

PRODUCTION OF RENEWABLE FUELS

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] The present application claims priority to US.. Provisional Application No. 62/563,577 filed September 26, 2017, which is incorporated herein by reference.

5

FIELD OF THE INVENTION

[0002] This invention relates to the production of hydrocarbons from renewable paraffinic feed stocks.

BACKGROUND

[0003] Biofuels that can be produced from renewable domestic resources offer an
10 alternative to petroleum-based fuels. In order to encourage the production and consumption of
biofuels in the United States, regulatory agencies have taken steps to mandate and incentivize
increased production of fuels from renewable sources. California's Low Carbon Fuel Standard
Program (LCFS) requires producers of petroleum-based fuels to reduce the carbon intensity of
15 their products, beginning with a quarter of a percent in 2011, and culminating in a 10 percent
total reduction in 2020. Petroleum importers, refiners, and wholesalers can either develop their
own low carbon fuel products, or buy LCFS Credits from other companies that develop and
sell low carbon alternative fuels.

[0004] Likewise, the United States Congress created the Renewable Fuel Standard
(RFS) program to reduce greenhouse gas emissions and expand the nation's renewable fuels
20 sector while reducing reliance on imported oil. This program was authorized under the Energy
Policy Act of 2005, and the program was further expanded under the Energy Independence and
Security Act of 2007. Being a national policy, the RFS program requires the replacement or
reduction of a petroleum-based transportation fuel, heating oil, or jet fuel with a certain volume
of renewable fuel. The four renewable fuel categories under the RFS program include biomass-
25 based diesel, cellulosic biofuel, advanced biofuel, and total renewable fuel.

[0005] Current commercial biofuel production methods include esterification of
triglycerides, fats, and fatty acids, transesterification of fatty esters, fermentation of sugar,
catalytic upgrading of sugars, and biogas- and biomass-to-liquids methods. These methods
have been primarily focused on the production of ethanol and biodiesel, and have not been very
30 successful for producing large quantities of non-oxygenated renewable fuels. However,

production of renewable hydrocarbons will help producers meet increasing environmental regulations and offer an attractive alternative for consumers that are interested in environmentally-friendly fuel alternatives which are replacements for non-renewable hydrocarbon components. Thus, there is a need in the industry for commercially feasible
5 methods for the production of fuels from renewable sources.

SUMMARY

[0006] The present disclosure provides a method for producing a renewable hydrocarbon product from renewable paraffinic feed stocks. The method may comprise providing the renewable paraffinic feed stock and converting the renewable paraffinic feed
10 stock into a renewable hydrocarbon product in a cracking unit. The renewable paraffinic feed stock may be obtained from various sources. In some aspects, the renewable paraffinic feed stock can be provided by hydrotreating renewable fat and renewable oil feed stocks. The renewable hydrocarbon product may include a number of different fractions, including gasoline, diesel, and aviation fuel. Conditions for the production of the renewable hydrocarbon
15 product may be adjusted to favor the production one fraction over others. For example, production conditions may be adjusted to favor the production of a renewable hydrocarbon product having a gasoline fraction as the major or primary constituent.

[0007] Some aspects of the present disclosure are directed to process for producing a renewable hydrocarbon fuel product comprising the steps of providing a renewable paraffinic
20 feed stock, and reacting the renewable paraffinic feed stock in a reaction zone under conditions sufficient to crack at least a portion of the renewable paraffinic feed stock to produce a renewable hydrocarbon fuel product. In some aspects, the reacting step comprises fluid catalytic cracking.

[0008] Some embodiments of the disclosure are directed to a renewable hydrocarbon
25 fuel product having a ^{14}C isotopic ratio characteristic of a blend of petroleum and at least 1% by volume non-petroleum origin, and comprising less than about 5% coke. Some embodiments are directed to a blended renewable hydrocarbon product comprising a first component comprising a renewable hydrocarbon fuel product having a ^{14}C isotopic ratio characteristic of a blend of petroleum and at least 1% by volume non-petroleum origin, and comprising less
30 than about 5% coke, and a second component comprising at least one of one or more petroleum fuel products and one or more renewable fuels.

BRIEF DESCRIPTION OF THE DRAWINGS

[0009] FIG. 1 is a flow diagram depicting the steps involved in the production of a renewable hydrocarbon product, *e.g.*, renewable gasoline.

