Background of the Invention

5 Atherosclerosis and other peripheral vascular diseases affect the quality of life of millions of people. Therefore, considerable attention has been directed towards understanding the etiology of hypercholesterolemia and hyperlipidemia and development of effective therapeutic strategies.

Hypercholesterolemia has been defined as plasma cholesterol level that exceeds arbitrarily defined value called "normal" level. Recently, it has been accepted that "ideal" plasma levels of cholesterol are much below the "normal" level of cholesterol in the general population and the risk of coronary artery disease (CAD) increases as cholesterol level rises above the "optimum" (or "ideal") value. There is clearly a definite cause and effect-relationship between hypercholesterolemia and CAD, particularly for individuals with multiple risk factors. Most of the cholesterol is present in the esterified forms with various lipoproteins such as Low density lipoprotein (LDL), Intermediate density lipoprotein (IDL), High density lipoprotein (HDL) and partially as Very low density lipoprotein (VLDL). Studies clearly indicate that there is an inverse correlation between CAD and atherosclerosis with serum HDL-cholesterol concentrations (Stampfer *et al.*, *N. Engl. J. Med.*, 325 (1991), 373-381). The risk of CAD increases with increasing levels of LDL and VLDL.

In CAD, generally "fatty streaks" in carotid, coronary and cerebral arteries, are found which are primarily free and esterified cholesterol. Miller *et al.*, (*Br. Med. J.*, 282 (1981), 1741-1744) have shown that increase in HDL-particles may decrease the number of sites of stenosis in coronary arteries of human, and high level of HDL-cholesterol may protect against the progression of atherosclerosis. Picardo *et al.*, *Arteriosclerosis* 6 (1986) 434-441 have shown by *in vitro* experiment that HDL is capable of removing cholesterol from cells. They suggest that HDL may deplete tissues of excess free cholesterol and transfer it to liver, which is known as reverse cholesterol transport, (Macikinnon *et al.*, *J. Biol. chem.* 261 (1986), 2548-2552). Therefore, agents that increase HDL cholesterol would have therapeutic significance for the treatment of hypercholesterolemia and coronary heart diseases (CHD).

Obesity is a disease highly prevalent in affluent societies and in the developing world and is a major cause of morbidity and mortality. It is a state of excess body fat accumulation. The causes of obesity are unclear. It is believed to be of genetic origin or promoted by an interaction between the genotype and environment. Irrespective of the

cause, the result is fat deposition due to imbalance between the energy intake versus energy expenditure. Dieting, exercise and appetite suppression have been a part of obesity treatment. There is a need for efficient therapy to fight this disease since it may lead to coronary heart disease, diabetes, stroke, hyperlipidemia, gout, osteoarthritis, reduced fertility and many other psychological and social problems.

Diabetes and/or insulin resistance is yet another disease which severely effects the quality of large population in the world. Insulin resistance is the diminished ability of insulin to exert its biological action across a broad range of concentrations. In insulin resistance, the body secretes abnormally high amounts of insulin to compensate for this defect; failing which, the plasma glucose concentration inevitably raises and develops into diabetes. Among the developed countries, diabetes mellitus is a common problem and is associated with a variety of abnormalities including obesity, hypertension, hyperlipidemia (*J. Clin. Invest.*, 75 (1985) 809-817; *N. Engl. J. Med* 317 (1987) 350-357; *J.-Clin. Endocrinol. Metab.*, 66 (1988) 580-583; *J. Clin. Invest.*, 68 (1975) 957 - 969) and other renal complications (patent publication No. WO 95/21608). It is now increasingly being recognized that insulin resistance and relative hyperinsulinemia have a contributory role in obesity, hypertension, atherosclerosis and type 2 diabetes mellitus. The association of insulin resistance with obesity, hypertension and angina has been described as a syndrome having insulin resistance as the central pathogenic link-Syndrom-X.

