

ABSTRACT

An ion elution unit generates metal ions by applying a voltage between electrodes. On the upstream and downstream sides of the electrodes are provided strainers. The strainer provided for the water feed valve of a washer is shared as the upstream-side strainer of the ion
5 elution unit. The water feed valve is composed of a main water feed valve set for a high flow rate and a sub water feed valve set for a low flow rate, and the ion elution unit is placed in the water feed passage connected to the main water feed valve.
