

COLD ROW ENCAPSULATION FOR SERVER FARM COOLING SYSTEM

TECHNICAL FIELD

The present disclosure relates generally to cooling systems for data centers.

BACKGROUND

5 The rapid growth of Internet services such as Web email, Web search, Web site hosting, and Web video sharing is creating increasingly high demand for computing and storage power from servers in data centers. While the performance of servers is improving, the power consumption of servers is also rising despite efforts in low power design of integrated circuits. For example, one of the most widely used
10 server processors, AMD's Opteron processor, runs at up to 95 watts. Intel's Xeon server processor runs at between 110 and 165 watts. Processors are only part of a server, however; other parts in a server such as cooling fans and storage devices consume additional power.

 Servers are typically placed in racks in a data center. There are a variety of
15 physical configurations for racks. A typical rack configuration includes mounting rails to which multiple units of equipment, such as server blades, are mounted and stacked vertically within the rack. One of the most widely used 19-inch rack is a standardized system for mounting equipment such as 1U or 2U servers. One rack unit on this type of rack typically is 1.75 inches high and 19 inches wide. A server that
20 can be installed in one rack unit is commonly designated as a 1U server. In data centers, a standard rack is usually densely populated with servers, storage devices, switches, and/or telecommunications equipment.

 A data center room should be maintained at acceptable temperatures and humidity for reliable operation of the servers, which typically have cooling fans that
25 draw air through the chassis for cooling. The power consumption of a rack densely stacked with servers powered by Opteron or Xeon processors may be between 7,000 and 15,000 watts. As a result, server racks can produce very concentrated heat loads. The heat dissipated by the servers in the racks is exhausted to the data center room. The heat collectively generated by densely populated racks can have an adverse effect
30 on the performance and reliability of the equipment in the racks, since they rely on the

surrounding air for cooling. Accordingly, heating, ventilation, air conditioning (HAVC) systems are often an important part of the design of an efficient data center.

A typical data center consumes 10 to 40 megawatts of power. The majority of energy consumption is divided between the operation of servers and HVAC systems.

5 HVAC systems have been estimated to account for between 25 to 40 per cent of power use in data centers. For a data center that consumes 40 megawatts of power, the HAVC systems may consume 10 to 16 megawatts of power. Significant cost savings can be achieved by utilizing efficient cooling systems and methods that reduce energy use. For example, reducing the power consumption of HVAC systems
10 from 25 percent to 10 percent of power used in data centers translates to a saving of 6 megawatts of power which is enough to power thousands of residential homes.

In a data center room, server racks are typically laid out in rows with alternating cold and hot aisles between them. All servers are installed into the racks to achieve a front-to-back airflow pattern that draws conditioned air in from the cold
15 rows, located in front of the rack, and ejects heat out through the hot rows behind the racks. A raised floor room design is commonly used to accommodate an underfloor air distribution system, where cooled air is supplied through vents in the raised floor along the cold aisles.

An important factor in efficient cooling of data centers is to manage the air
20 flow and circulation inside a data center. Computer Room Air Conditioners (CRAC) units supply cold air through floor tiles including vents between the racks. In addition to servers, CRAC units consume significant amounts of power as well. One CRAC unit may have up to three 5-horsepower motors and up to 150 CRAC units may be needed to cool a data center. The CRAC units collectively consume significant
25 amounts of power in a data center. For example, in a data center room with hot and cold row configuration, hot air from the hot rows is moved out of the hot row and circulated to the CRAC units. The CRAC units cool the air. Fans powered by the motors of the CRAC units supply the cooled air to an underfloor plenum defined by the raised sub-floor. The pressure created by driving the cooled air into the
30 underfloor plenum drives the cooled air upwardly through vents in the subfloor, supplying it to the cold aisles where the server racks are facing. To achieve a sufficient air flow rate, hundreds of powerful CRAC units may be installed throughout a typical data center room. However, since CRAC units are generally installed at the corners of the data center room, their ability to efficiently increase air

flow rate is negatively impacted. The cost of building a raised floor generally is high and the cooling efficiency generally is low due to inefficient air movement inside the data center room. In addition, the location of the floor vents requires careful planning throughout the design and construction of the data center to prevent short circuiting of supply air. Removing tiles to fix hot spots can cause problems throughout the system.

SUMMARY

The present invention provides systems and methods directed to efficient cooling of data centers. In a particular embodiment, the present invention provides a cold row encapsulation structure comprising at least one server rack port configured to interface with one or more server racks and a cooling module connected to the top surface of the cold row encapsulation structure. The server rack ports are configured to engage the server racks such that a front face of the server racks interface with the interior space defined by the cold row encapsulation structure. In some embodiments, the server rack ports and the server racks are connected by one or more hookup clips to facilitate engagement of the server racks and the ports and reduce air leakage into and out of the cold row encapsulation structure.

