HEPATITIS C VIRUS INHIBITORS

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims the benefit of U.S. Provisional Application Serial Number 60/865,034 filed November 9, 2006.

The present disclosure is generally directed to antiviral compounds, and more specifically directed to compounds which inhibit the function of the NS3 protease (also referred to herein as "serine protease") encoded by Hepatitis C virus (HCV), compositions comprising such compounds, and methods for inhibiting the function of the NS3 protease.

HCV is a major human pathogen, infecting an estimated 170 million persons worldwide - roughly five times the number infected by human immunodeficiency virus type 1. A substantial fraction of these HCV infected individuals develop serious progressive liver disease, including cirrhosis and hepatocellular carcinoma.

Presently, the most effective HCV therapy employs a combination of alpha-interferon and ribavirin, leading to sustained efficacy in 40% of patients. Recent clinical results demonstrate that pegylated alpha-interferon is superior to unmodified alpha-interferon as monotherapy. However, even with experimental therapeutic regimens involving combinations of pegylated alpha-interferon and ribavirin, a substantial fraction of patients do not have a sustained reduction in viral load. Thus, there is a clear and unmet need to develop effective therapeutics for treatment of HCV infection.

HCV is a positive-stranded RNA virus. Based on a comparison of the deduced amino acid sequence and the extensive similarity in the 5' untranslated region, HCV has been classified as a separate genus in the Flaviviridae family. All members of the Flaviviridae family have enveloped virions that contain a positive stranded RNA genome encoding all known virus-specific proteins *via* translation of a single, uninterrupted, open reading frame.

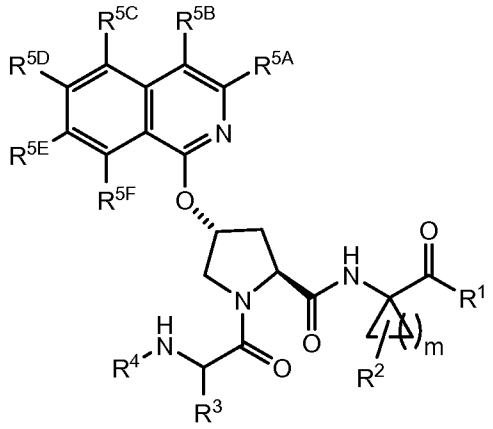

Considerable heterogeneity is found within the nucleotide and encoded amino acid sequence throughout the HCV genome. Six major genotypes have been characterized, and more than 50 subtypes have been described. The major genotypes of HCV differ in their distribution worldwide, and the clinical significance of the genetic heterogeneity of HCV remains elusive despite numerous studies of the

possible effect of genotypes on pathogenesis and therapy.

The single strand HCV RNA genome is approximately 9500 nucleotides in length and has a single open reading frame (ORF) encoding a single large polyprotein of about 3000 amino acids. In infected cells, this polyprotein is cleaved at multiple sites by cellular and viral proteases to produce the structural and non- structural (NS) proteins. In the case of HCV, the generation of mature non-structural proteins (NS2, NS3, NS4A, NS4B, NS5A, and NS5B) is effected by two viral proteases. The first one cleaves at the NS2-NS3 junction; the second one is a serine protease contained within the *N*-terminal region of NS3 and mediates all the subsequent cleavages downstream of NS3, both in cis, at the NS3-NS4A cleavage site, and in trans, for the remaining NS4A- NS4B, NS4B-NS5A, NS5A-NS5B sites. The NS4A protein appears to serve multiple functions, acting as a co-factor for the NS3 protease and possibly assisting in the membrane localization of NS3 and other viral replicase components. The complex formation of the NS3 protein with NS4A is essential for efficient polyprotein processing, enhancing the proteolytic cleavage at all of the sites. The NS3 protein also exhibits nucleoside triphosphatase and RNA helicase activities. NS5B is a RNA-dependent RNA polymerase that is involved in the replication of HCV.

The present disclosure provides peptide compounds that can inhibit the functioning of the NS3 protease, e.g., in combination with the NS4A protease. Further, the present disclosure describes the administration of combination therapy to a patient whereby a compound in accordance with the present disclosure, which is effective to inhibit the HCV NS3 protease, can be administered with one or two additional compounds having anti-HCV activity.

Other representative organic amines useful for the formation of base addition salts include ethylenediamine, ethanolamine, diethanolamine, piperidine, and piperazine.

As used herein, the term "anti-HCV activity" means the compound is effective to treat the HCV virus.

The term "compounds of the disclosure", and equivalent expressions, are meant to embrace compounds of formula (I), and pharmaceutically acceptable enantiomers, diastereomers, and salts thereof. Similarly, references to intermediates, are meant to embrace their salts where the context so permits.

The term "patient" includes both human and other mammals.

The term "pharmaceutical composition" means a composition comprising a compound of the disclosure in combination with at least one additional pharmaceutical carrier, i.e., adjuvant, excipient or vehicle, such as diluents, preserving agents, fillers, flow regulating agents, disintegrating agents, wetting agents, emulsifying agents, suspending agents, sweetening agents, flavoring agents, perfuming agents, antibacterial agents, antifungal agents, lubricating agents and dispensing agents, depending on the nature of the mode of administration and dosage forms. Ingredients listed in Remington's Pharmaceutical Sciences, 18th ed., Mack Publishing Company, Easton, PA (1999) for example, may be used.

The phrase "pharmaceutically acceptable" is employed herein to refer to those compounds, materials, compositions, and/or dosage forms which are, within the scope of sound medical judgment, suitable for use in contact with the tissues of patients without excessive toxicity, irritation, allergic response, or other problem or complication commensurate with a reasonable risk/benefit ratio.

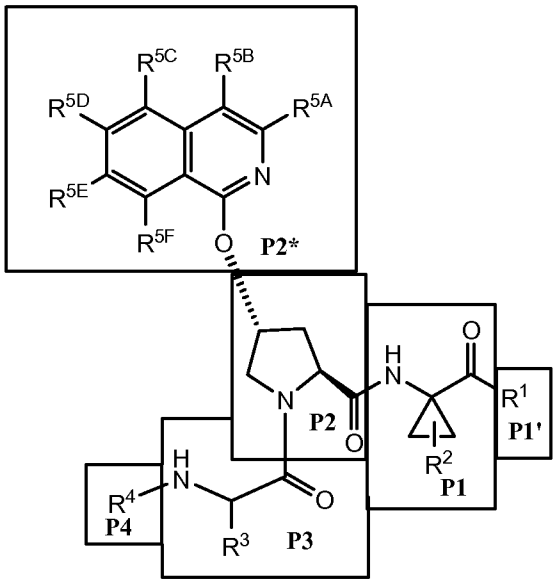

The term "therapeutically effective amount" means the total amount of each active component that is sufficient to show a meaningful patient benefit, e.g., a sustained reduction in viral load. When applied to an individual active ingredient, administered alone, the term refers to that ingredient alone. When applied to a combination, the term refers to combined amounts of the active ingredients that result in the therapeutic effect, whether administered in combination, serially or simultaneously.

The terms "treat" and "treating" refers to: (i) preventing a disease, disorder or condition from occurring in a patient which may be predisposed to the disease, disorder and/or condition but has not yet been diagnosed as having it; (ii) inhibiting the disease, disorder or condition, i.e., arresting its development; and/or (iii) relieving the disease, disorder or condition, i.e., causing regression of the disease, disorder and/or condition.

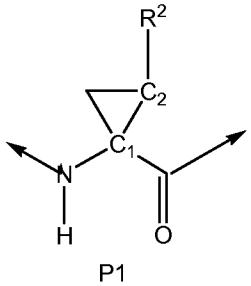

Where used in naming compounds of the present disclosure, the designations P1', P1, P2, P2*, P3, and P4, as used herein, map the relative positions of the amino acid residues of a protease inhibitor binding relative to the binding of the natural peptide cleavage substrate. Cleavage occurs in the natural substrate between P1 and P1' where the nonprime positions designate amino acids starting from the C-terminus end of the peptide natural cleavage site extending towards the *N*-terminus; whereas,

the prime positions emanate from the *N*-terminus end of the cleavage site designation and extend toward the C-terminus. For example, P1' refers to the first position away from the right hand end of the C-terminus of the cleavage site (i.e. *N*-terminus first position); whereas P1 starts the numbering from the left hand side of the C-terminus cleavage site, P2: second position from the C-terminus, etc.). (see Berger A. & Schechter I., Transactions of the Royal Society London series (1970), B257, 249-264].

The following figure shows the designations for the compounds of the present disclosure.

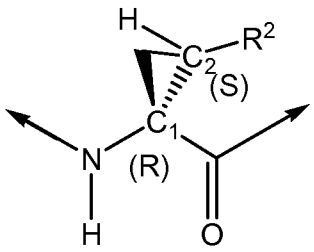

Asymmetric centers exist in the compounds of the present disclosure. For example, the compounds may include P1 cyclopropyl element of formula

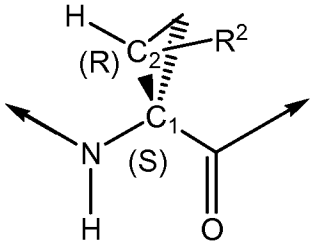

P1

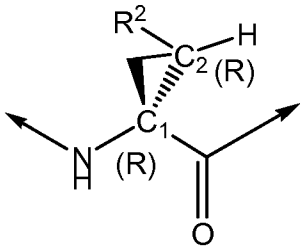

wherein C_1 and C_2 each represent an asymmetric carbon atom at positions 1 and 2 of the cyclopropyl ring.

It should be understood that the disclosure encompasses all stereochemical forms, or mixtures thereof, which possess the ability to inhibit HCV protease.

Certain compounds of the present disclosure may also exist in different stable conformational forms which may be separable. Torsional asymmetry due to restricted rotation about an asymmetric single bond, for example because of steric hindrance or ring strain, may permit separation of different conformers. The present disclosure includes each conformational isomer of these compounds and mixtures thereof.

Certain compounds of the present disclosure may exist in zwitterionic form and the present disclosure includes each zwitterionic form of these compounds and mixtures thereof.

When it is possible that, for use in therapy, therapeutically effective amounts of a compound of formula (I), as well as pharmaceutically acceptable salts thereof, may be administered as the raw chemical, it is possible to present the active ingredient as a pharmaceutical composition. Accordingly, the disclosure further

provides pharmaceutical compositions, which include therapeutically effective amounts of compounds of formula (I) or pharmaceutically acceptable salts thereof, and one or more pharmaceutically acceptable carriers, diluents, or excipients. The compounds of formula (I) and pharmaceutically acceptable salts thereof, are as described above. The carrier(s), diluent(s), or excipient(s) must be acceptable in the sense of being compatible with the other ingredients of the formulation and not deleterious to the recipient thereof. In accordance with another aspect of the disclosure there is also provided a process for the preparation of a pharmaceutical formulation including admixing a compound of formula (I), or a pharmaceutically acceptable salt thereof, with one or more pharmaceutically acceptable carriers, diluents, or excipients.

Pharmaceutical formulations may be presented in unit dose forms containing a predetermined amount of active ingredient per unit dose. Dosage levels of between about 0.01 and about 250 milligram per kilogram ("mg/kg") body weight per day, preferably between about 0.05 and about 100 mg/kg body weight per day of the compounds of the disclosure are typical in a monotherapy for the prevention and treatment of HCV mediated disease. Typically, the pharmaceutical compositions of this disclosure will be administered from about 1 to about 5 times per day or alternatively, as a continuous infusion. Such administration can be used as a chronic or acute therapy. The amount of active ingredient that may be combined with the carrier materials to produce a single dosage form will vary depending on the condition being treated, the severity of the condition, the time of administration, the route of administration, the rate of excretion of the compound employed, the duration of treatment, and the age, gender, weight, and condition of the patient. Preferred unit dosage formulations are those containing a daily dose or sub-dose, as herein above recited, or an appropriate fraction thereof, of an active ingredient. Generally, treatment is initiated with small dosages substantially less than the optimum dose of the compound. Thereafter, the dosage is increased by small increments until the optimum effect under the circumstances is reached. In general, the compound is most desirably administered at a concentration level that will generally afford antivirally effective results without causing any harmful or deleterious side effects.

When the compositions of this disclosure comprise a combination of a compound of the disclosure and one or more additional therapeutic or prophylactic

agent, both the compound and the additional agent are usually present at dosage levels of between about 10 to 150%, and more preferably between about 10 and 80% of the dosage normally administered in a monotherapy regimen.

Pharmaceutical formulations may be adapted for administration by any appropriate route, for example by the oral (including buccal or sublingual), rectal, nasal, topical (including buccal, sublingual, or transdermal), vaginal, or parenteral (including subcutaneous, intracutaneous, intramuscular, intra-articular, intrasynovial, intrasternal, intrathecal, intralesional, intravenous, or intradermal injections or infusions) route. Such formulations may be prepared by any method known in the art of pharmacy, for example by bringing into association the active ingredient with the carrier(s) or excipient(s).

Pharmaceutical formulations adapted for oral administration may be presented as discrete units such as capsules or tablets; powders or granules; solutions or suspensions in aqueous or non-aqueous liquids; edible foams or whips; or oil-in-water liquid emulsions or water-in-oil emulsions.

For instance, for oral administration in the form of a tablet or capsule, the active drug component can be combined with an oral, non-toxic pharmaceutically acceptable inert carrier such as ethanol, glycerol, water, and the like. Powders are prepared by comminuting the compound to a suitable fine size and mixing with a similarly comminuted pharmaceutical carrier such as an edible carbohydrate, as, for example, starch or mannitol. Flavoring, preservative, dispersing, and coloring agent can also be present.

Capsules are made by preparing a powder mixture, as described above, and filling formed gelatin sheaths. Glidants and lubricants such as colloidal silica, talc, magnesium stearate, calcium stearate, or solid polyethylene glycol can be added to the powder mixture before the filling operation. A disintegrating or solubilizing agent such as agar-agar, calcium carbonate, or sodium carbonate can also be added to improve the availability of the medicament when the capsule is ingested.

Moreover, when desired or necessary, suitable binders, lubricants, disintegrating agents, and coloring agents can also be incorporated into the mixture. Suitable binders include starch, gelatin, natural sugars such as glucose or beta-lactose, corn sweeteners, natural and synthetic gums such as acacia, tragacanth or sodium alginate, carboxymethylcellulose, polyethylene glycol, and the like.

Lubricants used in these dosage forms include sodium oleate, sodium chloride, and the like. Disintegrators include, without limitation, starch, methyl cellulose, agar, betonite, xanthan gum, and the like. Tablets are formulated, for example, by preparing a powder mixture, granulating or slugging, adding a lubricant and disintegrant, and pressing into tablets. A powder mixture is prepared by mixing the compound, suitable comminuted, with a diluent or base as described above, and optionally, with a binder such as carboxymethylcellulose, an aliginate, gelating, or polyvinyl pyrrolidone, a solution retardant such as paraffin, a resorption accelerator such as a quaternary salt and/or and absorption agent such as betonite, kaolin, or dicalcium phosphate. The powder mixture can be granulated by wetting with a binder such as syrup, starch paste, acadia mucilage, or solutions of cellulosic or polymeric materials and forcing through a screen. As an alternative to granulating, the powder mixture can be run through the tablet machine and the result is imperfectly formed slugs broken into granules. The granules can be lubricated to prevent sticking to the tablet forming dies by means of the addition of stearic acid, a stearate salt, talc, or mineral oil. The lubricated mixture is then compressed into tablets. The compounds of the present disclosure can also be combined with a free flowing inert carrier and compressed into tablets directly without going through the granulating or slugging steps. A clear or opaque protective coating consisting of a sealing coat of shellac, a coating of sugar or polymeric material, and a polish coating of wax can be provided. Dyestuffs can be added to these coatings to distinguish different unit dosages.

Oral fluids such as solution, syrups, and elixirs can be prepared in dosage unit form so that a given quantity contains a predetermined amount of the compound. Syrups can be prepared by dissolving the compound in a suitably flavored aqueous solution, while elixirs are prepared through the use of a non-toxic vehicle. Solubilizers and emulsifiers such as ethoxylated isostearyl alcohols and polyoxyethylene sorbitol ethers, preservatives, flavor additive such as peppermint oil or natural sweeteners, or saccharin or other artificial sweeteners, and the like can also be added.

Where appropriate, dosage unit formulations for oral administration can be microencapsulated. The formulation can also be prepared to prolong or sustain the release as for example by coating or embedding particulate material in polymers,

wax, or the like.

The compounds of formula (I), and pharmaceutically acceptable salts thereof, can also be administered in the form of liposome delivery systems, such as small unilamellar vesicles, large unilamellar vesicles, and multilamellar vesicles. Liposomes can be formed from a variety of phopholipids, such as cholesterol, stearylamine, or phophatidylcholines.

The compounds of formula (I) and pharmaceutically acceptable salts thereof may also be delivered by the use of monoclonal antibodies as individual carriers to which the compound molecules are coupled. The compounds may also be coupled with soluble polymers as targetable drug carriers. Such polymers can include polyvinylpyrrolidone, pyran copolymer, polyhydroxypropylmethacrylamidephenol, polyhydroxyethylaspartamidephenol, or polyethyleneoxidepolylysine substituted with palitoyl residues. Furthermore, the compounds may be coupled to a class of biodegradable polymers useful in achieving controlled release of a drug, for example, polylactic acid, polepsilon caprolactone, polyhydroxy butyric acid, polyorthoesters, polyacetals, polydihydropyrans, polycyanoacrylates, and cross-linked or amphipathic block copolymers of hydrogels.

Pharmaceutical formulations adapted for transdermal administration may be presented as discrete patches intended to remain in intimate contact with the epidermis of the recipient for a prolonged period of time. For example, the active ingredient may be delivered from the patch by iontophoresis as generally described in Pharmaceutical Research, 3(6), 318 (1986).

Pharmaceutical formulations adapted for topical administration may be formulated as ointments, creams, suspensions, lotions, powders, solutions, pastes, gels, sprays, aerosols, or oils.

For treatments of the eye or other external tissues, for example mouth and skin, the formulations are preferably applied as a topical ointment or cream. When formulated in an ointment, the active ingredient may be employed with either a paraffinic or a water-miscible ointment base. Alternatively, the active ingredient may be formulated in a cream with an oil-in-water cream base or a water-in oil base.