5 [0010] FIG. 2 is a flow diagram depicting steps involved in the production of a renewable hydrocarbon product, and potential uses of the renewable hydrocarbon product, including sales and further processing.

DETAILED DESCRIPTION

10 [0011] Various features and advantageous details are explained more fully with reference to the non-limiting embodiments that are illustrated in the accompanying drawing and detailed in the following description. It should be understood, however, that the detailed description and the specific examples, while indicating embodiments of the invention, are given by way of illustration only, and not by way of limitation. Various substitutions, modifications, additions, and/or rearrangements will become apparent to those of ordinary skill in the art from this disclosure.

15 [0012] In the following description, numerous specific details are provided to provide a thorough understanding of the disclosed embodiments. One of ordinary skill in the relevant art will recognize, however, that the invention may be practiced without one or more of the specific details, or with other methods, components, materials, and so forth. In other instances, well-known structures, materials, or operations are not shown or described in detail to avoid
20 obscuring aspects of the invention.

[0013] The present disclosure provides a method for producing a renewable hydrocarbon fuel product from a renewable paraffinic feed stock. The renewable paraffinic feed stock can be provided from various sources. In some aspects, the paraffinic feed stock is provided by hydrotreating renewable fat and renewable oil feed stocks. In some aspects, the
25 renewable paraffinic feed stock is provided by hydrotreating renewable fat and renewable oil feed stocks and blending the hydrotreated renewable fat and renewable oil feed stocks with other hydrocarbon streams, including crude oil, gas oil, fuel oils, diesel, and other petroleum distillates. The renewable paraffinic feed stock is then processed in a cracking unit, for example, a fluid catalytic cracking unit, to produce the renewable hydrocarbon fuel product.
30 The renewable fuel product may include a number of fractions, including, but not limited to, a fuel gas, ethylene, propylene, butylene, LPG, naphtha, gasoline, diesel, cycle oils, light cycle

oil, and cat unit bottoms (slurry/decant oil). The renewable hydrocarbon fuel product may be further refined, for example, separated into constituent fractions and/or blended with other hydrocarbons, such as petroleum-based hydrocarbons or one or more renewable fuels, for example, ethanol, to produce a renewable hydrocarbon blended fuel product. The production process is flexible; the cracking conditions may be altered in order to favor the selective production of one or more fractions.

[0014] Generally, in the step of providing renewable paraffinic feed stocks, the renewable fats and renewable oils used in the hydrotreating process are predominantly non-petroleum fats and oils. The renewable fats and renewable oils may originate from plant and animal sources. The fats and oils may include used cooking oil, recycled cooking oil, waste cooking oil, used vegetable oil, recycled vegetable oil, waste vegetable oil, rendered oils, animal fats, tallow, pork fat, chicken fat, fish oils, yellow grease, poultry fat, algal oils, algae-derived oils, soy oil, palm oil, palm fatty acids, plant-derived oils such as corn oil, canola oil, jatropha oil, olive oil, fatty acids, and seed oils, and the like. In one embodiment, the feed stock comprises at least 10% used cooking oil. In embodiments, the used stock comprises at least 10% used corn oil. In further embodiments, the feed stock comprises at least 10% used cooking oil and at least 10% used corn oil. The renewable fats and oils may be used alone, or may be used in combination. Low-quality grade fats and oils are customarily used for, or in some instances recycled into, animal feed stocks, personal care, and household products such as soap and detergent. The present disclosure provides a method for employing new and/or recycled renewable fats and oils as feed stocks for the production of renewable fuels such as gasoline, diesel, and aviation fuel, and chemical intermediates such as ethylene, propylene and butylene.

[0015] In some aspects, a process for producing a renewable hydrocarbon fuel product from a renewable paraffinic feed stock is provided. A renewable hydrocarbon fuel product includes a renewable hydrocarbon that can be further refined and a renewable hydrocarbon blend stock that may be further processed to produce a sellable product. The process includes providing a renewable paraffinic feed stock and reacting at least a portion of the renewable paraffinic feed stock in a reaction zone under conditions sufficient to crack at least a portion of the renewable paraffinic feed stock to produce a product stream comprising a renewable or partially-renewable hydrocarbon fuel product.