Some embodiments of the invention utilize cooling fans of the servers installed on the racks to draw cold air from cold row encapsulation structure from the front face of the server racks and to eject hot air from the back side of the server racks. Some embodiments of the invention obviate the need for raised subfloors, and the fans and other equipment for forcing cooled air into an underfloor plenum. The cooling module installed on top of the cold row encapsulation structure cools the hot air through cooling coils installed inside the cooling module. In some embodiments, cooled fluid is used inside the coils to exchange heat with hot air in the cooling module.

In one embodiment of the present invention, the systems and methods are directed to cooling hot air inside the data center server cooling room without introducing outside air. The hot air ejected by the server fans enters the cooling modules that may be located on top of the cold row encapsulation structure. The hot air is cooled by the water based cooling coils inside the cooling modules and the cooled air enters the cold row encapsulation structure through gravity and the lower pressure created inside the interior space of the cold row encapsulation structure. Server fans draw cold air from the server rack ports connected to the cold row

encapsulation structure to cool the servers and eject hot air from the back side of the server racks.

In other embodiments of the present invention, the systems and methods involve mixing outside cool air to cool the servers. In one embodiment, ceiling dampers in a data center may be controlled by a temperature control unit and opened up when the outside temperature reaches certain threshold value. Outside air enters the data center and passes through the cooling module installed on top of the cold row encapsulation structure. Server fans draw the cold air from the cold row encapsulation structure. Hot air is exhausted to the outside by the ceiling exhaust fans. In some embodiments, to control the moisture in the air in the data center server cooling room, especially when the outside air fails to meet the operating requirements for the servers and other equipment, humidifiers may be used to condition the outside air. In recent years, however, manufacturers of server equipment have significantly relaxed the humidity requirements due to technological advancement.

According to the first aspect of the present invention, there is provided a server cooling system, comprising an enclosure defining an interior space and comprising a rack port configured to engage a rack, the enclosure further comprising a top crossbar extending horizontally across and proximal to an upper edge of the rack port and a bottom crossbar extending horizontally across and proximal to a lower edge of the rack port; a cooling and mixing module operative to supply cooling air to the interior space defined by the enclosure; a rack including a crossbar and one or more rack-mounted units installed in the rack, wherein the rack is engaged in the rack port such that respective front faces of the one or more rack-mounted units interface with the interior space defined by the enclosure; one or more cooling fans operative to draw air from the interior space through the respective front faces of the one or more rack-mounted units and expel heated air from the one or more rack-mounted units; and a hookup clip securing the crossbar of the rack to the top or bottom crossbar of the enclosure.

According to the second aspect of the present invention, there is provided a server cooling system, comprising an enclosure defining an interior space and comprising a rack port configured to engage a rack, the enclosure further comprising a top crossbar extending horizontally across and proximal to an upper edge of the rack port and a bottom crossbar extending horizontally across and proximal to a lower edge of the rack port; a cooling and mixing module operative to supply cooling air

to the interior space defined by the enclosure; a rack including one or more crossbars and one or more rack-mounted units installed in the rack, wherein the rack is engaged in the rack port such that respective front faces of the one or more rack-mounted units interface with the interior space defined by the enclosure; one or more cooling fans operative to draw air from the interior space through the respective front faces of the one or more rack-mounted units and expel heated air from the one or more rack-mounted units; and one or more hookup clips securing the one or more crossbars of the rack to the top or bottom crossbars of the enclosure.

The following detailed description together with the accompanying drawings will provide a better understanding of the nature and advantages of various embodiments of the present invention.

DESCRIPTION OF THE DRAWINGS

FIG. 1 is a diagram showing an example cold row encapsulation structure and an example cooling module.

FIG. 2 is a diagram showing an example cold row encapsulation structure with integrated server racks and an example cooling module.

FIG. 3 is a diagram showing an example cold row encapsulation structure with integrated server racks, an example server placed on one of the server racks, and an example cooling module.

FIG. 4 is a diagram showing an example server with a server fan that draws cold air conditioned by an example cooling module.

FIG. 5 is a diagram showing an example data center server cooling room with a cold row encapsulation structure, a cooling module, exhaust fans on the roof, and a mixing chamber with dampers that controls the indoor and outdoor air circulation.

FIG. 6 is a diagram showing an example cold row encapsulation structure wherein a hookup clip is used to secure the top and bottom crossbar of the cold row encapsulation structure and the top and bottom crossbar of one or more server racks.

FIG. 7 is a diagram showing an example hookup clip securing two top crossbars.

FIG. 8 is a diagram showing an example hookup clip securing two bottom crossbars.