Pharmaceutical formulations adapted for topical administrations to the eye include eye drops wherein the active ingredient is dissolved or suspended in a suitable carrier, especially an aqueous solvent.

Pharmaceutical formulations adapted for topical administration in the mouth include lozenges, pastilles, and mouth washes.

Pharmaceutical formulations adapted for rectal administration may be presented as suppositories or as enemas.

Pharmaceutical formulations adapted for nasal administration wherein the carrier is a solid include a course powder having a particle size for example in the range 20 to 500 microns which is administered in the manner in which snuff is taken, i.e., by rapid inhalation through the nasal passage from a container of the powder held close up to the nose. Suitable formulations wherein the carrier is a liquid, for administration as a nasal spray or nasal drops, include aqueous or oil solutions of the active ingredient.

Pharmaceutical formulations adapted for administration by inhalation include fine particle dusts or mists, which may be generated by means of various types of metered, dose pressurized aerosols, nebulizers, or insufflators.

Pharmaceutical formulations adapted for vaginal administration may be presented as pessaries, tampons, creams, gels, pastes, foams, or spray formulations.

Pharmaceutical formulations adapted for parenteral administration include aqueous and non-aqueous sterile injection solutions which may contain anti-oxidants, buffers, bacteriostats, and soutes which render the formulation isotonic with the blood of the intended recipient; and aqueous and non-aqueous sterile suspensions which may include suspending agents and thickening agents. The formulations may be presented in unit-dose or multi-dose containers, for example sealed ampoules and vials, and may be stored in a freeze-dried (lyophilized) condition requiring only the addition of the sterile liquid carrier, for example water for injections, immediately prior to use. Extemporaneous injection solutions and suspensions may be prepared from sterile powders, granules, and tablets.

It should be understood that in addition to the ingredients particularly mentioned above, the formulations may include other agents conventional in the art having regard to the type of formulation in question, for example those suitable for oral administration may include flavoring agents.

Table 1 below lists some illustrative examples of compounds that can be administered with the compounds of this disclosure. The compounds of the disclosure can be administered with other anti-HCV activity compounds in

combination therapy, either jointly or separately, or by combining the compounds into a composition.

The starting materials useful to synthesize the compounds of the present disclosure are known to those skilled in the art and can be readily manufactured or are commercially available.

The following methods set forth below are provided for illustrative purposes and are not intended to limit the scope of the claims. It will be recognized that it may be necessary to prepare such a compound in which a functional group is protected using a conventional protecting group then to remove the protecting group to provide a compound of the present disclosure. The details concerning the use of protecting groups in accordance with the present disclosure are known to those skilled in the art.

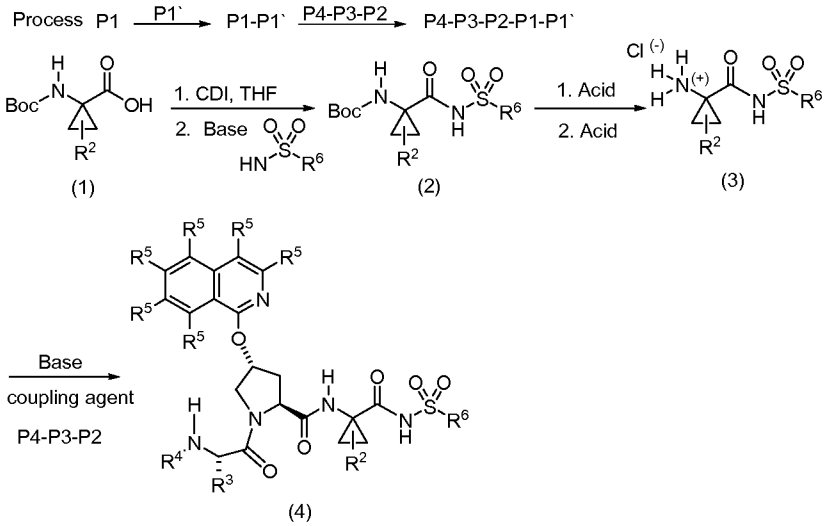

Scheme I shows the general process wherein compounds of Formula (I) are constructed by the coupling of tripeptide carboxylic acid intermediate (1) with a P1` sulfonamide. Said coupling reaction requires treatment of carboxylic acid (1) with a coupling reagent such as carbonyl diimidazole in a solvent such as THF, which can be heated to reflux, followed by the addition of the formed derivative of (1), to the P1` sulfonamide, in a solvent such as THF or methylene chloride in the presence of a base such as DBU.

Scheme I

An alternative process for the construction of compounds of Formula (I) is shown in Scheme II. Therein the P1` sulfonamide element is coupled to the P1 element using the process employed in Scheme 1. The resulting P1-P1` moiety can then be deprotected at its amino terminus. In this general example a Boc protecting group is employed but one skilled in the art would recognize that a number of suitable amino protecting groups could be employed in this process. The Boc protecting group can be removed using acid such as trifluoroacetic acid in a solvent such as dichloroethane to provide the deprotected amine as the TFA salt. Said TFA amine salt can be directly employed in the subsequent coupling reaction or as an alternative the TFA amine salt can be first converted to the HCl amine salt, and this HCl amine salt is used in said coupling reaction as shown in Scheme II. The coupling of said HCl amine salt (3) with the carboxyl terminus of a P4-P3-P2 intermediate can be achieved using coupling reagents, such as HATU, in solvents such as dichloromethane to provide compounds of Formula (I) (4).

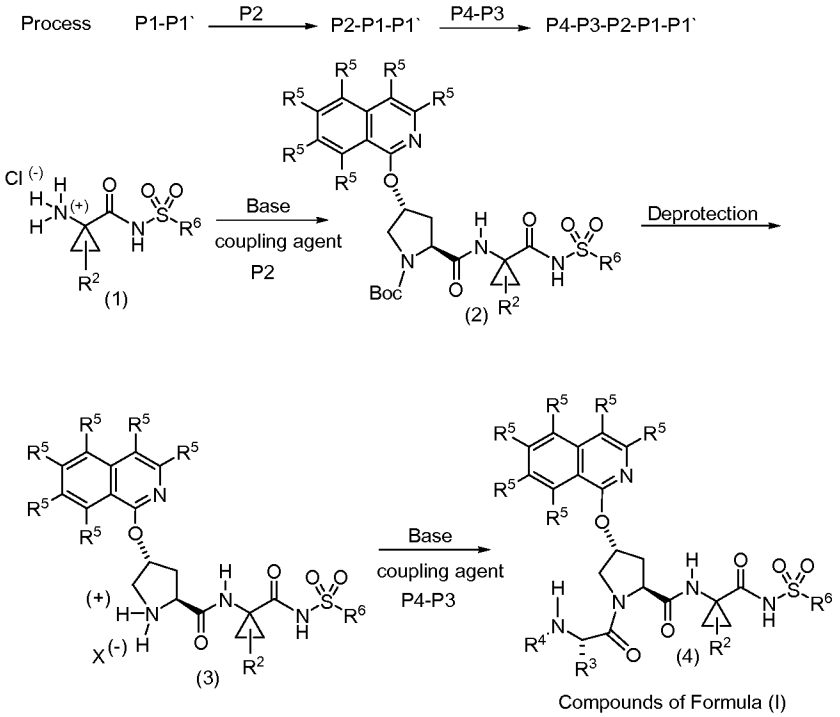

Scheme II

Compounds of Formula (I)

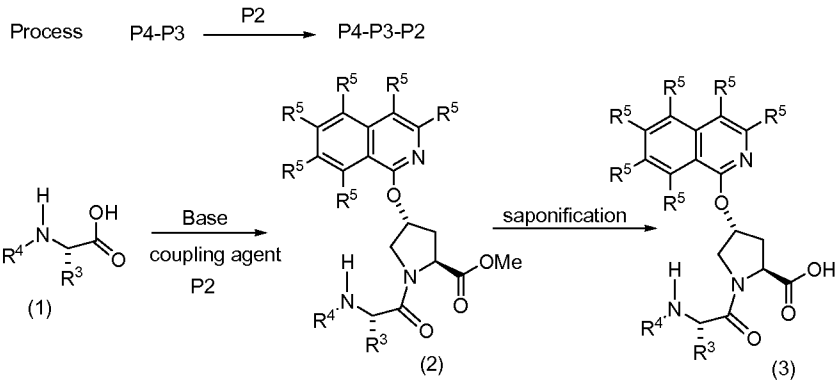

An alternative process for the construction of compounds of Formula (I) is shown in Scheme III. Here the hydrochloride salt of the P1-P1` terminal amine (1) is coupled to the free carboxyl group of the P2 element using coupling agents such as PyBOP, in the presence of a base such as diisopropylamine, and in a solvent such as methylene chloride. The resulting P2-P1-P1` intermediate can be converted to compounds of Formula (I) in a two step process wherein the first step is deprotection of the P2 amine terminus using an acid such as TFA in a solvent such as methylene chloride. The resulting trifluoroacetic acid salt can be coupled with the carboxyl terminus of the P4-P3 element using standard coupling agents such as PyBop in the presence of base such as diisopropyl amine, and using solvents such methylene chloride to provide compounds of Formula (I) (4).

Scheme III

The P4-P3-P2 intermediate utilized in the above schemes can be constructed as previously described with a further description of this process shown in general Scheme IV. The free carboxyl terminus of the P4-P3 intermediate (1), can be coupled to the amino terminus of the P2 element to provide the P4-P3-P2 dipeptide (2). The carboxyl terminus of the P4-P3-P2 intermediate can be deprotected by saponification of the ester group to provide P4-P3-P2 as the free carboxylic acid (3). Intermediates like (3) can be converted to compounds of Formula (I) using the methods described herein.

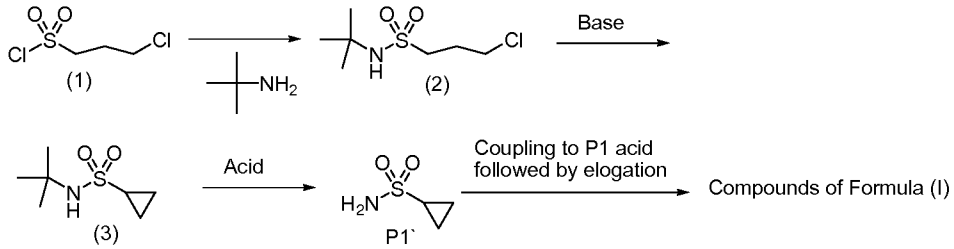

Scheme IV

In the construction of compounds of Formula (I), the P1` terminus is

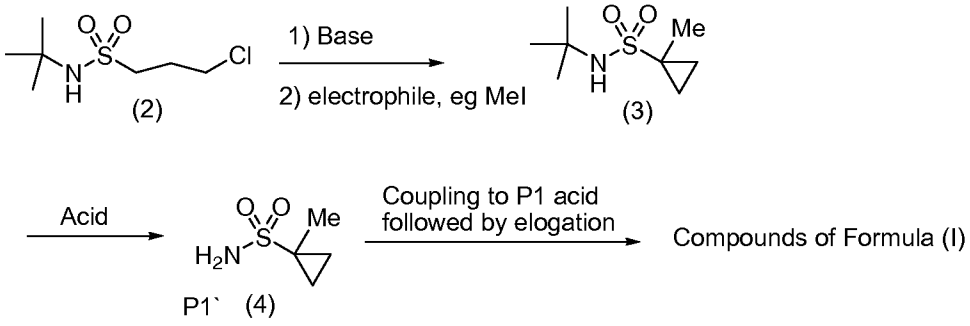

incorporated into the molecules using one of the general processes outlined above and described in more detail below. In some examples the P1` elements, that is the cycloalkyl or alkyl sulfonamides, are commercially available or can be prepared from the corresponding alkyl- or cycloalkylsulfonyl chloride by treating the sulfonyl chloride with ammonia. Alternatively, these sulfonamides can be synthesized using the general process outline in Scheme V. Commercially available 3-chloropropylsulfonyl chloride (1) is converted to a suitably protected sulfonamide, for example, by treatment with tert-butyl amine. The sulfonamide obtained (2) is then converted to the corresponding cycloalkylsulfonamide by treatment with two equivalents of a base such as butyllithium in a solvent such as THF at low temperature. The resulting cycloalkylsulfonamide can be deprotected by treatment with an acid to provide the desired unprotected cycloalkylsulfoamide.

Scheme V

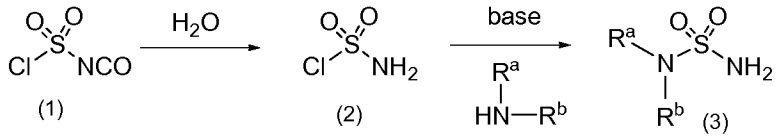

Substituted cycloalkylsulfonamides can also be incorporated into compounds of Formula (I) using a modification of the above said procedure. For example, intermediate 2 of Scheme VI can be treated with two equivalents of base such as butyllithium and the resulting reaction mixture can be treated with an electrophile such as methyl iodide to provide a substituted cycloalkylsulfonamide (3). This intermediate (3) can be deprotected at the N-terminus and the resulting compound (4) utilized as an intermediate in the preparation of compounds of Formula (I).

Scheme VI

The P1` intermediates employed in generating compounds of Formula (I) are in some cases derived from sulfamide derivatives. In such cases the sulfamide intermediates are available by several synthetic routes as, for example, by the pathway outlined in Scheme VII.

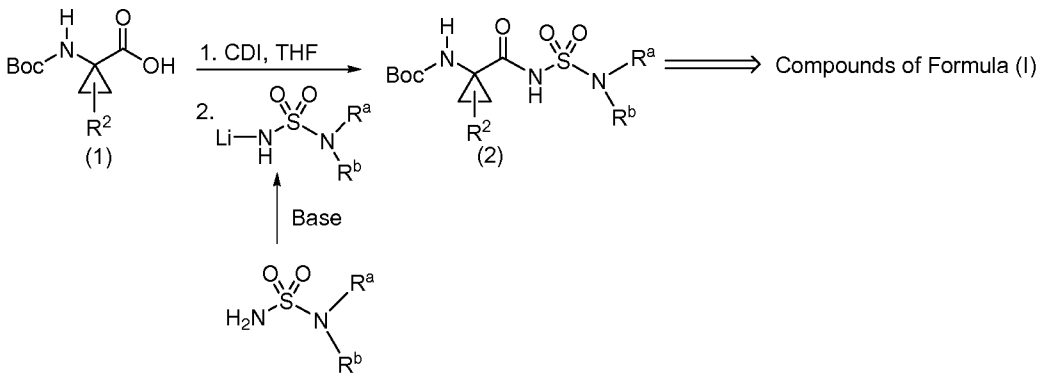

Scheme VII

Sulfamoyl chloride (2) can be prepared *in situ* by the addition of water (e.g., 1 equivalent) to chlorosulfonyl isocyanate 1 (e.g., 1 equivalent) in a solvent such as THF while maintained at a low temperature such as -20 °C. The resulting solution is then allowed to warm to 0 °C. To this solution a base, such as anhydrous triethylamine (eg., 1 equivalent), is added followed by an amine (eg., 1 equivalent). The reaction mixture is then warmed to room temperature, filtered, and the filtrate concentrated to provide the desired sulfamides (3).

The sulfamides can be incorporated into compounds of Formula (I) by several processes as, for example, by following the synthetic pathway defined in Scheme VIII. A carboxylic acid P1 element (1) is treated with an activating agent such as CDI. In a separate flask, a strong base is added to a solution of the above described sulfamide and the resulting reaction mixture is stirred for several hours after which this reaction mixture is added to the flask containing the activated carboxylic acid, to provide acylsulfamide derivatives (2). Intermediates like 2 can be converted to compounds of Formula (I) as described herein.

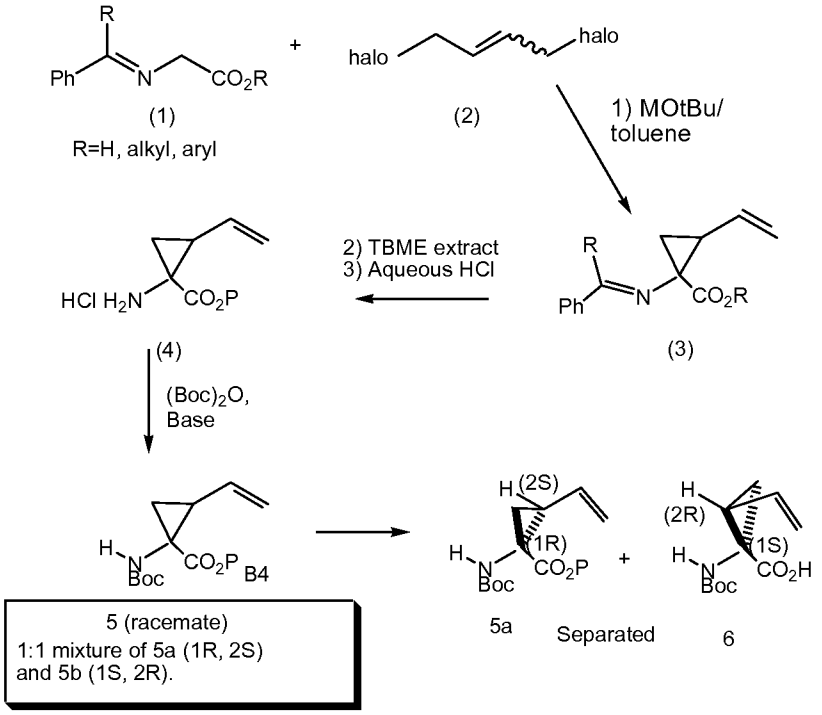

Scheme VIII

The P1 elements utilized in generating compounds of Formula (I) are in some cases commercially available, but are otherwise synthesized using the methods described herein and are subsequently incorporated into compounds of Formula (I) using the methods described herein. The substituted P1 cyclopropylamino acids can be synthesized following the general process outline in Scheme IX.