[0016] The renewable paraffinic feed stock may be provided from various sources. In some aspects, the renewable paraffinic feed stock can be provided by hydrotreating (and optionally and optionally isomerizing, dewaxing, and/or hydrocracking) a renewable feed stock (*e.g.*, renewable fats and/or renewable oils). The step of providing the renewable paraffinic feed stock may further comprise blending the hydrotreated renewable feed stock with an additional feed. In some aspects, hydrotreating the renewable feed stock involves contacting the renewable feed stock with a catalyst in the presence of hydrogen at elevated temperature to produce a hydrotreated renewable feed stock, which may be further hydro-processed or isomerized. Hydrotreating is understood to broadly refer to processes that treat a feed stock with hydrogen, and reactions that occur during hydrotreating include hydrodeoxygenation, hydrodesulfurization, hydrodenitritication, and saturation of olefins. The renewable feed stocks may comprise triglycerides and fatty acids (typically with chain lengths of C12-C24), anhydrides, esters, and combinations thereof. Esters may include mono-alcohol esters and polyol esters, such as triglycerides. The hydrotreating process may be a hydro-deoxygenation and hydrogenation process in which esters are cleaved, oxygenated compounds including acids and alcohols are reduced to the corresponding paraffins, and double bonds are saturated. Glycerin may be liberated during ester cleavage and hydrodeoxygenated to form propane. The hydrotreated renewable feed stock may include, in addition to propane, butane. More specifically, some butane, for example, n-butane, is produced during the hydrotreating process. In some aspects, the butane may be separated from the hydrotreated renewable feed stock and fed to an isomerization unit where it is converted to isobutane. In some embodiments, double bonds are reduced during hydrotreating. In some aspects, the hydrotreating process reduces the level of contaminants, including, but not limited to, Na, Ca, Mg, K, P, S, N, Cl, Si, Mg, K, Al, and oxygenated compounds. The renewable feed stock may be blended with a petroleum feed prior to or during the hydrotreating step. The hydrotreating process may be performed at a pressure ranging from about 100 psig to about 3,400 psig, preferably at a pressure ranging from about 400 psig to about 1,800 psig. In some aspects, the hydrotreating process is carried out at a temperature ranging from about 250 °C to about 430 °C. Catalysts for the hydrotreating process include, but are not limited to, Ni-Mo and Co-Mo catalysts. In some aspects, the hydrotreating process liquid hourly space velocity (LHSV) may range from about 0 to about 2.0 (hr⁻¹). A preferred hydrotreating reaction system includes at least one reactor, each of which has at least one or more catalyst beds. In some embodiments, the hydrotreating process is performed in a hydrotreating reactor having at least three beds.

[0017] While the preceding describes various approaches to hydrotreating a renewable feed stock, other approaches may be used to produce the renewable paraffinic feed stock.

[0018] In some aspects, the renewable feed stock is pre-treated prior to the hydrotreating step. Pre-treating may include one or more of a degumming step, a water-wash
5 step, a demetallation step, a bleaching step, an ion-exchange step, a full (or partial) hydrogenation step, an acid gas removal step, and a water removal step. Degumming involves removal of gums and phosphorus compounds, such as phospholipids. Demetallation involves removal of metals, some of which may be harmful to the hydrotreating catalyst. In some aspects, the demetallation process produces a feed stock having a metal contaminant level of
10 below 18 ppm. Acid gas removal includes removal of gases such as CO₂ and H₂S. Each of the pre-treating and hydrotreating steps may involve the use of one or more catalysts. The renewable feed stock may be blended with a petroleum feed prior to or during the pre-treating step.

[0019] In some aspects, the step of providing the renewable paraffinic feed stock
15 comprises blending the hydrotreated renewable feed stock with a petroleum-based intermediate, such as a conventional petroleum-based intermediate to be cracked, including gas oil, distillates, atmospheric tower bottoms, cycle oils, and/or crude oil, in an amount greater than 0% to less than 99% by volume of hydrotreated renewable feed stock. These amounts may also range from greater than 0% to less than 80%, greater than 0% to less than 70%, greater
20 than 0% to less than 60%, greater than 0% to less than 50%, greater than 0% to less than 40%, greater than 0% to less than 30%, greater than 0% to less than 20%, and greater than 0% to less than 10%, in each case by volume of hydrotreated renewable feed stock. In some aspects, the renewable paraffinic feed stock is reacted in a cracking unit essentially in the absence of a sulfur removal pre-treatment step prior to entry of the renewable paraffinic feed stock into the
25 cracking unit.

