

DESCRIPTION

Title of Invention

SLURRY, METHOD FOR PRODUCING POLISHING LIQUID, AND
POLISHING METHOD

5 Technical Field

[0001] The present invention relates to a slurry, a method for producing a polishing liquid, and a polishing method.

Background Art

10 [0002] In the manufacturing steps for semiconductor elements of recent years, the importance of processing technologies for density increase and micronization is increasing more and more. CMP (Chemical mechanical polishing) technology, which is one of the processing technologies, has become an essential technology for the formation of a shallow trench isolation (hereinafter, referred to as "STI"), flattening of
15 a pre-metal insulating material or an interlayer insulating material, formation of a plug or an embedded metal wiring, and the like in the manufacturing steps for semiconductor elements.

20 [0003] Regarding polishing liquids that are most commonly used, for example, silica-based polishing liquids containing silica (silicon oxide) particles such as fumed silica and colloidal silica as abrasive grains are mentioned. Silica-based polishing liquids have a feature of high flexibility of use, and by appropriately selecting the content of abrasive grains, pH, additives, and the like, polishing of a wide variety of materials can be achieved regardless of whether the material is an
25 insulating material or an electroconductive material.

[0004] Meanwhile, as a polishing liquid mainly used for insulating

materials such as silicon oxide, a demand for a polishing liquid containing cerium compound particles as abrasive grains is also increasing. For example, a cerium oxide-based polishing liquid containing cerium oxide particles as abrasive grains can polish silicon oxide at a high rate even when the abrasive grain content is lower than that in the silica-based polishing liquid (for example, see Patent Literatures 1 and 2 described below).

Summary of Invention

Technical Problem

[0006] Incidentally, in recent years, in the manufacturing steps for semiconductor elements, it is required to achieve further micronization of wiring, and polishing scratches generated at the time of polishing are becoming problematic. That is, when many coarse particles exist at the time of polishing, polishing scratches generated at the time of polishing tend to increase. In this regard, it is required to reduce coarse particles in a polishing liquid and a slurry provided for producing a polishing liquid. As the method of removing coarse particles, a

precipitation separation method, liquid cyclone, filtration, and the like are studied. From the viewpoint that influence on characteristics of the polishing liquid and the slurry is small and the viewpoint that reproducibility is excellent, there is a tendency that filtration is carried out.

[0007] However, in a conventional cerium oxide-based polishing liquid, a low removal rate (capture efficiency) of coarse particles in filtration becomes problematic. In this regard, in order to increase the removal rate of coarse particles, a method of decreasing a pore size of a filter is considered. However, in a case where the pore size of the filter is too small, there is a problem in that the removal rate of coarse particles is decreased due to clogging or a problem in that particle size distribution before and after filtration is changed due to particles adhering to a filtering material so as to decrease the polishing rate. From such reasons, there is a limit to adjust the removal rate of coarse particles by selection of a filter (such as adjustment of the pore size of a filter).

[0008] The present invention is directed to solve the problems described above, and an object of the present invention is to provide a slurry capable of obtaining an excellent removal rate for coarse particles in filtration. Furthermore, another object of the present invention is to provide a method for producing a polishing liquid by using the above-described slurry. Further, still another object of the present invention is to provide a polishing method using a polishing liquid obtained by the above-described method for producing a polishing liquid.

Solution to Problem

[0009] A slurry of an aspect of the present invention is a slurry containing abrasive grains and a liquid medium, in which the abrasive grains include first particles and second particles in contact with the first particles, the first particles contain cerium oxide, the second particles contain a cerium compound, and in a case where a content of the abrasive grains is 2.0% by mass, a BET specific surface area of a solid phase obtained when the slurry is subjected to centrifugal separation for 30 minutes at a centrifugal acceleration of 1.1×10^4 G is 24 m²/g or more.

[0010] According to the slurry of the aspect of the present invention, an excellent removal rate of coarse particles in filtration can be obtained. According to such a slurry, by removing coarse particles with filtration, it is possible to reduce polishing scratches generated at the time of polishing.

[0011] A method for producing a polishing liquid of another aspect of the present invention includes a step of filtering the aforementioned slurry. According to such a method for producing a polishing liquid, a polishing liquid capable of reducing polishing scratches generated at the time of polishing can be obtained.

[0012] A polishing method of still another aspect of the present invention includes a step of polishing a surface to be polished by using a polishing liquid obtained by the aforementioned method for producing a polishing liquid. According to such a polishing method, polishing scratches generated at the time of polishing can be reduced.

Advantageous Effects of Invention

[0013] According to the present invention, it is possible to provide a

slurry capable of obtaining an excellent removal rate of coarse particles in filtration. Furthermore, according to the present invention, it is possible to provide a method for producing a polishing liquid by using the above-described slurry. Further, according to the present invention, it is possible to provide a polishing method using a polishing liquid obtained by the above-described method for producing a polishing liquid. According to the present invention, it is possible to provide use of a slurry or a polishing liquid in polishing of silicon oxide.

Description of Embodiments

[0014] Hereinafter, embodiments of the present invention will be described in detail. However, the present invention is not limited to the following embodiments.

[0015] <Definition>

In the present specification, a numerical range that has been indicated by use of "to" indicates the range that includes the numerical values which are described before and after "to", as the minimum value and the maximum value, respectively. In the numerical ranges that are described stepwise in the present specification, the upper limit value or the lower limit value of the numerical range of a certain stage can be arbitrarily combined with the upper limit value or the lower limit value of the numerical range of another stage. In the numerical ranges that are described in the present specification, the upper limit value or the lower limit value of the numerical value range may be replaced with the value shown in the examples. "A or B" may include either one of A and B, and may also include both of A and B. Materials listed as examples in the present specification can be used singly or in

combinations of two or more, unless otherwise specifically indicated. In the present specification, when a plurality of substances corresponding to each component exist in the composition, the content of each component in the composition means the total amount of the plurality of substances that exist in the composition, unless otherwise specified. The term "step" includes not only an independent step but also a step by which an intended action of the step is achieved, though the step cannot be clearly distinguished from other steps.

[0016] As described later, a slurry and a polishing liquid of the present embodiment contain abrasive grains. The abrasive grains are also referred to as "abrasive particles"; however, in the present specification, the term "abrasive grains" is used. Abrasive grains are generally solid particles, and it is considered that at the time of polishing, an object to be removed is removed by the mechanical action (physical action) of the abrasive grains and the chemical action of the abrasive grains (mainly the surface of the abrasive grains); however, it is not limited to this.

[0017] The term "polishing liquid" (abrasive) is defined as a composition to be brought into contact with a surface to be polished, at the time of polishing. The term "polishing liquid" itself does not at all limit the components that are contained in the polishing liquid.

[0018] The weight average molecular weight in the present specification can be measured, for example, by a gel permeation chromatography method (GPC) under the following conditions using a calibration curve of standard polystyrene.

Instrument used: Hitachi L-6000 Model [manufactured by

Hitachi, Ltd.]

Column: Gel-Pak GL-R420 + Gel-Pak GL-R430 + Gel-Pak GL-R440 [manufactured by Hitachi Chemical Co., Ltd., trade names, three columns in total]

5 Eluent: tetrahydrofuran

Measurement temperature: 40°C

Flow rate: 1.75 mL/min

Detector: L-3300RI [manufactured by Hitachi, Ltd.]

[0019] The "specific surface area" indicates the total surface area of a
10 sample per unit mass. The specific surface area is called "BET
specific surface area" in the case of being measured by a BET method.
In a sample, particles having different specific surface areas may be
contained. In this case, information on the specific surface area (true
value) of each particle is not obtained, but an effective value obtained
15 by averaging contribution of all particles to the surface areas is
obtained. The BET specific surface area can be measured utilizing a
gas adsorption method, for example, by using a specific surface
area/fine pore size analysis device (trade name: QUADRASORB evo)
manufactured by Quantachrome Instruments under the following
20 conditions. As the BET specific surface area of the abrasive grains, an
average value of two measurements can be used.

Pretreatment: Vacuum deaeration (100°C, 2 hours)

Measurement method: Constant volume method

Adsorption gas: Nitrogen gas

25 Measurement temperature: 77.35 K

Measurement cell size: 1.5 cm³

Measurement item: A value of P/P_0 was changed in a range of 0 to 0.3 to measure several points

Analysis item: Specific surface area by BET multipoint method

Number of times of measurement: Changing a sample and performing measurement 2 times

[0020] The "coarse particles" indicate particulate substances that are significantly large in particle size distribution of the abrasive grains in the slurry or the polishing liquid. Materials for the coarse particles are not particularly limited, and examples thereof include coarse crystals or particle aggregates, foreign substances mixed from the outside, and complexes thereof. The shape of the coarse particles is not particularly limited, may be a spherical shape, a rod shape, or the like, may be a shape having a large aspect ratio, and may be a shape having unevenness on the surface. The lower limit of the size (particle size) of the coarse particles is, for example, 3 μm . However, the lower limit of the size of the coarse particles may be, for example, 0.5 μm , 1 μm , 2 μm , and the like as long as an excellent removal rate of the coarse particles is obtained.

[0021] <Slurry, polishing liquid, and production methods therefor>

The slurry of the present embodiment contains abrasive grains and a liquid medium as essential components. The abrasive grains include composite particles including first particles and second particles in contact with the first particles. The first particles contain cerium oxide and the second particles contain a cerium compound. In a case where a content of the abrasive grains is 2.0% by mass, a BET specific surface area of a solid phase obtained when the slurry of the present

embodiment is subjected to centrifugal separation for 30 minutes at a centrifugal acceleration of 1.1×10^4 G is $24 \text{ m}^2/\text{g}$ or more.