Hyperlipidemia is the primary cause for cardiovascular (CVD) and other peripheral vascular diseases. High risk of CVD is related to the higher LDL (Low Density Lipoprotein) and VLDL (Very Low Density Lipoprotein) seen in hyperlipidemia. Patients having glucose intolerance/insulin resistance in addition to hyperlipidemia have higher risk of CVD. Numerous studies in the past have shown that lowering of plasma triglycerides and total cholesterol, in particular LDL and VLDL and increasing HDL cholesterol help in preventing cardiovascular diseases.

Peroxisome Proliferator Activated Receptors (PPARs) are orphan receptors belonging to the steroid/retinoid receptor super family of ligand activated transcription factors. (Wilson T. M. and Wahli W., *Curr. Opin. Chem. Biol.*, 1997, Vol. 1, 235-241). Three mammalian Peroxisome Proliferator Activated Receptors (PPARs) have been isolated and termed PPAR- α , PPAR- γ and PPAR- δ . These PPARs regulate expression of target genes by binding to DNA sequence elements.

Certain compounds that activate or otherwise interact with one or more of the PPARs have been implicated in the regulation of triglyceride and cholesterol levels in

animal models. (U.S. patents 5,847,008; 5,859,051 and PCT publications WO 97/28149; WO 99/04815.

5 A wealth of information exists on the influence of PPAR α agonists on the cardiovascular risk profile for example fibrate class of compounds which are weak PPAR- α agonists correct atherogenic dyslipoproteinemia. Several angiographic intervention trials have demonstrated a beneficial action of these drugs on atherosclerotic lesion progression and results from primary and secondary prevention trials show a decreased incidence of cardiovascular events. (Ricote M. and Glass C. K.; Trends in Pharmacological Sciences; 2001; 22(9); 441-443.

10 Despite the fact that fibrates, which are weak PPAR- α activators, reduce the plasma triglyceride levels and elevate the levels of HDL-C simultaneously, they are not the drugs of choice, because of: low efficacy requiring high doses, incidence of Myositis and contra-indicated in patients with impaired renal and hepatic function and in pregnant and nursing women.

15 However there has been rapid progress in the understanding of the role of PPAR- α in different pathophysiological conditions in addition to the well-documented favourable effects on lipid profile. The inflammatory activation of aortic smooth muscle cells, which is the hallmark of atherosclerosis, seems to be inhibited by the enhanced PPAR- α activity. (Vamecq J. and Latruffe N; Lancet; 1999; 354; 141-148).

20 Recent evidence suggests the role of PPAR- α receptors in improving insulin sensitivity. It has been demonstrated that by lowering circulatory and muscle lipids in insulin-resistant rodent models such as obese Zucker rats, high fat-fed mice and sucrose-lard fed rats, PPAR- α ligands improve insulin sensitivity and obesity. Further the lipid lowering activity of the statins has been linked to a cross talk with PPAR- α receptor in addition to limited cholesterol availability. Some clinical trials have shown improvement in insulin sensitivity indices, wherein fibrates were employed. (Guerre-Millo M, Rounalt C. and Poulain P; Diabetes; 2001; 50; 2809-2814, Muoio D. M., Way J. M. and Tanner C. J.; Diabetes; 2002; 51; 901-909, Ye J, Doyle P. J. and Iglesias M. A.; Diabetes; 2001; 50; 411-417, and Roglans N, Sanguino E. and Peris C; JPET; 2002; 302; 232-239).

30 Thus there is an interesting evidence for PPAR- α agonists to be used for lipid control and as per recent evidence even for insulin resistance. Limitations of the currently available medications coupled with the fact that lipid abnormalities are on the rise worldover necessitate the discovery of more potent and safer PPAR- α agonists. In continuation of our research work on PPAR agonists (U.S. Patents 5,885,997; 6,054,453;

6,265,401: PCT application PCT/IB02/04275) to address this unmet need, a series of compounds have been synthesized which has been disclosed in the present invention.