[0020] In some embodiments, the renewable paraffinic feed stock has a boiling point range from 180 °C to 400 °C; if co-processed with petroleum based feed stocks, the boiling point range may be increased beyond these levels. In some aspects, the renewable paraffinic feed stock, derived from triglycerides and fatty acids, and absent any co-processing, comprises
30 greater than 90% paraffin compounds, and is substantially free of aromatic compounds; the renewable paraffinic feed stock may contain aromatic or naphthenic compounds if it includes at least some petroleum-based feed stocks or other known aromatic or naphthenic mixtures.

Petroleum and other renewable feed stocks may be blended or added, either before, during or after, the pre-treatment and/or hydrotreating step. The renewable paraffinic feed stock produced by the methods disclosed herein may have a lower cloud point and/or freezing point than a conventional, petroleum-based intermediate counterpart. In some aspects, the freezing point of the renewable paraffinic feed stock may range from -50 °C to 50 °C. In some aspects, the density of the renewable paraffinic feed stock may range from 0.7 to 0.92 grams per cubic centimeter. The renewable paraffinic feed stock may comprise 50 ppm or less, preferably 10 ppm or less, of Na, Ca, Mg, K, P, Mg, K, or other contaminants, providing no co-processing. In some embodiments, the renewable paraffinic feed stock has an oxygen content of less than 11%. In particular instances, the renewable paraffinic feed stock has an oxygen content of less than 1%. In some aspects, the renewable paraffinic feed stock is substantially free of fatty acids and/or fatty esters. The renewable paraffinic feed stock may contain propane, resulting from hydrogenation of glycerin. In some embodiments, at least a portion of any propane resulting from triglyceride hydrotreating (*i.e.*, hydrogenation of glycerin to propane), is separated from the hydrotreated renewable feed stock, and is fed to a cracking unit where it is cracked into lighter products. In some aspects, the renewable paraffinic feed stock has a ¹⁴C isotopic ratio characteristic of non-petroleum origin for the paraffinic feed stock or, a ¹⁴C isotopic ratio characteristic of a blend of petroleum and non-petroleum origins according to the percent by volume of each component. In some aspects, the renewable paraffinic feed stock comprises at least 80% C8-C20 hydrocarbons, preferably at least 90% C8-C20 hydrocarbons, and more preferably at least 95% C8-C20 hydrocarbons. In some embodiments, the renewable paraffinic feed stock is substantially free of aromatics and sulfur. In some aspects, the renewable paraffinic feed stock has a pour point in the range of -18 °C to 50 °C. In some embodiments, the renewable paraffinic feed stock has a flash point greater than 20 °C. In further embodiments, the renewable paraffinic feed stock has a California Air Resource Board Certified LCFS carbon intensity value less than 55, as defined at <https://www.arb.ca.gov/fuels/lcfs/fuelpathways/pathwaytable.htm>.

[0021] Optionally, in the step of providing the renewable paraffinic feed stock, hydrotreated renewable feed stock stream may be further processed to reduce the pour point of the provided renewable paraffinic feed stock. This may include commonly known refining steps such as dewaxing, isomerization, and/or hydrocracking. Alternatively the hydrotreated renewable feed stock may be blended with other petroleum or renewable based materials in order to lower the pour point of the provided renewable paraffinic feed stock prior to routing

to an FCC unit. Lowering the pour point to the range of -18 °C to 50 °C will aid in reducing gelling or solidification that may otherwise occur prior to cracking in an FCC unit.