[0022] By filtering the slurry of the present embodiment, an excellent removal rate of coarse particles can be obtained. According to such a slurry, by removing coarse particles with filtration, it is possible to reduce polishing scratches generated at the time of polishing. In a case where the removal rate of coarse particles is large, the number of coarse particles tends to be easily decreased, and polishing scratches can be effectively reduced. The reasons why an excellent removal rate of coarse particles is obtained in this way are, for example, the reasons to be as follows. However, the reasons are not limited to the reasons to be as follows.

[0023] That is, in a case where the second particles containing a cerium compound is in contact with the first particles containing cerium oxide, gravitational interaction between particles is speculated to be generated. Such interaction is not particularly limited, and examples thereof include electrostatic attraction, covalent bond, van der Waals force, dipole-dipole interaction, hydrophobic bond, hydrogen bond, and depletion effect caused by a difference in concentration between polymeric molecules or nanoparticles. It has been considered that, in a conventional slurry, the aforementioned interaction causes the aggregation of particles and causes coarse particles to increase.

[0024] On the other hand, the composite particles in the present embodiment can maintain a dispersion state even in a case where interaction is generated. The reason for this is speculated that repulsive interaction between the second particles is generated. That

is, other second particles (such as particles not in contact with the first particles) are difficult to approach the second particles in contact with the first particles. Therefore, it is speculated that new adsorption of the second particles is suppressed, and thus, coarse aggregates are not formed. It is speculated that, since the repulsive interaction between the second particles is sufficiently larger than the gravitational interaction between the first particles and the second particles, the composite particles in the present embodiment can maintain a dispersion state. The aforementioned repulsive interaction is not particularly limited, and examples thereof include electrostatic repulsive force, osmotic pressure, and steric repulsion by a surface adsorption layer.

[0025] On the other hand, regarding the coarse particles, it is speculated that a balance between the aforementioned conflicting interactions is different from that in the composite particles. Here, it has been known that the gravitational interaction (such as van der Waals force) inevitably acting between particles increases as the particle size increases. Therefore, regarding the coarse particles having a large particle size, other particles are easily adsorbed, and the aggregation suppression effect based on the repulsive interaction between the second particles is hardly expressed. That is, even if the coarse particles are covered with the second particles, the second particles can be consecutively adsorbed. Therefore, it is speculated that, when the first particles, the second particles, or aggregates thereof are adsorbed to the coarse particles, coarse particles having a large particle size are formed. In this way, the particle size of the coarse particles is selectively increased, and thus

it is speculated that the removal rate of the coarse particles is easily increased by capturing the coarse particles by the filtering material.

[0026] Further, in the present embodiment, the BET specific surface area in the solid phase obtained by centrifugal separation is in the above-described range, and thereby, as described in the following reason, an excellent removal rate of coarse particles can be obtained.

[0027] That is, generally, particles in the liquid medium adhere to other substances (for example, other particles) different from the liquid medium (for example, water) and thereby the particles tend to be stabilized. The reason for this is that the area in contact with the liquid medium of the particles is reduced by adhesion to other substances, and thus the interface energy between the liquid medium and the particles can be minimized. In particular, in the case of particles having a large specific surface area, a change amount in the area in contact with the liquid medium is largely different before and after adhesion, and thus it is speculated that the particles tend to be likely to adhere to other substances.

[0028] In speculation of the present inventor, although the specific surface area of the coarse particles in the slurry is not necessarily large, in a case where other particles having a larger specific surface area (hereinafter, referred to as "particles A", for example, second particles) are adsorbed to the surface of the coarse particles, a phenomenon that the coarse particles act like particles having a specific surface area equal to or more than the specific surface area which the particles originally have may occur. That is, it is considered that, since the particles A having a large specific surface area are adsorbed to coarse particles to

increase the adherability of the coarse particles with respect to a filtering material, the coarse particles are easily removed with filtration.

[0029] On the other hand, the amount of the particles A having a large specific surface area, which is to be adsorbed to the coarse particles, is determined by the strength of the interaction between the particles A and other particles (ease of adsorption). The details of such interaction are not clear, but in a case where any particles have a tendency of being easily adsorbed to other particles, it is considered that these particles also have a tendency of being easily adsorbed to the coarse particles similarly.

[0030] According to findings of the present inventor, it is found that particles having a relatively large secondary particle size are mainly contained in the solid phase obtained when the slurry having a content of the abrasive grains of 2.0% by mass is subjected to centrifugal separation for 30 minutes at a centrifugal acceleration of 1.1×10^4 G. According to the centrifugal separation of the above-described conditions, particles having a large specific surface area are easy to be sufficiently recovered. The BET specific surface area of the solid phase indicates the total surface area of particles per unit mass. Therefore, it is considered that, in a case where the BET specific surface area of the solid phase is increased, the following requirement (a) and requirement (b) are established:

(a) particles having a large specific surface area are present in the slurry; and

(b) secondary particle size of particles having a large specific surface area is large.

[0031] In the speculation of the present inventor, in a case where the requirement (b) in addition to the requirement (a) is satisfied, the above-described interaction acting between the "particles having a large specific surface area" and other particles is large. Therefore, it is considered that, since these particles are easily adsorbed also to the coarse particles, the adherability of the coarse particles with respect to the other substances is easily increased. From such reasons, the BET specific surface area in the solid phase obtained by centrifugal separation is in the above-described range, and thereby the removal rate of coarse particles can be improved.

[0032] Meanwhile, by adjusting the method for producing particles, it is considered to avoid generation of coarse particles and mixing of coarse particles into a slurry and a polishing liquid. For example, a method of liquid-phase synthesizing microparticles is easier to reduce mixing of coarse particles than a method of pulverizing and micronizing particles of polycrystals (for example, polycrystal of cerium oxide). However, in such a method, in order to prevent unintentional generation of coarse particles, it is necessary to micronize particles by optimizing production conditions of particles. In this case, when the crystallite diameter of particles is small, mechanical polishing action is difficult to be obtained so that the polishing rate tends to be decreased, and thus it is difficult to achieve a high polishing rate for an insulating material while effectively reducing coarse particles.

[0033] On the other hand, according to the present embodiment, it is possible to achieve a high polishing rate for an insulating material (for example, silicon oxide) while effectively reducing coarse particles.

The reasons why the polishing rate for an insulating material is improved in this way are, for example, the reasons to be as follows. However, the reasons are not limited to the reasons to be as follows.

[0034] That is, the first particles containing cerium oxide and having a larger particle size than that of the second particles have strong mechanical action (mechanical property) with respect to an insulating material as compared to the second particles. On the other hand, the second particles containing a cerium compound and having a smaller particle size than that of the first particles have small mechanical action with respect to an insulating material as compared to the first particles, but have strong chemical action (chemical property) with respect to an insulating material since the specific surface area (surface area per unit mass) in the whole particle is large. Therefore, a synergetic effect of improving the polishing rate is easily obtained by using the first particles having strong mechanical action and the second particles having strong chemical action. Thereby, a high polishing rate for an insulating material can be achieved.

[0035] According to the present embodiment, since a high polishing rate for an insulating material can be achieved, by adjusting the content of the abrasive grains to be decreased, it is also possible to reduce coarse particles. Furthermore, generally, as the content of abrasive grains is increased, polishing scratches tend to be easily generated. On the other hand, according to the present embodiment, since a sufficient polishing rate can be obtained even in a case where the content of the abrasive grains is small, by using a small amount of abrasive grains, an insulating material can be polished with fewer polishing scratches while

a sufficient polishing rate is achieved.

[0036] As described above, in a case where a content of the abrasive grains is 2.0% by mass, a BET specific surface area of a solid phase obtained when the slurry is subjected to centrifugal separation for 30 minutes at a centrifugal acceleration of 1.1×10^4 G is $24 \text{ m}^2/\text{g}$ or more, from the viewpoint of obtaining an excellent removal rate of the coarse particles. As the BET specific surface area of the solid phase, the BET specific surface area after drying the solid phase obtained by centrifugal separation of the slurry can be used. The lower limit of the BET specific surface area of the solid phase is preferably $25 \text{ m}^2/\text{g}$ or more, more preferably $28 \text{ m}^2/\text{g}$ or more, further preferably $30 \text{ m}^2/\text{g}$ or more, particularly preferably $35 \text{ m}^2/\text{g}$ or more, and extremely preferably $40 \text{ m}^2/\text{g}$ or more, from the viewpoint of easily obtaining an excellent removal rate of coarse particles. The upper limit of the BET specific surface area of the solid phase is preferably $200 \text{ m}^2/\text{g}$ or less from the viewpoint that the aggregation of particles is easily suppressed since the particles are difficult to adhere to each other.

[0037] The polishing liquid (CMP polishing liquid) of the present embodiment can be obtained, for example, by filtering the slurry of the present embodiment. The method for producing a polishing liquid of the present embodiment includes a filtering step of filtering the slurry of the present embodiment.

[0038] In the filtering step, the coarse particles can be removed by using a filter (filtering material). The shape of the filter is not particularly limited, and examples thereof include a disk type and a cartridge type. A cartridge type filter may be processed into the form

of pleat from the viewpoint of enhancing liquid permeability.

[0039] Examples of materials constituting a filter include polypropylene, nylon, glass, polyester, polyether sulfone, polytetrafluoroethylene, polycarbonate, polyvinylidene fluoride, and a cellulose derivative. These materials may be processed into the form of a membrane or a fiber.

[0040] The pore size (nominal pore size) of the filter is preferably in the following range. The lower limit of the pore size of the filter is preferably 0.10 μm or more and more preferably 0.20 μm or more, from the viewpoint that a filtration rate is excellent, the viewpoint that the particle size distribution is hardly changed, and the viewpoint that the filter life (clogging prevention effect) is excellent. The upper limit of the pore size of the filter is preferably 3.0 μm or less, more preferably 2.0 μm or less, further preferably 1.0 μm or less, particularly preferably 0.80 μm or less, and extremely preferably 0.50 μm or less, from the viewpoint of easily obtaining an excellent removal rate of coarse particles. From the above-described viewpoints, the pore size of the filter is preferably 0.10 to 3.0 μm .