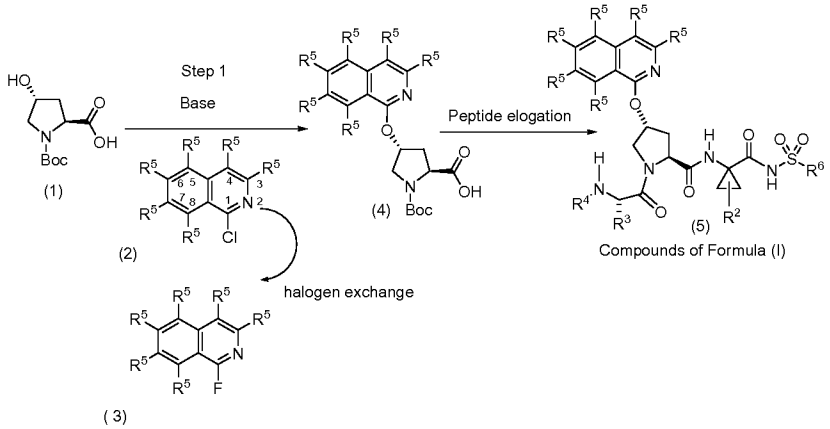

Treatment of commercially available or easily synthesized imine (1) with 1,4-dihalobutene (2) in presence of a base provides the resulting imine (3). Acid hydrolysis of 3 then provides 4, which has an allyl substituent syn to the carboxyl group, as a major product. The amine moiety of 4 can protected using a Boc group to provide the fully protected amino acid 5. This intermediate is a racemate which can be resolved by an enzymatic process wherein the ester moiety of 5 is cleaved by a protease to provide the corresponding carboxylic acid. Without being bound to any particular theory, it is believed that this reaction is selective in that one of the enantiomers undergoes the reaction at a much greater rate than its mirror image providing for a kinetic resolution of the intermediate racemate. In the examples cited herein, the more preferred stereoisomer for integration into compounds of Formula (I) is 5a which houses the (1R, 2S) stereochemistry. In the presence of the enzyme, this enantiomer does not undergo ester cleavage and thereby this enantiomer,5a, is recovered from the reaction mixture. However, the less preferred enantiomer ,5b, which houses the (1S, 2R) stereochemistry, undergoes ester cleavage, i.e., hydrolysis, to provide the free acid 6. Upon completion of this reaction, the ester 5a can be separated from the acid product 6 by routine methods such as, for example, aqueous extraction methods or chromotography.

Scheme IX

Procedures for making P2 intermediates and compounds of Formula (I) are shown in the schemes below. It should be noted that in many cases reactions are depicted for only one position of an intermediate. However, it is to be understood that such reactions could be used to impart modifications to other positions within this intermediate. Moreover, said intermediates, reaction conditions, and methods given in the specific examples are broadly applicable to compounds with other substitution patterns. Both general and specific examples are non-limiting.

Scheme X

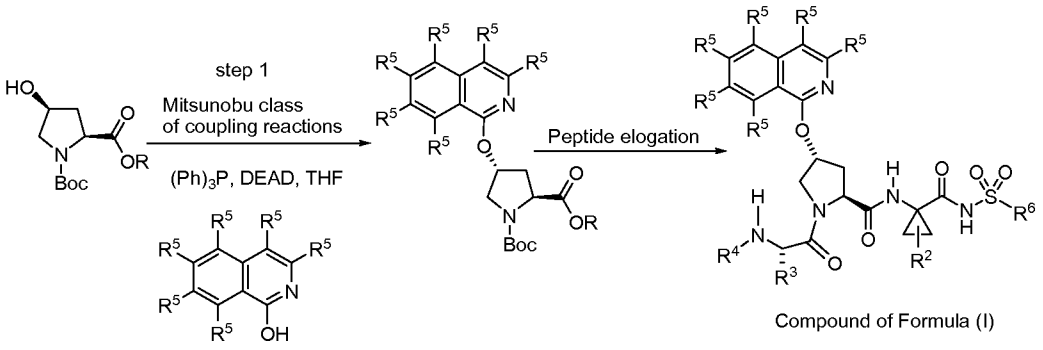

Scheme X shows the coupling of an N-protected C4-hydroxyproline moiety

with a heterocycle to form intermediate (4) and the subsequent modification of said intermediate (4) to a compound of Formula (I) by the process of peptide elongation as described herein. It should be noted that in the first step, that is the coupling of the C4-hydroxy proline group with the heteroaryl element, a base is employed. One skilled in the art would recognized that this coupling can be done using bases such as potassium tert-butoxide, or sodium hydride, in a solvent such as DMF or DMSO or THF. This coupling to the isoquinoline ring system occurs at the C1 position (numbering for isoquinoline ring system shown in intermediate 2 of Scheme XI) and is directed by the chloro group which is displaced in this process. It should be noted that alternative leaving groups can be utilized at this position (e.g., fluoro) as shown in the scheme. Said fluoro intermediates (3) are available from the corresponding chloro compound using literature procedures described herein.

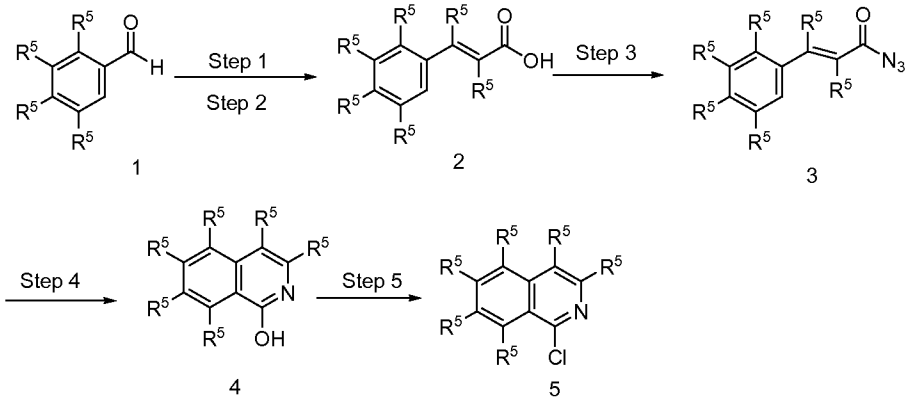

An alternative to the method described above for the coupling of the C4-hydroxyproline to the isoquinoline nucleus is provided in the Mitsunobu reaction as depicted in step 1 of Scheme XI. In this general reaction scheme a C4-hydroxy proline derivative is coupled to an isoquinoline ring system. This reaction makes use of reagents such as triphenylphosphine and DEAD (diethylazodicarboxylate) in aprotic solvents such as THF or dioxane and can be used for the formation of heteroaryl ethers. Note that in the course of this coupling reaction the stereochemistry of the C4 chiral center in the C4-hydroxyproline derivative is inverted and thereby it is necessary to use the C4-hydroxyproline derivative housing the (S) stereochemistry at the C4 position as starting material (as shown in Scheme XI). It should be noted that numerous modifications and improvements of the Mitsunobu reaction have been described in the literature, the teachings of which are incorporated herein.

Scheme XI

In examples herein, isoquinolines are incorporated into the final compounds and specifically into the P2 region of said compounds. One skilled in the art would recognize that a number of general methods are available for the synthesis of isoquinolines. Moreoever, the isoquinolines generated by these methods can be readily incorporated into final compounds of Formula (I) using the processes described herein. One general methodology for the synthesis of isoquinolines is shown in Scheme XII, wherein cinnamic acid derivatives, shown in general form as structure (2), are converted to 1-chloroisoquinolines in a four step process. The chloroisoquinolines can be subsequently used in coupling reactions to C4-hydroxyproline derivatives as described herein. The conversion of cinnamic acids to chloroquinolines begins with the treatment of cinnamic acid with an alkylcholorformate in the presence of a base. The resulting anhydride is then treated with sodium azide which results in the formation of an acylazide (3) as shown in the scheme. Alternate methods are available for the formation of acylazides from carboxylic acids as for example said carboxylic acid can be treated with diphenylphosphorylazide (DPPA) in an aprotic solvent such as methylene chloride in the presence of a base. In the next step of the reaction sequence the acylazide (3) is coverted to the corresponding isoquinolone (4) while heating to a temperature of approximately 190 °C in a high boiling solvent such a diphenylmethane. This reaction is general and provides moderate to good yields of substituted isoquinolone from the corresponding cinnamic acid derivatives. It should noted that said cinnamic acid derivatives are available commercially or can be obtained from the corresponding benzaldehyde (1) derivative by direct condensation with malonic acid or derivatives thereof and also by employing a Wittig reaction. The intermediate isoquinolones (4) of Scheme XII can be converted to the corresponding 1-chloroisoquinoline by treatment with phosphorous oxychloride. This reaction is general and can be applied to the isoquinolones shown herein.

An alternative method for the synthesis of the isoquinoline ring system is the Pomeranz-Fritsh procedure. This general method is outlined in Scheme XIII. The process begins with the conversion of a benzaldehyde derivative (1) to a functionalized imine (2). The imine is then converted to the isoquinoline ring system by treatment with acid at elevated temperature. This isoquinoline synthesis of Scheme XIII is general, and it should be noted that this process is particularly useful in procuring isoquinoline intermediates that are substituted at the C8 position. The intermediate isoquinolines (3) can be converted to the corresponding 1-chloroquinolines (5) in a two step process as shown. The first step in this sequence is the formation of the isoquinoline N-oxide(4) by treatment of isoquinoline (3) with meta-chloroperbenzoic acid in an aprotic solvent such as dichloromethane. Intermediate (4) can be converted to the corresponding 1-chloroquinoline by treatment with phosphorous oxychloroide in refluxing chloroform. Note that this two step process is general for the formation of chloroisoquinolines from isoquinolones.

Another method for the synthesis of the isoquinoline ring system is shown in Scheme XIV. In this process an ortho-alkylbenzamide derivative (1) is treated with a strong base such as tert-butyllithium in a solvent such as THF at low temperature. To this reaction mixture is then added a nitrile derivative, which undergoes an addition reaction with the anion derived from deprotonation of (1), resulting in the formation of (2). This reaction is general and can be used for the formation of substituted isoquinolines. Intermediate (2) of Scheme XIV can be converted to the corresponding 1-chloroquinoline by the methods described herein.

Scheme XIV

An additional method for the synthesis of isoquinolines is shown in Scheme XV. The deprotonation of intermediate (1) using tert-butyllithium is described above. In the present method however, the intermediate anion is trapped by an ester, resulting in the formation of intermediate (2) as shown below. In a subsequent reaction, ketone (2) is condensed with ammoniumn acetate at elevated temperature providing for the formation of quinolone (3). This reaction is general and can be applied to the construction of substituted isoquinolones which can then be converted to the corresponding 1-chloroisoquinolines as described herein.

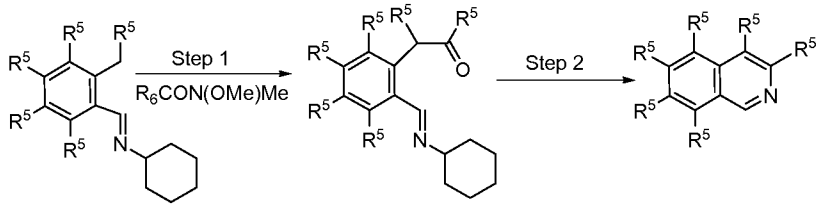

Scheme XV

Another method for the construction of isoquinolines is found in Scheme XVI. In the first step of this process an ortho-alkylarylimine derivatives such as (1) are subjected to deprotonation conditions (sec-butyl lithium, THF) and the resulting anion is quenched by the addition of an activated carboxylic acid derivative such as a Weinreb amide. The resulting ketoimine (2) can be converted to the corresponding isoquinoline by condensation with ammonium acetate at elevated temperatures. This

method is general and can be used for the synthesis of substituted isoquinolines. The isoquinolines can be converted to the corresponding 1-chloroquinoline by the methods described herein.

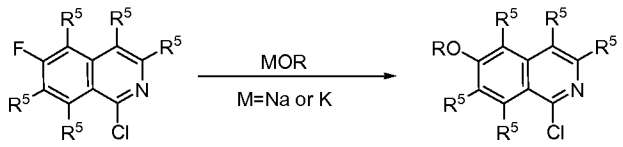

Scheme XVI

The isoquinolines described herein, and which are incorporated into the compounds of Formula (I), can be further functionalized. It is obvious to one skilled in the art that additional functionalization of said heterocycles can be done either before or after incorporation of these functionalities into compounds of Formula (I). The following schemes illustrate this point. For example Scheme XVII shows the conversion of a 1-chloro-6-fluoro-isoquinoline to the corresponding 1-chloro-6-alkoxy-isoquinoline species, by treatment of (1) with a sodium or potassium alkoxide species in the alcohol solvent from which the alkoxide is derived at room temperature. In some cases it may be necessary to heat the reaction to drive it to completion. The chloroquinoline can be incorporated into a compound of Formula (I) using the art described herein.

Scheme XVII

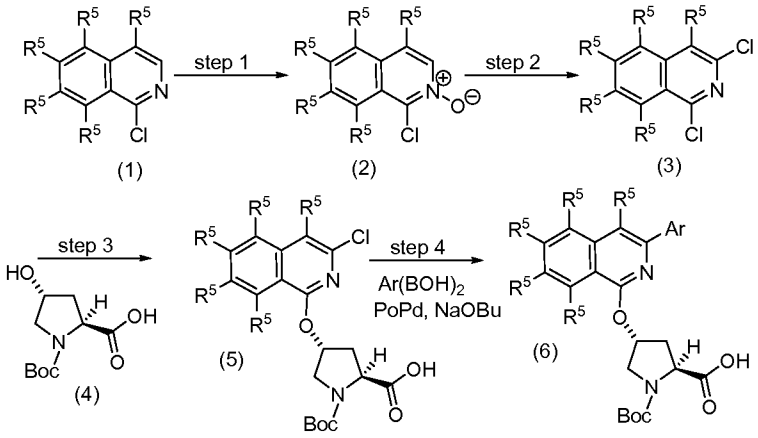

(1) (2)

Scheme XVIII provides a general example for the modification of isoquinolines as defined herein by employing palladium mediated coupling reactions. The couplings can be employed to functionalize a heterocycle at each position of the ring system provided the ring is suitably activated or functionalized, as for example with a chloride as shown in the scheme. This sequence begins with 1-chloroisoquinoline (1) which upon treatment with metachloroperbenzoic acid can be converted to the corresponding N-oxide (2). Intermediate (2) can be converted to the

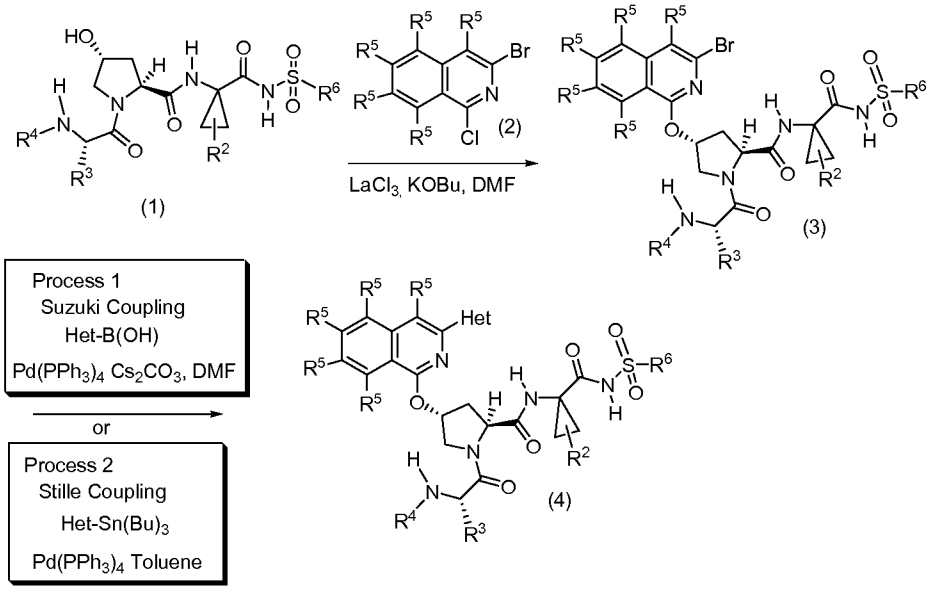

corresponding 1,3-dichloroisoquinoline (3) by treatment with phosphorous oxychloride in refluxing chloroform. Intermediate (3) can be coupled with N-Boc-4-hydroxyproline by the methods described herein to provide intermediate (5) as shown in the scheme. Intermediate (5) can undergo a Suzuki coupling with an aryl boronic acid, in the presence of a palladium reagent and base, and in a solvent such as THF or toluene or DMF to provide the C3-arylisoquinoline intermediate (6). Heteroarylboronic acids can also be employed in this palladium-mediated coupling process to provide C3-heteroarylisoquinolines. Intermediate (6) can be converted into final compounds of Formula (I) by the methods described herein.

Scheme XVIII

Palladium mediated couplings of isoquinoline systems with aryl or heteroaryl elements can also be employed at a later synthetic stage in the construction of compounds of Formula (I) as shown in Scheme XIX. Tripeptide acylsulfonamide intermediate (1) is coupled to a 1-chloro-3-bromoisoquinoline (2) using the previously described process to provide intermediate (3). The coupling of (1) and (2) is most efficient in the presence of a catalyst such as lanthanum chloride as described herein. The isoquinoline ring system of intermediate (3) can be further functionalized by employing either Suzuki couplings (Process 1: subjecting (3) to heteroaryl or aryl boronic acids in the presence of a palladium catalyst such as palladium tetrakistriphenylphosphine and a base such as cesium carbonate in solvents such as DMF) or Stille couplings (Process 2: subjecting (3) to heteraryl or aryl tin dervatives in the presence of a palladium catalyst such as palladium tetrakistriphenylphosphine in solvents such as toluene).

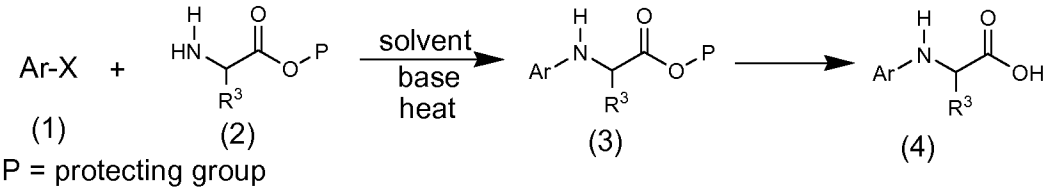

Scheme XIX

The P3 amino acids employed in the present invention are either commercially available or can be prepared using methods known to those of ordinary skill in the art. Non-limiting routes for the preparation of the P3 amino acid include:

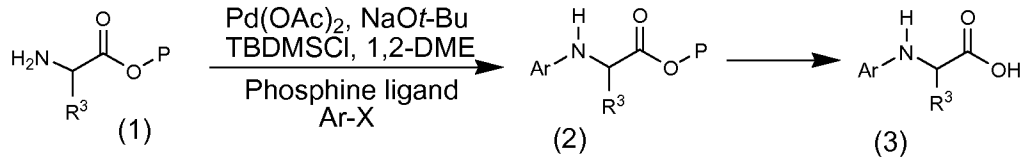

Route 1: Nucleophilic aromatic substitution of a sufficiently electrophilic aromatic or heteroaromatic species (1) with an amino acid ester (2) as shown in Scheme XX. This reaction is then followed by a simple ester cleavage of 3 to provide the desired amino acid (4).