[0022] In some aspects, conditions sufficient to crack at least a portion of the renewable paraffinic feed stock comprise reacting the renewable paraffinic feed stock in a cracking unit, such as a fluid catalytic cracking unit or hydrocracking unit. In some aspects, conditions sufficient to crack at least a portion of the renewable paraffinic feed stock comprise contacting the renewable paraffinic feed stock with a fluid catalytic cracking catalyst in a fluid catalytic cracking reactor at elevated temperature and pressure. In some aspects, the temperature may range from 400 °C to 800 °C. In other embodiments, the temperature may range from about 475 °C to about 600 °C, preferably from about 490 °C to about 600 °C, and more preferably from about 500 °C to about 550 °C. In some embodiments, the pressure may range from greater than 0 to 80 psig. In other embodiments, the pressure may range from about 5 to about 80 psig, preferably from about 10 to about 55 psig. The catalyst may be an aluminosilicate catalyst, such as a zeolite catalyst, or other catalyst commonly used in a fluidized cracking reactor. In some embodiments, a catalyst to oil feed ratio may range from about 2:1 to about 20:1 by weight, preferably from about 4:1 to about 10:1. In some aspects, a reactor stripping steam/catalyst ratio may range from about 0.5 to about 6 pounds steam/1,000 pounds catalyst, preferably about 2 pounds steam/1,000 pounds catalyst. In some embodiments, the composition has a catalyst-to-feed stock ratio ranging from 2:1 to 10:1 by weight, and the renewable paraffinic feed stock fed to the reactor has an oxygen content of less than 11% and is substantially free of fatty acids and/or fatty esters. In some embodiments, the amount of the composition is greater than 100 kilograms.

[0023] In a specific embodiment, cracking of the renewable paraffinic feed stock is performed in a fluidized bed reactor with a catalyst made up of finely divided or particulate solid material. In a particular aspect, cracking of the renewable paraffinic feed stock is performed in a fluid catalytic cracking unit (FCC). In a fluid catalytic cracking unit, the catalyst is suspended in a reaction zone by passing liquid, gas, and/or vapor through the catalyst particles. The renewable paraffinic feed stock comes into contact with the fluidized catalyst particles which catalyze the cracking reaction. The cracking conditions (temperature, pressure, catalyst to oil ratio) may be adjusted such that the cracking process (yield, conversion, selectivity, etc.) meets the requirements of production. During the cracking process, coke (solid carbonaceous material) becomes deposited on the catalyst particles. The catalyst

particles are partially deactivated by the deposition of coke and may be transferred to a stripping zone for removing adsorbed hydrocarbons and gases from catalyst. The stripped catalyst particles are transferred to a regeneration zone for oxidative coke removal by using air or oxygen-enriched air. The regenerated catalyst particles may then be reintroduced into the reaction zone for continued cracking catalysis. The cracking process may involve cyclically repeating the cracking and catalyst regeneration steps to continuously produce the renewable hydrocarbon fuel product. In a specific embodiment, the process is run continuously for at least 1 month, preferably for at least 6 months. In various embodiments, the reacting or cracking step produces renewable hydrocarbon fuel product in an amount of at least 100 liters per day.

10 **[0024]** Referring now to **Figure 1**, a flow diagram is depicted with an embodiment of the steps involved in the production of a renewable hydrocarbon fuel product. In this embodiment, a renewable paraffinic feed stock is transported to a fluid catalytic cracking unit and reacted with a cracking catalyst under appropriate cracking conditions to yield a renewable hydrocarbon fuel product with properties similar to petroleum-derived components.

15 **[0025]** Referring to **Figure 2**, a flow diagram is depicted with an embodiment of the steps involved in the production of a renewable hydrocarbon fuel product, which may be further refined or further blended to produce a renewable blended product or partially renewable blended product, for example, renewable gasoline. In this embodiment, a renewable paraffinic feed stock is transported to a fluid catalytic cracking unit and reacted with a cracking catalyst

20 under appropriate cracking conditions to yield a renewable hydrocarbon fuel product with properties similar to petroleum-derived components. As shown, this renewable hydrocarbon fuel product may be sold as is or further treated, for example, blended, hydroprocessed or alkylated.

25 **[0026]** Some aspects of the disclosure are directed towards a hydrocarbon fuel product in industrially relevant amounts by cracking, preferably fluid catalytic cracking (FCC), of a renewable paraffinic feed stock as described herein, wherein the renewable paraffinic feed stock can be processed in the cracking unit essentially by itself, or co-processed as a blend with an additional feed stock stream. In such cases, the product from the cracking unit is a renewable hydrocarbon fuel product produced in an industrially relevant amount by the process as

30 described herein. By industrially relevant amounts is meant amounts that enter the consumer market rather than laboratory scale amounts. In one example, industrially relevant amounts are

produced continuously at greater than 100 liters renewable hydrocarbon fuel product per day for a time period of at least one month.