[0041] The filtration may be carried out in a single stage, and a multi-stage treatment in which a plurality of filters are combined may be performed. Furthermore, the slurry may be caused to pass through a single filter once, and a circulation treatment may be performed with respect to the same filter in plural times.

[0042] (Abrasive grains)

As described above, the abrasive grains in the present embodiment include composite particles including first particles and

second particles in contact with the first particles.

[0043] The particle size of the second particles is preferably smaller than the particle size of the first particles. The magnitude relationship in particle size between the first particles and the second particles can be determined from SEM images of the composite particles, or the like. In general, particles having a small particle size have a larger surface area per unit mass than that of particles having a large particle size, and thus have higher reaction activity. On the other hand, the mechanical action (mechanical polishing force) of particles having a small particle size is smaller than that of particles having a large particle size. However, in the present embodiment, even in a case where the particle size of the second particles is smaller than the particle size of the first particles, the synergetic effect of the first particles and the second particles can be expressed and both of excellent reaction activity and excellent mechanical action can be easily achieved.

[0044] The lower limit of the particle size of the first particles is preferably 15 nm or more, more preferably 25 nm or more, further preferably 35 nm or more, particularly preferably 40 nm or more, extremely preferably 50 nm or more, highly preferably 80 nm or more, and even more preferably 100 nm or more, from the viewpoint that the polishing rate for an insulating material is further improved. The upper limit of the particle size of the first particles is preferably 1000 nm or less, more preferably 800 nm or less, further preferably 600 nm or less, particularly preferably 400 nm or less, extremely preferably 300 nm or less, highly preferably 200 nm or less, and even more preferably 150 nm or less, from the viewpoint of improving the dispersibility of the

abrasive grains and the viewpoint of easily suppressing scratches at a polished surface. From the above-described viewpoints, the particle size of the first particles is more preferably 15 to 1000 nm. The average particle size (average secondary particle size) of the first particles may be in the above ranges.

[0045] The lower limit of the particle size of the second particles is preferably 1 nm or more, more preferably 2 nm or more, and further preferably 3 nm or more, from the viewpoint that the polishing rate for an insulating material is further improved. The upper limit of the particle size of the second particles is preferably 50 nm or less, more preferably 30 nm or less, further preferably 25 nm or less, particularly preferably 20 nm or less, extremely preferably 15 nm or less, and highly preferably 10 nm or less, from the viewpoint of improving the dispersibility of the abrasive grains and the viewpoint of easily suppressing scratches at a polished surface. From the above-described viewpoints, the particle size of the second particles is more preferably 1 to 50 nm. The average particle size (average secondary particle size) of the second particles may be in the above ranges.

[0046] The average particle size (average secondary particle size) of the abrasive grains (the entire abrasive grains including composite particles) in the slurry or the polishing liquid is preferably in the following range. The lower limit of the average particle size of the abrasive grains is preferably 16 nm or more, more preferably 20 nm or more, further preferably 30 nm or more, particularly preferably 40 nm or more, extremely preferably 50 nm or more, highly preferably 100 nm or more, even more preferably 120 nm or more, further preferably 140 nm or

more, particularly preferably 150 nm or more, and extremely preferably 155 nm or more, from the viewpoint that the polishing rate for an insulating material is further improved. The upper limit of the average particle size of the abrasive grains is preferably 1050 nm or less, more preferably 1000 nm or less, further preferably 800 nm or less, particularly preferably 600 nm or less, extremely preferably 500 nm or less, highly preferably 400 nm or less, even more preferably 300 nm or less, further preferably 200 nm or less, and particularly preferably 160 nm or less, from the viewpoint that the particle size distribution hardly changes, the viewpoint of improving the dispersibility of the abrasive grains, and the viewpoint of easily suppressing scratches at a polished surface. From the above-described viewpoints, the average particle size of the abrasive grains is more preferably 16 to 1050 nm.

[0047] The average particle size can be measured, for example, using a light diffraction scattering type particle size distribution meter (for example, trade name: N5 manufactured by Beckman Coulter, Inc. or trade name: MICROTRAC MT3300EXII manufactured by MicrotracBEL Corp.).

[0048] The BET specific surface area of the first particles is preferably smaller than the BET specific surface area of the second particles from the viewpoint that the polishing rate for an insulating material is further improved. In the first particles having a small BET specific surface area, the crystallite diameter is small and crystallizability is high so that a strong mechanical action (mechanical property) effect with respect to an insulating material is easily obtained. In the second particles having a large BET specific surface area, the reactivity with an insulating

material based on the chemical action (chemical property) is high. In particular, in a case where the second particles contain cerium hydroxide, high reactivity between the second particles and an insulating material is easily obtained by the action of the hydroxyl group. Therefore, it is speculated that the polishing rate for an insulating material is further improved by a synergistic effect obtainable by using the first particles having strong mechanical action and the second particles having strong chemical action.

[0049] The BET specific surface area of the first particles may be in the following range before or after being in contact with the second particles. The BET specific surface area of the first particles may be, for example, 5 m²/g or more, 10 m²/g or more, 15 m²/g or more, and 20 m²/g or more. The BET specific surface area of the first particles is preferably 50 m²/g or less, more preferably 40 m²/g or less, further preferably 30 m²/g or less, and particularly preferably 25 m²/g or less, from the viewpoint that the polishing rate for an insulating material is further improved. The BET specific surface area of the first particles may be 5 to 50 m²/g.

[0050] The BET specific surface area of the second particles may be in the following range before or after being in contact with the first particles. The BET specific surface area of the second particles is preferably 100 m²/g or more, more preferably 150 m²/g or more, further preferably 180 m²/g or more, and particularly preferably 200 m²/g or more, from the viewpoint that the polishing rate for an insulating material is further improved. The BET specific surface area of the second particles may be 500 m²/g or less, 400 m²/g or less, 300 m²/g or

less, and 250 m²/g or less. The BET specific surface area of the second particles may be 100 to 500 m²/g.

[0051] The first particles can have a negative zeta potential. The second particles can have a positive zeta potential. The zeta potential represents the surface potential of a particle. The zeta potential can be measured, for example, using a dynamic light scattering type zeta potential measuring apparatus (for example, trade name: DelsaNano C manufactured by Beckman Coulter, Inc.). The zeta potential of the particles can be adjusted using an additive. For example, by bringing a material having a phosphoric acid group (for example, an inorganic phosphate such as ammonium dihydrogen phosphate, dipotassium hydrogen phosphate, or sodium diphosphate), a material having a carboxyl group (for example, polyacrylic acid), or the like into contact with particles containing cerium oxide, particles having a negative zeta potential can be obtained.

[0052] The first particles contain cerium oxide (for example, ceria) and the second particles contain a cerium compound. Examples of the cerium compound of the second particles include cerium hydroxide and cerium oxide. As the cerium compound of the second particles, a compound different from cerium oxide can be used. The cerium compound preferably contains cerium hydroxide. The abrasive grains containing cerium hydroxide have higher reactivity (chemical action) with an insulating material (for example, silicon oxide) by the action of the hydroxyl group than particles composed of silica, cerium oxide, or the like, and an insulating material can be polished at a higher polishing rate. The cerium hydroxide is, for example, a compound containing

tetravalent cerium (Ce^{4+}) and at least one hydroxide ion (OH^-). The cerium hydroxide may contain an anion (for example, nitrate ion NO_3^- and sulfate ion SO_4^{2-}) other than a hydroxide ion. For example, the cerium hydroxide may also contain an anion (for example, nitrate ion NO_3^- and sulfate ion SO_4^{2-}) bonded to tetravalent cerium.

[0053] The cerium hydroxide can be prepared by reacting a cerium salt with an alkali source (base). The cerium hydroxide is preferably prepared by mixing a cerium salt with an alkali liquid (for example, alkali aqueous solution). Thereby, it is possible to obtain particles having an extremely fine particle size, and easily obtain an excellent effect of reducing polishing scratches. Such a technique is disclosed in, for example, Patent Literatures 3 and 4. The cerium hydroxide can be obtained by mixing a cerium salt solution (for example, a cerium salt aqueous solution) with alkali liquid. Examples of the cerium salt include $\text{Ce}(\text{NO}_3)_4$, $\text{Ce}(\text{SO}_4)_2$, $\text{Ce}(\text{NH}_4)_2(\text{NO}_3)_6$, and $\text{Ce}(\text{NH}_4)_4(\text{SO}_4)_4$.

[0054] It is considered that particles including $\text{Ce}(\text{OH})_a\text{X}_b$ (in the formula, $a + b \times c = 4$) composed of tetravalent cerium (Ce^{4+}), one to three hydroxide ions (OH^-), and one to three anions (X^c) are generated (incidentally, such particles are also "cerium hydroxide") depending on production conditions of cerium hydroxide and the like. It is considered that, in $\text{Ce}(\text{OH})_a\text{X}_b$, an electron-withdrawing anion (X^c) acts to enhance reactivity of the hydroxide ion and the polishing rate is improved with the increase in abundance of $\text{Ce}(\text{OH})_a\text{X}_b$. Examples of the anions (X^c) include NO_3^- and SO_4^{2-} . It is considered that the particles containing cerium hydroxide can contain not only $\text{Ce}(\text{OH})_a\text{X}_b$ but also $\text{Ce}(\text{OH})_4$, CeO_2 , or the like.

[0055] The containing of $\text{Ce}(\text{OH})_a\text{X}_b$ in the particles containing cerium hydroxide can be confirmed by a method for detecting a peak corresponding to the anions (X^c) with FT-IR ATR method (Fourier transform Infra Red Spectrometer Attenuated Total Reflection method) after washing the particles with pure water well. The existence of the anions (X^c) can also be confirmed by XPS method (X-ray Photoelectron Spectroscopy).