Scheme XX

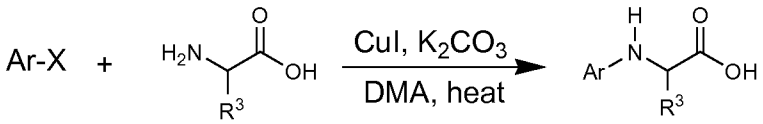

Route 2: A Buchwald-Hartwig type reaction which involves palladium-catalyzed coupling an aryl or heteroaryl halide bond with a suitably protected amino acid (1) as shown in Scheme XXI. Simple saponification of intermediate 2 provides the desired amino acid (3). (Shen, Q.; Shekhar, S; Stambuli, J. P.; Hartwig, J. F. *Angew. Chem. Int. Ed.* **2005**, *44*, 1371-1375.):

Scheme XXI

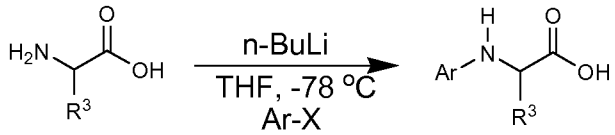

Route 3: A coupling process whereby an aryl or heteroaryl halide and a free amino acid are coupled *via* a CuI mediated process to give the arylamino acid directly as shown in Scheme XXII (Ma, D.; Zhang, Y.; Yao, J.; Wu, S.; Tao, F. *J. Am. Chem. Soc.* **1998**, *120*, 12459-12467.)

Scheme XXII

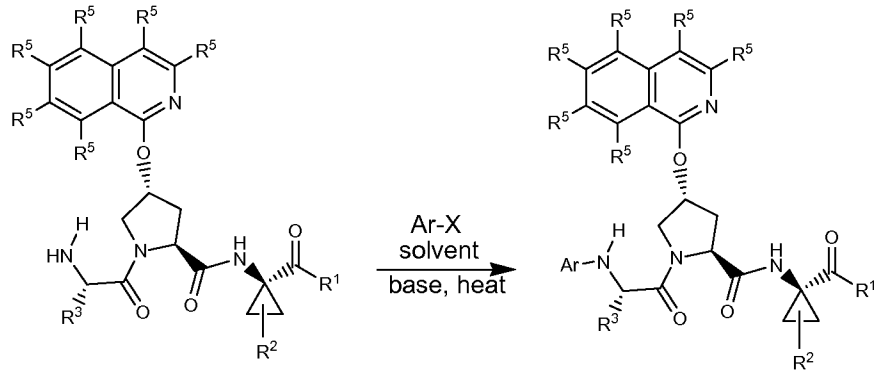

Route 4: A process which employs nucleophilic displacement of the dianion of a free amino acid and an aryl or heteroaryl halide, typically a fluoride (similar to Saitton, S.; Kihlberg, J.; Luthman, K. *Tetrahedron* **2004**, *60*, 6113-6120.):

In some cases, as shown in Scheme XXIII, access to the aminoaryl final products can be achieved by direct nucleophilic aromatic substitution of the aryl ring with a fully assembled core tripeptide having a free amino group at the terminus of the P3 subregion.

A solution of the racemic *N*-Boc-(1R,2S)/(1S,2R)-1-amino-2-vinylcyclopropane carboxylic acid ethyl ester (85g) in 850 mL of DMSO was then added over a period of 40 minutes. The reaction temperature was then maintained at 40 °C for 24.5 hours during which time the pH of the mixture was adjusted to 8.0 at the 1.5 hour and 19.5 hour time points using 50% NaOH in water. After 24.5 hours, the enantio-excess of the ester was determined to be 97.2%, and the reaction was cooled to room temperature (26 °C) and stirred overnight (16 hours) after which the enantio-excess of the ester was determined to be 100%. The pH of the reaction mixture was then adjusted to 8.5 with 50% NaOH and the resulting mixture was extracted with MTBE (2 x 2 L). The combined MTBE extract was then washed with 5% $NaHCO_3$ (3 x 100 mL), water (3 x 100 mL), and concentrated *in vacuo* to give the enantiomerically pure *N*-Boc-(1R,2S)/-1-amino-2-vinylcyclopropane carboxylic acid ethyl ester as light yellow solid (42.55 g; purity: 97% @ 210 nm, containing no acid; 100% enantiomeric excess ("ee").

The aqueous layer from the extraction process was then acidified to pH 2 with 50% H_2SO_4 and extracted with MTBE (2 x 2 L). The MTBE extract was washed with water (3 x 100 mL) and concentrated to give the acid as light yellow solid (42.74 g; purity: 99% @ 210 nm, containing no ester).

Scheme 1

Step 1:

To a solution of 1(*R*)-tert-butoxycarbonylamino-2(*S*)-vinyl-cyclopropanecarboxylic acid ethyl ester (3.28 g, 13.2 mmol) in THF (7 mL) and methanol (7 mL) was added a suspension of LiOH (1.27 g, 53.0 mmol) in water (14 mL). The mixture was stirred overnight at room temperature. To the mixture was added 1.0M NaOH (15 mL), water (20 mL) and ethyl acetate (20 mL). The mixture was shaken, the phases were separated, and the organic phase was again extracted with 20 mL 0.5M NaOH. The combined aqueous phases were acidified with 1.0M

HCl until pH = 4 and extracted with ethyl acetate (3 x 40mL). The combined organic extracts were washed with brine, dried ($MgSO_4$), and filtered to provide the desired product as a white solid (2.62 g, 87%). ^{1}H NMR: (DMSO-d_6) δ1.22-1.26 (m, 1H), 1.37 (s, 9H), 1.50-1.52 (m, 1H), 2.05 (q, J = 9 Hz, 1H), 5.04 (d, J = 10 Hz, 1H), 5.22 (d, J = 17 Hz, 1H), 5.64-5.71 (m, 1H), 7.18, 7.53 (s, NH (rotamers), 12.4 (br s, 1H)); LC-MS MS *m/z* 228 (M^+ + H).

Step 2:

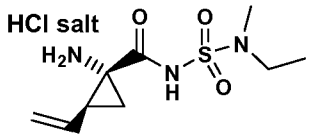

A solution of the product of Step 1 (2.62 g, 11.5 mmol) and CDI (2.43 g, 15.0 mmol) in THF (40 mL) was heated at reflux for 50 minutes under nitrogen. The solution was cooled to room temperature and transferred by cannula to a solution of cyclopropylsulfonamide (1.82 g, 15.0 mmol) in THF (10 mL). To the resulting solution was added DBU (2.40 mL, 16.1 mmol) and stirring was continued for 20 hours. The mixture was quenched with 1.0M HCl to pH = 1, and THF was evaporated *in vacuo*. The suspension was extracted with ethyl acetate (2 x 50 mL) and the organic extracts were combined and dried (Na_2SO_4). Filtration, concentration, and purification by recrystallization from hexanes-ethyl acetate (1:1) provideed the desired product (2.4 g) as a white solid. The mother liquor was purified by a Biotage 40S column (eluted 9% acetone in dichloromethane) to give a second batch of the desired product (1.1 g). Both batches were combined (total yield 92%). ^{1}H NMR: (DMSO-d_6) δ 0.96-1.10 (m, 4H), 1.22 (dd, J = 5.5, 9.5 Hz, 1H), 1.39 (s, 9H), 1.70 (t, J = 5.5 Hz, 1H), 2.19-2.24 (m, 1H), 2.90 (m, 1H), 5.08 (d, J = 10 Hz, 1H), 5.23 (d, J = 17 Hz, 1H), 5.45 (m, 1H), 6.85, 7.22 (s, NH (rotamers)); LC-MS, MS *m/z* 331 (M^+ + H).

Step 3:

A solution of the product of Step 2 (3.5 g, 10.6 mmol) in dichloromethane (35 mL) and TFA (32 mL) was stirred at room temperature for 1.5 hours. The volatiles were removed *in vacuo* and the residue suspended in 1.0M HCl in diethyl ether (20 mL) and concentrated *in vacuo*. This procedure was repeated once. The resulting mixture was triturated with pentane and filtered to give the title compound as a hygroscopic, off-white solid (2.60 g, 92%). ^{1}H NMR (DMSO-d_6) δ 1.01-1.15 (m,

4H), 1.69-1.73 (m, 1H), 1.99-2.02 (m, 1H), 2.38 (q, J = 9 Hz, 1H), 2.92-2.97 (m, 1H), 5.20 (d, J = 11 Hz, 1H), 5.33 (d, J = 17 Hz, 1H), 5.52-5.59 (m, 1H), 9.17 (br s, 3H); LC-MS, MS *m/z* 231 (M^+ + H).

13. Preparation of P1-P1' sulfamide derivative

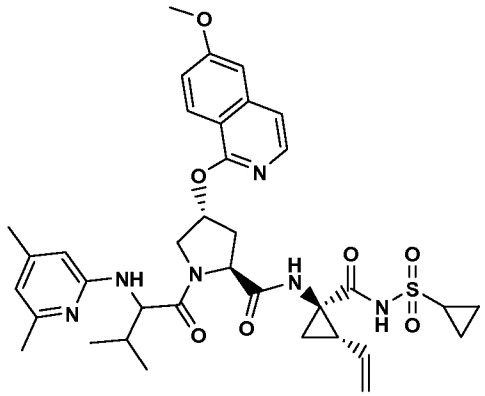

To a solution of (1R, 2S) 1-*tert*-butoxycarbonylamino-2-vinyl-cyclopropanecarboxylic acid (217 mg, 1.194 mmol) in THF (5 mL), was added CDI (290 mg, 1.791 mmol) and the reaction mixture was heated to reflux for 45 minutes. In another round-bottomed flask, LiHMDS (1.0M solution in hexanes, 2.4 mL, 2.4 mmol) was added to a solution of *N*-ethylmethylsulfamide (330 mg, 2.388 mmol) in THF (5 mL) and the reaction mixture was stirred at room temperature for 1 hour. The two reaction mixtures were combined and stirred at room temperature for 2 hours. Water was added to quench the reaction and the reaction solution was extracted with ethyl acetate. The organic layer was separated and dried over $MgSO_4$. Filtration and concentration gave crude product which was purified by preparative HPLC to provide the desired *N*-Boc protected *N*-acylsulfamide. The Boc protecting group was then removed as the compound was dissolved in 4N HCl solution in dioxane (2mL) and stirred at room temperature for 4 hours. Concentration provided a brownish oil as the HCl salt. Iterative crystallizations from isopropanol of the concentrated material gave pure product as large colorless flakes (58.3 g, 67% yield). LC-MS, MS *m/z* 714 ($M^+ + H$).

Step 2:

To a stirred solution of the product of Step 1, Example 3 (15.0 g, 21.0 mmol) in dry dichloromethane (200 mL) was added TFA (100 mL). The mixture was stirred

Compound 7

Scheme 1

Step 1:

To a mixture of 2-chloropyridine (0.205 g, 1.80 mmol) and sodium *tert*-butoxide (0.590 g, 6.13 mmol) in dry 1,2-dichloroethane (1 mL) was added a pre-mixed solution of $Pd(OAc)_2$ (0.0405 g, 0.180 mmol) and (*R*)-(-)-1-[(*S*)-(dicyclohexylphosphino)ferrocenyl] ethyl di-*tert*-butyl phosphine (0.100 g, 0.180 mmol, Strem Chemicals catalog # 26-0975, CAS # [158923-11-6]) in dry 1,2-dimethoxyethane (1 mL). The mixture was shaken, and was quickly treated with TBDMSCl (0.598 g, 3.97 mmol). The mixture was shaken briefly, and quickly added valine *tert*-butyl ester hydrochloride (0.454 g, 2.16 mmol) and shook again. A moderate exotherm resulted immediately. After 10 minutes stirring, the mixture was added to rapidly stirred pH = 7 buffer solution (50 mL). Added ethyl acetate (50 mL) and shook and separated the phases. The aqueous was saturated by addition of NaCl and was extracted again with ethyl acetate (2 x 50 mL). The organic extracts were combined and washed with brine (20 mL), dried over $MgSO_4$, filtered and concentrated *in vacuo* to a dark residue. The crude product was purified by flash silica gel chromatography (8:1 hexanes:ethyl acetate) to give a colorless liquid (0.365 g) which was determined to contain the desired product plus 0.6 equivalents of TBDMS byproduct. The material was carried on to the next step without further purification. Approximate yield was 61%. LC-MS, MS *m/z* 251 ($M^+ + H$).

Step 2:

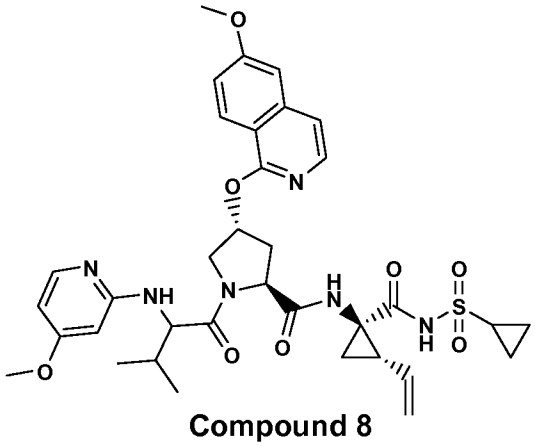

The product of Step 1, Example 7 (0.944g, 3.03 mmol) was dissolved in dichloromethane (10 mL) and treated with TFA (10 mL). The mixture was stirred at room temperature for 1.5 hours and was then concentrated *in vacuo*. The residue was then purified by reverse phase preparative HPLC, and then purified further by flash silica gel chromatography (gradient, 10:1 dichloromethane:methanol to 5:1 dichloromethane:methanol) to give a colorless waxy solid (0.126 g, 59.0% yield). LC-MS, MS *m/z* 195 (M^+ + H).

Step 3:

To a mixture of the product of Step 5, Example 1 (0.250 g, 0.436 mmol) and NMM (0.176 g, 1.74 mmol) in dichloromethane (2 mL) was added the product of Step 2, Example 7 (0.085 g, 0.44 mmol) and HATU (0.199 g, 0.523 mmol). The mixture was stirred at room temperature for 96 hours. The solvent was removed, the viscous brown residue was dissolved in ethyl acetate (50 mL), and the solution was washed with 1.0M aqueous HCl. The aqueous extracts were combined and extracted with ethyl acetate, and the organic phases were combined and washed with 10% aqueous sodium carbonate and then with brine. The organic phase was dried over anhydrous $MgSO_4$, filtered and concentrated to a residue which was purified by reverse phase preparative HPLC to give Compound 7 (0.243 g, 45% yield) as a white solid. Compound 7 was the major of two isomers formed in the reaction with identical MS *m/z* by LCMS. The minor isomer (more retained on the reverse phase preparative HPLC column than the major isomer) was not isolated. ^{1}H NMR (500 MHz, MeOD) δ ppm 0.99 (d, *J*=6.71 Hz, 3 H) 1.12 (d, *J*=6.41 Hz, 3 H) 1.14 - 1.19 (m, 2 H) 1.24 - 1.31 (m, 1 H) 1.31 - 1.37 (m, 1 H) 1.48 (dd, *J*=9.46, 5.49 Hz, 1 H) 1.95 (dd, *J*=8.09, 5.34 Hz, 1 H) 2.32 (q, *J*=8.85 Hz, 1 H) 2.42 (ddd, *J*=13.96, 10.15, 4.27 Hz, 1 H) 2.47 - 2.55 (m, 1 H) 2.68 (dd, *J*=13.73, 7.02 Hz, 1 H) 3.02 (ddd, *J*=12.59, 8.16, 4.88 Hz, 1 H) 3.37 (s, 1 H) 3.95 (s, 3 H) 4.22 (dd, 1 H) 4.31 (d, *J*=11.90 Hz, 1 H) 4.34 (d, *J*=8.54 Hz, 1 H) 4.70 (dd, *J*=10.22, 7.17 Hz, 1 H) 5.17 (d, *J*=10.38 Hz, 1 H) 5.36 (d, *J*=17.09 Hz, 1 H) 5.82 (ddd, *J*=17.24, 9.61, 9.46 Hz, 1 H) 5.97 (t, *J*=3.20 Hz, 1 H) 6.93 (t, *J*=6.71 Hz, 1 H) 7.02 (d, *J*=9.16 Hz, 1 H) 7.14 (dd, *J*=9.00, 2.29 Hz, 1 H) 7.23 (d, *J*=2.14 Hz, 1 H) 7.31 (d, *J*=6.10 Hz, 1 H) 7.83 (t, *J*=7.93 Hz, 1 H) 7.88 (d, *J*=6.41 Hz, 1 H) 7.93 (d, *J*=6.10 Hz, 1 H) 8.03 (d, *J*=9.16

To a mixture of 3-chloropyridine (0.410 g, 3.61 mmol) and sodium *tert*-butoxide (1.18 g, 12.3 mmol) in dry 1,2-dichloroethane (5 mL) was added a pre-mixed solution of $Pd(OAc)_2$ (0.0405 g, 0.180 mmol) and (*R*)-(-)-1-[(*S*)-(dicyclohexylphosphino) ferrocenyl] ethyl di-*tert*-butyl phosphine (0.100 g, 0.180 mmol, Strem Chemicals catalog # 26-0975, CAS # [158923-11-6]) in dry 1,2-dimethoxyethane (2 mL). The mixture was shaken briefly, treated quickly with *tert*-leucine *tert*-butyl ester hydrochloride (0.970 g, 4.33 mmol) and shaken again. The mixture was heated to 100 °C for 20 hours, added to a rapidly stirred mixture of pH = 7 buffer solution (100 mL) and 1.0M aqueous HCl (12 mL), treated with ethyl acetate, and shaken. The phases were allowed to separate and the organic extract was washed with brine, dried over $MgSO_4$, filtered and concentrated *in vacuo* to a deep orange residue. The crude product was purified by flash silica gel chromatography (linear gradient 100% hexanes to 1:1 hexanes:ethyl acetate) to give a flesh colored solid (0.583 g, 61.1% yield). LC-MS, MS *m/z* 265 ($M^+ + H$).

