosphere (e.g., in atmosphere fluidically isolated from ambient air). In some embodiments, the converting step is performed in an atmosphere having a humidity of at least 0% and up to 100% humidity.

The step of converting the silicon-containing precursor sol coating at least a portion of the porous support membrane into the silica-based ceramic (e.g., via a hydrolysis and condensation reaction) may be performed at any of a variety of temperatures, depending on the composition of the silicon-containing precursor sol and the desired properties of the anion exchange membrane. In some embodiments, the converting step occurs at room temperature or cooler, while in some embodiments, the converting step occurs at elevated temperatures. In some such cases, the coated porous support membrane is kept in a dryer (e.g., an oven) during the converting step. For

– 78 –

example, FIG. 6 shows an exemplary coated porous support 20 optionally being kept in a dryer 24 during at least a portion of step 3, according to some embodiments. In some embodiments, the converting step is performed with the coated porous support membrane kept in an environment having a temperature of greater than or equal to 0°C, greater than or equal to 20°C, or higher. In some embodiments, the converting step is performed with the coated porous support membrane being kept in an environment having a temperature of less than or equal to 150°C, less than or equal to 80°C, less than or equal to 60°C, or less. Combinations of these ranges are possible. For example, in some embodiments, the converting step is performed with the coated porous support membrane kept in an environment having a temperature of greater than or equal to 0°C and less than or equal to 150°C, greater than or equal to 0°C and less than or equal to 80°C, or greater than or equal to 20°C and less than or equal to 60°C. The temperature of the conditions under which the converting step (e.g., hydrolysis and condensation of the silicon-containing precursor sol to form the silica-based ceramic) occurs may be relatively low compared to certain existing techniques for forming ceramics, such as high-temperature sintering and calcination. In some cases, the use of relatively low temperatures to form the silica-based ceramic allows for the costs and resources needed to fabricate the anion exchange membrane to be reduced compared to certain existing techniques.

In some embodiments, the converting step can be performed while the coated porous support membrane is positioned on, or in contact with, a surface. For example, in some embodiments, the converting step can be performed while the coated porous support membrane is positioned on a relatively flat surface, or relatively flat and porous surface. However, it should be understood that the coated porous support membrane need not be positioned on or in contact with the surface during the converting step. In some embodiments, the coated porous support membrane is positioned with a horizontal orientation with respect to a surface (e.g., a horizontal orientation with respect to a surface of an oven), while in some embodiments, the coated porous support membrane is positioned with a vertical orientation with respect to a surface (e.g., a vertical orientation with respect to a surface of an oven).

In some embodiments, the converting step can optionally be terminated to conclude step 3. For example, in some embodiments, the reaction taking place during the converting step (e.g., the hydrolysis and condensation reaction) can be quenched by

– 79 –

applying an aqueous solution. The aqueous solution can be applied using standard coating processes such as dip, spray, blade, screen printing. For example, in some embodiments, quenching the reaction comprises contacting the converted coated porous support membrane with an aqueous solution (e.g., via application of the aqueous solution to the converted coated porous support membrane, via submersion of the coated porous support membrane within the aqueous solution, etc.). In some embodiments, the aqueous solution used to quench the reaction has a pH of greater than or equal to -1, greater than or equal to zero, greater than or equal to 1, greater than or equal to 2, greater than or equal to 3, greater than or equal to 4, greater than or equal to 5, greater than equal to 6, greater than or equal to 7, greater than or equal to 8, greater than or equal to 9, greater than or equal to 10, or greater. In some embodiments, the aqueous solution used to quench the reaction has a pH of less than or equal to 14, less than or equal to 13, less than or equal to 12, less than or equal to 11, less than or equal to 10, less than or equal to nine, less than or equal to 8, less than or equal to 7, less than or equal to 6, less than or equal to 5, less than or equal to 4, less than or equal to 3, or less. Combinations of these ranges are possible. For example, in some embodiments, the aqueous solution used to quench the reaction has a pH of greater than or equal to -1 and less than or equal to 14, greater than or equal to -1 and less than or equal to 7, greater than or equal to 5 and less than or equal to 7.

20 In some instances, it is desirable to remove excess silica-based ceramic on the anion exchange membrane (e.g., to reduce or eliminate surface excess). Excess silica-based ceramic can be removed using any of a variety of suitable methods. Exemplary methods include, but are not limited to, removal via mechanical squeegee, removal via air knife, and/or removal via heating (e.g., to an elevated temperature).

25 In some embodiments, the method for fabricating the anion exchange membrane described herein is completed following step 3 described above. For example, in some embodiments, a membrane 282 produced following step 3 is a fully fabricated anion exchange membrane (e.g., anion exchange membrane 150 described herein). In some cases, steps of the method described above can be repeated. For example, in some
30 embodiments, step 2 and step 3 of the fabrication method can be repeated. Repeating steps 2 and 3 can, in some cases, result in increased coating on and/or with the porous support membrane with the silica-based ceramic. For example, repeating steps 2 and 3 may allow for the silicon-containing precursor sol to infiltrate regions of the porous

– 80 –

support membrane that were not infiltrated by the silicon-containing precursor sol during previous performances of step 2. Such repetitions of steps 2 and 3 may, in some cases, result in up to 100% filling of the porous support membrane by the silica-based ceramic. It should be understood, however, that repeating steps 2 and 3 above too many times
5 may, in some cases, cause a buildup of surface excess of silica-based ceramic on the porous support membrane. In other words, in some cases, a layer of silica-based ceramic having too large a thickness may result on the exterior surface of the anion exchange membrane, which in some cases may be detrimental to the performance of the anion exchange membrane in certain applications. It has been observed that, in some cases,
10 performing steps 2 and 3 described above a total of between 1-3 times may result in anion exchange membranes having beneficial performance characteristics. It has been observed that, in some cases, performing steps 2 and 3 described above a total of between 1-6 times (e.g., 4-6 times) may result in anion exchange membranes having beneficial performance characteristics.

15 As mentioned above, in some embodiments, a fully-fabricated anion exchange membrane can be prepared upon the completion of step 3 as described above and shown in FIG. 6. For example, in some embodiments in which the silicon-containing precursor sol includes a component comprising a functional group (e.g., a silane comprising a quaternary ammonium group) that is desirable to be in the finished anion exchange
20 membrane, that functional group may be present in the anion exchange membrane produced following step 3, thereby making the anion exchange membrane produced upon the completion of step 3 suitable for certain applications without further modification. As one non-limiting example, in some embodiments in which the silicon-containing precursor sol comprises a tetraalkylorthosilicate (e.g., TEOS) and a
25 trialkoxysilylalkyl-N,N,N-trialkylammonium ((e.g., trimethoxysilylpropyl-N,N,N-trimethylammonium, TMAPS) as precursors, no further modification of the anion exchange membrane following the completion of step three may be necessary, at least because the anion exchange membrane at this stage comprises quaternary ammonium groups.

30 However, in some embodiments, one or more additional steps may be performed following step 3 of the methods described herein. For example, in some embodiments, the porous support membrane coated with the silica-based ceramic does not comprise functional groups (e.g., quaternary ammonium groups) that are desired to be present in

– 81 –

the completed anion exchange membrane following step 3. For example, in some embodiments, the silicon-containing precursor sol used to coat the porous support membrane does not comprise a component comprising the desired functional group. As one non-limiting example, in some embodiments the silicon-containing precursor sol
5 comprises a tetraalkylorthosilicate (e.g., TEOS) and a silane comprising a moiety comprising a leaving group (e.g., a halo group, a tosylate group, a trifluoromethane group) as precursors. In some such cases, further chemical reactions may need to be performed to convert the moiety comprising a leaving group to a desired quaternary ammonium group (e.g., via a nucleophilic substitution). As such, in some cases, further
10 chemical reactions may be performed to form the desired functional groups.

In some embodiments, an optional step of exposing the coated porous support membrane following step 3 to water may be performed. For example, as shown in FIG. 6, an optional step 4 in which membrane 282 is contacted with water can be performed. Exposing the coated porous support membrane following step 3 to water may, in some
15 embodiments, result in the removal of certain components that may be undesirable in follow-up steps of the fabrication process. For example, in some embodiments, exposing the coated porous support membrane to water may remove acid from the membrane structure. Water can be applied using one or more standard coating processes such as dip, spray, blade, and screen printing.

20 In some embodiments, a method for forming the anion exchange membrane comprises a step of exposing a porous support membrane, at least a portion of which is coated with the silica-based ceramic comprising an a moiety comprising a leaving group, to an amine. As shown in FIG. 6, in some embodiments, membrane 282 comprises a porous support membrane coated with a silica-based ceramic comprising a moiety
25 comprising a leaving group, and membrane 282 is exposed to an amine in solution 272 during optional step 5. In some embodiments, the method further reacting the amine with the moiety to release the leaving group and form a quaternary ammonium group covalently bound to the silica-based ceramic. In some such cases, the steps of exposing the porous support membrane to the amine and reacting the moiety with the amine to
30 form a quaternary ammonium group results in the anion exchange membrane comprising a quaternary ammonium group (e.g., covalently bound to the silica-based ceramic).