[0027] In some aspects, the renewable hydrocarbon fuel product has a ^{14}C isotopic ratio characteristic of a blend of petroleum and non-petroleum origins with at least 1% by volume of non-petroleum origins, *i.e.*, derived from the renewable paraffinic feed stock. In some aspects of the invention, the renewable hydrocarbon fuel product comprises less than about 5% coke. In some embodiments, the renewable hydrocarbon fuel product has a boiling point ranging from 180 °C to 400 °C. In some aspects, the renewable hydrocarbon fuel product has a specific gravity between about 0.55 and about 0.92, preferably between about 0.72 and about 0.92. In some embodiments, the renewable hydrocarbon fuel product has a cloud point between about -20 °C and about 50 °C. In some aspects, the renewable hydrocarbon fuel product has an isoparaffin to normal paraffin ratio of about 0.0 to about 9.0. An isoparaffin to normal paraffin ratio of 0.0 corresponds to a renewable hydrocarbon fuel product having essentially no isoparaffin. The renewable hydrocarbon fuel product may have less than 20 ppm of Na, Ca, Mg, K, P, Mg, K, or other contaminants. In some aspects, the renewable hydrocarbon fuel product has less than 10 ppm of Na, Ca, Mg, K, P, Mg, K, or other contaminants. In some aspects, the renewable hydrocarbon fuel product may have a sulfur content less than about 0.2 weight % of a total weight of the renewable hydrocarbon fuel product. In some aspects, the freezing point of the renewable hydrocarbon fuel product may range from -50 °C to 50 °C. In particular aspects, the freezing point of the renewable hydrocarbon fuel product may range from -20 °C to 40 °C.

[0028] The renewable hydrocarbon fuel product may have a lower cloud point and/or freezing point than a conventional, petroleum-based blend stock counterpart. In some aspects, the renewable hydrocarbon fuel product may be used as a blend stock and combined with one or more petroleum fuel products and/or renewable fuels. Upon blending with other products, the blending of materials will change the properties of the renewable hydrocarbon fuel product or blend stock. Examples of renewable fuels include but are not limited ethanol, propanol, and butanol. Petroleum-based streams include, but are not limited to gasoline, diesel, aviation fuel, or other hydrocarbon streams obtained by refining of petroleum. The amount of petroleum-based stream blended with the renewable hydrocarbon fuel product may be greater than 0% to less than 99% by volume of renewable hydrocarbon fuel product. These amounts may also range from greater than 0% to less than 80%, greater than 0% to less than 70%, greater than

0% to less than 60%, greater than 0% to less than 50%, greater than 0% to less than 40%, greater than 0% to less than 30%, greater than 0% to less than 20%, and greater than 0% to less than 10%, in each case by volume of renewable hydrocarbon fuel product. In particular aspects, the renewable hydrocarbon fuel product is blended to produce a product selected from gasoline, aviation fuel, light cycle oil, and diesel. The renewable hydrocarbon fuel product or the blended product used to produce gasoline or aviation fuel may have an octane rating ranging from 40 to 110, preferably from 50 to 98. In particular aspects, the octane rating may range from 80 to 95. The octane rating is defined as the number average of research octane number (RON) and motor octane number (MON). Some aspects of the disclosure are directed to gasoline comprising at least 1% by volume of the renewable hydrocarbon fuel product produced in an industrially relevant amount. Some aspects of the disclosure are directed to aviation fuel comprising at least 1% by volume of the renewable hydrocarbon fuel product produced in an industrially relevant amount. Some aspects of the disclosure are directed to light cycle oil comprising at least 1% by volume of the renewable hydrocarbon fuel product produced in an industrially relevant amount.

[0029] The renewable hydrocarbon fuel product may be sold or further processed. Examples of further processing include blending, hydroprocessing, or alkylating at least a portion of the renewable hydrocarbon fuel product. The renewable hydrocarbon fuel product may be separated into two or more constituent streams. Constituent streams include but are not limited to a fuel gas stream, an ethylene stream, a propylene stream, a butylene stream, an LPG stream, a naphtha stream, an olefin stream, a diesel stream, a gasoline stream, a light cycle oil stream, an aviation fuel stream, a cat unit bottoms (slurry/decant oil) stream, and other hydrocarbon streams. In some aspects, a constituent stream may be further processed. In specific embodiments, an olefinic constituent stream may be sent to an alkylation unit and/or a dimersol unit for further processing. In addition, olefins from the constituent streams may be further separated and recovered for use in renewable plastics and petrochemicals.