Step 2:

The product of Step 1, Example 13 (0.200g, 0.756 mmol) was dissolved in dichloromethane (5 mL) and treated with TFA (5 mL). The mixture was stirred at

room temperature for 5 hours and was then concentrated *in vacuo*. The residue was then dissolved in 1,2-dichloroethane (15 mL) and again concentrated *in vacuo*. The residue was then dissolved in dichloromethane (3 mL) and was added dropwise to rapidly stirred 2.0M HCl in ether (40 mL). The resulting beige precipitate was isolated by filtration and allowed to air dry. Beige powder (0.160 g, 86.4% yield). LC-MS, MS *m/z* 209 (M^+ + H).

Step 3:

To a mixture of the product of Step 5, Example 1 (0.242 g, 0.422 mmol) and NMM (0.203 g, 2.01 mmol) in dichloromethane (2 mL) was added the product of Step 2, Example 13 (0.098 g, 0.40 mmol) and HATU (0.242 g, 0.422 mmol). The mixture was stirred at room temperature for 18 hours. The solvent was removed *in vacuo* and the viscous brown residue was directly purified by reverse phase preparative HPLC to give two compounds in good purity with identical MS *m/z*. Compound 13A (0.154 g, 41.6% yield) was the first of the two isomers to elute from the reverse phase preparative HPLC column and was obtained as an off-white solid bis-TFA salt. Compound 13B (0.118 g, 31.9% yield) was the second of the two isomers to elute from the reverse phase preparative HPLC column and was obtained as a beige powder bis-TFA salt.

Scheme 1

Step 1:

2-Bromo-4,6-dimethylpyridine (0.839 g, 4.51 mmol), sodium *tert*-butoxide (1.47 g, 15.3 mmol), *tert*-leucine *tert*-butyl ester hydrochloride (1.21 g, 5.41 mmol) and TBDMSCl (1.5 g, 9.9 mmol) were combined and treated with 1,2-dimethoxyethane (6 mL). The mixture was shaken and a pre-mixed solution of $Pd(OAc)_2$ (0.202 g, 0.902 mmol) and (*R*)-(-)-1-[(*S*)-(dicyclohexylphosphino) ferrocenyl] ethyl di-*tert*-butyl phosphine (0.500 g, 0.902 mmol, Strem Chemicals catalog # 26-0975, CAS # [158923-11-6]) in dry 1,2-dimethoxyethane (2 mL) was immediately added. A moderate exotherm resulted and the mixture became deep brown in color. After 10 minutes, the mixture was orange in color. The mixture was stirred at room temperature for 72 hours. The mixture was then added to a rapidly stirred mixture of pH = 7 buffer solution (75 mL) and 1.0M aqueous HCl (15 mL). Ethyl acetate (40 mL) was added and the mixture was shaken and separated the phases. The aqueous phase was extracted with ethyl acetate (2 x 50 mL). The organic extracts were combined and washed with brine (40 mL), dried over $MgSO_4$, filtered and concentrated *in vacuo* to a brown residue. The crude product was purified by flash silica gel chromatography (linear gradient 100% hexanes to 10:1 hexanes:ethyl acetate) to give a yellow oil (0.786 g) which was determined to contain the desired product plus 1.9 equivalents of TBDMS byproduct. The material was

carried on to the next step without further purification. LC-MS, MS *m/z* 293 (M^+ + H).

Step 2:

The product of Step 1, Example 14 (0.750 g) was dissolved in dichloromethane (10 mL) and treated with TFA (10 mL). The mixture was stirred at room temperature for 7 hours and was then concentrated *in vacuo*. The residue was then dissolved in 1,2-dichloroethane (15 mL) and again concentrated *in vacuo*. The residue was then dissolved in dichloromethane (3 mL) and was added dropwise to rapidly stirred 2M HCl in diethyl ether (40 mL). No precipitation occurred. Iterative precipitations of the crude material from dichloromethane using hexanes and ethyl acetate as the countersolvents eventually yielded a yellow powder (0.286 g, 23% yield over 2 steps). LC-MS, MS *m/z* 237 (M^+ + H).

The mixture was stirred at room temperature for 18 hours. Additional product of Step 2, Example 14 (0.049 g, 0.18 mmol), HATU (0.082 g, 0.216 mmol) and NMM (0.0381 g, 0.377 mmol) were added to the mixture, and the solution was stirred at 40 °C overnight. The solvent was removed *in vacuo* and the residue was directly purified by reverse phase preparative HPLC to give two separate compounds with identical MS *m/z*. Compound 14A (0.118 g, 37.8% yield) was the first of the two isomers to elute from the reverse phase preparative HPLC column and was obtained as an off-white powder bis-TFA salt. Compound 14B (0.044 g, 14.1% yield) was the second of the two isomers to elute from the reverse phase preparative HPLC column and was obtained as a beige powder bis-TFA salt.

Example 15: Preparation of Compounds 15A and 15B

Compounds 15A and 15B

Scheme 1

Step 1:

L-*tert*-Leucine (0.840 g, 6.40 mmol), K_2CO_3 (1.33 g, 9.60 mmol) and CuI (0.122 g, 0.64 mmol) were combined in a 35 mL Chemglass pressure vessel. Bromobenzene (1.01 g, 6.4 mmol) and DMA (8 mL) were added, the vessel headspace was with nitrogen, the vessel was sealed, and the mixture was heated to 90 °C overnight. Additional DMA (8 mL) was added to facilitate stirring and the mix was heated to 130 °C overnight. With only a small amount of product formation as determined by LCMS, the mixture was charged with an excess of CuI (approximately 1 g), the reaction was resealed and heated to 130 °C for 2 days. The mixture was cooled to room temperature and treated with 1.0M aqueous HCl until pH = 5 was achieved, then pH = 7 buffer (50 mL) and ethyl acetate (50 mL) were added and the mixture was shaken and phases were separated. The aqueous phase was extracted with ethyl acetate (2 x 50 mL), and the organics were combined and washed with brine, dried over $MgSO_4$, filtered and concentrated *in vacuo* to a solid residue. Purification by silica gel flash chromatography (20:1 dichloromethane:methanol) gave a waxy flesh-colored solid (0.286 g) which contained approximately 1.2 equivalents of entrained DMA by ^1H NMR. LC-MS, MS *m/z* 208 ($M^+ + H$).

Step 2:

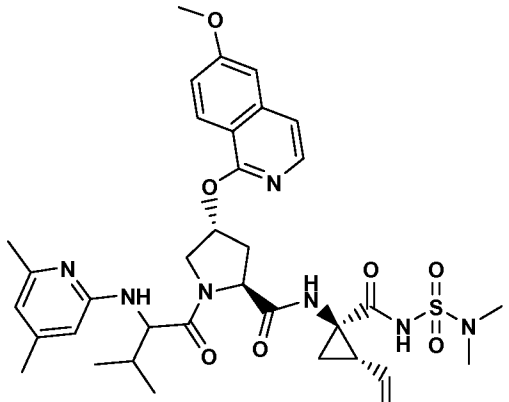

To a mixture of the product of Step 5, Example 1 (0.200 g, 0.349 mmol) and NMM (0.141 g, 1.40 mmol) in dichloromethane (2 mL) was added the product of Step 1, Example 15 (0.108 g, 0.35 mmol, 67% pure) and HATU (0.160 g, 0.418 mmol). The mixture was stirred at room temperature for 18 hours. The solvent was removed *in vacuo* and to the residue was added ethyl acetate (30 mL) and water (30 mL). Not all solids dissolved. The mixture was transferred to a 250 mL round bottom flask with 1:1 dichloromethane:methanol solvent, and the mixture was concentrated *in vacuo* until the organic solvents were removed, leaving the aqueous phase and undissolved solids. It was determined by LCMS that a crude purification had occurred where the aqueous phase held mostly water soluble byproducts with little product, and the solid consisted mostly of product. The solid was filtered from the liquid to give a white powder (0.225 g). Further purification of the white powder by reverse phase preparative HPLC gave two separate compounds with identical MS *m/z*. Compound 15A (0.124 g, 38.8% yield) was the first of the two isomers to elute from the reverse phase preparative HPLC column and was obtained as a brown powder bis-TFA salt. Step 1:

A solution of 4-methoxy-2-methylbenzoic acid (10.2 g, 61.4 mmol) in dichloromethane (200 mL) was treated slowly with oxalyl chloride. A drop of DMF was added and the reaction was stirred at room temperature for 12 hours. The mixture was then treated with 1,1,3,3-tetramethylguanidine (14.9 g, 128.9 mmol) and stirred at room temperature for 4 hours. The mixture was washed with 5% aqueous citric acid (2 x 100 mL). The aqueous phase was back-extracted with

dichloromethane (2 x 100 mL), and the organic phases were combined, dried over anhydrous $MgSO_4$, filtered, and concentrated to provide a minimal amount of desired product. The aqueous phase was made basic by addition of 10.0M aqueous NaOH until pH = 13 was achieved and was then extracted with dichloromethane (4 x 200 mL). The organic phases were combined, dried over anhydrous $MgSO_4$, filtered and concentrated. The resulting oil was combined with the earlier obtained product and the mixture was treated with diethyl ether to give a white precipitate which was removed by filtration. The filtrate was concentrated to give the desired product (11.3 g, 70% yield) as a viscous yellow oil. ^{1}H NMR (CD_3OD) δ 2.54 (s, 3H), 3.97 (s, 6H), 3.79 (s, 3H), 6.60 (d, J = 9.2 Hz, 1H), 6.75 (s, 1H), 7.65 (d, J = 8.9 Hz, 1H). LC-MS, MS *m/z* 264 (M^+ + H).

Step 2:

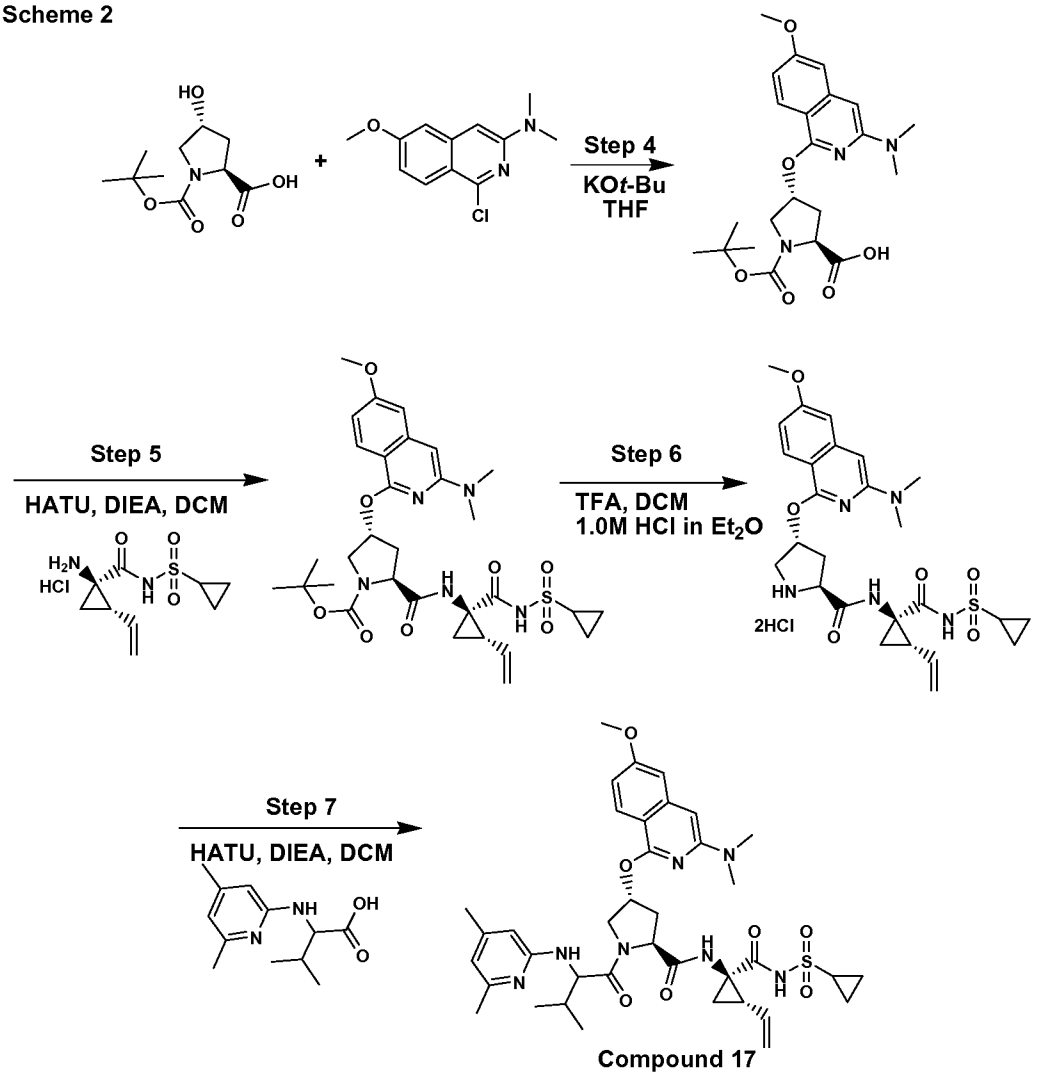

A solution of the product of Step 1, Example 17 (0.461 g, 1.78 mmol) in THF (5 mL) at 0 °C was treated with LDA solution (1.8M in THF/hexanes, 1.2 mL, 2.14 mmol). The reaction was stirred at room temperature for 5 hours and was then treated with additional LDA (1 mL) and stirred at room temperature for 14 hours. The mixture was quenched with saturated ammonium chloride (10 mL) and extracted with ethyl acetate (3 x 25 mL). The organic phases were combined, dried over anhydrous $MgSO_4$, filtered and concentrated. The concentrate was dissolved in minimal dichloromethane and diethyl ether was added. The resulting precipitate was collected by filtration to provide the desired product (0.312 g, 80% yield) as a brown solid. ^{1}H NMR (CD_3OD) δ 2.94 (s, 6H), 3.86 (s, 3H), 5.71 (s, 1H), 6.75 (dd, J = 8.9, 2.4 Hz, 1H), 6.83 (d, J = 2.4 Hz, 1H). 7.97 (d, J = 9.2 Hz, 1H). LC-MS, MS *m/z* 219 (M^+ + H).

Step 3:

The product of Step 2, Example 17 (10.0 g, 45.8 mmol) was treated with $POCl_3$ (43 mL) and the mixture was heated to 110 °C for 5 hours in a Chemglass pressure vessel. Upon cooling to room temperature, the resulting cake was dissolved in dichloromethane (200 mL) and the solution was quenched by slow addition of saturated aqueous sodium bicarbonate. Vigorous gas evolution ensued. When gas

evolution ceased, the mixture was shaken in a separatory funnel and the phases were separated. The aqueous phase was extracted with dichloromethane (3 x 200 mL). The combined organic phase was washed with brine, dried over anhydrous $MgSO_4$, filtered and concentrated. Diethyl ether was added to the residue to effect the precipitation of a black solid which was collected by filtration and washed with ether. Thus was obtained the desired product (5.72 g, 53.0% yield). LC-MS, MS *m/z* 237 ($M^+ + H$).

Scheme 2

Step 4:

To a solution of Boc-Hyp-OH (5.60 g, 24.2 mmol) in THF (100 mL) was added potassium *tert*-butoxide (1.0M in THF, 53.2 mL, 53.2 mmol). The mixture

turned brown and became a gel which broke with vigorous stirring. After 15 minutes, the product of Step 3, Example 17 (5.72 g, 24.2 mmol) was added in portions. The mixture was heated to 70 °C for 48 hours. The mixture was quenched by addition of 1.0M HCl and was then extracted with ethyl acetate. The aqueous phase was extracted with ethyl acetate once more. The organic phases were combined and washed with brine, dried over $MgSO_4$, and filtered. The filtrate was evaporated *in vacuo* to dryness to give the desired product. LC-MS, MS *m/z* 430 (M -H).

Step 5:

The solvent was removed in vacuo, and the residue was taken up in ethyl acetate (200 mL) and washed with water (100 mL). The phases were separated and the aqueous phase was back-extracted with ethyl acetate (3 x 100 mL). The combined organic phase was washed with 0.10 M aqueous HCl (100 mL), then with 10% aqueous sodium carbonate (50 mL) and finally with brine. The organic phase was dried over $MgSO_4$, filtered, and concentrated to give a dark brown foamy solid. The product was purified by flash silica gel chromatography (95:5 dichloromethane:methanol) to give a brown solid (12.9 g, 97% yield). LC-MS, MS *m/z* 642 (M -H).

Step 6:

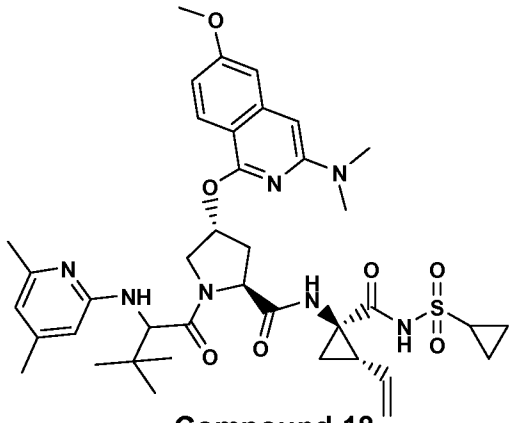

To a solution of the product of Step 5, Example 17 (12.7 g, 19.6 mmol) in 1:1 dichloromethane:1,2-dichloroethane (100 mL) was added TFA (50 mL). The mixture was stirred at room temperature for 30 minutes and was then concentrated *in vacuo*. The residue was redissolved in 1,2-dichloroethane (100 mL) and again concentrated *in vacuo*. The residue was then dissolved in dichloromethane (50 mL) and was added dropwise to vigorously stirred 1.0M HCl in diethyl ether (500 mL). The resulting light brown solid precipitate was isolated by filtration and washed with 1.0M HCl in diethyl ether to give a brown powder (10.2 g, 85.0% yield). LC-MS, MS *m/z* 544

(M^+ + H).