In some embodiments, the silica-based ceramic comprising the moiety comprising the leaving group comprises a relatively high percentage of silicon. For

– 82 –

example, in some embodiments, the silica-based ceramic comprises Si in an amount greater than or equal to 6 wt%, greater than or equal to 10 wt%, greater than equal to 12 wt%, greater than or equal to 15 wt%, greater than or equal to 17 wt%, greater than or equal to 20 wt%, greater than or equal to 24 wt%, greater than or equal to 30 wt%,
5 greater than or equal to 40 wt%, greater than or equal to 60 wt%, or more in the silica-based ceramic. In some embodiments, the silica-based ceramic comprises Si in an amount less than or equal to 60 wt%, less than or equal to 50 wt%, less than or equal to 47 wt%, less than or equal to 40 wt%, less than or equal to 30 wt%, less than or equal to 28 wt%, less than or equal to 26 wt%, less than or equal to 24 wt%, less than or equal to
10 22 wt%, less than or equal to 20 wt%, less than or equal to 17 wt%, or less in the silica-based ceramic. Combinations of these ranges are possible. For example, in some embodiments, the silica-based ceramic comprises Si in an amount greater than or equal to 6 wt% and less than or equal to 60 wt%, or greater than or equal to 17 wt% and less than or equal to 26 wt% in the silica-based ceramic.

15 The moiety comprising the leaving group may be any functional group that, upon a nucleophilic substitution step, can release a leaving group to form a quaternary ammonium group. For example, in some embodiments, the moiety comprising the leaving group is substituted alkyl group (e.g., a haloalkyl group such as a chloropropyl group.

20 The amine may be any amine suitable to react with the moiety comprising the leaving group to form a quaternary ammonium group. In some embodiments, the amine is a tertiary amine. In some embodiments, the amine is trimethylamine.

Exposing the porous support membrane, coated with the silica-based ceramic comprising a moiety comprising the leaving group, to the amine agent may comprise the
25 step of applying the amine to the coated membrane in any of a variety of suitable ways. For example, as mentioned above, in some embodiments, the exposing step comprises exposing the coated porous support membrane to a solution containing the amine (e.g., solution 272 in FIG. 6). The amine can be applied to the coated porous support membrane, in some cases, using standard coating processes, such as dip coating, spray
30 coating, roll coating, blade coating, or screen printing. In some embodiments, the amine (e.g., trimethylamine) may be applied to the coated porous support membrane by applying (e.g., via dipping) a solution comprising at least 1 vol%, at least 5 vol%, at least 10 vol%, at least 15 vol%, at least 20 vol%, or more amine (e.g., triethylamine). In some

– 83 –

embodiments, the amine (e.g., trimethylamine) may be applied to the coated porous support membrane by applying (e.g., via dipping) an solution comprising less than or equal to 50 vol%, less than or equal to 40 vol%, less than or equal to 30 vol%, less than or equal to 25 vol%, less than or equal to 20 vol%, less than or equal to 15 vol%, less than or equal to 10 vol%, or less, amine (e.g., trimethylamine). Combinations of these ranges are possible. For example, in some embodiments, an amine may be applied to the coated porous support membrane by applying an solution comprising greater than or equal to 1 vol% and less than or equal to 50 vol%, greater than or equal to 10 vol% and less than or equal to 50 vol%, or greater than or equal to 20 vol% and less than or equal to 50 vol% of amine (e.g., trimethylamine).

In some embodiments, the step of reacting the moiety comprising the leaving group with the amine to form quaternary ammonium group is performed using a solution comprising the amine that is kept at a suitable temperature. For example, in some embodiments, a solution comprising the amine used for the reaction has a temperature of greater than or equal to 0°C, greater than or equal to 20°C, or more. In some embodiments, the solution comprising the amine used for the reaction has a temperature of less than or equal to 100°C, less than or equal to 60°C, less than or equal to 50°C, or less. Combinations of these ranges are possible. For example, in some embodiments, the solution comprising the solution comprising the amine used for the reaction has a temperature of greater than or equal to 0°C and less than or equal to 100°C, greater than or equal to 0°C and less than or equal to 60°C, or greater than or equal to 20°C and less than or equal to 50°C. The duration of the oxidation reaction that converts the moiety comprising the leaving group to a quaternary ammonium group may depend on the reaction kinetics as well as, for example, the concentration of leaving groups (e.g., halo groups such as chloro groups) on or within the coated porous support comprising the silica-based ceramic. In some cases, the reaction may proceed for at least 1 minute, at least 30 minutes, at least 1 hour, or more. In some cases, the reaction may proceed for less than or equal to 1 week, less than or equal to 48 hours, less than or equal to 24 hours, or less. Combinations of these ranges are possible. For example, in some embodiments, the reaction may proceed for greater than or equal to 1 minute and less than or equal to 1 week, greater than or equal to 30 minutes in less than or equal to 48 hours, or greater than or equal to 1 hour and less than or equal to 24 hours.

– 84 –

In some embodiments, an optional drying step can be performed on the anion exchange membrane following the reaction of the amine and the moiety comprising the leaving group to form a quaternary ammonium group. FIG. 6 shows optional step 6, where a reacted membrane 284 comprising quaternary ammonium groups is dried by
5 being kept in an optional dryer 26, according to some embodiments. It should be understood however, that in some embodiments, the drying step can be performed without keeping the reacted anion exchange membrane in a dryer. In some embodiments, the step of drying the reacted anion exchange membrane comprising a quaternary ammonium group proceeds for at least 1 second, at least 1 minute, at least 30
10 minutes, at least 1 hour, at least 2 hours, at least 4 hours, or more. In some embodiments, the step of drying the reacted anion exchange membrane comprising a quaternary ammonium group proceeds for up to 24 hours, up to 2 days, up to one week, up to 2 weeks, or more. Combinations of these ranges are possible. For example, in some embodiments, the step of drying the reacted anion exchange membrane comprising
15 a quaternary ammonium group proceeds for at least 1 second and up to 2 weeks, at least 2 hours and up to 2 days, or at least 4 hours and up to 24 hours. The step of drying the reacted anion exchange membrane comprising a quaternary ammonium group can be performing in any of a variety of conditions. In some cases, the drying step is performed in an open atmosphere (e.g., open to ambient air), while in some embodiments the drying
20 step is performed in a sealed atmosphere (e.g., in atmosphere fluidically isolated from ambient air). In some embodiments, the drying step is performed in an atmosphere having a humidity of at least 0% and up to 100% humidity.

The step of drying the reacted anion exchange membrane comprising a quaternary ammonium group may be performed at any of a variety of temperatures. In
25 some embodiments, the drying step occurs at room temperature or cooler, while in some embodiments, the drying step occurs at elevated temperatures. In some embodiments, the drying step is performed with the reacted anion exchange membrane kept in an environment having a temperature of greater than or equal to 0°C, greater than or equal to 20°C, or higher. In some embodiments, the drying step is performed with the coated
30 porous support membrane kept in an environment having a temperature of less than or equal to 150°C, less than or equal to 80°C, less than or equal to 60°C, or less. Combinations of these ranges are possible. For example, in some embodiments, the drying step is performed with the reacted anion exchange membrane kept in an

environment having a temperature of greater than or equal to 0°C and less than or equal to 150°C, greater than or equal to 0°C and less than or equal to 80°C, or greater than or equal to 20°C and less than or equal to 60°C. In some cases, the resulting anion exchange membrane following the reacting step and/or the optional drying step may be
5 suitable for using in any of a variety of applications.

In some embodiments, the anion exchange materials described herein is not in the form of a membrane. For example, in some embodiments, the anion exchange material may comprise a silica-based ceramic comprising quaternary ammonium groups covalently bound to the silica-based ceramic as described herein, but without being in the
10 form of a membrane. In some such cases, the anion exchange material comprises a silica-based ceramic as described herein, but does not necessarily comprise a porous support membrane (e.g., upon and/or in which the silica-based ceramic is coated). One non-limiting example of an anion exchange material that is not in the form of a membrane is an ion exchange resin. In some embodiments, the anion exchange material
15 is in the form of a bead (e.g., as an anion exchange bead comprising the silica-based ceramic described herein), formed, for example, using an emulsion method. As a non-limiting example, FIG. 7 shows a schematic depiction of an anion exchange material 300 comprising a silica-based ceramic 150, with anion exchange material 300 being in the form of a bead, according to some embodiments. In some cases, silica-based ceramic
20 150 comprises quaternary ammonium groups covalently bound to the silica-based ceramic, as shown in FIG. 7, according to some embodiments.