[0030] In various embodiments, the renewable paraffinic intermediate described herein, or the renewable hydrocarbon fuel product described herein, or both, may be used in existing infrastructure for petroleum-based equivalents without the need for modification of existing physical units including pipelines, holding units, and reactors.

[0031] A “glyceride” is an ester of glycerol and at least carboxylic acid. Glycerides include mono-, di-, and triglycerides. The terms “a” and “an” are defined as one or more unless

this disclosure explicitly requires otherwise. The term “substantially” is defined as being largely but not necessarily wholly what is specified (and include wholly what is specified) as understood by one of ordinary skill in the art. In any disclosed embodiment, the term “substantially” may be substituted with “within [a percentage] of” what is specified, where the percentage includes .1, 1, 5, and 10 percent. The terms “comprise” (and any form of comprise, such as “comprises” and “comprising”), “have” (and any form of have, such as “has” and “having”), “include” (and any form of include, such as “includes” and “including”) and “contain” (and any form of contain, such as “contains” and “containing”) are open-ended linking verbs. As a result, a catalyst composition that “comprises,” “has,” “includes” or “contains” one or more elements possesses those one or more elements, but is not limited to possessing only those one or more elements. Likewise, an element of a system or composition that “comprises,” “has,” “includes” or “contains” one or more features possesses those one or more features, but is not limited to possessing only those one or more features.

[0032] The feature or features of one embodiment may be applied to other embodiments, even though not described or illustrated, unless expressly prohibited by this disclosure or the nature of the embodiments. Any embodiment of any of the disclosed composition, system, or process can consist of or consist essentially of, rather than comprise/include/contain/have, any of the described elements and/or features and/or steps. Thus, in any of the claims, the term “consisting of” or “consisting essentially of” can be substituted for any of the open-ended linking verbs recited above, in order to change the scope of a given claim from what it would otherwise be using the open-ended linking verb. Details associated with the embodiments described above and others are presented below.

EXAMPLES

Example 1 - Renewable Paraffinic Feed Stock Produced By Hydrotreating:

[0033] In a hydrotreating process, 100 bbl of a renewable triglyceride react with 1,800 scf/bbl of hydrogen to produce 106 bbl of a mixture of hydrocarbons. In an exemplary hydrotreating process, 100 bbl of a renewable triglyceride will produce 106 bbl of hydrocarbons with a specific gravity of approximately 0.78 and small amounts of light gases. The hydrotreating process produces more hydrocarbons per unit volume of starting triglyceride, and does not require an additional methanol source. Oxygen-containing compounds are largely converted into the corresponding hydrocarbons, water, CO, and CO₂.

Example 2 - Characterization And Comparison Of Renewable FCC Products:

5 [0034] Cracking a petroleum-based feed in an FCC yields a higher amount of coke as compared with a renewable paraffinic feed stock. The coke produced (wt%) during cracking of a petroleum-based feed is greater than 6 wt%. By contrast, cracking a renewable paraffinic feed stock yields approximately 2.2 wt% coke. As a result of the reduced coke production, the renewable intermediate can be fed to the cracking unit at a higher rate, the cracking unit can be operated at more severe reaction conditions, and the catalyst to oil ratio can be increased, which would result in increased product conversion.

[0035] **Table 1 Petroleum-Based vs. Renewable Intermediate FCC Yields**

Petroleum-Based FCC Yields		Renewable Paraffinic Feed Stock FCC Yields	
	Liquid Volume %		Liquid Volume %
LPG	33.4	LPG	39.2
Gasoline	47.1	Gasoline	40.4
LCO	21.8	LCO	35.4
Slurry	6.0	Slurry	1.4
Coke, wt%	6.3	Coke, wt%	2.2
Total	108.3	Total	116.4

10 [0036] Implementation of the renewable hydrocarbon production methods disclosed herein presents an economically viable, environmentally friendly approach to supplement current petroleum-based fuel production methods. The methods disclosed herein demonstrate desirable process conditions, and allow for the acquisition of valuable environmental regulation credits to use and sell.