[0056] The composite particles including the first particles and the second particles can be obtained by bringing the first particles and the second particles into contact with each other using a homogenizer, a nanomizer, a ball mill, a bead mill, a sonicator, or the like; by bringing the first particles and the second particles each having opposing charges to each other into contact with each other; by bringing the first particles and the second particles into contact with each other in a state of a small content of the particles; or the like.

[0057] According to the present embodiment, it is possible to provide a method for producing abrasive grains, the method including a step of bringing first particles containing cerium oxide into contact with second particles containing a cerium compound. The BET specific surface area before or after contact of the first particles and/or the second particles may be in the aforementioned range. According to the present embodiment, it is possible to provide a method for producing a slurry, the method including a step of obtaining abrasive grains by the aforementioned method for producing abrasive grains.

[0058] The lower limit of the content of cerium oxide in the first particles is preferably 50% by mass or more, more preferably 70% by

mass or more, further preferably 90% by mass or more, and particularly preferably 95% by mass or more, on the basis of the entire first particles (the entire first particles contained in the slurry or the polishing liquid; the same applies hereinafter), from the viewpoint that the polishing rate for an insulating material is further improved. The first particles may be an embodiment substantially composed of cerium oxide (an embodiment in which substantially 100% by mass of the first particles are cerium oxide).

[0059] The lower limit of the content of the cerium compound in the second particles is preferably 50% by mass or more, more preferably 70% by mass or more, further preferably 90% by mass or more, and particularly preferably 95% by mass or more, on the basis of the entire second particles (the entire second particles contained in the slurry or the polishing liquid; the same applies hereinafter), from the viewpoint that the polishing rate for an insulating material is further improved. The second particles may be an embodiment substantially composed of a cerium compound (an embodiment in which substantially 100% by mass of the second particles are a cerium compound).

[0060] The content of the second particles can be estimated on the basis of a value of absorbance of equation below which is obtained by a spectrophotometer when light having a specific wavelength is transmitted through the slurry or the polishing liquid. That is, in a case where particles absorb light having a specific wavelength, the light transmittance of a region containing these particles is decreased. The light transmittance is decreased not only by absorption of the particles but also by scattering, but in the second particles, the influence of

scattering is small. Therefore, in the present embodiment, the content of the second particles can be estimated on the basis of a value of absorbance calculated by equation below.

$$\text{Absorbance} = -\text{LOG}_{10}(\text{Light transmittance [\%]}/100)$$

[0061] The content of the first particles in the abrasive grains is preferably in the following range on the basis of the entire abrasive grains (the entire abrasive grains contained in the slurry or the polishing liquid). The lower limit of the content of the first particles is preferably 50% by mass or more, more preferably more than 50% by mass, further preferably 60% by mass or more, particularly preferably 70% by mass or more, extremely preferably 75% by mass or more, highly preferably 80% by mass or more, and even more preferably 85% by mass or more, from the viewpoint that the polishing rate for an insulating material is further improved. The upper limit of the content of the first particles is preferably 97% by mass or less, more preferably 95% by mass or less, further preferably 93% by mass or less, particularly preferably 90% by mass or less, extremely preferably 88% by mass or less, and highly preferably 86% by mass or less, from the viewpoint that the polishing rate for an insulating material is further improved. From the above-described viewpoints, the content of the first particles is more preferably 50 to 97% by mass.

[0062] The content of the second particles in the abrasive grains is preferably in the following range on the basis of the entire abrasive grains (the entire abrasive grains contained in the slurry or the polishing liquid). The lower limit of the content of the second particles is preferably 3% by mass or more, more preferably 5% by mass or more,

further preferably 7% by mass or more, particularly preferably 10% by mass or more, extremely preferably 12% by mass or more, and highly preferably 14% by mass or more, from the viewpoint that the polishing rate for an insulating material is further improved. The upper limit of the content of the second particles is preferably 50% by mass or less, more preferably less than 50% by mass, further preferably 40% by mass or less, particularly preferably 30% by mass or less, extremely preferably 25% by mass or less, highly preferably 20% by mass or less, and even more preferably 15% by mass or less, from the viewpoint that the polishing rate for an insulating material is further improved. From the above-described viewpoints, the content of the second particles is more preferably 3 to 50% by mass.

[0063] The content of cerium oxide in the abrasive grains is preferably in the following range on the basis of the entire abrasive grains (the entire abrasive grains contained in the slurry or the polishing liquid). The lower limit of the content of cerium oxide is preferably 50% by mass or more, more preferably more than 50% by mass, further preferably 60% by mass or more, particularly preferably 70% by mass or more, extremely preferably 75% by mass or more, highly preferably 80% by mass or more, and even more preferably 85% by mass or more, from the viewpoint that the polishing rate for an insulating material is further improved. The upper limit of the content of cerium oxide is preferably 97% by mass or less, more preferably 95% by mass or less, further preferably 93% by mass or less, particularly preferably 90% by mass or less, extremely preferably 88% by mass or less, and highly preferably 86% by mass or less, from the viewpoint that the polishing

rate for an insulating material is further improved. From the above-described viewpoints, the content of cerium oxide is more preferably 50 to 97% by mass.

[0064] The content of cerium hydroxide in the abrasive grains is preferably in the following range on the basis of the entire abrasive grains (the entire abrasive grains contained in the slurry or the polishing liquid). The lower limit of the content of cerium hydroxide in the abrasive grains is preferably 3% by mass or more, more preferably 5% by mass or more, further preferably 7% by mass or more, particularly preferably 10% by mass or more, extremely preferably 12% by mass or more, and highly preferably 14% by mass or more, from the viewpoint that the polishing rate for an insulating material is further improved. The upper limit of the content of cerium hydroxide in the abrasive grains is preferably 50% by mass or less, more preferably less than 50% by mass, further preferably 40% by mass or less, particularly preferably 30% by mass or less, extremely preferably 25% by mass or less, highly preferably 20% by mass or less, and even more preferably 15% by mass or less, from the viewpoint that the polishing rate for an insulating material is further improved. From the above-described viewpoints, the content of cerium hydroxide in the abrasive grains is more preferably 3 to 50% by mass.

[0065] The content of the first particles in the slurry or the polishing liquid is preferably in the following range on the basis of the total amount of the first particles and the second particles. The lower limit of the content of the first particles is preferably 50% by mass or more, more preferably more than 50% by mass, further preferably 60% by

mass or more, particularly preferably 70% by mass or more, extremely preferably 75% by mass or more, highly preferably 80% by mass or more, and even more preferably 85% by mass or more, from the viewpoint that the polishing rate for an insulating material is further improved. The upper limit of the content of the first particles is preferably 97% by mass or less, more preferably 95% by mass or less, further preferably 93% by mass or less, particularly preferably 90% by mass or less, extremely preferably 88% by mass or less, and highly preferably 86% by mass or less, from the viewpoint that the polishing rate for an insulating material is further improved. From the above-described viewpoints, the content of the first particles is more preferably 50 to 97% by mass.

[0066] The content of the second particles in the slurry or the polishing liquid is preferably in the following range on the basis of the total amount of the first particles and the second particles. The lower limit of the content of the second particles is preferably 3% by mass or more, more preferably 5% by mass or more, further preferably 7% by mass or more, particularly preferably 10% by mass or more, extremely preferably 12% by mass or more, and highly preferably 14% by mass or more, from the viewpoint that the polishing rate for an insulating material is further improved. The upper limit of the content of the second particles is preferably 50% by mass or less, more preferably less than 50% by mass, further preferably 40% by mass or less, particularly preferably 30% by mass or less, extremely preferably 25% by mass or less, highly preferably 20% by mass or less, and even more preferably 15% by mass or less, from the viewpoint that the polishing rate for an

insulating material is further improved. From the above-described viewpoints, the content of the second particles is more preferably 3 to 50% by mass.

[0067] The content of the first particles in the slurry is preferably in the following range on the basis of the total mass of the slurry. The lower limit of the content of the first particles is preferably 0.05% by mass or more, more preferably 0.08% by mass or more, further preferably 0.1% by mass or more, particularly preferably 0.5% by mass or more, extremely preferably 0.8% by mass or more, and highly preferably 1% by mass or more, from the viewpoint that the polishing rate for an insulating material is further improved. The upper limit of the content of the first particles is preferably 10% by mass or less, more preferably 8% by mass or less, further preferably 5% by mass or less, particularly preferably 4% by mass or less, extremely preferably 3% by mass or less, and highly preferably 2% by mass or less, from the viewpoint of enhancing the storage stability of the slurry. From the above-described viewpoints, the content of the first particles is more preferably 0.05 to 10% by mass.

[0068] The content of the first particles in the polishing liquid is preferably in the following range on the basis of the total mass of the polishing liquid. The lower limit of the content of the first particles is preferably 0.005% by mass or more, more preferably 0.008% by mass or more, further preferably 0.01% by mass or more, particularly preferably 0.05% by mass or more, extremely preferably 0.07% by mass or more, and highly preferably 0.08% by mass or more, from the viewpoint that the polishing rate for an insulating material is further

improved. The upper limit of the content of the first particles is preferably 10% by mass or less, more preferably 5% by mass or less, further preferably 1% by mass or less, particularly preferably 0.5% by mass or less, extremely preferably 0.3% by mass or less, highly preferably 0.2% by mass or less, and even more preferably 0.1% by mass or less, from the viewpoint of enhancing the storage stability of the polishing liquid and the viewpoint of easily suppressing scratches at a polished surface. From the above-described viewpoints, the content of the first particles is more preferably 0.005 to 1% by mass.