In some embodiments, the anion exchange material (e.g., resin) is in the form of a plurality of particles (e.g., a powder) comprising functional groups (e.g., silica-based ceramic comprising quaternary ammonium groups). In some embodiments, the anion
25 exchange material in the form of particles (e.g., a powder) is formed by mechanically breaking silica-based ceramic described herein (e.g., via any suitable technique known in the art, such as milling). The anion exchange material particles may be packed into an ion exchange column and used in any of a variety of applications. In some
embodiments, the anion exchange material is in the form of a plurality of particles (e.g.,
30 a powder) having a mean maximum cross-sectional dimension of greater than or equal to 1 µm, greater than or equal to 2 µm, greater than or equal to 5 µm, greater than or equal to 8 µm, greater than or equal to 10 µm, greater than or equal to 15 µm, greater than or equal to 20 µm, greater than or equal to 30 µm, greater than or equal to 50 µm, greater

– 86 –

than or equal to 75 μm , greater than or equal to 100 μm , greater than or equal to 200 μm , greater than or equal to 500 μm , greater than or equal to 1 mm, or greater. In some embodiments, the anion exchange material is in the form of a plurality of particles (e.g., a powder) having a mean maximum cross-sectional dimension of less than or equal to 10 mm, less than or equal to 5 mm, less than or equal to 2 mm, less than or equal to 1 mm, less than or equal to 500 μm , less than or equal to 200 μm , less than or equal to 100 μm , less than or equal to 80 μm , less than or equal to 60 μm , less than or equal to 50 μm , less than or equal to 40 μm , less than or equal to 25 μm , or less. Combinations of these ranges are possible. For example, in some embodiments, the anion exchange material is in the form of a plurality of particles (e.g., a powder) having a mean maximum cross-sectional dimension of greater than or equal to 1 μm and less than or equal to 10 mm.

In some embodiments, an anion exchange material (e.g., a bead, particles) comprising a silica-based ceramic that comprises quaternary ammonium groups covalently bound to the silica-based ceramic is provided, where the silica-based ceramic comprises a relatively high amount of Si in the silica-based ceramic, as described above. In some embodiments, the silica-based ceramic of the anion exchange material (e.g., a bead) comprises relatively small pores (e.g., pores having a number average pore diameter of less than or equal to 10 nm or less), as described above. In some embodiments, the anion exchange material (e.g., in the form of a bead) has a relatively high anion exchange capacity (e.g., greater than 0.01 meq/g of anion exchange membrane).

In some embodiments, an anion exchange material that is not in the form of a membrane can be prepared by reacting a silica-based ceramic comprising a moiety comprising a leaving group with an amine, where the silica-based ceramic is not a part of a membrane. For example, in some embodiments an anion exchange membrane comprising a silica-based ceramic that is in the form of a resin (e.g., comprising a plurality of particles or beads) and that comprises quaternary ammonium groups can be fabricated using a reacting step similar to that described above with respect to the anion exchange membranes. For example, some embodiments comprise exposing a resin comprising a silica-based ceramic comprising a moiety comprising a leaving group (e.g., a substituted alkyl group comprising a halo group) to an amine, as described above (e.g., triethylamine). In some embodiments, the methods further releasing the leaving group and forming a quaternary ammonium group.

– 87 –

In some embodiments, the silica-based ceramic of the resin includes Si in an amount greater than or equal to 6 wt%, greater than or equal to 10 wt%, greater than or equal to 12 wt%, greater than or equal to 15 wt%, greater than or equal to 17 wt%, greater than or equal to 20 wt%, greater than or equal to 24 wt%, greater than or equal to 30 wt%, greater than or equal to 40 wt%, greater than or equal to 60 wt%, or more in the silica-based ceramic. In some embodiments, the silica-based ceramic of the resin includes Si in an amount less than or equal to 60 wt%, less than or equal to 50 wt%, less than or equal to 47 wt%, less than or equal to 40 wt%, less than or equal to 30 wt%, less than or equal to 28 wt%, less than or equal to 26 wt%, less than or equal to 24 wt%, less than or equal to 22 wt%, less than or equal to 20 wt%, less than or equal to 17 wt%, or less in the silica-based ceramic. Combinations of these ranges are possible. For example, in some embodiments, the silica-based ceramic comprises Si in an amount greater than or equal to 6 wt% and less than or equal to 60 wt%, or greater than or equal to 17 wt% and less than or equal to 26 wt% in the silica-based ceramic of the resin. In some embodiments, the silica-based ceramic of the resin that includes Si in an amount according to the weight percentage ranges above is a resin that comprises a leaving group, as described herein.

The anion exchange membranes and materials described herein may be used in any of a variety of applications. For example, in some embodiments, an anion exchange membrane described herein is used in an electrochemical application. In some cases, the electrochemical application involves applying a current or voltage in order to, for example, achieve separation of charged ionic species. Using an anion exchange membrane in an electrochemical application may comprise contacting the anion exchange membrane with an electrolyte. In some embodiments, using the anion exchange membrane in an electrochemical application may comprise passing current through an electrode in electrical communication with the electrolyte. For example, in some embodiments, the anion exchange membrane is incorporated into an electrochemical device (e.g., battery, fuel cell, electrolytic device, etc.). In some such embodiments, the electrochemical apparatus comprises an electrolyte (e.g., a fluid (liquid) electrolyte or a solid electrolyte) in contact with the anion exchange membrane and an electrode in electrical communication with the electrolyte. In some embodiments, the electrochemical apparatus comprises one or more gases (e.g., in contact with the anion exchange membrane) during at least a portion of a charging and/or discharging

– 88 –

process (e.g., a fuel cell). Examples of such gas include, but are not limited to, oxygen gas (O_2), hydrogen gas (H_2), carbon dioxide (CO_2), methane (CH_4), and combinations thereof. In some cases, current is passed through the electrode (e.g., during an electrochemical reaction) during operation (e.g., a charge or discharge process) of the electrochemical apparatus. In some embodiments in which the anion exchange membrane is incorporated into an electrochemical device, the anion exchange membrane is paired with an anion exchange membrane. In some cases, the anion exchange membrane may be loaded into a cell, and multiple such cells may be loaded into a stack containing more than one anion exchange membrane. Non-limiting examples of electrochemical applications of the anion exchange membrane include electrodialysis, batteries (e.g., redox flow batteries), fuel cells, chemical commodity production (e.g., chloro-alkali production), electrolysis, demineralization, wastewater treatment, chromatography, electrodeionization, desalting (e.g., enhanced oil recovery (EOR) desalting, organic wastewater desalting), chemical contaminant removal from wastewater (e.g., ammonia removal from wastewater), water treatment (e.g., mine runoff and tailings treatment), food and beverage production, dairy/whey purification, wine stabilization, biological purifications, biochemical production, coating (e.g., electrodeposition coating), desalination processes, ultra-pure water production, recovery of plating solutions, recovery of amines, acid recovery processes, caustic recovery processes, and acid removal processes (e.g., removing tartaric acid, malic acid, citric acid). It should be understood that in some cases, the anion exchange membrane can be used in separations applications other than those involving the application of an electric field. For example, in some embodiments, the anion exchange membrane is used for dialysis techniques. One non-limiting example includes diffusion dialysis (DD). Diffusion dialysis can be used in acid recovery processes (e.g., using a concentration gradient to selectively transport anions).

In some embodiments, an anion exchange membrane described herein is used as an adsorbent material. For example, in some embodiments, the anion exchange membrane is incorporated into an adsorption apparatus. In some such embodiments, the anion exchange membrane is used as an adsorbent material to remove liquid from a gas stream. In some cases, the anion exchange membrane is used as an adsorbent material to remove dissolved ions from a liquid stream (e.g., in an ion exchange process). In some embodiments, using the anion exchange membrane as an adsorbent material comprises

– 89 –

flowing a fluid through the anion exchange membrane. In some such embodiments, using the anion exchange membrane as an adsorbent material further comprises adsorbing a component (e.g., liquid when removing liquid from a gas stream, ions when removing ions from a liquid stream) of the fluid that is flowed through the anion exchange membrane. Non-limiting examples of uses of the anion exchange membrane described herein as an adsorbent material include using the anion exchange membrane in a pervaporator system, a dehumidifier system, and/or a desiccant or climate control system.

In some embodiments, an anion exchange membrane described herein is used in a separation application. In some such embodiments, the anion exchange membrane is used in a separation application that comprises applying a transmembrane pressure to the anion exchange membrane. Non-limiting examples of separation applications in which the anion exchange membrane is used by applying a transmembrane pressure to the anion exchange membrane include reverse osmosis, microfiltration (e.g., organic solvent microfiltration, aqueous solvent microfiltration), nanofiltration (e.g., organic solvent nanofiltration, aqueous solvent nanofiltration), and ultrafiltration applications. For example, in some embodiments, the anion exchange membrane is incorporated into a reverse osmosis apparatus, a filtration apparatus, or an ultrafiltration apparatus. Applying a transmembrane pressure to the anion exchange membrane may, in some cases, comprise contacting the anion exchange membrane with a liquid (e.g., a liquid solution) and applying a hydrostatic or hydraulic pressure to the liquid such that a transmembrane pressure is applied to the anion exchange membrane. In some such embodiments, at least a portion of the liquid passes through the anion exchange membrane (e.g., from a first side of the anion exchange membrane to a second side of the anion exchange membrane as a permeate).

As mentioned above, in some embodiments, anion exchange materials that are not in the form of a membrane are also described herein (e.g., in the form of a resin comprising a plurality of silica-based ceramic particles or beads). The anion exchange material, which may comprise silica-based ceramic comprising functional groups as described herein, can be used in any of a variety of applications. For example, in some embodiments, a resin comprising the anion exchange materials described herein is packed into an ion exchange column. In some such embodiments, the ion exchange column comprising the anion exchange material can be used for waste treatment (e.g.,

– 90 –

nuclear waste treatment), and purification processes such as ultrapure water production or protein & biologics purifications.