5

DESCRIPTION OF EXAMPLE EMBODIMENT(S)

The following example embodiments and their aspects are described and illustrated in conjunction with apparatuses, methods, and systems which are meant to be illustrative examples, not limiting in scope.

10 FIG. 1 illustrates an example cooling module 100 and an example cold row encapsulation structure 106. The cold row encapsulation structure 106 may have a frame, panels, doors, and server rack ports. A server rack port is an opening on the cold row encapsulation structure 106 that can be connected to a server rack. The cold row encapsulation structure 106 may be made of a variety of materials such as steel,
15 composite materials, or carbon materials that create a housing defining an interior space including at least one server rack port that allows a rack mounted unit to interface with the interior space. In some embodiments, the cold row encapsulation structure 106 may be mounted directly to the floor surface and no raised floor is required in a data center cooling room for cooled air. In other embodiments, a raised
20 sub-floor may be used.

The cooling module 100 may be located and positioned on top of the cold row encapsulation structure 106 and connected to the top surface of the cold row encapsulation structure 106. The cooling module 100 comprises one or more cooling coils 102. Fluid passing inside the cooling coils 102 is used to exchange heat with
25 relatively hot air passing through the cooling module 100, thereby cooling the air. In one embodiment, the cooling module 100 further comprises an enclosure inside which the cooling coils 102 are located. The cooling module enclosure may have one or more openings 104 through which air enter the enclosure. In some embodiments, the openings 104 may comprise air filters. The cooling module enclosure may have one
30 or more openings connected to the top surface of the cold row encapsulation structure 106, through which openings cold air exits the cooling module and enters the interior space defined by the cold row encapsulation structure.

In some embodiments, water is used inside the cooling coils 102 as heat exchangers. Water pumps, water cooling equipment, and associated plumbing (not

illustrated) supplies cooled water to the cooling coils 102. In other embodiments, other types of liquid or fluid, such as a water-glycol solution, steam, or a refrigerant may be used inside the cooling coils 102 as heat exchangers.

In some embodiments, the cooling coils 102 may be serpentine-shaped lines of tubing. In other embodiments, the cooling coils 102 may be in other shapes such as straight lines of tubing. Depending on the size of the cold row encapsulation structure 106, the cooling requirements, the velocity of air flow, and the physical characteristics of the cooling coils 102, the number of cooling coils in the cooling module 100 may vary. In one embodiment, two cooling coils are used inside the cooling module 100.

Since cold air is generally heavier than hot air, the cold air cooled by the cooling coils 102 generally moves downward into the interior space defined by the cold row encapsulation structure 106 which may be located below and connected to the cooling module 100. The cold row encapsulation structure 106 comprises an enclosure which defines an interior space. The enclosure comprises at least one server rack port 110 configured to interface with a plurality of server racks. The server rack port 110 is configured to interface with the server racks such that a front face of the server racks intersects the interior space of the cold row encapsulation structure 106. In one embodiment, six standard server racks may be connected to the server rack port 110. In another embodiment, twelve standard server racks may be connected to the server rack port 110. The servers are installed into the racks to achieve a front-to-back airflow pattern that draws conditioned air in from the cold row encapsulation structure 106 in the front, and ejects heat out behind the racks.

In one embodiment, the cold row encapsulation structure 106 may comprise more than one server rack port 110. A server rack port 110 may engage a server rack such that the front face of servers or other devices installed in the server interface with the interior space defined by the cold row encapsulation structure 106. This configuration achieves a front-to-back airflow pattern, where the cooling fans of the servers or other rack-mounted units draw air from the interior space and exhaust air heated by the processor(s) and other components out the back panel, as illustrated in FIG. 4. In some embodiments, the server rack and the cold row encapsulation structure may be connected by one or more hookup clips as illustrated in FIG. 6; conditioned cold air inside the interior space of the cold row encapsulation structure 106 is drawn by the server fans inside the servers to cool the servers. In other embodiments, the server rack and the cold row encapsulation structure 106 are placed

next to each other so that conditioned cold air inside the interior space of the cold row encapsulation structure 106 can be drawn to the servers by the server fans inside the servers. The relatively hot air is circulated to the cooling module 100 on top of the cold row encapsulation structure 106 and exchanges heat with the cooling coils 102.

5 Cold air from the cooling module 100 sinks to the cold row encapsulation structure 106 and is drawn to the back of the servers by server fans inside the servers. In some embodiments, server racks are sparsely populated with servers and other equipment. Since servers and other equipment are stacked vertically within the rack, the scarcity may create open gaps to the interior space of the cold row encapsulation structure.

10 Cold air may leak from the interior space of the cold row encapsulation structure 106, and hot air may circulate back to the interior space, thereby reducing the cooling efficiency. To prevent air leakage, the gaps may be blocked by panels mounted to the server rack that prevent air from escaping and entering the cold row encapsulation structure through the gaps.