[0069] The content of the second particles in the slurry is preferably in the following range on the basis of the total mass of the slurry. The lower limit of the content of the second particles is preferably 0.05% by mass or more, more preferably 0.1% by mass or more, further preferably 0.15% by mass or more, particularly preferably 0.2% by mass or more, extremely preferably 0.25% by mass or more, highly preferably 0.275% by mass or more, even more preferably 0.3% by mass or more, further preferably 0.325% by mass or more, and particularly preferably 0.35% by mass or more, from the viewpoint of further enhancing a chemical interaction between the abrasive grains and a surface to be polished so that the polishing rate for an insulating material is further improved. The upper limit of the content of the second particles is preferably 5% by mass or less, more preferably 3% by mass or less, further preferably 1% by mass or less, particularly preferably 0.5% by mass or less, and extremely preferably 0.4% by mass or less, from the viewpoints of easily avoiding the aggregation of the abrasive grains, and easily obtaining a more favorable chemical

interaction between the abrasive grains and a surface to be polished to easily utilize the properties of the abrasive grains effectively. From the above-described viewpoints, the content of the second particles is more preferably 0.05 to 5% by mass.

5 [0070] The content of the second particles in the polishing liquid is preferably in the following range on the basis of the total mass of the polishing liquid. The lower limit of the content of the second particles is preferably 0.001% by mass or more, more preferably 0.003% by mass or more, further preferably 0.005% by mass or more, particularly
10 preferably 0.008% by mass or more, extremely preferably 0.01% by mass or more, highly preferably 0.012% by mass or more, and even more preferably 0.014% by mass or more, from the viewpoint of further enhancing a chemical interaction between the abrasive grains and a surface to be polished so that the polishing rate for an insulating
15 material is further improved. The upper limit of the content of the second particles is preferably 1% by mass or less, more preferably 0.5% by mass or less, further preferably 0.1% by mass or less, particularly preferably 0.05% by mass or less, extremely preferably 0.03% by mass or less, highly preferably 0.02% by mass or less, and even more
20 preferably 0.015% by mass or less, from the viewpoints of easily avoiding the aggregation of the abrasive grains, and easily obtaining a more favorable chemical interaction between the abrasive grains and a surface to be polished to easily utilize the properties of the abrasive grains effectively. From the above-described viewpoints, the content
25 of the second particles is more preferably 0.001 to 1% by mass.

[0071] The content of cerium oxide in the slurry is preferably in the

following range on the basis of the total mass of the slurry. The lower limit of the content of cerium oxide is preferably 0.05% by mass or more, more preferably 0.08% by mass or more, further preferably 0.1% by mass or more, particularly preferably 0.5% by mass or more, extremely preferably 0.8% by mass or more, and highly preferably 1% by mass or more, from the viewpoint that the polishing rate for an insulating material is further improved. The upper limit of the content of cerium oxide is preferably 10% by mass or less, more preferably 8% by mass or less, further preferably 5% by mass or less, particularly preferably 4% by mass or less, extremely preferably 3% by mass or less, and highly preferably 2% by mass or less, from the viewpoint of enhancing the storage stability of the slurry. From the above-described viewpoints, the content of cerium oxide is more preferably 0.05 to 10% by mass.

[0072] The content of cerium oxide in the polishing liquid is preferably in the following range on the basis of the total mass of the polishing liquid. The lower limit of the content of cerium oxide is preferably 0.005% by mass or more, more preferably 0.008% by mass or more, further preferably 0.01% by mass or more, particularly preferably 0.05% by mass or more, extremely preferably 0.07% by mass or more, and highly preferably 0.08% by mass or more, from the viewpoint that the polishing rate for an insulating material is further improved. The upper limit of the content of cerium oxide is preferably 10% by mass or less, more preferably 5% by mass or less, further preferably 1% by mass or less, particularly preferably 0.5% by mass or less, extremely preferably 0.3% by mass or less, highly preferably 0.2% by mass or

less, and even more preferably 0.1% by mass or less, from the viewpoint of enhancing the storage stability of the polishing liquid and the viewpoint of easily suppressing scratches at a polished surface. From the above-described viewpoints, the content of cerium oxide is more preferably 0.005 to 1% by mass.

[0073] The content of cerium hydroxide in the slurry is preferably in the following range on the basis of the total mass of the slurry. The lower limit of the content of cerium hydroxide is preferably 0.05% by mass or more, more preferably 0.1% by mass or more, further preferably 0.15% by mass or more, particularly preferably 0.2% by mass or more, extremely preferably 0.25% by mass or more, highly preferably 0.275% by mass or more, even more preferably 0.3% by mass or more, further preferably 0.325% by mass or more, and particularly preferably 0.35% by mass or more, from the viewpoint of further enhancing a chemical interaction between the abrasive grains and a surface to be polished so that the polishing rate for an insulating material is further improved. The upper limit of the content of cerium hydroxide is preferably 5% by mass or less, more preferably 3% by mass or less, further preferably 1% by mass or less, particularly preferably 0.5% by mass or less, and extremely preferably 0.4% by mass or less, from the viewpoints of easily avoiding the aggregation of the abrasive grains, and easily obtaining a more favorable chemical interaction between the abrasive grains and a surface to be polished to easily utilize the properties of the abrasive grains effectively. From the above-described viewpoints, the content of cerium hydroxide is more preferably 0.05 to 5% by mass.

[0074] The content of cerium hydroxide in the polishing liquid is preferably in the following range on the basis of the total mass of the polishing liquid. The lower limit of the content of cerium hydroxide is preferably 0.001% by mass or more, more preferably 0.003% by mass or more, further preferably 0.005% by mass or more, particularly preferably 0.008% by mass or more, extremely preferably 0.01% by mass or more, highly preferably 0.012% by mass or more, and even more preferably 0.014% by mass or more, from the viewpoint of further enhancing a chemical interaction between the abrasive grains and a surface to be polished so that the polishing rate for an insulating material is further improved. The upper limit of the content of cerium hydroxide is preferably 1% by mass or less, more preferably 0.5% by mass or less, further preferably 0.1% by mass or less, particularly preferably 0.05% by mass or less, extremely preferably 0.03% by mass or less, highly preferably 0.02% by mass or less, and even more preferably 0.015% by mass or less, from the viewpoints of easily avoiding the aggregation of the abrasive grains, and easily obtaining a more favorable chemical interaction between the abrasive grains and a surface to be polished to easily utilize the properties of the abrasive grains effectively. From the above-described viewpoints, the content of cerium hydroxide is more preferably 0.001 to 1% by mass.

[0075] The content of the abrasive grains in the slurry is preferably in the following range on the basis of the total mass of the slurry. The lower limit of the content of the abrasive grains is preferably 0.01% by mass or more, more preferably 0.05% by mass or more, further preferably 0.1% by mass or more, particularly preferably 0.5% by mass

or more, extremely preferably 1% by mass or more, highly preferably 1.5% by mass or more, even more preferably 2% by mass or more, further preferably 2.1% by mass or more, particularly preferably 2.2% by mass or more, extremely preferably 2.3% by mass or more, and
5 highly preferably 2.35% by mass or more, from the viewpoint that the polishing rate for an insulating material is further improved. The upper limit of the content of the abrasive grains is preferably 10% by mass or less, more preferably 8% by mass or less, further preferably 5% by mass or less, particularly preferably 4% by mass or less, and
10 extremely preferably 3% by mass or less, from the viewpoint of enhancing the storage stability of the slurry. From the above-described viewpoints, the content of the abrasive grains is more preferably 0.01 to 10% by mass.

[0076] The content of the abrasive grains in the polishing liquid is
15 preferably in the following range on the basis of the total mass of the polishing liquid. The lower limit of the content of the abrasive grains is preferably 0.01% by mass or more, more preferably 0.02% by mass or more, further preferably 0.03% by mass or more, particularly preferably 0.05% by mass or more, extremely preferably 0.08% by mass
20 or more, and highly preferably 0.1% by mass or more, from the viewpoint that the polishing rate for an insulating material is further improved. The upper limit of the content of the abrasive grains is preferably 10% by mass or less, more preferably 5% by mass or less, further preferably 3% by mass or less, particularly preferably 1% by
25 mass or less, extremely preferably 0.5% by mass or less, highly preferably 0.3% by mass or less, and even more preferably 0.2% by

mass or less, from the viewpoint of enhancing the storage stability of the polishing liquid and the viewpoint of easily suppressing scratches at a polished surface. From the above-described viewpoints, the content of the abrasive grains is more preferably 0.01 to 10% by mass.

5 [0077] The slurry or the polishing liquid of the present embodiment may contain particles other than the composite particles including the first particles and the second particles. Examples of such other particles include the first particles not in contact with the second particles; the second particles not in contact with the first particles; and
10 third particles composed of silica, alumina, zirconia, yttria, or the like (particles not including the first particles and the second particles).

[0078] (Liquid medium)

The liquid medium is not particularly limited; however, water such as deionized water or ultrapure water is preferred. The content of
15 the liquid medium may be the balance of the slurry or the polishing liquid remaining after excluding the contents of other constituent components, and the content is not particularly limited.

[0079] (Optional components)

The slurry or the polishing liquid of the present embodiment
20 may further contain optional additives. Examples of the optional additives include a material having a carboxyl group (excluding a compound corresponding to a polyoxyalkylene compound or a water-soluble polymer), a polyoxyalkylene compound, a water-soluble polymer, an oxidizing agent (for example, hydrogen peroxide), and a
25 dispersant (for example, a phosphoric acid-based inorganic salt). The respective additives can be used singly or in combination of two or

more kinds thereof.

[0080] Examples of the material having a carboxyl group include monocarboxylic acids such as acetic acid, propionic acid, butyric acid, and valeric acid; hydroxy acids such as lactic acid, malic acid, and citric acid; dicarboxylic acids such as malonic acid, succinic acid, fumaric acid, and maleic acid; polycarboxylic acids such as polyacrylic acid and polymaleic acid; and amino acids such as arginine, histidine, and lysine.

[0081] Examples of the polyoxyalkylene compound include a polyalkylene glycol and a polyoxyalkylene derivative.

[0082] Examples of the polyalkylene glycol include polyethylene glycol, polypropylene glycol, and polybutylene glycol. The polyalkylene glycol is preferably at least one selected from the group consisting of polyethylene glycol and polypropylene glycol, and is more preferably polyethylene glycol.