Definitions of specific functional groups and chemical terms are described in more detail below. For purposes of this invention, the chemical elements are identified in accordance with the Periodic Table of the Elements, CAS version, Handbook of Chemistry and Physics, 75th Ed., inside cover, and specific functional groups are generally defined as described therein. Additionally, general principles of organic chemistry, as well as specific functional moieties and reactivity, are described in Organic Chemistry, Thomas Sorrell, University Science Books, Sausalito: 1999, the entire contents of which are incorporated herein by reference.

As used herein, the term “aliphatic” refers to alkyl, alkenyl, alkynyl, and carbocyclic groups. Likewise, the term “heteroaliphatic” refers to heteroalkyl, heteroalkenyl, heteroalkynyl, and heterocyclic groups.

The term “alkyl” is given its ordinary meaning in the art and refers to the radical of saturated aliphatic groups, including straight-chain alkyl groups, branched-chain alkyl groups, cycloalkyl (alicyclic) groups, alkyl substituted cycloalkyl groups, and cycloalkyl substituted alkyl groups. In some cases, the alkyl group may be a lower alkyl group, *i.e.*, an alkyl group having 1 to 10 carbon atoms (*e.g.*, methyl, ethyl, propyl, butyl, pentyl, hexyl, heptyl, octyl, nonyl, or decyl). In some embodiments, a straight chain or branched chain alkyl may have 30 or fewer carbon atoms in its backbone, and, in some cases, 20 or fewer. In some embodiments, a straight chain or branched chain alkyl may have 12 or fewer carbon atoms in its backbone (*e.g.*, C₁-C₁₂ for straight chain, C₃-C₁₂ for branched chain), 6 or fewer, or 4 or fewer. Likewise, cycloalkyls may have from 3-10 carbon atoms in their ring structure, or 5, 6, or 7 carbons in the ring structure. Examples of alkyl groups include, but are not limited to, methyl, ethyl, propyl, isopropyl, cyclopropyl, butyl, isobutyl, *t*-butyl, cyclobutyl, hexyl, and cyclohexyl.

The term “alkylene” as used herein refers to a bivalent alkyl group. An “alkylene” group is a polymethylene group, *i.e.*, -(CH₂)_z-, wherein *z* is a positive integer, *e.g.*, from 1 to 20, from 1 to 10, from 1 to 6, from 1 to 4, from 1 to 3, from 1 to 2, or from 2 to 3. A substituted alkylene chain is a polymethylene group in which one or more methylene hydrogen atoms are replaced with a substituent. Suitable substituents include those described herein for a substituted aliphatic group. Alkylene groups may be cyclic or acyclic, branched or unbranched, substituted or unsubstituted.

– 91 –

Generally, the suffix “-ene” is used to describe a bivalent group. Thus, any of the terms defined herein can be modified with the suffix “-ene” to describe a bivalent version of that moiety. For example, a bivalent carbocycle is “carbocyclylene”, a bivalent aryl ring is “arylene”, a bivalent benzene ring is “phenylene”, a bivalent heterocycle is “heterocyclylene”, a bivalent heteroaryl ring is “heteroarylene”, a bivalent alkyl chain is “alkylene”, a bivalent alkenyl chain is “alkenylene”, a bivalent alkynyl chain is “alkynylene”, a bivalent heteroalkyl chain is “heteroalkylene”, a bivalent heteroalkenyl chain is “heteroalkenylene”, a bivalent heteroalkynyl chain is “heteroalkynylene”, and so forth.

The term “aryl” is given its ordinary meaning in the art and refers to aromatic carbocyclic groups, optionally substituted, having a single ring (e.g., phenyl), multiple rings (e.g., biphenyl), or multiple fused rings in which at least one is aromatic (e.g., 1,2,3,4-tetrahydronaphthyl, naphthyl, anthryl, or phenanthryl). That is, at least one ring may have a conjugated pi electron system, while other, adjoining rings can be cycloalkyls, cycloalkenyls, cycloalkynyls, aryls, and/or heterocyclyls. The aryl group may be optionally substituted, as described herein. Substituents include, but are not limited to, any of the previously mentioned substituents, i.e., the substituents recited for aliphatic moieties, or for other moieties as disclosed herein, resulting in the formation of a stable compound. In some cases, an aryl group is a stable mono- or polycyclic unsaturated moiety having preferably 3-14 carbon atoms, each of which may be substituted or unsubstituted. “Carbocyclic aryl groups” refer to aryl groups wherein the ring atoms on the aromatic ring are carbon atoms. Carbocyclic aryl groups include monocyclic carbocyclic aryl groups and polycyclic or fused compounds (e.g., two or more adjacent ring atoms are common to two adjoining rings) such as naphthyl groups.

The term “arylene,” as used herein refers to an aryl biradical derived from an aryl group, as defined herein, by removal of two hydrogen atoms. Arylene groups may be substituted or unsubstituted. Arylene group substituents include, but are not limited to, any of the substituents described herein, that result in the formation of a stable moiety. Additionally, arylene groups may be incorporated as a linker group into an alkylene, alkenylene, alkynylene, heteroalkylene, heteroalkenylene, or heteroalkynylene group, as defined herein. Arylene groups may be branched or unbranched.

The terms “halo” and “halogen” as used herein refer to an atom selected from the group consisting of fluorine, chlorine, bromine, and iodine.

– 92 –

The term “alkoxy” as used herein refers to an alkyl group, as previously defined, attached to the parent molecular moiety through an oxygen atom or through a sulfur atom. In certain embodiments, the alkyl group contains 1-20 aliphatic carbon atoms. In certain other embodiments, the alkyl group contains 1-10 aliphatic carbon atoms. In yet
5 other embodiments, the alkyl, alkenyl, and alkynyl groups employed in the invention contain 1-8 aliphatic carbon atoms. In still other embodiments, the alkyl group contains 1-6 aliphatic carbon atoms. In yet other embodiments, the alkyl group contains 1-4 aliphatic carbon atoms. Examples of alkoxy, include but are not limited to, methoxy, ethoxy, propoxy, isopropoxy, *n*-butoxy, *t*-butoxy, neopentoxy, and *n*-hexoxy. Examples
10 of thioalkyl include, but are not limited to, methylthio, ethylthio, propylthio, isopropylthio, *n*-butylthio, and the like. Alkoxy groups may be cyclic or acyclic, branched or unbranched, substituted or unsubstituted.

As used herein, quaternary ammonium groups include quaternary ($-N^+R_xR_yR_z$) amine groups (e.g., quaternary ammonium salts), where R_x , R_y , and R_z are independently
15 an aliphatic, alicyclic, heteroaliphatic, heterocyclic, aryl, or heteroaryl moiety, as defined herein. In some embodiments, quaternary ammonium groups include $N^+(C_{1-4} \text{ alkyl})_4$ salts.

The term “heterocyclyl” or “heterocyclic” refers to a radical of a 3- to 14-membered non-aromatic ring system having ring carbon atoms and 1 to 4 ring
20 heteroatoms, wherein each heteroatom is independently selected from nitrogen, oxygen, and sulfur (“3-14 membered heterocyclyl”). In heterocyclyl groups that contain one or more nitrogen atoms, the point of attachment can be a carbon or nitrogen atom, as valency permits. A heterocyclyl group can either be monocyclic (“monocyclic heterocyclyl”) or polycyclic (e.g., a fused, bridged or spiro ring system such as a bicyclic
25 system (“bicyclic heterocyclyl”) or tricyclic system (“tricyclic heterocyclyl”)), and can be saturated or can contain one or more carbon-carbon double or triple bonds. Heterocyclyl polycyclic ring systems can include one or more heteroatoms in one or both rings. “Heterocyclyl” also includes ring systems wherein the heterocyclyl ring, as
30 defined above, is fused with one or more carbocyclyl groups wherein the point of attachment is either on the carbocyclyl or heterocyclyl ring, or ring systems wherein the heterocyclyl ring, as defined above, is fused with one or more aryl or heteroaryl groups, wherein the point of attachment is on the heterocyclyl ring, and in such instances, the number of ring members continue to designate the number of ring members in the

heterocyclyl ring system. Unless otherwise specified, each instance of heterocyclyl is independently unsubstituted (an “unsubstituted heterocyclyl”) or substituted (a “substituted heterocyclyl”) with one or more substituents. In certain embodiments, the heterocyclyl group is an unsubstituted 3-14 membered heterocyclyl. In certain
5 embodiments, the heterocyclyl group is a substituted 3-14 membered heterocyclyl.

 The term “heteroaryl” refers to a radical of a 5-14 membered monocyclic or polycyclic (e.g., bicyclic, tricyclic) $4n+2$ aromatic ring system (e.g., having 6, 10, or 14 π electrons shared in a cyclic array) having ring carbon atoms and 1-4 ring heteroatoms provided in the aromatic ring system, wherein each heteroatom is independently selected
10 from nitrogen, oxygen, and sulfur (“5-14 membered heteroaryl”). In heteroaryl groups that contain one or more nitrogen atoms, the point of attachment can be a carbon or nitrogen atom, as valency permits. Heteroaryl polycyclic ring systems can include one or more heteroatoms in one or both rings. “Heteroaryl” includes ring systems wherein the heteroaryl ring, as defined above, is fused with one or more carbocyclyl or heterocyclyl
15 groups wherein the point of attachment is on the heteroaryl ring, and in such instances, the number of ring members continue to designate the number of ring members in the heteroaryl ring system. “Heteroaryl” also includes ring systems wherein the heteroaryl ring, as defined above, is fused with one or more aryl groups wherein the point of attachment is either on the aryl or heteroaryl ring, and in such instances, the number of
20 ring members designates the number of ring members in the fused polycyclic (aryl/heteroaryl) ring system. Polycyclic heteroaryl groups wherein one ring does not contain a heteroatom (e.g., indolyl, quinoliny, carbazolyl, and the like) the point of attachment can be on either ring, i.e., either the ring bearing a heteroatom (e.g., 2-indolyl) or the ring that does not contain a heteroatom (e.g., 5-indolyl).