Additional 2-(4,6-dimethylpyridin-2-ylamino)-3-methylbutanoic acid (0.0465 g, 0.210 mmol) and HATU (0.080 g, 0.21 mmol) were added and the mixture was stirred at room temperature for an additional 14 hours. Solvent was removed and the residue was redissolved in ethyl acetate (50 mL) and washed with 1.0M aqueous HCl (2 x 5 mL). The aqueous extracts were combined and back-extracted with ethyl acetate (50 mL), and the organic phases were combined and washed with 10% aqueous sodium carbonate and then with brine. The organic phase was dried over anhydrous $MgSO_4$, filtered, and concentrated to a residue which was purified by reverse phase preparative HPLC to give Compound 17 (0.037 g, 10.8% yield) as a brown powder bis-HCl salt. ^{1}H NMR (500 MHz, *MeOD*) δ ppm 1.02 (d, *J*=6.7 Hz, 3 H), 1.10 (d, *J*=6.4 Hz, 3 H), 1.12 - 1.18 (m, 3 H), 1.22 - 1.30 (m, 2 H), 1.35 (t, *J*=7.3 Hz, 1 H), 1.46 (dd, *J*=9.6, 5.3 Hz, 1 H), 1.95 (dd, *J*=7.9, 5.5 Hz, 1 H), 2.22 (s, 3 H), 2.28 - 2.36 (m, 2 H), 2.41 (s, 3 H), 2.52 (d, *J*=14.6 Hz, 1 H), 2.66 (dd, *J*=13.7, 7.3 Hz, 1 H), 2.96 - 3.03 (m, 2 H), 3.21 (s, 6 H), 3.91 (s, 3 H), 4.01 - 4.06 (m, 1 H), 4.18 (dd, *J*=11.9, 3.4 Hz, 1 H), 4.31 (d, *J*=11.9 Hz, 1 H), 4.56 (d, *J*=7.0 Hz, 1 H), 4.68 (dd, *J*=9.9, 7.2 Hz, 1 H), 5.14 - 5.19 (m, 1 H), 5.35 (d, *J*=17.1 Hz, 1 H), 5.75 - 5.85 (m, 1 H), 6.01 (s, 1 H), 6.60 (s, 1 H), 6.69 (s, 1 H), 6.83 (d, *J*=8.9 Hz, 1 H), 7.05 (s, 1 H), 7.81 (d, *J*=9.2 Hz, 1 H); LC-MS, MS *m/z* 748 (M^+ + H).

Example 22: Preparation of Compounds 22A and 22B:

Compounds 22A and 22B

Scheme 1 of Example 22

Step 1:

A slurry of 3-chloro-6-methylbezoic acid (17.0 g, 0.10 mol) in thionyl chloride (23.5 ml, 0.30 mol) was heated slowly to a gentle reflux and maintained at this temperature for 2h. The reaction mixture was then cooled to RT and the excess thionyl chloride removed in vacuo. The residue was taken up in DCM (50 ml), and the solvent then removed in vacuo. (It should be noted that this process was repeated several times to ensure removal of residual thionyl chloride and HCl). The resulting product was then dissolved in THF (80 ml) which was used directly in the next reaction as described below.

Step 2:

To a solution of 30% ammonia (58 ml) in water (240 ml), cooled by salt-ice bath (-10 °C), was added dropwise a THF solution of the product of Step 1 above. After the addition was complete, the resulting reaction mixture (slurry) was stirred at -10 °C for 1 hr. The reaction mixture was then warmed to room temperature and decanted. The remaining solid in the reaction vessel was then triturated with water (50 ml). This process of trituration and decanting was then repeated. The remaining solid was then filtered and the filter cake washed with water. The solid was then dried in vacuo overnight to yield 13.8 g (82%) of desired product as a white crystalline material. ^{1}H NMR (DMSO-D_6) δ ppm 2.33 (s, 3H), 7.24-7.27 (m, 1H), 7.35-7.38 (m , 2H), 7.44 (b, 1H), 7.80 (b, 1H); ^{13}C NMR (100 MHz, DMSO-D_6) δ ppm 18.87, 126.64, 128.86, 129.81, 132.31, 134.19, 138.65, 169.41; LC-MS, MS *m/z* 170.

Step 4:

A mixture of the product of Step 3 and KOtBu (14.7 g, 131 mmol) in THF (300 ml) was heated to reflux and maintained at this temperature for 2 hr (reaction mixture became a dark solution upon heating). The volume of the reaction mixture was then reduced by distilling off approximately 100 ml of solvent. The resulting solution was then carefully poured into water (1 L) and the resulting mixture was acidified with 1M HCl to a resulting pH of 4. The mixture was then filtered, and the collected solid was washed thoroughly with water, then dried in vacuo overnight to yield 7.0 g (60%) of the desired product as a off-white powder.

Step 6:

A heterogeneous solution of the product of Step 5 (47 g, 182 mmol) in $POCl_3$ (200 mL, 2.15 mol) slowly heated to reflux over a period of 1 h. The reaction mixture

was maintained at reflux for 4 h. The reaction mixture was then cooled to room temperature and concentrated in vacuo to remove excess $POCl_3$. The resulting residue was then taken-up into 600 mL of CH_2Cl_2, cooled to at -35 °C, then neutralized carefully with 1 N NaOH (400 mL) until the mixture was slightly basic (pH = 8). The resulting organic layer was separated, washed with water, dried over $MgSO_4$ and concentrated in vacuo. The resulting residue was crystallized from EtOAc (approximately 50 mL) to give 32 g of desired product. The collected solid was washed with 10% EtOAc/Hexanes (3 x 50 ml).

The mother liquid was concentrated and purified by Biotage (elution with 16% EtOAc in hexanes) to give 4 g of the desired product as a solid.

^1H NMR (400 MHz, $CDCl_3$) δ ppm 7.80 (dd, J=8.81, 2.01 Hz, 1 H), 8.14 (d, J=9.06 Hz, 1 H), 8.34 (d, J=1.76 Hz, 1 H), 8.48 (s, 1 H); ^{13}C NMR (100 MHz, DMSO-D_6) δ ppm 118.39, 125.06, 127.59, 128.71, 133.89, 134.14, 134.93, 143.18, 148.98; LC-MS, MS *m/z* 275.

The resulting solution was stirred for 0.5 h, after such time, $(i\text{-}PrO)_3B$ (37 ml, 160 mmol) was added dropwise via syringe over 10 min (maintaining the internal temperature < -65 °C). The resulting reaction mixture was stirred for 0.5 h. After checking the reaction by LC/MS for completion, 80 ml of 30% H_2O_2 (776 mmol) was added dropwise via addition funnel over 10 min (the internal temperature rose to -60 °C during addition), followed by addition of 80 ml of 1 N NaOH (80 mmol). The cooling bath was removed, and the reaction mixture was allowed to warm to room temperature and stirred at room temperature for additional 1 h. After conforming the completion of the reaction by LC/MS, the reaction mixture was then cooled to -40 °C, and a solution of 100 g of Na_2SO_3 (0.793 moles) in 400 ml of water was added dropwise via addition funnel as a means to quench excess H_2O_2 over 30 min (maintaining the internal temperature 5-10 °C). The resulting slurry was then neutralized with 6 N HCl (approximately 50 ml) at 0□C till pH ~ 6, then diluted with 500 ml of EtOAc and decanted to a 2 L separatory funnel. The combined organic layers were washed with brine (300 ml x 3), then water (200 ml x 3), dried over $MgSO_4$ and concentrated to give a crude product which was triturated with 50 ml of EtOAc. The solid was collected by filtration, rinsed with EtOAc (3 x 25 ml) and dried to give desired product (2 runs: 12.0 g, 70% and 13.8 g, 81%). The filtrates were combined, concentrated and purified by Biotage eluted with 35% EtOAc in hexanes to give 2.1 g of product. Overall, 44.4 g of bromide gave 27.9 g (81%) of 4-OH product.

The reaction mixture was allowed to warm to room temperature, then stirred for 14 h. The solution was then concentrated and the resulting solid was recrystallized from EtOAc (about 50 mL) to give 8.1 g of the desired product which was washed with 25% EtOAc in hexances; 20 x3 times. The mother liquid was concentrated and purified by Biotage (elution with 16 % EtOAc in hexanes) to provide 3.2 g of the desired product as a solid.

Step 2:

The product of Step 1, Example 25, (0.809 g, 2.91 mmol) was dissolved in dichloromethane (20 mL) and treated with TFA (20 mL). The mixture was stirred at room temperature for 20 h and was then concentrated *in vacuo*. The residue was then dissolved in 1,2-dichloroethane (15 mL) and again concentrated *in vacuo* to give a brown oil. The residue was then dissolved in minimum DCM and added dropwise to a rapidly stirred mixture of 2.0M HCl in ether (30 mL), diethyl ether (30 mL) and 1,2-DCE (50 mL). The mixture was stirred for 10 min and was then concentrated *in vacuo*. The resulting brown foamy solid was then taken up in 1.0M aqueous HCl and the solution was concentrated in vacuo to give a glassy yellow solid (0.600 g, 80 % yield). 1H NMR (500 MHz, DMSO-D_6) δ ppm 1.05 (s, 9 H) 2.35 (s, 3 H) 4.02 (d, *J*=9.77 Hz, 1 H) 7.03 (d, *J*=9.77 Hz, 1 H) 7.68 (s, 1 H) 7.95 (s, 1 H) 8.13 (s, 1 H) LC-MS, MS *m/z* 223 (M^+ + H).

The mixture was stirred at room temperature for 20 hours. The solvent was removed *in vacuo* and the crude mixture was purified by reverse phase preparative HPLC to give compound 25 (0.1421 g, 44.7% yield) as a white powder bis-TFA salt. ^{1}H NMR (500 MHz, CD_3OD) δ ppm 1.07 - 1.21 (m, 11 H) 1.23 - 1.34 (m, 2 H) 1.45 (dd, *J*=9.46, 5.19 Hz, 1 H) 1.93 (dd, *J*=8.09, 5.65 Hz, 1 H) 2.14 (s, 3 H) 2.22 - 2.32 (m, 2 H) 2.59 (dd, *J*=13.73, 7.32 Hz, 1 H) 2.96 - 3.05 (m, 1 H) 4.01 (dd, *J*=12.21, 3.05 Hz, 1 H) 4.04 (s, 3 H) 4.26 (s, 1 H) 4.33 (d, *J*=12.21 Hz, 1 H) 4.66 (dd, *J*=10.22, 7.48 Hz, 1 H) 5.16 (d, *J*=10.38 Hz, 1 H) 5.34 (d, *J*=17.40 Hz, 1 H) 5.72 - 5.83 (m, 1 H) 5.89 (s, 1 H) 7.48 (s, 1 H) 7.59 (s, 1 H) 7.67 - 7.72 (m, 2 H) 7.81 (d, *J*=2.14 Hz, 1 H) 7.96 (d, *J*=1.83 Hz, 1 H) 8.11 (d, *J*=8.85 Hz, 1 H) 9.27 (s, 1 H); LC-MS, MS *m/z* 740 (M^+ + H).

Scheme 1

Step 1:

L-tert-leucine (0.734 g, 5.60 mmol) was suspended with stirring in dry THF (10 mL). The suspension was cooled to -78 °C, and n-buLi, 2.5M in hexanes (4.48 mL, 11.2 mmol) was added dropwise. The yellow mixture was stirred at -78 °C for 30 min, then the cold bath was removed and the suspension was allowed to warm to rt for 25 min. The mixture was again cooled to -78 °C, and 2-fluoro-6-methylpyridine (0.311 g, 2.80 mmol) was added dropwise. The color changed from yellow to deep orange and finally brown over time. The cold bath was removed and the mixture was stirred at rt overnight. The crude mixture was poured into rapidly stirred saturated aqueous ammonium chloride solution (100 mL) and EtOAc (50 mL) was added. The phases were separated, and the aqueous phase was extracted with EtOAc (2 x 50 mL). The aqueous phase had to be saturated with NaCl and extracted with DCM (4 x 100 mL) to remove the product. The organics were combined and concentrated *in* vacuo to a residue. Purification of the residue by reverse phase preparative HPLC gave the product as a sticky yellow oil (0.279 g, 44.8% yield) TFA salt. ^{1}H NMR (300 MHz, CHLOROFORM-D) δ ppm 1.02 (s, 9 H) 2.49 (s, 3 H) 3.94 (s, 1 H) 3.96 - 4.16 (m, 1 H) 6.54 (d, *J*=7.32 Hz, 1 H) 6.70 (d, *J*=8.78 Hz, 1 H) 7.63 - 7.73 (m, 1 H); LC-MS, MS *m/z* 223 (M^+ + H).

Scheme 1

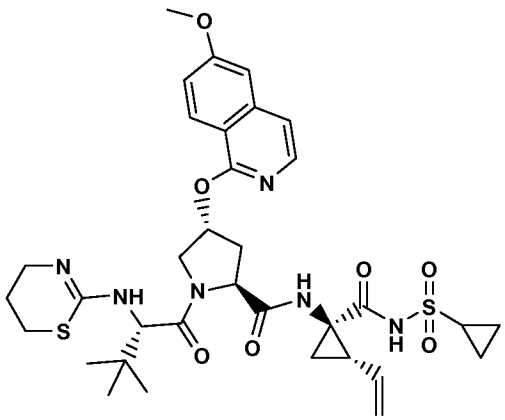

Step 1:

To a solution mixture of product of step 2, Example 3 (1.5g, 2.18 mmol) and DIEA (0.707 g, 5.46 mmol) in DCM (20 mL) was added Fmoc-thioisocyanate (0.799, 2.84 mmol). Reaction mixture was stirred at for 48 h. Reaction was not completed as determined by LC/MS, then was added more Fmoc-thioisocyanate (0.307 g, 1.09 mmol). Reaction mixture was allowed to stir at rt for an additional 24 h. White solid precipitation by-product was removed by vacuum filtration and washed with EtOAc. The liquid filtrate was concentrated, the resulting residue redissolved in EtOAc (100 mL) and washed with 2 x 25 mL H_2O. The aqueous layers were combined and extracted with EtOAc (50 mL). The combined organic layer was washed with brine, dried over $MgSO_4$, filtered and concentrated to a yellow solid. More un-identified by-products were removed by trituration with EtOAc, chilled to 0 °C; solid precipitation was filtered and discared. The liquid filtration was concentrated and residue was purified through a column of SiO_2 which was eluted with 3:1, 1:1 then 1:3 hexanes:EtOAc to give the product of step 1, Example 35 (0.798 g, 41% yield) as a light yellow foarmy solid. LC-MS, MS *m/z* 895 (M^+ + H).

Step 2:

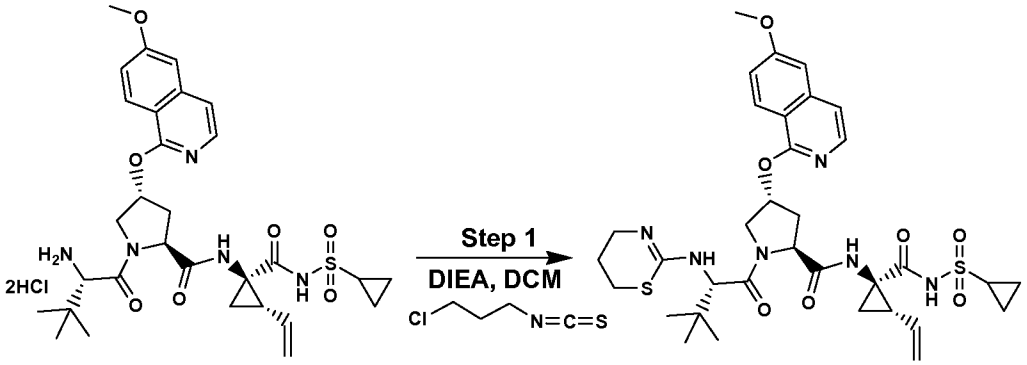

To a yellow solution of the product form step 1, Example 35 (0.489 g, 0.546 mmol) in DMF (4 mL) was added piperidine (1 mL). Reaction was stirred at rt. After 5h solvent was removed under vaccuo and dried to give a solid glassy crude product which was taken up in DMF (5 mL) and treated with 1-bromo-2-butanone (0.275 g, 1.64 mmol). Reaction mixture was stirred at rt overnight. After 14h, solvent was removed under vacuo to give viscous red oil which was redissolved in MeOH and filtered to remove brown gel like substance. The liquid filtrated was concentrated and remaining residue was purified br reversed phase HPLC to give Example 35 (139.7, 35% yield) as a light yellow solid. ^{1}H NMR (500 MHz) δ ppm 0.81 (t, *J*=7.5 Hz, 3 H), 1.06 - 1.12 (m, 3 H), 1.14 (s, 9 H), 1.25 - 1.30 (m, 2 H), 1.46 (dd, *J*=9.6, 5.3 Hz, 1 H), 1.91 (dd, *J*=8.1, 5.3 Hz, 1 H), 1.93 - 1.97 (m, 1 H), 1.99 - 2.07 (m, 1 H), 2.23 - 2.29 (m, 1 H), 2.30 - 2.36 (m, 1 H), 2.59 (dd, *J*=13.4, 6.7 Hz, 1 H), 3.96 (s, 3 H), 4.15 (dd, *J*=11.7, 3.8 Hz, 1 H), 4.46 (s, 1 H), 4.57 (dd, *J*=10.5, 6.9 Hz, 1 H), 4.68 (d, *J*=11.6 Hz, 1 H), 5.15 (d, *J*=10.4 Hz, 1 H), 5.32 (d, *J*=17.1 Hz, 1 H), 5.75 (s, 1 H), 5.76 - 5.82 (m, 1 H), 5.90 (s, 1 H), 7.09 (dd, *J*=8.9, 2.4 Hz, 1 H), 7.23 (d, *J*=2.4 Hz, 1 H), 7.29 (d, *J*=5.8 Hz, 1 H), 7.89 (d, *J*=9.2 Hz, 1 H), 7.93 (d, *J*=6.1 Hz, 1 H). Step 1:

To a solution mixture of the product of step 2, example 3 (0.267 g, 0.389 mmol) and DIEA (0.101 g, 0.778 mmol) in DCM (4 mL) was added 3-chloropropyl isothiocyanate (0.053 g, 0.389 mmol) and heated to 45 °C. After 3 h, solvent was removed and residue was redissolved in hot EtOAc with minimal DCM, Et_2O was added to effect light green precipitation which was obtained by filtration. Example 37: Preparation of Compound 37: N-(5,6-dihydro-4H-1,3-thiazin-2-yl)-3-methyl-L-valyl-(4R)-N-((1R,2S)-1-((cyclopropylsulfonyl)carbamoyl)-2-vinylcyclopropyl)-4-((6-methoxy-3-(4-(trifluoromethoxy)phenyl)-1-isoquinolinyl)oxy)-L-prolinamide

Compound 37

Scheme 1

Step 1:

A mixture of 4-methoxy-2-methyl-benzoic acid (25.3 g, 152 mmol) in 1:1 DCM:DCE was treated with oxalyl chloride (38.6 g, 304 mmol), followed by addition of DMF (0.111 g, 1.50 mmol). Vigorous gas evolution ensued, and the reaction eventually became clear after 1 h. The volatiles were removed *in vacuo* and the white solid residue was placed under high vacuum for 2 h. The crude material was redissolved in DCM (200 mL) and the mixture was cooled to 0 °C. Diethylamine (22.8 g, 312 mmol) was added dropwise with stirring. The mixture was allowed to warm to rt for 1 h with stirring. The mixture was concentrated *in vacuo* to approximately 1/3 volume, and Et_2O (300 mL) was added and the mixture was chilled. The solid precipitate which had formed was removed by filtration. The filtrate was concentrated to give a viscous brown oil which was redissolved in DCM

(200 mL) and washed with 0.1M HCl (2 x 50 mL). The organic phase was dried over $MgSO_4$, filtered and concentrated *in vacuo* to give the desired product (33.1 g, 98% yield). LC-MS, MS *m/z* 222 (M^++H).