15 [0037] The claims are not to be interpreted as including means-plus- or step-plus-function limitations, unless such a limitation is explicitly recited in a given claim using the phrase(s) “means for” or “step for,” respectively.

CLAIMS

1. A process for producing a renewable hydrocarbon fuel product, the process comprising the steps of:
 - providing a renewable paraffinic feed stock;
 - reacting said renewable paraffinic feed stock in a reaction zone under conditions sufficient to crack at least a portion of said renewable paraffinic feed stock to produce a renewable hydrocarbon fuel product.
2. The process of claim 1, wherein said reacting step comprises fluid catalytic cracking.
3. The process of claim 1, wherein conditions sufficient to crack at least a portion of said renewable paraffinic feed stock comprise a reaction temperature ranging from 400 °C to 800 °C.
4. The process of claim 1, wherein conditions sufficient to crack at least a portion of said renewable paraffinic feed stock comprise a reactor pressure ranging from greater than 0 to 80 psig.
5. The process of claim 1, further comprising the step of blending said renewable paraffinic feed stock with a petroleum-based feed to produce a renewable paraffinic feed stock blend.
6. The process of claim 5, wherein said renewable paraffinic feed stock blended with said petroleum-based feed is in a range selected from greater than 0% and less than 99%, greater than 0% and less than 80%, greater than 0% and less than 70%, greater than 0% and less than 60%, greater than 0% and less than 50%, greater than 0% and less than 40%, greater than 0% and less than 30%, greater than 0% and less than 20%, or greater than 0% and less than 10% by volume of said renewable paraffinic feed stock.
7. The process of claim 1, further comprising the step of blending said renewable hydrocarbon fuel product with a petroleum fuel product and/or with one or more renewable fuels.
8. The process of claim 1, further comprising the step of separating said renewable hydrocarbon fuel product into two or more constituent streams.

9. The process of claim 8, wherein said two or more constituent streams comprise at least two of a fuel gas stream, an ethylene stream, a propylene stream, a butylene stream, an LPG stream, a naphtha stream, an olefin stream, a diesel stream, a gasoline stream, a light cycle oil stream, a jet fuel stream, and a cat unit bottoms (slurry/decant oil) stream.
10. The process of claim 9, wherein at least one constituent stream is an olefin stream, and further comprising the step of feeding said olefin stream to an alkylation unit and/or a dimersol unit.
11. The process of claim 1, wherein said reacting step is performed in the absence of a sulfur removal pre-treatment step of said renewable paraffinic feed stock.
12. A renewable hydrocarbon fuel product produced in an industrially relevant amount by the process according to claim 1.
13. A renewable hydrocarbon fuel product having a ^{14}C isotopic ratio characteristic of a blend of petroleum and at least 1% by volume non-petroleum origin and comprising less than about 5% coke.
14. Gasoline comprising at least 1% by volume of the renewable hydrocarbon fuel product of claim 13.
15. Aviation fuel comprising at least 1% by volume of the renewable hydrocarbon fuel product of claim 13.
16. Light cycle oil or diesel comprising at least 1% by volume of the renewable hydrocarbon fuel product of claim 13.
17. The product of claim 13, wherein said renewable hydrocarbon fuel product has an octane rating ranging from about 40 to about 110.
18. The product of claim 13, wherein said renewable hydrocarbon fuel product has a specific gravity between about 0.55 and about 0.92.
19. The product of claim 13, wherein said renewable hydrocarbon fuel product has a sulfur content of less than about 0.2 % by weight of a total weight of said renewable hydrocarbon fuel product.

20. The product of claim 13, wherein said renewable hydrocarbon fuel product has a cloud point between about -20 °C and about 50 °C.
21. The product of claim 13, wherein said renewable hydrocarbon fuel product has an isoparaffin to normal paraffin ratio of about 0.0 to about 9.0.
22. A blended renewable hydrocarbon product, comprising a first component comprising renewable hydrocarbon fuel product having a ¹⁴C isotopic ratio characteristic of a blend of petroleum and at least 1% by volume non-petroleum origin and comprising less than about 5% coke, and a second component comprising at least one of one or more petroleum fuel products and one or more renewable fuels.