25 As used herein, a “leaving group” (LG) is an art-understood term referring to a molecular fragment that departs with a pair of electrons in heterolytic bond cleavage, wherein the molecular fragment is an anion or neutral molecule. As used herein, a leaving group can be an atom or a group capable of being displaced by a nucleophile. See, for example, Smith, March Advanced Organic Chemistry 6th ed. (501-502).

30 It will be appreciated that the above groups and/or compounds, as described herein, may be optionally substituted with any number of substituents or functional moieties. That is, any of the above groups may be optionally substituted. As used herein, the term “substituted” is contemplated to include all permissible substituents of

– 94 –

organic compounds, “permissible” being in the context of the chemical rules of valence known to those of ordinary skill in the art. In general, the term “substituted” whether preceded by the term “optionally” or not, and substituents contained in formulas of this invention, refer to the replacement of hydrogen radicals in a given structure with the radical of a specified substituent. When more than one position in any given structure may be substituted with more than one substituent selected from a specified group, the substituent may be either the same or different at every position. It will be understood that “substituted” also includes that the substitution results in a stable compound, *e.g.*, which does not spontaneously undergo transformation such as by rearrangement, cyclization, elimination, *etc.* In some cases, “substituted” may generally refer to replacement of a hydrogen with a substituent as described herein. However, “substituted,” as used herein, does not encompass replacement and/or alteration of a key functional group by which a molecule is identified, *e.g.*, such that the “substituted” functional group becomes, through substitution, a different functional group. For example, a “substituted phenyl group” must still comprise the phenyl moiety and cannot be modified by substitution, in this definition, to become, *e.g.*, a pyridine ring. In a broad aspect, the permissible substituents include acyclic and cyclic, branched and unbranched, carbocyclic and heterocyclic, aromatic and nonaromatic substituents of organic compounds. Illustrative substituents include, for example, those described herein. The permissible substituents can be one or more and the same or different for appropriate organic compounds. For purposes of this invention, the heteroatoms such as nitrogen may have hydrogen substituents and/or any permissible substituents of organic compounds described herein which satisfy the valencies of the heteroatoms. Furthermore, this invention is not intended to be limited in any manner by the permissible substituents of organic compounds. Combinations of substituents and variables envisioned by this invention are preferably those that result in the formation of stable compounds useful for the formation of an imaging agent or an imaging agent precursor. The term “stable,” as used herein, preferably refers to compounds which possess stability sufficient to allow manufacture and which maintain the integrity of the compound for a sufficient period of time to be detected and preferably for a sufficient period of time to be useful for the purposes detailed herein.

Examples of substituents include, but are not limited to, halogen, azide, alkyl, aralkyl, alkenyl, alkynyl, cycloalkyl, hydroxyl, alkoxy, amino, nitro, sulfhydryl, imino,

– 95 –

amido, phosphonate, phosphinate, carbonyl, carboxyl, silyl, ether, alkylthio, sulfonyl, sulfonamido, ketone, aldehyde, ester, heterocyclyl, aromatic or heteroaromatic moieties, -CF₃, -CN, aryl, aryloxy, perhaloalkoxy, aralkoxy, heteroaryl, heteroaryloxy, heteroarylalkyl, heteroaralkoxy, azido, amino, halide, alkylthio, oxo, acylalkyl, carboxy esters, -carboxamido, acyloxy, aminoalkyl, alkylaminoaryl, alkylaryl, alkylaminoalkyl, alkoxyaryl, arylamino, aralkylamino, alkylsulfonyl, -carboxamidoalkylaryl, -carboxamidoaryl, hydroxyalkyl, haloalkyl, alkylaminoalkylcarboxy-, aminocarboxamidoalkyl-, cyano, alkoxyalkyl, perhaloalkyl, arylalkyloxyalkyl, and the like.

10 United States Provisional Application Serial No. 62/857,227, filed June 4, 2019, and entitled “CERAMIC ANION EXCHANGE MATERIALS,” is incorporated herein by reference in its entirety for all purposes.

The following examples are intended to illustrate certain embodiments of the present invention, but do not exemplify the full scope of the invention.

15 **EXAMPLE 1**

This example shows performance characteristics and structural properties of an exemplary anion exchange membrane. The anion exchange membranes of this example fabricated on a non-woven glass porous support membrane with polymer edging according to the following procedure. The porous support membranes were made of borosilicate glass fibers without a binder with an average (mean) pore size of 1 micron. The porous support membranes were initially 254 microns thick prior to sol-gel impregnation. The porous support membranes were initially edged with a UV curable silicone to form a disk with an outer diameter of 35 mm and an inner active area diameter between 10 mm – 15 mm. An initial mixture containing a 65:35 mass ratio of TEOS : N-trimethoxysilylpropyl-N,N,N-trimethylammonium chloride, 50% in methanol (TMAPS) was prepared and 0.3 M hydrochloric acid was added to achieve a final water:silicon molar ratio (R) of 2 and 4. This mixture was agitated and heated to 40 °C for 4 hours before being applied to the porous support membranes. The coated porous support membranes were allowed to dry overnight, and for comparison a set with a second coat was applied following the same procedure. The membranes were soaked in 0.5 M NaCl before characterization, where they were found to have apparent anion permselectivity between 82% and 96% (FIG. 8A); chloride ion conductivities between 0.0008 S/cm and 0.001 S/cm (FIG. 8B); and osmotic water permeances between 2.95

– 96 –

mL.m⁻².h⁻¹.bar⁻¹ and 5.2 mL.m⁻².h⁻¹.bar⁻¹ (FIG. 8C). Samples prepared similarly had anion exchange capacities between 0.61 meq/g and 0.95 meq/g. SAXS analysis (based on the data and model fit shown in FIG. 8D) showed that the membranes prepared with a molar ratio of water:silicon equal to 4 had average volumetric porosity of 9.5%, average pore radius of 5.1 Å, and average log-normal polydispersity index of 0.24.

EXAMPLE 2

This example shows structural properties of an exemplary anion exchange membrane. The anion exchange membranes of this example were fabricated on a non-woven glass porous support membrane with polymer edging according to the following procedure. The porous support membranes were made of borosilicate glass fibers without a binder with an average (mean) pore size of 1 micron. The porous support membranes were initially 254 microns thick prior to sol-gel impregnation. The porous support membranes were initially edged with a UV curable silicone to form a disk with an outer diameter of 35 mm and an inner active area diameter between 10 mm – 15 mm. Initial mixtures containing different mole ratios (2:1, 4:1, 6:1, 8:1 and 10:1) of TEOS : N-trimethoxysilylpropyl-N,N,N-trimethylammonium chloride (TMAPS), 50% in methanol were prepared and 0.3 M hydrochloric acid was added to each to achieve a final water:silicon molar ratio (R) of 2. This mixture was agitated and heated to 40 °C for 4 hours before being applied to the porous support membranes. The coated porous support membranes were allowed to dry overnight, and a second coat was applied following the same procedure. SAXS analysis (based on the data and Teubner-Strey model fit shown in FIG. 9A) showed that the membranes had pores with a radius ranging from 6 Å to 20 Å and volumetric porosity ranging from 4% to 22%. A 6:1 TEOS:TMAPS ratio resulted in a pore radius of 6.1 Å and volumetric porosity of 21%, as shown in FIGS. 9B-9C. FIG. 9D shows the anion exchange capacity for the same membranes.

EXAMPLE 3

This example shows performance characteristics and structural properties of an exemplary anion exchange membrane. The anion exchange membranes of this example were fabricated on a non-woven porous polymer support membrane of two different

– 97 –

thicknesses (190 and 210 microns) with no polymer edging following a similar procedure to that explained in Example 2, but with a mole ratio of 6:1 for TEOS to TMAPS and an R value of 2. The mixture was aged for 1 hour at 40°C, and then underwent an additional open aging step at 100°C for 30 minutes prior to being coated
5 onto the porous support. The coated support was allowed to dry for 2 hours at room temperature before repeating the coating procedure. This final membrane had 4 coats before being allowed to dry overnight. The anion exchange membranes were soaked in a 0.5 M NaCl solution before characterization. The anion exchange membranes were found to have apparent anion permselectivities between 92-94% (see FIG. 10A), with
10 chloride ion conductivities between 0.0062 and 0.0079 S/cm (see FIG. 10B). Membranes prepared in a similar manner were found to have an average anion exchange capacity of 1.4 meq/g.