Step 2:

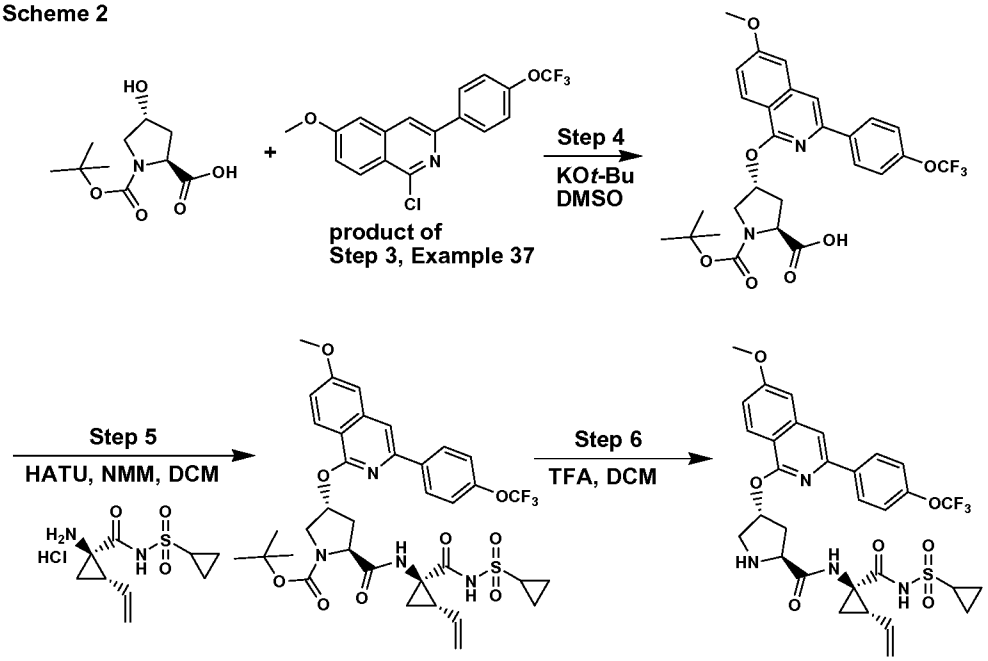

To a stirred solution of N,N-diethyl-4-methoxy-2-methyl-benzamide (10.0 g, 45.2 mmol) in THF (150 mL) at –78 °C under nitrogen atmosphere was added *t*-BuLi (29.2 mL of 1.7M in pentane, 49.7 mmol) dropwise. The resulting red solution was kept at this temperature for additional 10 min before dropwise addition of 4-(trifluoromethoxy)-benzonitrile (9.49 g, 49.7 mmol). The brown solution was stirred at -78 °C for 2 h; tests by LCMS showed incomplete reaction. Thus to the mixture was added an additional amount of 4-(trifluoromethoxy)-benzonitrile (3.38 g, 18.1 mmol) and the resulting mixture was stirred for an additional 1 h. The mixture was then allowed to warm to rt and was quenched by pouring into aqueous 1.0M HCl (50 mL). EtOAc (100 mL) was added and the mixture was shaken and phases were separated. A precipitate occurred within the EtOAc phase which was isolated by filtration and allowed to dry (3.0 g). This 3.0 g of isolated solid was determined to be impure product and was set aside for later purification. The EtOAc filtrate was set aside. The aqueous acid washes were combined and extracted with DCM (3 x 100 mL). The DCM extracts were combined, washed with brine, dried over $MgSO_4$, filtered and concentrated *in vacuo*. This residue was combined with the original EtOAc filtrate and the combined organics were concentrated to a slurry. A solid was isolated by filtration to give the desired product (8.84 g, 58.0% yield). LC-MS, MS *m/z* 336 (M^++H).

Step 3:

The solid product from Step 2, Example 37 (8.84 g, 26.4 mmol) was dissolved in $POCl_3$ (100 mL) and the mixture was heated to reflux for 3 h. The mixture was concentrated *in vacuo*, and to the resulting residue was added water (100 mL) and EtOAc (100 mL). The rapidly stirred mixture was treated slowly with solid sodium bicarbonate until pH = 7 was reached. The phases were separated, and the aqueous phase was extracted with EtOAc (2 x 40 mL). The organic extracts were combined and washed with saturated aqueous sodium bicarbonate (40 mL) and then

with brine (40 mL), dried over $MgSO_4$, filtered and concentrated *in vacuo*. The product (9.21 g, 98.7% yield) was isolated without chromatography as a slightly yellow viscous oil. ^{1}H NMR (500 MHz, CHLOROFORM-D) δ ppm 3.97 (s, 3 H) 7.11 (d, *J*=2.44 Hz, 1 H) 7.26 (dd, *J*=9.46, 2.44 Hz, 1 H) 7.31 (d, *J*=8.85 Hz, 2 H) 7.84 (s, 1 H) 8.10 (d, *J*=8.85 Hz, 2 H) 8.20 (d, *J*=9.46 Hz, 1 H); LC-MS, MS *m/z* 354 (M^++H).

Scheme 2

Step 4:

To a mechanically stirred solution of Boc-Hyp-OH (6.31 g, 27.3 mmol) in DMSO (100 mL) was added solid potassium *tert*-butoxide (8.05 g, 68.2 mmol). The mixture was stirred for 1.5 h, and the product of Step 3, Example 37 (20.0 g, g, 74.2 mmol) was added in two portions over 15 min. The resulting suspension was stirred for 3 h at rt. The suspension was then diluted with a mixture of pH = 4 buffer (500 mL) and 1.0 M HCl (41 mL) and extracted with EtOAc (3 x 150 mL). The organic extracts were combined and washed with pH = 4 buffer (75 mL) and then with brine (50 mL). The organic was then extracted with a mixture of 1.0M NaOH (30 mL) and water (50 mL) twice, and the combined basic extracts were washed with EtOAc (30 mL). The aqueous basic extracts were treated with 1.0M HCl (approximately 60 mL)

until pH = 4 was achieved, and the desired product was then extracted into EtOAc (3 x 100 mL). The extracts were combined, dried over $MgSO_4$ and filtered. The filtrate was evaporated *in vacuo* to dryness to give a foamy solid. The desired product (13.2 g, 92.7% yield) was isolated after purification by silica gel column chromatography (step gradient DCM, then 40:1 DCM:MeOH, then 10:1 DCM:MeOH) as a glassy solid. LC-MS, MS *m/z* 549 (M^++H).

Step 5:

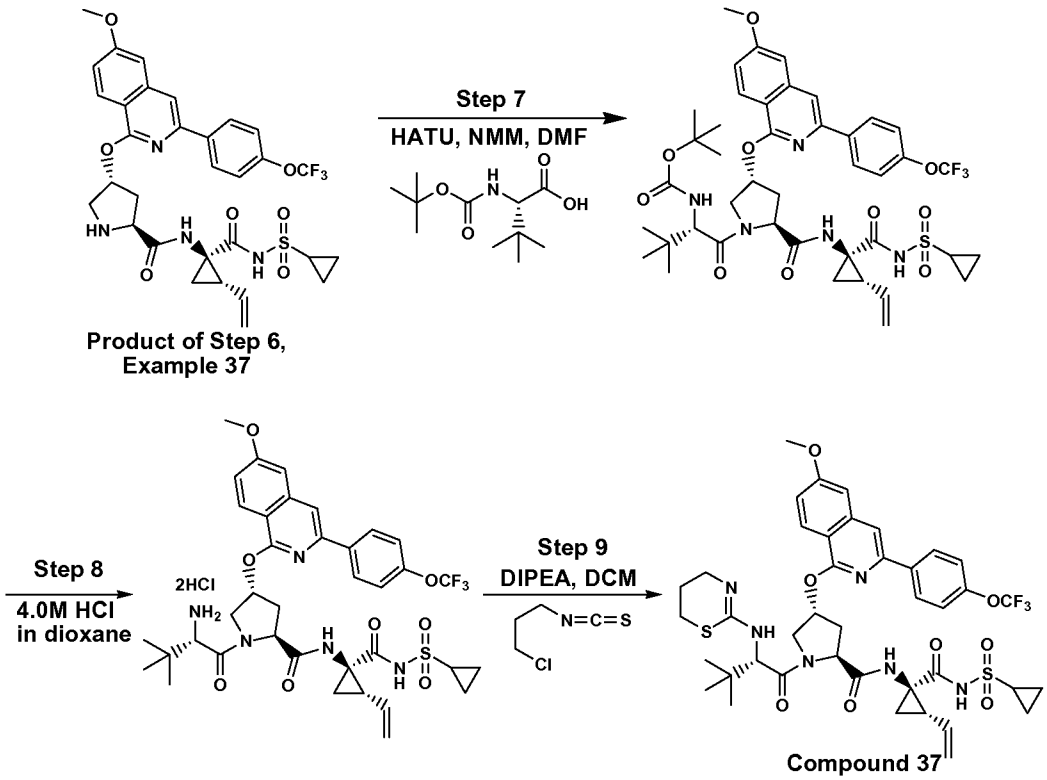

A mixture of the product of Step 4, Example 37 (12.3 g, 22.4 mmol), NMM (6.80 g, 67.3 mmol) and cyclopropanesulfonic acid (1-(*R*)-amino-2-(*S*)-vinyl-cyclopropanecarbonyl)-amide HCl salt (6.28 g, 23.5 mmol) in DCM (250 mL) was treated with HATU (10.23 g, 26.9 mmol), and the resulting solution was stirred at rt overnight. Compounds 233A and 233B

Step 1

Step 1:

The mixture was stirred overnight at room temperature. Solvent was removed, and the material was dried under high vacuum. This material was used directly in the next step without further purification.

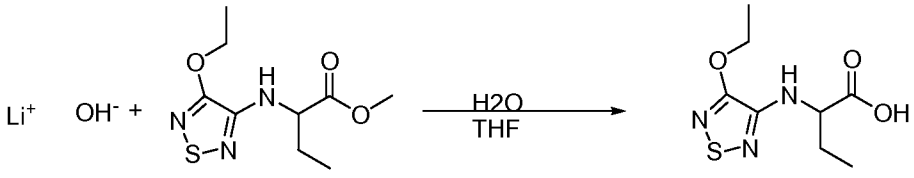

step 2

Step 2:

To a yellow solution of the product of example 233, step 1 (0.157 g, .6 mmol) in CH_2Cl_2 (8 ml) at -78°C was added triiodophosphine (0.247 g, 0.600 mmol). An orange suspension was obtained. The reaction mixture was diluted with ethyl acetate (15ml) and washed with sodium bisulfite (2 g in 10 ml of water), H_2O, and sat NaCl. The organic was dried over Na_2SO_4, filtered and concentrated. The crude product was purified by silica gel column (elution with 5-15 % ethyl acetate in hexanes). A colorless oil was thus obtained.

Example of preparations of P2 isoquinoline intermediates for incorporation into compounds of Formula 1

Method A

Step 1:

To a solution of 3-methoxy cinnamic acid (11.04 g, 62 mmol) and triethylamine (12.52 g, 124 mmol) in acetone (80 mL) was added ethyl chloroformate (approximately 1.5 equivalents) dropwise at 0^0C. After stirring at this temperature for 1 h, aqueous NaN_3 (6.40 g, 100 mmol in 35 mL H_2O; appropriate precautions must be taken when using sodium azide) was added dropwise and the reaction mixture was stirred for 16 h at the ambient temperature. Water (100 mL) was added to the mixture and the volatile was removed in vacuo. The resulting slurry was extracted with toluene (3X50 mL) and the combined organic layers were dried over $MgSO_4$. This dried solution was added dropwise to a heated solution of diphenylmethane (50 mL) and tributylamine (30 mL) at 190^0C. The toluene was distilled off as added. After complete addition, the reaction temperature was raised to 210^0C for 2 h. After cooling, the precipitated product was collected by filtration, washed with hexane (2X50 mL), and dried to yield the desired product as a white solid (5.53 g, 51%) (Nicolas Briet *at el*, Tetrahedron, 2002, 5761-5766). MS *m/z* 176 (M^++H).

An altenative procedure to the above employs diphenylphosphoryl azide for the conversion of the carboxylic acid to the corresponding acylazide. In a one pot procedure then the acid is converted to the corresponding quinolone. The process is described below for the prepapration of 4-methyl-*2H*-isoquinolin-1-one from 3-phenyl-but-2-enoic acid:

A solution of 3-phenyl-but-2-enoic acid (16.2 g), diphenylphosphoryl azide (27.5 g), and triethylamine (10.1 g) in benzene (100 mL) was stirred for 1 h. After filtration

through a silica gel plug washing with benzene and concentration, the residue was dissolved in diphenylmethane (80 mL) and refluxed for 3 h. After cooling to rt, solids were collected through a plug washing with benzene and dried to give 10 g (63%) of the desired 4-methyl-*2H*-isoquinolin-1-one as a solid. ^{1}H NMR (400 MHz, CD_3OD) δ ppm 2.30 (s, 3 H), 7.00 (s, 1 H), 7.54 (m, 1 H), 7.77 (m, 2 H), 8.33 (d, *J*=7.34 Hz, 1 H).

Step 2:

6-Methoxy-*2H*-isoquinolin-1-one (5.0 g, 28.4 mmol) in $POCl_3$ (10 mL) was heated to gentle reflux for 3 h the evaporated *in vacuo* (Nicolas Briet *at el*, **Tetrahedron**, 2002, 5761-5766). The residue was poured into iced water (20 mL) and neutralized to pH 10 with 10 M NaOH. Extracted with $CHCl_3$. The organic layer was washed with brine, dried over $MgSO_4$, filtered, evaporated. The residue was purified by flash chromatography (1:1 hexane-EtOAc) to afford 4.41 g (80%) of the desired product as a white solid.

^{1}H NMR (CD_3OD) δ 3.98 (s, 3H), 7.34-7.38 (m, 2 H), 7.69 (d, *J*=5.5 Hz, 1H), 8.10 (d, *J*=6.0 Hz, 1H), 8.23 (d, *J*=9.5 Hz, 1H). MS *m/z* 194 (M^++H).

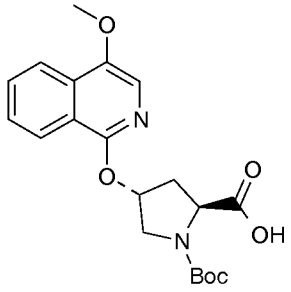

Step 3:

To a solution of N-BOC-3-(*R*)-hydroxy-L-proline (892 mg, 3.89 mmol) in DMSO (40 mL) at the ambient temperature was added potassium tert-butoxide (1.34 g, 12.0 mmol) in one portion. The formed suspension was stirred at this temperature for 30 min before being cooled to 10^0C. 1-chloro-6-methoxy-isoquinoline (example 11, Step 2) (785 mg, 4.05 mmol) was added as solid in one portion and the final mixture was stirred at the ambient temperature for 12 h. Quenched with iced 5% citric acid (aq), extracted with EtOAC (100 mL). The aqueous phase was extracted with EtOAC again. The combined organic layers were washed with 5% citric acid (aq) and brine respectively, dried over $MgSO_4$, filtered. The filtrate was evaporated in vacuo to dryness to yield 1.49 g (99%) of the desired product as an off-white foam. This material was used in the next step reaction as crude without further purification.

^{1}H NMR (CD_3OD) δ 1.42, 1.44 (rotamers, 9H), 2.38-2.43 (m, 1H), 2.66-2.72 (m, 1H), 3.80-3.87 (m, 2H), 3.92 (s, 3H), 4.44-4.52 (m, 1H), 5.73 (b, 1H), 7.16-7.18 (m,

2H), 7.24-7.25 (m, 1H), 7.87-7.88 (m, 1H), 8.07 (d, *J*=8.5 Hz, 1H). MS *m/z* 389 (M^++H).

Method B

Step 1:

A mixture of 4-methoxy-2-methyl-benzoic acid (5.00 g, 30.1 mmol) and thionyl chloride (20.0 g, 0.17 mol) was heated to reflux for 30 min. Removed the volatile in vacuo. After pumping overnight, the viscous oily acid chloride was used as crude for the next reaction without any purification.

To a solution of 4-methoxy-2-methyl-benzoyl chloride in CH_2Cl_2 (60 mL) at 0^0C was added diethylamine dropwise. The formed mixture was allowed to warm up to the ambient temperature for 2 h with stirring. Removed the volatiles in vacuo. The residue was triturated with EtOAc (100 mL) and filtered. The filtrate was washed with 1M HCl , 1M NaOH and brine, dried over $MgSO_4$. Evaporation of the solvent yielded 6.51 g (98%) of the desired product as a viscous oil. MS *m/z* 222 (M^++H).