[0083] A polyoxyalkylene derivative is, for example, a compound obtained by introducing a functional group or a substituent to a polyalkylene glycol, or a compound obtained by adding a polyalkylene oxide to an organic compound. Examples of the functional group or a substituent include an alkyl ether group, an alkyl phenyl ether group, a phenyl ether group, a styrenated phenyl ether group, a glyceryl ether group, an alkylamine group, a fatty acid ester group, and a glycol ester group. Examples of the polyoxyalkylene derivative include a polyoxyethylene alkyl ether, polyoxyethylene bisphenol ether (for example, manufactured by NIPPON NYUKAZAI CO., LTD., BA GLYCOL series), polyoxyethylene styrenated phenyl ether (for example, manufactured by Kao Corporation, EMULGEN series), a

polyoxyethylene alkyl phenyl ether (for example, manufactured by DKS Co. Ltd., NOIGEN EA series), a polyoxyalkylene polyglyceryl ether (for example, manufactured by Sakamoto Yakuhin Kogyo Co., Ltd., SC-E series and SC-P series), a polyoxyethylene sorbitan fatty acid ester (for example, manufactured by DKS Co. Ltd., SORGEN TW series), a polyoxyethylene fatty acid ester (for example, manufactured by Kao Corporation, EMANON series), a polyoxyethylene alkylamine (for example, manufactured by DKS Co. Ltd., AMIRADIN D), and other compounds having a polyalkylene oxide added thereto (for example, manufactured by Nissin Chemical Co., Ltd., SURFINOL 465, and manufactured by NIPPON NYUKAZAI CO., LTD., TMP series).

[0084] The "water-soluble polymer" is defined as a polymer which is dissolved in 100 g of water in an amount of 0.1 g or more. A polymer that corresponds to the polyoxyalkylene compound is not to be included in the "water-soluble polymer". The water-soluble polymer is not particularly limited, and examples include acrylic polymers such as polyacrylamide and polydimethylacrylamide; polysaccharides such as carboxymethyl cellulose, agar, curdlan, dextrin, cyclodextrin, and pullulan; vinyl-based polymers such as polyvinyl alcohol, polyvinylpyrrolidone, and polyacrolein; glycerin-based polymers such as polyglycerin and a polyglycerin derivative; and polyethylene glycol.

[0085] (Characteristics of slurry or polishing liquid)

The lower limit of the pH of the slurry or the polishing liquid of the present embodiment is preferably 2.0 or more, more preferably 2.5 or more, further preferably 2.8 or more, particularly preferably 3.0 or more, extremely preferably 3.2 or more, highly preferably 3.5 or more,

even more preferably 4.0 or more, further preferably 4.2 or more, and particularly preferably 4.3 or more, from the viewpoint that the polishing rate for an insulating material is further improved. The upper limit of the pH is preferably 7.0 or less, more preferably 6.5 or less, further preferably 6.0 or less, particularly preferably 5.0 or less, extremely preferably 4.8 or less, highly preferably 4.7 or less, even more preferably 4.6 or less, further preferably 4.5 or less, and particularly preferably 4.4 or less, from the viewpoint that the storage stability of the slurry or the polishing liquid is further improved. From the above-described viewpoints, the pH is more preferably 2.0 to 7.0. The pH is defined as the pH at a liquid temperature of 25°C.

[0086] The pH can be adjusted by means of an acid component such as an inorganic acid or an organic acid; an alkali component such as ammonia, sodium hydroxide, tetramethylammonium hydroxide (TMAH), imidazole, or an alkanolamine; or the like. A buffering agent may be added in order to stabilize the pH. A buffering agent may be added as a buffer solution (a liquid containing a buffering agent). Examples of such a buffer solution include an acetate buffer solution and a phthalate buffer solution.

[0087] The pH can be measured by a pH meter (for example, Model No. PHL-40 manufactured by DKK-TOA CORPORATION). Specifically, for example, a pH meter is subjected to two-point calibration using a phthalate pH buffer solution (pH: 4.01) and a neutral phosphate pH buffer solution (pH: 6.86) as standard buffer solutions, subsequently the electrode of the pH meter is introduced into the slurry or the polishing liquid, and the value after being stabilized after a lapse

of two minutes or longer is measured. Both of the liquid temperatures are set to 25°C.

[0088] In a case where the slurry or the polishing liquid of the present embodiment is used as a CMP polishing liquid, the constituent components of the polishing liquid may be stored as a one-pack polishing liquid, or may be stored as a multi-pack (for example, two-pack) polishing liquid set in which the constituent components of the polishing liquid are divided into a first liquid and a second liquid such that the first liquid containing abrasive grains and a liquid medium, and the second liquid (additive liquid) containing additives and a liquid medium are mixed to form the polishing liquid. The second liquid may contain, for example, an oxidizing agent. The constituent components of the polishing liquid may be stored as a polishing liquid set divided into three or more liquids.

[0089] In the polishing liquid set, the first liquid and the second liquid are mixed immediately before polishing or during polishing to prepare the polishing liquid. Furthermore, a one-pack polishing liquid may be stored as a stock solution for a polishing liquid with a reduced liquid medium content and used by dilution with a liquid medium at the time of polishing. A multi-pack polishing liquid set may be stored as a stock solution for a first liquid and a stock solution for a second liquid with reduced liquid medium contents, and used by dilution with a liquid medium at the time of polishing.

[0090] <Polishing method>

A first embodiment of the polishing method (such as a polishing method of a base substrate) of the present embodiment includes a step

of polishing a surface to be polished by using a polishing liquid obtained by the above-described method for producing a polishing liquid. A second embodiment of the polishing method (such as a polishing method of a base substrate) of the present embodiment includes a polishing step of polishing a surface to be polished (such as a surface to be polished of a base substrate) by using the above-described slurry (the slurry before filtration) as a polishing liquid. According to the present embodiment, a high polishing rate for an insulating material can be achieved. The slurry of the present embodiment can be used as, for example, a polishing liquid (CMP polishing liquid). The polishing liquid in the polishing step may be a polishing liquid obtained by mixing the first liquid and the second liquid of the above-described polishing liquid set. The surface to be polished contains, for example, silicon oxide.

[0091] According to the present embodiment, it is possible to provide use of a slurry or a polishing liquid in polishing of a surface to be polished containing silicon oxide. According to the present embodiment, it is possible to provide use of a slurry or a polishing liquid in a flattening step of a base substrate surface that is the manufacturing technology of semiconductor elements. According to the present embodiment, it is possible to provide use of a slurry or a polishing liquid in a flattening step of STI insulating materials, pre-metal insulating materials, or interlayer insulating materials.

[0092] In the polishing step, for example, in a state where a material to be polished of the base substrate that has the material to be polished is pressed against a polishing pad (polishing cloth) of a polishing platen,

the slurry or the polishing liquid is supplied between the material to be polished and the polishing pad, and the base substrate and the polishing platen are moved relative to each other to polish the surface to be polished of the material to be polished. In the polishing step, for example, at least a part of a material to be polished is removed by polishing.

[0093] As the base substrate that is to be polished, a substrate to be polished or the like is exemplified. As the substrate to be polished, for example, a base substrate in which a material to be polished is formed on a substrate for semiconductor element production (for example, a semiconductor substrate in which an STI pattern, a gate pattern, a wiring pattern, or the like is formed) is exemplified. Examples of the material to be polished include an insulating material such as silicon oxide. The material to be polished may be a single material or a plurality of materials. In a case where a plurality of materials are exposed on a surface to be polished, they can be considered as a material to be polished. The material to be polished may be in the form of a film (film to be polished) or may be an insulating film such as a silicon oxide film.

[0094] By polishing a material to be polished (for example, an insulating material such as silicon oxide) formed on such a substrate with the slurry or the polishing liquid and removing an excess part, it is possible to eliminate irregularities on the surface of a material to be polished and to produce a smooth surface over the entire surface of the polished material.

[0095] In the polishing method of the present embodiment, as a

polishing apparatus, it is possible to use a common polishing apparatus which has a holder capable of holding a base substrate having a surface to be polished and a polishing platen to which a polishing pad can be pasted. A motor or the like in which the number of rotations can be changed is attached to each of the holder and the polishing platen. As the polishing apparatus, for example, polishing apparatus: F-REX300 manufactured by EBARA CORPORATION, or polishing apparatus: MIRRA manufactured by Applied Materials, Inc. can be used.

[0096] As the polishing pad, common unwoven cloth, a foamed body, an unfoamed body, and the like can be used. As the material for the polishing pad, it is possible to use a resin such as polyurethane, an acrylic resin, polyester, an acrylic-ester copolymer, polytetrafluoroethylene, polypropylene, polyethylene, poly-4-methylpentene, cellulose, cellulose ester, polyamide (for example, Nylon (trade name) and aramid), polyimide, polyimidamide, a polysiloxane copolymer, an oxirane compound, a phenolic resin, polystyrene, polycarbonate, or an epoxy resin. Particularly, from the viewpoint of obtaining further excellent polishing rate and flattening properties, the material for the polishing pad is preferably at least one selected from the group consisting of a foamed polyurethane and a non-foamed polyurethane. It is preferable that the polishing pad is subjected to groove processing, by which the slurry or the polishing liquid accumulates thereon.

[0097] Polishing conditions are not limited, but the upper limit of the rotation speed of a polishing platen is preferably 200 min^{-1} ($\text{min}^{-1} = \text{rpm}$) or less such that the base substrate is not let out, and the upper

limit of the polishing pressure to be applied to the base substrate (processing load) is preferably 100 kPa or less from the viewpoint of easily suppressing the generation of polishing scratches. The slurry or the polishing liquid is preferably continuously supplied to the polishing pad with a pump or the like during polishing. There are no limitations on the supply amount for this, however, it is preferable that the surface of the polishing pad is always covered with the slurry or the polishing liquid.