FIG. 11 shows a cross-sectional SEM image of one of the anion exchange membranes of this example. In FIG. 11, the cross section includes the non-woven
15 porous polymer support membrane shown as the dark polymer fibers occupying the center horizontal region of the cross-section. Some of the polymer fibers run horizontally in the plane of the figure, while others run in a direction perpendicular to the plane of the figure and appear as circles in the cross-section. The cross section includes the nanoporous silica-based ceramic of the anion exchange membrane as the dense,
20 uniform slab-like lighter-contrast material surrounding on and within the porous support membrane.

EXAMPLE 4

This example shows performance characteristics and structural properties of an
25 exemplary anion exchange membrane. The anion exchange membranes of this example were fabricated on a non-woven porous glass support membrane with polymer edging following a similar procedure to that explained in Example 2, but with a mole ratio of 6:1 for TEOS to TMAPS and an R value of 2 and between 2 to 5 coats. The time taken to coat the sol on the samples (between 15 and 60 minutes) and whether the samples were
30 dried in an open or closed atmosphere were varied to investigate performance variations. All samples were soaked in 0.5 M NaCl solutions prior to characterization. The apparent permselectivities for these samples were found to be between 88% and 100% (See FIG.

– 98 –

11A). The chloride ion conductivities were between 0.0009 S/cm and 0.003 S/cm (See FIG. 11B).

FIG. 11C shows a cross-sectional SEM image of one of the anion exchange membranes of this example. In FIG. 11C, the cross section includes the non-woven porous polymer support membrane shown as the dark polymer fibers 401 occupying the center horizontal region of the cross-section. Some of the polymer fibers run horizontally in the plane of the figure, while others run in a direction perpendicular to the plane of the figure and appear as circles in the cross-section. The cross section includes the nanoporous silica-based ceramic of the anion exchange membrane as the dense, uniform slab-like lighter-contrast material 402 on and within the porous support membrane.

While several embodiments of the present invention have been described and illustrated herein, those of ordinary skill in the art will readily envision a variety of other means and/or structures for performing the functions and/or obtaining the results and/or one or more of the advantages described herein, and each of such variations and/or modifications is deemed to be within the scope of the present invention. More generally, those skilled in the art will readily appreciate that all parameters, dimensions, materials, and configurations described herein are meant to be exemplary and that the actual parameters, dimensions, materials, and/or configurations will depend upon the specific application or applications for which the teachings of the present invention is/are used. Those skilled in the art will recognize, or be able to ascertain using no more than routine experimentation, many equivalents to the specific embodiments of the invention described herein. It is, therefore, to be understood that the foregoing embodiments are presented by way of example only and that, within the scope of the appended claims and equivalents thereto, the invention may be practiced otherwise than as specifically described and claimed. The present invention is directed to each individual feature, system, article, material, and/or method described herein. In addition, any combination of two or more such features, systems, articles, materials, and/or methods, if such features, systems, articles, materials, and/or methods are not mutually inconsistent, is included within the scope of the present invention.

– 99 –

The indefinite articles “a” and “an,” as used herein in the specification and in the claims, unless clearly indicated to the contrary, should be understood to mean “at least one.”

5 The phrase “and/or,” as used herein in the specification and in the claims, should be understood to mean “either or both” of the elements so conjoined, i.e., elements that are conjunctively present in some cases and disjunctively present in other cases. Other elements may optionally be present other than the elements specifically identified by the “and/or” clause, whether related or unrelated to those elements specifically identified unless clearly indicated to the contrary. Thus, as a non-limiting example, a reference to
10 “A and/or B,” when used in conjunction with open-ended language such as “comprising” can refer, in one embodiment, to A without B (optionally including elements other than B); in another embodiment, to B without A (optionally including elements other than A); in yet another embodiment, to both A and B (optionally including other elements); etc.

As used herein in the specification and in the claims, “or” should be understood
15 to have the same meaning as “and/or” as defined above. For example, when separating items in a list, “or” or “and/or” shall be interpreted as being inclusive, i.e., the inclusion of at least one, but also including more than one, of a number or list of elements, and, optionally, additional unlisted items. Only terms clearly indicated to the contrary, such as “only one of” or “exactly one of,” or, when used in the claims, “consisting of,” will
20 refer to the inclusion of exactly one element of a number or list of elements. In general, the term “or” as used herein shall only be interpreted as indicating exclusive alternatives (i.e. “one or the other but not both”) when preceded by terms of exclusivity, such as “either,” “one of,” “only one of,” or “exactly one of.” “Consisting essentially of,” when used in the claims, shall have its ordinary meaning as used in the field of patent law.

25 As used herein in the specification and in the claims, the phrase “at least one,” in reference to a list of one or more elements, should be understood to mean at least one element selected from any one or more of the elements in the list of elements, but not necessarily including at least one of each and every element specifically listed within the list of elements and not excluding any combinations of elements in the list of elements.
30 This definition also allows that elements may optionally be present other than the elements specifically identified within the list of elements to which the phrase “at least one” refers, whether related or unrelated to those elements specifically identified. Thus, as a non-limiting example, “at least one of A and B” (or, equivalently, “at least one of A

– 100 –

or B,” or, equivalently “at least one of A and/or B”) can refer, in one embodiment, to at least one, optionally including more than one, A, with no B present (and optionally including elements other than B); in another embodiment, to at least one, optionally including more than one, B, with no A present (and optionally including elements other than A); in yet another embodiment, to at least one, optionally including more than one, A, and at least one, optionally including more than one, B (and optionally including other elements); etc.

In the claims, as well as in the specification above, all transitional phrases such as “comprising,” “including,” “carrying,” “having,” “containing,” “involving,” “holding,” and the like are to be understood to be open-ended, i.e., to mean including but not limited to. Only the transitional phrases “consisting of” and “consisting essentially of” shall be closed or semi-closed transitional phrases, respectively, as set forth in the United States Patent Office Manual of Patent Examining Procedures, Section 2111.03.

– 101 –

CLAIMS

What is claimed is:

1. An anion exchange membrane, comprising:
5 a porous support membrane; and
a silica-based ceramic that coats at least a portion of the porous support membrane, wherein the silica-based ceramic comprises quaternary ammonium groups covalently bound to the silica-based ceramic, and wherein the silica-based ceramic has an average pore diameter of less than or equal to 10 nm.
10
2. An anion exchange membrane, comprising:
a porous support membrane; and
a silica-based ceramic that forms a coating on and/or within the porous support membrane, wherein the silica-based ceramic comprises quaternary ammonium groups
15 covalently bound to the silica-based ceramic, and wherein the anion exchange membrane has a chloride ion conductivity of greater than or equal to 0.00001 S/cm.
3. An anion exchange membrane, comprising:
a silica-based ceramic, wherein the anion exchange membrane has a water uptake
20 of greater than or equal to 10 wt% and a linear expansion of less than or equal to 10%.
4. An anion exchange membrane, comprising:
a porous support membrane; and
a silica-based ceramic that coats at least a portion of the porous support
25 membrane, wherein the silica-based ceramic comprises quaternary ammonium groups covalently bound to the silica-based ceramic, and wherein greater than or equal to 50% of the pore volume of the porous support membrane is filled by the silica-based ceramic.
5. An anion exchange membrane, comprising:
30 a porous support membrane; and
a silica-based ceramic that forms a coating on and/or within the porous support membrane, wherein the silica-based ceramic comprises quaternary ammonium groups

– 102 –

covalently bound to the silica-based ceramic, and wherein the anion exchange membrane has an anion exchange capacity of greater than or equal to 0.01 meq/g.

6. An anion exchange membrane, comprising:
 - 5 a porous support membrane; and
 - a silica-based ceramic that coats at least a portion of the porous support membrane, wherein the silica-based ceramic comprises quaternary ammonium groups covalently bound to the silica-based ceramic, and wherein the quaternary ammonium groups are present in the anion exchange membrane in an amount of greater than or
 - 10 equal to 0.01 mmol per gram of the anion exchange membrane.

7. An anion exchange material, comprising:
 - a silica-based ceramic that comprises quaternary ammonium groups covalently bound to the silica-based ceramic, wherein the silica-based ceramic comprises Si in an
 - 15 amount greater than or equal to 6 wt% of the silica-based ceramic,
 - wherein the anion exchange material has an anion exchange capacity of greater than or equal to 0.01 meq/g, and
 - wherein the silica-based ceramic has an average pore diameter of less than 10 nm.

- 20 8. An anion exchange membrane, comprising:
 - a silica-based ceramic comprising Si in an amount greater than or equal to 6 wt% of the silica-based ceramic, wherein the anion exchange membrane has an anion exchange capacity of greater than or equal to 0.01 meq/g.

- 25 9. An anion exchange membrane, comprising:
 - a silica-based ceramic, wherein the anion exchange membrane has an anion exchange capacity of greater than or equal to 0.01 meq/g and a linear expansion of less than or equal to 10%.

- 30 10. An anion exchange membrane, comprising:
 - a silica-based ceramic comprising Si in an amount greater than or equal to 6 wt% of the silica-based ceramic, wherein the anion exchange membrane has an anion permselectivity of greater than or equal to 65%.

11. An anion exchange membrane, comprising:
 a silica-based ceramic comprising Si in an amount greater than or equal to 6 wt% of the silica-based ceramic, wherein the anion exchange membrane has a chloride ion conductivity of greater than or equal to 0.00001 S/cm.