Step 2:

To a solution of N,N-diethyl-4-methoxy-2-methyl-benzamide (221 mg, 1.0 mmol) in THF (2 mL) at -78^0C was added n-BuLi (0.84 mL of 2.5 M in hexane, 2.10 mmol) dropwise. The formed orange solution was kept at this temperature for additional 30 min before dropwise addition of benzonitrile (103 mg, 1.0 mmol). The final solution was allowed to warm up to the ambient temperature over night with stirring. Quenched with iced 5% citric acid. Filtered, washed with water, dried. Trituration with 2:1 hexane-EtOAc (5 mL) yielded 205 mg (82%) of the desired product as a white solid.

Biological Studies

HCV NS3/4A protease complex enzyme assays and cell-based HCV replicon assays were utilized in the present disclosure, and were prepared, conducted and validated as follows:

Generation of recombinant HCV NS3/4A protease complex

HCV NS3 protease complexes, derived from the BMS strain, H77 strain or J4L6S strain, were generated, as described below. These purified recombinant proteins were generated for use in a homogeneous assay (see below) to provide an indication of how effective compounds of the present disclosure would be in inhibiting HCV NS3 proteolytic activity.

Serum from an HCV-infected patient was obtained from Dr. T. Wright, San Francisco Hospital. An engineered full-length cDNA (compliment deoxyribonucleic acid) template of the HCV genome (BMS strain) was constructed from DNA fragments obtained by reverse transcription-PCR (RT-PCR) of serum RNA (ribonucleic acid) and using primers selected on the basis of homology between other genotype 1a strains. From the determination of the entire genome sequence, a genotype 1a was assigned to the HCV isolate according to the classification of Simmonds et al. (See P Simmonds, KA Rose, S Graham, SW Chan, F McOmish, BC Dow, EA Follett, PL Yap and H Marsden, *J. Clin. Microbiol.*, 31(6), 1493-1503 (1993)). The amino acid sequence of the nonstructural region, NS2-5B, was shown to be >97% identical to HCV genotype 1a (H77) and 87% identical to genotype 1b (J4L6S). The infectious clones, H77 (1a genotype) and J4L6S (1b genotype) were obtained from R. Purcell (NIH) and the sequences are published in Genbank (AAB67036, see Yanagi,M., Purcell,R.H., Emerson,S.U. and Bukh,J. *Proc. Natl. Acad. Sci. U.S.A.* 94(16), 8738-8743 (1997); AF054247, see Yanagi,M., St Claire,M., Shapiro,M., Emerson,S.U., Purcell,R.H. and Bukh,J. *Virology* 244 (1), 161-172. (1998)).

The H77 and J4L6S strains were used for production of recombinant NS3/4A protease complexes. DNA encoding the recombinant HCV NS3/4A protease complex (amino acids 1027 to 1711) for these strains was manipulated as described by P. Gallinari et al. (see Gallinari P, Paolini C, Brennan D, Nardi C, Steinkuhler C, De Francesco R. *Biochemistry* 38(17):5620-32, (1999)). Briefly, a three-lysine solubilizing tail was added at the 3'-end of the NS4A coding region. The cysteine in the P1 position of the NS4A-NS4B cleavage site (amino acid 1711) was changed to a glycine to avoid the proteolytic cleavage of the lysine tag. Furthermore, a cysteine to serine mutation was introduced by PCR at amino acid position 1454 to prevent the autolytic cleavage in the NS3 helicase domain. The variant DNA fragment was cloned in the pET21b bacterial expression vector (Novagen) and the NS3/4A complex was expressed in Escherichia. coli strain BL21 (DE3) (Invitrogen) following the protocol described by P. Gallinari et al. (see Gallinari P, Brennan D, Nardi C, Brunetti M, Tomei L, Steinkuhler C, De Francesco R., *J Virol.* 72(8):6758-69 (1998)) with modifications. Briefly, the NS3/4A protease complex expression was induced with 0.5 millimolar (mM) Isopropyl β-D-1-thiogalactopyranoside (IPTG) for 22 hours (h) at 20°C. A typical fermentation (1 Liter (L)) yielded approximately 10 grams (g) of wet cell paste. The cells were resuspended in lysis buffer (10 mL/g) consisting of 25 mM *N*-(2-Hydroxyethyl)Piperazine-*N*'-(2-Ethane Sulfonic acid) (HEPES), pH 7.5, 20% glycerol, 500 mM Sodium Chloride (NaCl), 0.5% Triton X-100, 1 microgram/milliliter ("μg/mL") lysozyme, 5 mM Magnesium Chloride ($MgCl_2$), 1 μg/ml DnaseI, 5mM β-Mercaptoethanol (βME), Protease inhibitor-Ethylenediamine Tetraacetic acid (EDTA) free (Roche), homogenized and incubated for 20 minutes (min) at 4 °C. The homogenate was sonicated and clarified by ultra-centrifugation at 235000 g for 1 hour at 4 °C. Imidazole was added to the supernatant to a final concentration of 15 mM and the pH adjusted to 8.0. The crude protein extract was loaded on a Nickel-Nitrilotriacetic acid (Ni-NTA) column pre-equilibrated with buffer B (25 mM HEPES, pH 8.0, 20% glycerol, 500 mM NaCl, 0.5% Triton X-100, 15 mM imidazole, 5 mM βME). The sample was loaded at a flow rate of 1 mL/min. The column was washed with 15 column volumes of buffer C (same as buffer B except with 0.2% Triton X-100). The protein was eluted with 5 column volumes of buffer D (same as buffer C except with 200 mM Imidazole).

NS3/4A protease complex-containing fractions were pooled and loaded on a desalting column Superdex-S200 pre-equilibrated with buffer D (25 mM HEPES, pH 7.5, 20% glycerol, 300 mM NaCl, 0.2% Triton X-100, 10 mM βME). Sample was loaded at a flow rate of 1 mL/min. NS3/4A protease complex-containing fractions were pooled and concentrated to approximately 0.5 mg/ml. The purity of the NS3/4A protease complexes, derived from the BMS, H77 and J4L6S strains, were judged to be greater than 90% by SDS-PAGE and mass spectrometry analyses. The enzyme was stored at -80 °C, thawed on ice and diluted prior to use in assay buffer.

FRET peptide assay to monitor HCV NS3/4A proteolytic activty

The purpose of this in vitro assay was to measure the inhibition of HCV NS3 protease complexes, derived from the BMS strain, H77 strain or J4L6S strain, as described above, by compounds of the present disclosure. This assay provides an indication of how effective compounds of the present disclosure would be in inhibiting HCV NS3 proteolytic activity.

In order to monitor HCV NS3/4A protease activity, an NS3/4A peptide substrate was used. The substrate was RET S1 (Resonance Energy Transfer Depsipeptide Substrate; AnaSpec, Inc. cat # 22991) (FRET peptide), described by Taliani et al. in Anal. Biochem. 240(2):60-67 (1996). The sequence of this peptide is loosely based on the NS4A/NS4B natural cleavage site for the HCV NS3 protease except there is an ester linkage rather than an amide bond at the cleavage site. The peptide also contains a fluorescence donor, EDANS, near one end of the peptide and an acceptor, DABCYL, near the other end. The fluorescence of the peptide is quenched by intermolecular resonance energy transfer (RET) between the donor and the acceptor, but as the NS3 protease cleaves the peptide the products are released from RET quenching and the fluorescence of the donor becomes apparent.

The peptide substrate was incubated with one of the three recombinant NS3/4A protease complexes, in the absence or presence of a compound of the present disclosure. The inhibitory effects of a compound were determined by monitoring the formation of fluorescent reaction product in real time using a Cytofluor Series 4000.

The reagents were as follow: HEPES and Glycerol (Ultrapure) were obtained from GIBCO-BRL. Dimethyl Sulfoxide (DMSO) was obtained from Sigma. β-

Mercaptoethanol was obtained from Bio Rad.

Assay buffer: 50 mM HEPES, pH 7.5; 0.15 M NaCl; 0.1% Triton; 15% Glycerol; 10 mM βME. Substrate: 2 μM final concentration (from a 2 mM stock solution in DMSO stored at -20°C). HCV NS3/4A protease type 1a (1b), 2-3 nM final concentration (from a 5 μM stock solution in 25 mM HEPES, pH 7.5, 20% glycerol, 300 mM NaCl, 0.2% Triton-X100, 10 mM βME). For compounds with potencies approaching the assay limit, the assay was made more sensitive by adding 50 μg/ml Bovine Serum Albumin (Sigma) to the assay buffer and reducing the end protease concentration to 300 pM.

The assay was performed in a 96-well polystyrene black plate from Falcon. Each well contained 25 μl NS3/4A protease complex in assay buffer, 50 μl of a compound of the present disclosure in 10% DMSO/assay buffer and 25 μl substrate in assay buffer. A control (no compound) was also prepared on the same assay plate. The enzyme complex was mixed with compound or control solution for 1 min before initiating the enzymatic reaction by the addition of substrate. The assay plate was read immediately using the Cytofluor Series 4000 (Perspective Biosystems). The instrument was set to read an emission of 340 nm and excitation of 490 nm at 25 °C. Reactions were generally followed for approximately 15 minutes .

The percent inhibition was calculated with the following equation:

$$100-[(\delta F_{inh}/\delta F_{con})x100]$$

where δF is the change in fluorescence over the linear range of the curve. A non-linear curve fit was applied to the inhibition-concentration data, and the 50% effective concentration (IC_{50}) was calculated by the use of Excel XLfit software using the equation, y=A+((B-A)/(1+((C/x)^D))).

Compounds of the present disclosure, which were tested against more than one type of NS3/4A complex, were found to have similar inhibitory properties though the compounds uniformly demonstrated greater potency against the 1b strains as compared to the 1a strains.

Specificity Assays

The specificity assays were performed to demonstrate the in vitro selectivity of the compounds of the present disclosure in inhibiting HCV NS3/4A protease

complex as compared to other serine or cysteine proteases.

The specificities of compounds of the present disclosure were determined against a variety of serine proteases: human neutrophil elastase (HNE), porcine pancreatic elastase (PPE) and human pancreatic chymotrypsin and one cysteine protease: human liver cathepsin B. In all cases a 96-well plate format protocol using either colorimetric p-nitroaniline (pNA) substrate or fluorometric Amino-Methyl-Coumarin (AMC) specific for each enzyme was used as described previously (PCT Patent Application No. WO 00/09543) with some modifications to the serine protease assays. All enzymes were purchased from Sigma, EMDbiosciences while the substrates were from Bachem, Sigma and EMDbiosciences.

The pNA assay for Chymotrypsin included a 1 h enzyme-inhibitor pre-incubation at room temperature followed by addition of substrate and hydrolysis to ~15% conversion as measured on a Spectramax Pro microplate reader. Compound concentrations varied from 100 to 0.4 μM depending on their potency. Cathepsin B, HNE, and PPE assays each was initiated by addition of substrate to enzyme-inhibitor pre-incubated for 10 min at room temperature and hydrolysis to 15% conversion as measured on cytofluor.

The final conditions for each assay were as follows:

50 mM Tris(hydroxymethyl) aminomethane hydrochloride (Tris-HCl) pH 8, 0.5 M Sodium Sulfate (Na_2SO_4), 50 mM NaCl, 0.1 mM EDTA, 3% DMSO, 0.01% Tween-20 with 100 μM succ-AAPF-pNA and 250 pM Chymotrypsin.

50mM Tris-HCl, pH 8.0, 50 mM NaCl, 0.1mM EDTA, 3% DMSO, 0.02% Tween-20, 5 μM succ-AAPV-AMC and 20 nM HNE or 8 nM PPE;

100 mM NaOAC (Sodium Acetate) pH 5.5, 3% DMSO, 1 mM TCEP (Tris(2-carboxyethyl)phosphine hydrochloride), 5 nM Cathepsin B (enzyme stock activated in buffer containing 20 mM TCEP before use), and 2 μM Z-FR-AMC diluted in H_2O.

The percentage of inhibition was calculated using the formula:

$$[1-((UV_{inh}-UV_{blank})/(UV_{ctl}-UV_{blank}))] \times 100$$

A non-linear curve fit was applied to the inhibition-concentration data, and the 50% effective concentration (IC_{50}) was calculated by the use of Excel XLfit software.

Generation of HCV Replicon

An HCV replicon whole cell system was established as described by Lohmann V, Korner F, Koch J, Herian U, Theilmann L, Bartenschlager R., Science 285(5424):110-3 (1999). This system enabled us to evaluate the effects of our HCV Protease compounds on HCV RNA replication. Briefly, using the HCV strain 1b sequence described in the Lohmann paper (Assession number: AJ238799), an HCV cDNA was synthesized by Operon Technologies, Inc. (Alameda, CA), and the full-length replicon was then assembled in plasmid pGem9zf(+) (Promega, Madison, WI) using standard molecular biology techniques. The replicon consists of (i) the HCV 5' UTR fused to the first 12 amino acids of the capsid protein, (ii) the neomycin phosphotransferase gene (neo), (iii) the IRES from encephalomyocarditis virus (EMCV), and (iv) HCV NS3 to NS5B genes and the HCV 3' UTR. Plasmid DNAs were linearized with ScaI and RNA transcripts were synthesized in vitro using the T7 MegaScript transcription kit (Ambion, Austin, TX) according to manufacturer's directions. In vitro transcripts of the cDNA were transfected into the human hepatoma cell line, HUH-7. Selection for cells constitutively expressing the HCV replicon was achieved in the presence of the selectable marker, neomycin (G418). Resulting cell lines were characterized for positive and negative strand RNA production and protein production over time.

HCV Replicon FRET Assay

The HCV replicon FRET assay was developed to monitor the inhibitory effects of compounds described in the disclosure on HCV viral replication. HUH-7 cells, constitutively expressing the HCV replicon, were grown in Dulbecco's Modified Eagle Media (DMEM) (Gibco-BRL) containing 10% Fetal calf serum (FCS) (Sigma) and 1 mg/ml G418 (Gibco-BRL). Cells were seeded the night before (1.5×10^4 cells/well) in 96-well tissue-culture sterile plates. Compound and no compound controls were prepared in DMEM containing 4% FCS, 1:100

Penicillin/Streptomysin (Gibco-BRL), 1:100 L-glutamine and 5% DMSO in the dilution plate (0.5% DMSO final concentration in the assay). Compound/DMSO mixes were added to the cells and incubated for 4 days at 37 °C. After 4 days, cells were first assessed for cytotoxicity using alamar Blue (Trek Diagnotstic Systems) for a CC_{50} reading. The toxicity of compound (CC_{50}) was determined by adding $1/10^{th}$ volume of alamarBlue to the media incubating the cells. After 4 hours, the fluorescence signal from each well was read, with an excitation wavelength at 530 nm and an emission wavelength of 580 nm, using the Cytofluor Series 4000 (Perspective Biosystems). Plates were then rinsed thoroughly with Phosphate-Buffered Saline (PBS) (3 times 150 µl). The cells were lysed with 25 µl of a lysis assay reagent containing an HCV protease substrate (5X cell Luciferase cell culture lysis reagent (Promega #E153A) diluted to 1X with distilled water, NaCl added to 150 mM final, the FRET peptide substrate (as described for the enzyme assay above) diluted to 10 µM final from a 2 mM stock in 100% DMSO. The plate was then placed into the Cytofluor 4000 instrument which had been set to 340 nm excitation/490 nm emissions, automatic mode for 21 cycles and the plate read in a kinetic mode. EC_{50} determinations were carried out as described for the IC_{50} determinations.

HCV Replicon Luciferase Reporter Assay

As a secondary assay, EC_{50} determinations from the replicon FRET assay were confirmed in a replicon luciferase reporter assay. Utilization of a replicon luciferase reporter assay was first described by Krieger et al (Krieger N, Lohmann V, and Bartenschlager R, *J. Virol.* 75(10):4614-4624 (2001)). The replicon construct described for our FRET assay was modified by inserting cDNA encoding a humanized form of the Renilla luciferase gene and a linker sequence fused directly to the 3'-end of the luciferase gene. This insert was introduced into the replicon construct using an Asc1 restriction site located in core, directly upstream of the neomycin marker gene. The adaptive mutation at position 1179 (serine to isoleucine) was also introduced (Blight KJ, Kolykhalov, AA, Rice, CM, *Science* 290(5498):1972-1974). A stable cell line constitutively expressing this HCV replicon construct was generated as described above. The luciferase reporter assay

was set up as described for the HCV replicon FRET assay with the following modifications. Following 4 days in a 37 °C/5% CO_2 incubator, cells were analyzed for Renilla Luciferase activity using the Promega Dual-Glo Luciferase Assay System. Media (100 µl) was removed from each well containing cells. To the remaining 50 µl of media, 50 µl of Dual-Glo Luciferase Reagent was added, and plates rocked for 10 min to 2 h at room temperature. Dual-Glo Stop & Glo Reagent (50 µl) was then added to each well, and plates were rocked again for an additional 10 min to 2 h at room temperature. Plates were read on a Packard TopCount NXT using a luminescence program.

The percentage inhibition was calculated using the formula below:

$$\% \text{ control} = \frac{\text{average luciferase signal in experimental wells (+ compound)}}{\text{average luciferase signal in DMSO control wells (- compound)}}$$

The values were graphed and analyzed using XLfit to obtain the EC_{50} value.

Representative compounds of the disclosure were assessed in the HCV enzyme assays, HCV replicon cell assay and/or in several of the outlined specificity assays. For example, Compound 18 was found to have an IC_{50} of 3.4 nanomolar (nM) against the NS3/4A BMS strain in the enzyme assay. Similar potency values were obtained with the published H77 (IC_{50} of 1.2 nM) and J4L6S (IC_{50} of 0.9 nM) strains. The EC_{50} value in the replicon FRET assay was 9 nM and 1.1 nM in the replicon Luciferase assay.

In the specificity assays, the same compound was found to have the following activity: HLE > 1.56 µM; PPE > 1.56 µM; Chymotrypsin > 50 µM; Cathepsin B > 50 µM. These results indicate this family of compounds is highly specific for the NS3 protease and many of these members inhibit HCV replicon replication.

It should be understood that the compounds of the present disclosure may inhibit all genotypes of HCV.

The compounds of the current disclosure were tested and found to have activities in the ranges as follow:

IC_{50} Activity Range (NS3/4A BMS Strain): A is > 0.2 µM; B is 0.02-0.2 µM; C is

0.6-20 nM.

EC_{50} Activity Ranges (for compounds tested): A is > 1 μM; B is 0.1-1 μM; C is 3-100 nM.