[0098] The present embodiment is preferably used for polishing a surface to be polished containing silicon oxide. The present embodiment can be suitably used in formation of an STI and polishing of an interlayer insulating material at a high rate. The lower limit of the polishing rate for an insulating material (for example, silicon oxide) is preferably 150 nm/min or more, more preferably 200 nm/min or more, further preferably 300 nm/min or more, and particularly preferably 400 nm/min or more.

[0099] The present embodiment can also be used in polishing of a pre-metal insulating material. Examples of the pre-metal insulating material include silicon oxide, phosphorus-silicate glass, boron-phosphorus-silicate glass, silicon oxyfluoride, and fluorinated amorphous carbon.

[0100] The present embodiment can also be applied to materials other than the insulating material such as silicon oxide. Examples of such a material include high permittivity materials such as Hf-based, Ti-based, and Ta-based oxides; semiconductor materials such as silicon, amorphous silicon, SiC, SiGe, Ge, GaN, GaP, GaAs, and organic

semiconductors; phase-change materials such as GeSbTe; inorganic electroconductive materials such as ITO; and polymer resin materials such as polyimide-based, polybenzoxazole-based, acrylic, epoxy-based, and phenol-based materials.

5 [0101] The present embodiment can be applied not only to film-like objects to be polished, but also to various types of substrates made of glass, silicon, SiC, SiGe, Ge, GaN, GaP, GaAs, sapphire, plastics, or the like.

10 [0102] The present embodiment can be used not only for the production of semiconductor elements, but also for the production of image display devices such as TFT or organic EL; optical components such as a photomask, a lens, a prism, an optical fiber, or a single crystal scintillator; optical elements such as an optical switching element or an optical waveguide; light-emitting elements such as a solid laser or a
15 blue laser LED; and magnetic storage devices such as a magnetic disc or a magnetic head.

Examples

20 [0103] Hereinafter, the present invention will be specifically described based on Examples; however, the present invention is not limited to the following Examples.

[0104] <Preparation of cerium oxide slurry>

25 Particles containing cerium oxide (first particles; hereinafter, referred to as "cerium oxide particles"; cerium oxide particles A) and trade name: ammonium dihydrogen phosphate manufactured by Wako Pure Chemical Industries, Ltd. (molecular weight: 97.99) were mixed to prepare a cerium oxide slurry A (pH: 7) containing 5.0% by mass (solid

content amount) of the cerium oxide particles. The mixing amount of the ammonium dihydrogen phosphate was adjusted to 1% by mass on the basis of the total amount of the cerium oxide particles.

[0105] An adequate amount of the cerium oxide slurry A was introduced into trade name: MICROTRAC MT3300EXII manufactured by MicrotracBEL Corp., and the average particle size of the cerium oxide particles was measured. The displayed average particle size value was obtained as the average particle size (average secondary particle size). The average particle size of the cerium oxide particles in the cerium oxide slurry A was 145 nm.

[0106] An adequate amount of the cerium oxide slurry A was introduced into trade name: DelsaNano C manufactured by Beckman Coulter, Inc. and measurement was performed twice at 25°C. The average value of the displayed zeta potentials was obtained as the zeta potential. The zeta potential of the cerium oxide particles in the cerium oxide slurry A was -55 mV.

[0107] 100 g of the cerium oxide slurry A was introduced into a centrifugal separator (trade name: himac CR7) manufactured by Hitachi Koki Co., Ltd. and then subjected to centrifugal separation for 30 minutes at a centrifugal acceleration of 1.1×10^4 G. The supernatant solution was removed, the solid phase was vacuum-dried, and then the solid phase was pulverized by using a mortar to obtain finer-grained powder. After this powder was introduced into a vacuum measurement cell (volume: 1.5 cm^3), the amount of adsorption of nitrogen gas in 77.35 K was measured by using a specific surface area/fine pore size analysis device (trade name: QUADRASORB evo)

manufactured by Quantachrome Instruments to thereby obtain a BET specific surface area (m^2/g). The BET specific surface area was $22.9 \text{ m}^2/\text{g}$.

[0108] <Preparation of cerium hydroxide slurry>

5 (Synthesis of cerium hydroxide)

480 g of an aqueous 50% by mass $\text{Ce}(\text{NH}_4)_2(\text{NO}_3)_6$ solution (trade name: CAN50 liquid manufactured by Nihon Kagaku Sangyo Co., Ltd.) was mixed with 7450 g of pure water to obtain a solution. Next, while this solution was stirred, 750 g of an aqueous solution of imidazole (10% by mass aqueous solution, 1.47 mol/L) was added dropwise thereto at a mixing rate of 5 mL/min , and thereby a precipitate containing cerium hydroxide was obtained. The cerium hydroxide was synthesized at a temperature of 20°C and a stirring speed of 500 min^{-1} . The stirring was performed using a 3-blade pitch paddle with a total blade section length of 5 cm.

[0109] The obtained precipitate (precipitate containing cerium hydroxide) was subjected to centrifugal separation (4000 min^{-1} , for 5 minutes), and then subjected to solid-liquid separation with removal of a liquid phase by decantation. 10 g of the particles obtained by solid-liquid separation were mixed with 990 g of water, and then the particles were dispersed in water using an ultrasonic cleaner, thereby preparing a cerium hydroxide slurry (content of particles: 1.0% by mass) containing particles that contained cerium hydroxide (second particles; hereinafter, referred to as "cerium hydroxide particles").

25 [0110] (Measurement of average particle size)

When the average particle size (average secondary particle size)

of the cerium hydroxide particles in the cerium hydroxide slurry was measured using trade name: N5 manufactured by Beckman Coulter, Inc., a value of 10 nm was obtained. The measuring method was as follows. First, about 1 mL of a measuring sample (cerium hydroxide slurry, aqueous dispersion liquid) containing 1.0% by mass of cerium hydroxide particles was introduced into a 1-cm square cell, and then the cell was placed in the N5. Measurement was performed at 25°C with the refractive index set to 1.333 and the viscosity set to 0.887 mPa·s as the measuring sample information of N5 software, and the value displayed as Unimodal Size Mean was read off.

[0111] (Measurement of zeta potential)

An adequate amount of the cerium hydroxide slurry was introduced into trade name: DelsaNano C manufactured by Beckman Coulter, Inc. and measurement was performed twice at 25°C. The average value of the displayed zeta potentials was obtained as the zeta potential. The zeta potential of the cerium hydroxide particles in the cerium hydroxide slurry was +50 mV.

[0112] 7 g of the cerium hydroxide slurry was introduced into a tube having a size of 1.6 cm (inner diameter) × 7.6 cm (length). Next, the tube was set in a centrifugal separator (trade name: Optima MAX-TL) manufactured by Beckman Coulter, Inc., and then centrifugal separation was performed for 60 minutes at a centrifugal acceleration of 2.9×10^5 G and a setting temperature of 25°C so as to separate the supernatant solution and the solid phase. The supernatant solution was removed, the solid phase was vacuum-dried, and then the solid phase was pulverized by using a mortar to obtain finer-grained powder. After this

powder was introduced into a vacuum measurement cell (volume: 1.5 cm³), the amount of adsorption of nitrogen gas in 77.35 K was measured by using a specific surface area/fine pore size analysis device (trade name: QUADRASORB evo) manufactured by Quantachrome Instruments to thereby obtain a BET specific surface area (m²/g). The BET specific surface area was 212 m²/g.

[0113] (Structural analysis of cerium hydroxide particles)

An adequate amount of the cerium hydroxide slurry was taken and vacuum-dried to isolate the cerium hydroxide particles, and then, sufficiently washed with pure water to obtain a sample. When the obtained sample was measured by FT-IR ATR method, a peak based on nitrate ion (NO₃⁻) was observed in addition to a peak based on hydroxide ion (OH⁻). Furthermore, when the same sample was measured by XPS (N-XPS) for nitrogen, a peak based on nitrate ion was observed while no peak based on NH₄⁺ was observed. These results confirmed that the cerium hydroxide particles at least partially contained particles having nitrate ion bonded to a cerium element. Furthermore, since particles having hydroxide ion bonded to a cerium element were at least partially contained in the cerium hydroxide particles, it was confirmed that the cerium hydroxide particles contained cerium hydroxide. These results confirmed that the cerium hydroxide contained a hydroxide ion bonded to a cerium element.

[0114] <Preparation of slurry>

(Example 1)

While stirring at a rotation speed of 300 rpm using a stirring blade of two blades, 150 g of the cerium hydroxide slurry and 150 g of

ion-exchange water were mixed to obtain a mixed liquid. Subsequently, after mixing 200 g of the cerium oxide slurry A in the mixed liquid while stirring the mixed liquid, stirring was performed while being irradiated with ultrasonic waves using an ultrasonic cleaner (device name: US-105) manufactured by SND Co., Ltd. Thereby, a test slurry containing composite particles including cerium oxide particles and cerium hydroxide particles that were in contact with the cerium oxide particles (content of cerium oxide particles: 2.0% by mass, content of cerium hydroxide particles: 0.3% by mass) was prepared.

[0115] (Example 2)

By mixing cerium oxide particles (cerium oxide particles B different from the cerium oxide particles A), trade name: polyacrylic acid 5000 (weight average molecular weight: 5000) manufactured by Wako Pure Chemical Industries, Ltd., and ion-exchange water, a cerium oxide slurry B (content of cerium oxide particles: 5.0% by mass) was prepared. The mixing amount of the polyacrylic acid was adjusted to 1% by mass on the basis of the total amount of the cerium oxide particles. Similarly to the cerium oxide slurry A, the average particle size and the zeta potential of the cerium oxide particles in the cerium oxide slurry B were measured, and the average particle size and the zeta potential were 145 nm and -55 mV, respectively.