The compound(s) of the formula (I) as defined above is clinically administered to mammals, including man, via either oral or parenteral routes. Administration by the oral route is preferred being more convenient and avoiding the possible pain and irritation of injection. However, in circumstances where the patient cannot swallow the medication, or absorption following oral administration is impaired, as by disease or other abnormality, it is essential that the drug be administered parenterally. By either route, the dosage is in the range of about 0.01 to about 100 mg/kg body weight of the subject per day or preferably about 0.01 to about 50 mg/kg body weight per day administered singly or as a divided dose. However, the optimum dosage for the individual subject being treated will be determined by the person responsible for treatment, generally smaller doses being administered initially and thereafter increments made to determine the most suitable dosage.

The compounds of the present invention lower random blood sugar level, triglyceride, total cholesterol, LDL, VLDL and increase HDL by agonistic mechanism. This may be demonstrated by *in vitro* as well as *in vivo* animal experiments.

c) **Determination of HMG CoA reductase inhibition activity**

Liver microsome bound reductase is prepared from 2% cholestyramine fed rats at mid-dark cycle. Spectrophotometric assays are carried out in 100 mM KH₂PO₄, 4 mM DTT, 0.2 mM NADPH, 0.3 mM HMG CoA and 125 μ g of liver microsomal enzyme. Total reaction mixture volume was kept as 1 ml. Reaction was started by addition of HMG CoA. Reaction mixture is incubated at 37 °C for 30 min and decrease in absorbance at 340 nm was recorded. Reaction mixture without substrate was used as blank (Goldstein, J. L. and Brown, M. S. Progress in understanding the LDL receptor and HMG CoA reductase, two membrane proteins that regulate the plasma cholesterol. J. Lipid Res. 1984, 25: 1450 – 1461). The test compounds will inhibit the HMG CoA reductase enzyme.

a) **Efficacy in genetic models**

Mutation in colonies of laboratory animals and different sensitivities to dietary regimens has made the development of animal models with non-insulin dependent diabetes and hyperlipidemia associated with obesity and insulin resistance possible. Genetic models such as db/db and ob/ob (Diabetes, (1982) 31(1) : 1- 6) mice and Zucker fa/fa rats have been developed by the various laboratories for understanding the pathophysiology of disease and testing the efficacy of new antidiabetic compounds (Diabetes, (1983) 32: 830-838; Annu. Rep. Sankyo Res. Lab. (1994). 46: 1-57). The homozygous animals, C57 BL/KsJ-db/db mice developed by Jackson Laboratory, US, are obese, hyperglycemic, hyperinsulinemic and insulin resistant (J. Clin. Invest., (1990) 85: 962-967), whereas heterozygous are lean and normoglycemic. In db/db model, mouse progressively develops insulinopenia with age, a feature commonly observed in late stages of human type II diabetes when blood sugar levels are insufficiently controlled. The state of pancreas and its course vary according to the models. Since this model resembles that of type II diabetes mellitus, the compounds of the present invention will be tested for blood sugar and triglycerides lowering activities.

Male C57BL/KsJ-db/db mice of 8 to 14 weeks age, having body weight range of 35 to 60 grams, bred at Dr. Reddy's Research Foundation (DRF) animal house, were used in the experiment. The mice are provided with standard feed (National Institute of Nutrition (NIN), Hyderabad, India) and acidified water, ad libitum. The animals having more than 350 mg / dl blood sugar will be used for testing. The number of animals in each group will be 4.

Test compounds are suspended on 0.25% carboxymethyl cellulose and administered to test group at a dose of 0.1 mg to 30 mg / kg through oral gavage daily for 6 days. The control group receives vehicle (dose 10 ml / kg). On 6th day the blood samples will be collected one hour after administration of test compounds / vehicle for assessing the biological activity.

