

ABSTRACT

An object is to prevent access to a protection-target communication device and to be capable of outputting data from the protection-target communication device to other communication devices with a simple configuration.

5 Provided is a communication connection apparatus that controls connection of a communication line between a first communication device and a second communication device, the communication connection apparatus including: a first

10 connection port to which a connection line to the first communication device is connected, and that includes a first transmission unit through which a signal output from the first communication device passes and a first reception unit through which a signal input to the first

15 communication device passes; a second connection port to which a connection line to the second communication device is connected, and that includes a second transmission unit through which a signal output from the second communication device passes and a second reception unit through which a

20 signal input to the second communication device passes; a first connection line that connects the first transmission unit and the second reception unit to each other; and a simulated-signal input unit that inputs, to the first reception unit, a first signal which is a signal for

25 recognizing that the first communication device is connectable to other devices, wherein when a simulated signal is being input to the first reception unit, the first reception unit and the second transmission unit are physically disconnected from each other.