[0116] The same operation as in Example 1 was performed, except that the cerium oxide slurry B was used instead of the cerium oxide slurry A, and thereby a test slurry containing composite particles including cerium oxide particles and cerium hydroxide particles in contact with the cerium oxide particles (content of cerium oxide particles: 2.0% by

mass, content of cerium hydroxide particles: 0.3% by mass) was prepared.

[0117] (Example 3)

The same operation as in Example 1 was performed, except that the amount of the cerium hydroxide slurry used was changed, and thereby a test slurry containing composite particles including cerium oxide particles and cerium hydroxide particles in contact with the cerium oxide particles (content of cerium oxide particles: 2.0% by mass, content of cerium hydroxide particles: 0.13% by mass) was prepared.

[0118] (Example 4)

The same operation as in Example 1 was performed, except that the amount of the cerium hydroxide slurry used was changed, and thereby a test slurry containing composite particles including cerium oxide particles and cerium hydroxide particles in contact with the cerium oxide particles (content of cerium oxide particles: 2.0% by mass, content of cerium hydroxide particles: 0.07% by mass) was prepared.

[0119] (Comparative Example 1)

By mixing the cerium oxide slurry A and ion-exchange water, a test slurry containing cerium oxide particles (content of cerium oxide particles: 2.0% by mass) was prepared.

[0120] (Comparative Example 2)

By mixing the cerium oxide slurry B and ion-exchange water, a test slurry containing cerium oxide particles (content of cerium oxide particles: 2.0% by mass) was prepared.

[0121] (Comparative Example 3)

By mixing cerium oxide particles (cerium oxide particles C

different from the cerium oxide particles A and B), acetic acid (manufactured by Wako Pure Chemical Industries, Ltd.), and ion-exchange water, a test slurry containing cerium oxide particles (content of cerium oxide particles: 2.0% by mass) was prepared. The mixing amount of the acetic acid was 1.0% by mass on the basis of the total amount of the cerium oxide particles.

[0122] (Comparative Example 4)

By mixing colloidal ceria particles having a primary particle size of 50 nm (cerium oxide particles D different from the cerium oxide particles A, B, and C) and ion-exchange water, a test slurry containing cerium oxide particles (content of cerium oxide particles: 2.0% by mass (solid content amount)) was prepared.

[0123] (Comparative Example 5)

The same operation as in Example 1 was performed, except that the amount of the cerium hydroxide slurry used was changed, and thereby a test slurry containing composite particles including cerium oxide particles and cerium hydroxide particles in contact with the cerium oxide particles (content of cerium oxide particles: 2.0% by mass, content of cerium hydroxide particles: 0.01% by mass) was prepared.

[0124] <Average particle size of abrasive grains>

Each of the test slurries mentioned above was introduced in an adequate amount into trade name: MICROTRAC MT3300EXII manufactured by MicrotracBEL Corp., and measurement of the average particle size of the abrasive grains was performed. The displayed average particle size value was obtained as the average particle size (average secondary particle size) of the abrasive grains. The

measurement results are shown in Table 1.

[0125] <BET specific surface area of solid phase>

(Preparation of particulate powder)

The content of the abrasive grains of the test slurry was adjusted with ion-exchange water as necessary, and thereby a measuring sample having a content of the abrasive grains (the total amount of the abrasive grains) of 2.0% by mass was obtained. Next, 100 g of the measuring sample was introduced into a centrifugal separator (trade name: himac CR7) manufactured by Hitachi Koki Co., Ltd. and then subjected to centrifugal separation for 30 minutes at a centrifugal acceleration of 1.1×10^4 G. The supernatant solution was removed, and then the solid phase was vacuum-dried. Then, the solid phase was pulverized by using a mortar to obtain finer-grained powder (particulate powder).

[0126] (Measurement of BET specific surface area)

After the aforementioned powder was introduced into a vacuum measurement cell (volume: 1.5 cm^3), the amount of adsorption of nitrogen gas in 77.35 K was measured by using a specific surface area/fine pore size analysis device (trade name: QUADRASORB evo) manufactured by Quantachrome Instruments to thereby obtain a BET specific surface area (m^2/g). An average value of two measurements was obtained as the BET specific surface area of the abrasive grains. The measurement results are shown in Table 1.

[0127] <Removal rate of coarse particles>

(Filtration of slurry)

The content of the abrasive grains of the test slurry was adjusted with ion-exchange water as necessary, and thereby 200 g of a measuring

sample having a content of the abrasive grains (the total amount of the abrasive grains) of 2.0% by mass was prepared. The aforementioned measuring sample was introduced into a cylindrical simple filtration apparatus in which a 47-mm ϕ disk filter (trade name: SCP-005, filtering material: polypropylene, nominal pore size: 0.5 μ m) manufactured by ROKI TECHNO CO., LTD. is set, the measuring sample was then pressure-fed at 0.2 MPa, and thereby the measuring sample (filtrate) passing through the filter was recovered. Without performing a circulation treatment, the filtration was performed by causing the slurry to pass through a single filter once.

[0128] (Measurement of removal rate)

By adding 10 g of the measuring sample (each measuring sample before and after filtration) and 90 g of ion-exchange water to a 100-mL container, the measuring sample was diluted 10-fold, and then the container was set in a mix rotor. From the viewpoint of adjusting to a range below the measurement limit of the upper limit of the number of coarse particles in the measuring apparatus, the measuring sample was diluted as described above. Next, stirring was performed for 10 minutes at a rotation speed of 100 rpm. Subsequently, the container was gently set in a light interception type liquid-borne particle sensor (device name: KS-71) manufactured by RION Co., Ltd., and then the number of coarse particles (LPC: Large Particle Counts, an average value of measurement at five times) having a size (particle size) of 3 μ m or more at each time before and after filtration was measured under the following measurement conditions. The removal rate of coarse particles (Removal rate of coarse particles [%] = (1 - (LPC after

filtration [number/mL])/(LPC before filtration [number/mL])) × 100)
was calculated on the basis of the number of coarse particles before and
after filtration of the measuring sample. The measurement results are
shown in Table 1.

5 Measurement flow rate: 10 mL/times

Flow rate: 60 mL/min

Number of times of measurement: 5 times

[0129] Incidentally, as a result of measuring the removal rate of coarse
particles under the same conditions as described above with respect to
10 ion-exchange water used in adjustment of the content of the abrasive
grains after performing the filtration, it was confirmed that the removal
rate of coarse particles was 50% or less, and the content of the coarse
particles in the ion-exchange water was small. Thereby, it was
confirmed that the LPC is not more overrated than the true value by the
15 coarse particles in the ion-exchange water used in preparation of a
measuring sample for the removal rate and mixing of foreign substances
adhering to the container.

[0130] <CMP evaluation>

Ion-exchange water was added to the filtrate obtained by
20 performing the same filtration as described above, and thereby a CMP
polishing liquid having a content of the abrasive grains (the total
amount of the abrasive grains) of 0.1% by mass was obtained. The
substrate to be polished was polished by using this CMP polishing
liquid under the polishing conditions below.

25 [CMP polishing conditions]

Polishing apparatus: MIRRA (manufactured by Applied

Materials, Inc.)

Flow rate of polishing liquid: 200 mL/min

Substrate to be polished: As a blanket wafer having no pattern formed thereon, a substrate to be polished having a silicon oxide film having a thickness of 2 μm , which had been formed by a plasma CVD method, on a silicon substrate was used.

Polishing pad: Foamed polyurethane resin having closed pores (manufactured by Dow Chemical Japan Ltd., Product No.: IC1010)

Polishing pressure: 13 kPa (2.0 psi)

Rotation numbers of substrate to be polished and polishing platen: Substrate to be polished/polishing platen = 93/87 rpm

Polishing time: 1 minute

Washing of wafer: After a CMP treatment, washing was performed with water while applying an ultrasonic wave, and then drying was performed with a spin dryer.

[0131] The polishing rate for a silicon oxide film (SiO_2RR) that had been polished and washed under the above-described conditions was obtained by the formula below. The results are shown in Table 1. The film thickness difference of the silicon oxide film before and after polishing was obtained using a light interference type film thickness measuring apparatus (trade name: F80 manufactured by Filmetrics Japan, Inc.).

Polishing rate (RR) = (Film thickness difference [nm] of silicon oxide film before and after polishing)/(Polishing time: 1 [min])

[0132] [Table 1]

	Example				Comparative Example				
	1	2	3	4	1	2	3	4	5
Abrasive grains	Composite particles				Ceria particles				
Average particle size (nm)	155	155	155	155	145	145	140	140	155
BET specific surface area (m ² /g)	42.2	39.1	31.4	28.7	22.9	22.7	18.4	14.8	23.9
Removal rate of coarse particles (%)	97	91	82	77	48	32	24	20	56
Polishing rate (nm/min)	401	388	204	199	245	221	480	442	211

CLAIMS

1. A slurry comprising abrasive grains and a liquid medium,
wherein
the abrasive grains include first particles and second particles in
5 contact with the first particles,
the first particles contain cerium oxide,
the second particles contain a cerium compound, and
in a case where a content of the abrasive grains is 2.0% by mass,
a BET specific surface area of a solid phase obtained when the slurry is
10 subjected to centrifugal separation for 30 minutes at a centrifugal
acceleration of 1.1×10^4 G is $24 \text{ m}^2/\text{g}$ or more.
2. The slurry according to claim 1, wherein the cerium compound
contains cerium hydroxide.
3. The slurry according to claim 1 or 2, wherein an average particle
15 size of the abrasive grains is 16 to 1050 nm.
4. The slurry according to any one of claims 1 to 3, wherein a
content of the abrasive grains is 0.01 to 10% by mass.
5. A method for producing a polishing liquid, the method
comprising a step of filtering the slurry according to any one of claims 1
20 to 4.
6. A polishing method comprising a step of polishing a surface to
be polished by using a polishing liquid obtained by the method for
producing a polishing liquid according to claim 5.
7. The polishing method according to claim 6, wherein the surface
25 to be polished contains silicon oxide.