The random blood sugar and triglyceride levels can be measured by collecting blood (100 μ l) through orbital sinus, using heparinised capillary in tubes containing EDTA which was centrifuged to obtain plasma. The plasma glucose and triglyceride levels can be measured spectrometrically, by glucose oxidase and glycerol-3-PO₄ oxidase/peroxidase enzyme (Dr. Reddy's Lab. Diagnostic Division Kits, Hyderabad, India) methods respectively.

The blood sugar and triglycerides lowering activities of the test compound are calculated according to the formula.

b) Plasma triglyceride and Cholesterol lowering activity in hypercholesterolemic rat models

Male Sprague Dawley rats (NIN stock) were bred in DRF animal house. Animals were maintained under 12 hour light and dark cycle at 25 ± 1 °C. Rats of 180 - 200 gram body weight range were used for the experiment. Animals are made hypercholesterolemic by feeding 2% cholesterol and 1% sodium cholate mixed with standard laboratory chow [National Institute of Nutrition (NIN), Hyderabad, India] for 6 days. Throughout the experimental period the animals were maintained on the same diet (Petit, D., Bonnefis, M.

T., Rey, C and Infante, R. Effects of ciprofibrate on liver lipids and lipoprotein synthesis in normo- and hyperlipidemic rats. *Atherosclerosis*. 1988. 74: 215 – 225).

The test compounds can be administered orally at a dose 0.1 to 30 mg/kg/day for 3 days. Control group was treated with vehicle alone (0.25% Carboxymethylcellulose; dose 10 ml/kg).

The blood samples can be collected in fed state 1 hour after drug administration on 0 and 3 day of compound treatment. The blood can be collected from the retro-orbital sinus through heparinised capillary in EDTA containing tubes. After centrifugation, plasma sample will be separated for total cholesterol, HDL and triglyceride estimations. Measurement of plasma triglyceride, total cholesterol and HDL were done using commercial kits (Dr. Reddy's Laboratory, Diagnostic Division, India). LDL and VLDL cholesterol can be calculated from the data obtained for total cholesterol, HDL and triglyceride. The reductions of various parameters examined are calculated according to the formula.

c) Plasma triglyceride and total cholesterol lowering activity in Swiss albino mice

Male Swiss albino mice (SAM) were obtained from NIN and housed in DRF animal house. All these animals are maintained under 12 hour light and dark cycle at $25 \pm 1^{\circ}\text{C}$. Animals are given standard laboratory chow (NIN, Hyderabad, India) and water, *ad libitum*. SAM of 20 - 25 g body weight range and Guinea pigs of 500 - 700 g body weight range are used (Oliver, P., Plancke, M. O., Marzin, D., Clavey, V., Sauzieres, J and Fruchart, J. C. Effects of fenofibrate, gemfibrozil and nicotinic acid on plasma lipoprotein levels in normal and hyperlipidemic mice. *Atherosclerosis*. 1988. 70: 107 – 114).

The test compounds can be administered orally to Swiss albino mice at 0.3 to 30 mg/kg/day dose for 6 days. Control mice are treated with vehicle (0.25% Carboxymethylcellulose; dose 10 ml/kg). The test compounds are administered orally to Guinea pigs at 0.3 to 30 mg/kg/day dose for 6 days. Control animals are treated with vehicle (0.25% Carboxymethylcellulose; dose 5 ml/kg).

The blood samples can be collected in fed state 1 hour after drug administration on 0 and 6 day of treatment. The blood can be collected from the retro-orbital sinus through heparinised capillary in EDTA containing tubes. After centrifugation, plasma sample was separated for triglyceride (Wieland, O. Methods of Enzymatic analysis. Bergermeyer, H. O., Ed., 1963. 211 - 214; Trinder, P. Ann. Clin. Biochem. 1969. 6: 24 - 27). Measurement of plasma triglyceride is done using commercial kits (Dr. Reddy's Diagnostic Division, Hyderabad, India).