5

12. An anion exchange membrane, comprising:
 a silica-based ceramic, wherein the anion exchange membrane has a chloride ion conductivity of greater than or equal to 0.00001 S/cm and a linear expansion of less than or equal to 10%.

10

13. An anion exchange membrane, comprising:
 a silica-based ceramic comprising Si in an amount greater than or equal to 6 wt% of the silica-based ceramic, wherein the anion exchange membrane has an osmotic water permeance of less than or equal to 100 mL/(hr·bar·m²).

15

14. An anion exchange membrane, comprising:
 a silica-based ceramic comprising Si in an amount greater than or equal to 6 wt% of the silica-based ceramic, the silica-based ceramic comprising pores, wherein an average diameter of the pores of the silica-based ceramic is larger when the anion exchange membrane is in a hydrated state than when the anion exchange membrane is in a dry state by a factor of greater than or equal to 1.1.

20

15. An anion exchange membrane, comprising:
 a silica-based ceramic comprising Si in an amount greater than or equal to 6 wt% of the silica-based ceramic, the silica-based ceramic comprising pores, wherein:
 when the anion exchange membrane is in a dry state, the pores of the silica-based ceramic fit a model of small angle scattering spectra with intensity (I) as a function of a scattering vector, q , as follows:

25

$$I(q) = \frac{1}{a+c_1q^2+c_2q^4} + bck,$$

30

wherein a , c_1 , and c_2 are adjustable parameters and bck is background scattering; and

– 104 –

when the anion exchange membrane is in a hydrated state the pores of the silica-based ceramic fit a core-shell model of small angle scattering spectra with intensity (I) as a function of a scattering vector, q , as follows:

$$\begin{aligned}
 I(q) &= P(q)S(q) + bck, \\
 5 \quad S(q) &= 1 + \frac{D_f \Gamma(D_f - 1)}{[1 + 1/q\xi]^2]^{(D_f - 1)/2}} \frac{\sin[(D_f - 1)\tan^{-1}(q\xi)]}{(qR_0)^{D_f}}, \\
 P(q) &= \frac{scale}{V_s} \left[3V_c(\rho_c - \rho_s) \frac{[\sin(qr_c) - qr_c \cos(qr_c)]}{(qr_c)^3} + 3V_s(\rho_s - \right. \\
 &\quad \left. \rho_{block}) \frac{[\sin(qr_s) - qr_s \cos(qr_s)]}{(qr_s)^3} \right]^2 + bck,
 \end{aligned}$$

wherein R_0 is a radius of the building blocks (pores), $\rho_{solvent}$ is a
 10 scattering length density of the silica-based ceramic, D_f is a fractal
 dimension, ξ is a correlation length, Γ is the standard mathematical gamma
 function, $scale$ is a volume fraction of building blocks of the measured
 silica-based ceramic, V_c is a volume of the core, V_s is a volume of the shell,
 15 ρ_c is a scattering length density of the core, ρ_s is a scattering length density
 of the shell, ρ_{block} is a scattering length density of the pores, r_c is a radius
 of the core, r_s is a radius of the shell, and bck is background scattering.

16. A method for using the anion exchange membrane of any one of claims 1-6, 8-
 15, and 21-113 in an electrochemical application, comprising:
 20 contacting the anion exchange membrane with an electrolyte; and
 passing current through an electrode in electrical communication with the
 electrolyte.

17. A method for using the anion exchange material of any one of claims 7 and 21-
 25 113 in an electrochemical application, comprising:
 contacting the anion exchange material with an electrolyte; and
 passing current through an electrode in electrical communication with the
 electrolyte.

– 105 –

18. A method for using the anion exchange membrane of any one of claims 1-6, 8-15, and 21-113 as an adsorbent material, comprising flowing a fluid through the anion exchange membrane; and
adsorbing a component of the fluid.

5

19. A method for using the anion exchange material of any one of claims 7 and 21-113 as an adsorbent material, comprising flowing a fluid through the anion exchange material; and
adsorbing a component of the fluid.

10

20. A method for using the anion exchange membrane of any one of claims 1-6, 8-15, and 21-113 in a separation application, comprising applying a transmembrane pressure to the anion exchange membrane.

15

21. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, further comprising a porous support membrane coated by the silica-based ceramic

20

22. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic comprises quaternary ammonium groups covalently bound to the silica-based ceramic.

25

23. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic has an average pore diameter of less than or equal to 10 nm.

30

24. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the quaternary ammonium groups are directly adjacent to a surface of the porous support membrane.

25. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the quaternary ammonium groups are present in the

– 106 –

anion exchange membrane or anion exchange material in an amount of 0.01 mmol per gram of the anion exchange membrane or anion exchange material.

26. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the quaternary ammonium groups are present in the anion exchange membrane or anion exchange material in an amount of 0.1 mmol per gram of the anion exchange membrane or anion exchange material.

27. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the quaternary ammonium groups are substantially homogeneously distributed within the silica-based ceramic based on the average amount of quaternary ammonium groups across a thickness of the coating.

28. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the quaternary ammonium groups are substantially homogeneously distributed within the silica-based ceramic based on the maximum amount of quaternary ammonium groups across a thickness of the coating.

29. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane or anion exchange material has an anion exchange capacity of greater than or equal to 0.01 meq/g.

30. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane or anion exchange material has an anion exchange capacity of greater than or equal to 0.1 meq/g.

31. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic comprises Si in an amount greater than or equal to 6 wt% of the silica-based ceramic.

32. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic comprises Si in an amount greater than or equal to 1.5 mol% of the silica-based ceramic.

33. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane has a linear expansion of less than or equal to 10%.

5

34. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane has a linear expansion of less than or equal to 5%.

10 35. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane has an anion permselectivity of greater than or equal to 65%.

15 36. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane has a chloride conductivity of greater than or equal to 0.00001 S/cm.

20 37. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane has an osmotic water permeance of less than or equal to 100 mL/(hr·bar·m²).

25 38. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane has an osmotic water permeance of less than or equal to 50 mL/(hr·bar·m²).

25

39. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein no intervening layers are present between the silica-based ceramic comprising the quaternary ammonium groups and porous support membrane.

30

40. The anion exchange membrane, anion exchange material, or method of any preceding claim, wherein the silica-based ceramic comprises pores, and wherein an average diameter of the pores of the silica-based ceramic is larger when the anion

– 108 –

exchange membrane is in a hydrated state than when the anion exchange membrane is in a dry state by a factor of greater than or equal to 1.1.

41. The anion exchange membrane, anion exchange material, or method of any preceding claim, wherein the silica-based ceramic comprises pores, and wherein an average diameter of the pores of the silica-based ceramic is larger when the anion exchange membrane is in a hydrated state than when the anion exchange membrane is in a dry state by a factor of less than or equal to 5.

42. The anion exchange membrane, anion exchange material, or method of any preceding claim, wherein the silica-based ceramic comprises pores, and wherein:
when the anion exchange membrane or anion exchange material is in a dry state, the pores of the silica-based ceramic fit a model of small angle scattering spectra with intensity (I) as a function of a scattering vector, q , as follows:

$$I(q) = \frac{1}{a+c_1q^2+c_2q^4} + bck,$$

wherein a , c_1 , and c_2 are adjustable parameters and bck is background scattering; and

when the anion exchange membrane or anion exchange material is in a hydrated state the pores of the silica-based ceramic fit a core-shell model of small angle scattering spectra with intensity (I) as a function of a scattering vector, q , as follows:

$$I(q) = P(q)S(q) + bck,$$

$$S(q) = 1 + \frac{D_f \Gamma(D_f - 1)}{[1 + 1/(q\xi)^2]^{(D_f - 1)/2}} \frac{\sin[(D_f - 1)\tan^{-1}(q\xi)]}{(qR_0)^{D_f}},$$

$$P(q) = \frac{scale}{V_s} \left[3V_c(\rho_c - \rho_s) \frac{[\sin(qr_c) - qr_c \cos(qr_c)]}{(qr_c)^3} + 3V_s(\rho_s - \rho_{block}) \frac{[\sin(qr_s) - qr_s \cos(qr_s)]}{(qr_s)^3} \right]^2 + bck,$$

wherein R_0 is a radius of the building blocks (pores), $\rho_{solvent}$ is a scattering length density of the silica-based ceramic, D_f is a fractal dimension, ξ is a correlation length, Γ is the standard mathematical gamma

– 109 –

function, *scale* is a volume fraction of building blocks of the measured silica-based ceramic, V_c is a volume of the core, V_s is a volume of the shell, ρ_c is a scattering length density of the core, ρ_s is a scattering length density of the shell, ρ_{block} is a scattering length density of the pores, r_c is a radius of the core, r_s is a radius of the shell, and *bck* is background scattering.

43. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic forms a single layer on the porous support membrane.

10

44. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the quaternary ammonium groups are within 1 μm of a surface of the porous support membrane.

15 45. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic is sol-gel derived.

46. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic is derived from the co-
20 condensation of a silicon-containing precursor comprising an ammonium group or a moiety comprising a leaving group.

47. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic has a silicon to nitrogen molar
25 ratio of greater than or equal to 1:1.

48. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic has a silicon to nitrogen molar ratio of less than or equal to 120:1.

30

– 110 –

49. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic has a silicon to carbon molar ratio of greater than or equal to 1:100.

5 50. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic has a silicon to carbon molar ratio of greater than or equal to 1:50.

10 51. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic has a silicon to carbon molar ratio of less than or equal to 3,000:1.

15 52. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic is derived from a mixture containing a silane comprising nitrogen.

53. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic is derived from a mixture comprising a compound having structure (IV):

wherein R^1 , R^2 , and R^3 are independently chosen from optionally-substituted C_{1-18} alkoxy and halo, L is chosen from optionally-substituted C_{1-18} alkylene and arylene, and X is a leaving group.

25 54. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic is derived from a mixture comprising a compound having structure (V):

- 111 -

wherein A¹ is independently chosen from hydrogen, methyl, ethyl, propyl, or butyl, n is greater than or equal to 1 and less than or equal to 18, and X is a leaving group.

5

55. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein X is chosen from chloro, bromo, iodo, tosyl, and trifluoromethanesulfonyl.

10 56. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica ceramic is derived from a mixture comprising (3-chloropropyl)triethoxysilane.

15 57. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic is derived from a mixture comprising a compound having structure (VI):

wherein R⁴, R⁵, and R⁶ are independently chosen from optionally-substituted C₁₋₁₈ alkoxy and halo, L is chosen from optionally-substituted C₁₋₁₈ alkylene and arylene, and R⁷, R⁸, and R⁹ are independently chosen from optionally-substituted C₁₋₁₈ alkyl, cyclyl, and aryl.

20

– 112 –

58. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic is derived from a mixture comprising a compound having structure (VII):

5 where A^2 is independently chosen from hydrogen, methyl, ethyl, propyl, or butyl, n is greater than or equal to 1 and less than or equal to 18, and R^{10} , R^{11} , and R^{12} are independently chosen from methyl, ethyl, propyl, butyl, cyclohexyl, and benzyl.

10 59. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic is derived from a mixture comprising trimethoxysilylpropyl-N,N,N-trimethylammonium.

15 60. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic is derived from a mixture comprising a compound having structure (VIII):

wherein R^{13} is independently chosen from hydrogen or optionally-substituted C_{1-18} alkyl.

20

61. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic is derived from a mixture comprising a compound having a structure of tetraethyl orthosilicate.

– 113 –

62. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic is derived from a mixture comprising a compound having structure (VIII), a compound having structure (IV), and water in a molar ratio of 1:0.01-20:1-30.

5

63. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic is derived from a mixture comprising a compound having structure (VIII), a compound having structure (VI), and water in a molar ratio of 1:0.01-10:1-30.

10

64. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic has an average pore diameter of less than or equal to 1 μm .

15

65. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic has an average pore diameter of less than or equal to 2 nm.

20

66. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic has an average pore diameter of greater than or equal to 0.25 nm.

25

67. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane or material has a volumetric porosity of greater than or equal to 1%.

30

68. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane or material has a volumetric porosity of less than or equal to 70%.

69. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the pores of the silica-based ceramic have an aspect ratio of less than or equal to 40:1.

– 114 –

70. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the pores of the silica-based ceramic have an ordered structure.

5 71. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the pores of the silica-based ceramic are substantially spherical.

72. The anion exchange membrane, anion exchange material, or method of any one
10 of the preceding claims, wherein the pores of the silica-based ceramic fit a spherical model of small angle scattering spectra with a χ^2/N value of less than or equal to 10, where N is the number of points small-angle scattering data points over the spherical model fitting range.

15 73. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the silica-based ceramic has a fractal porous structure.

74. The anion exchange membrane, anion exchange material, or method of any one
of the preceding claims, wherein the pores of the silica-based ceramic have a log-normal
20 polydispersity index of pore radius of less than or equal to 0.8.

75. The anion exchange membrane, anion exchange material, or method of any one
of the preceding claims, wherein the porous support membrane comprises pores having
an average pore diameter of greater than or equal to 50 nm in the absence of the silica-
25 based ceramic.

76. The anion exchange membrane, anion exchange material, or method of any one
of the preceding claims, wherein the porous support membrane comprises pores having
an average pore diameter of less than or equal to 50 μm in the absence of the silica-based
30 ceramic.

– 115 –

77. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the porous support membrane has a cross-sectional thickness of greater than or equal to 3 μm .

5 78. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the porous support membrane has a cross-sectional thickness of less than or equal to 1,000 μm .

79. The anion exchange membrane, anion exchange material, or method of any one
10 of the preceding claims, wherein the porous support membrane has a volumetric porosity of greater than or equal to 10%.

80. The anion exchange membrane, anion exchange material, or method of any one
15 of the preceding claims, wherein the porous support membrane has a volumetric porosity of less than or equal to 99%.

81. The anion exchange membrane, anion exchange material, or method of any one
of the preceding claims, wherein the porous support membrane comprises support
components having an average diameter of greater than or equal to 10 nm.

20

82. The anion exchange membrane, anion exchange material, or method of any one
of the preceding claims, wherein the porous support membrane comprises support
components having an average diameter of less than or equal to 50 μm .

25 83. The anion exchange membrane, anion exchange material, or method of any one
of the preceding claims, wherein the support components are chosen from fibers, strands,
and wires.

84. The anion exchange membrane, anion exchange material, or method of any one
30 of the preceding claims, wherein the porous support membrane is in the form of a non-
woven fabric or mesh, veil, knit fabric, woven fabric or mesh, open-cell structure, fibril
and node structure, or open-cell foam.

– 116 –

85. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the porous support membrane comprises a polymeric material.

5 86. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the polymeric material comprises polypropylene, polyethylene, polyvinyl chloride, polystyrene, polyamide, polyimide, polyacetonitrile, polyvinylacetate, polyethylene glycol, poly ether ether ketone, polysulfone, polyacrylamide, polydimethylsiloxane, polyvinylidene fluoride, polyacrylic acid,
10 polyvinyl alcohol, polyphenylene sulfide, polytetrafluoroethylene, cellulose, microfillibrated cellulose, nanofillibrated cellulose, or combinations or derivatives thereof.

87. The anion exchange membrane, anion exchange material, or method of any one
15 of the preceding claims, wherein the porous support membrane comprises a ceramic material.

88. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the ceramic material comprises borosilicate glass, silica,
20 titania, zirconia, alumina, silicon carbide, silicon nitride, boron nitride, lithium silicate, potassium silicate, tin oxide, iron oxide, or combinations thereof.

89. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the porous support membrane comprises metal and/or a
25 metal alloy.

90. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the metal and/or metal alloy comprise iron or steel.

30 91. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the porous support membrane comprises one or more amphiphilic molecules on the surface of the support membrane.

– 117 –

92. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the amphiphilic molecule comprises a sodium alkyl sulfates, a dialkyl sulfosuccinate, or an alkyltrimethylammonium halide.

5 93. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein greater than or equal to 50% of the pore volume of the porous support membrane is filled by the silica-based ceramic.

10 94. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane comprises an edging material comprising a polymeric material.

15 95. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane comprises an edging material comprising silicone, epoxy, polyurethane, acrylic, silicone rubber, poly(styrene-isoprene-styrene), poly(styrene-isobutylene-styrene), polypropylene, polyethylene, polyvinyl chloride, polystyrene, polyamide, polyimide, polyacetonitrile, polyvinylacetate, polyethylene glycol, poly ether ether ketone, polysulfone, polyacrylamide, polydimethylsiloxane, polyvinylidene fluoride, polyacrylic acid, 20 polyvinyl alcohol, polyphenylene sulfide, polytetrafluoroethylene, cellulose, or combinations or derivatives thereof.

25 96. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane or anion exchange material has a water uptake of greater than or equal to 1%.

97. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane has a linear expansion of less than or equal to 0.5%.

30

98. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane has a linear expansion of greater than or equal to 0.01%.

– 118 –

99. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane or anion exchange material has an anion permselectivity of greater than or equal to 85%.

5 100. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the porous support membrane has a mechanical burst pressure of greater than or equal to 1.5 N.

10 101. The anion exchange membrane, anion exchange material, or method of any preceding claim, wherein the porous support membrane has a mechanical burst pressure of greater than or equal to 2.0 pounds per square inch (PSI).

15 102. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the leaving group is chosen from chloro, bromo, iodo, tosyl, and trifluoromethanesulfonyl.

103. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the leaving group is chloro.

20 104. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the amine is a tertiary amine.

105. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the amine is trimethylamine.

25

106. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange material is in the form of a resin.

30 107. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange material is in the form of a plurality of particles.

– 119 –

108. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the particles have a mean maximum cross-sectional dimension of greater than or equal to 1 μm .

5 109. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the particles have a mean maximum cross-sectional dimension of less than or equal to 1 μm .

10 110. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange material is in the form of a bead.

111. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane is incorporated into an electrochemical device.

15

112. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane is incorporated into a reverse osmosis, nanofiltration, or ultrafiltration apparatus.

20 113. The anion exchange membrane, anion exchange material, or method of any one of the preceding claims, wherein the anion exchange membrane is incorporated into an adsorption apparatus.

25