15 In one embodiment, the cold row encapsulation structure 106 may further comprise stability control units 114 on the bottom. The stability control units 114 may comprise components that are built to withstand seismic movements during natural disasters such as earthquakes. In some embodiments, the stability control units 114 may have devices for scrolling that can be quickly released to easily move
20 the cold row encapsulation structure 106. When stability control units 114 are used, the cold row encapsulation structure 106 may be raised from the ground. As a result, cold air may leak and hot air may enter from the bottom side of the cold row encapsulation structure 106. To prevent air leakage, in one embodiment, the bottom side of the cold row encapsulation structure 106 may be enclosed by a panel that seals
25 the bottom surface, on which panel the stability control units 114 may be attached.

In one embodiment, one or more doors 108 may be installed on the enclosure of the cold row encapsulation structure 106. The door 108 may be opened and closed so that data center personnel may enter the cold row encapsulation structure for a variety of tasks such as server maintenance. The door 108 may be insulated to prevent
30 cold air from leaking out of the cold row encapsulation structure 106.

The dimension of the cold row encapsulation structure 106 can vary considerably depending on the desired number of server racks, the cooling requirements of the servers, and the like. In one embodiment, six to twelve standard server racks may be connected to respective server rack ports 110 of the cold row

encapsulation structure 106. Another six to twelve standard server racks may be connected to the server rack ports on the opposite side of the cold row encapsulation structure. The distance between the opposing server rack ports may be 4 feet. The height of the cold row encapsulation structure 106 may be 12 feet and the depth may also be 12 feet.

FIG. 2 illustrates an example cooling module 200, a cold row encapsulation structure 206, and server racks 208 and 210. The system in this example is similar to the one shown in FIG. 1 except that the server racks are illustrated as engaged in the server rack ports of the cold row encapsulation structure 206. The servers may be installed into the integrated server racks 208 and 210 to achieve a front-to-back airflow pattern. The front face of the integrated server racks 208 and 210 intersects the interior space of the cold row encapsulation structure 206. The server fans inside the servers draw cold air from the cold row encapsulation structure 206 to cool the servers and blow out relatively hot air from the back of the server racks. Hot air is then circulated to the cooling module 200 through one or more openings 204 and exchanges heat with the one or more cooling coils 202. The cooling module 200 may be located on top of the cold row encapsulation structure 206 and may be connected to the top surface of the cold row encapsulation structure 206 through an opening on the top side of the cold row encapsulation structure 206 and the bottom side the cooling module 200. Cold air generally moves downwards, especially when server fans are drawing cold air from the cold row encapsulation structure creating lower air pressure in the interior space of the cold row encapsulation structure 206.

FIG. 3 illustrates an example cooling module 300, cold row encapsulation structure 302, server racks 304, and an example server 306 placed on a server rack. The system in this example is similar to the one shown in FIG. 2. Conditioned cold air enters the cold row encapsulation structure 302 through the cooling module 300 placed on top of the cold row encapsulation structure 302. Server fans inside the server 306 draw conditioned cold air from the interior space of the cold row encapsulation structure 302 and cools the server 306.

FIG. 4 illustrates an example cooling module 400, cooling coils 402, server 404 and server fan 406 inside the server 404. Conditioned cold air from the cooling module 400 and cooling coils 402 is drawn by the server fan 406 and passes through the server 404 to cool the server. Relatively hot air is then blown out of the server 404 by the server fan 406.

The cooling systems illustrated in Figures 1 and 2 can operate in an interior space defined by a data center server cooling room, as disclosed above, to draw air from the interior space of the data center server cooling room, and provide cooled air to the interior of the cold row encapsulation structure 106. In some implementations, however, the cooling systems may also operate in connection with a data center server cooling room that includes air flow controls that allow outside air to be used. FIG. 5 illustrates an example data center server cooling room 500 with one or more ceiling exhaust fans 516, ceiling dampers 514 which controls outside air intake, a mixing chamber 518, and dampers 512 that control circulation of air entering into the mixing chamber 518. The cooling module 502 comprises one or more cooling coils 504 and is connected to the mixing chamber 518. The top surface of the cold row encapsulation structure 506 is connected to the cooling module 502. Server rack ports 508 on the enclosure of the cold row encapsulation structure 506 are connected to the server racks 510. The servers may be installed into the server racks to achieve a front-to-back airflow pattern. The front face of the server racks intersects the interior space of the cold row encapsulation structure 506. The server fans inside the servers draw cold air from the cold row encapsulation structure 506 to cool the servers and eject hot air server racks.

The server cooling room 500 may be operated in two modes. In one mode, no outside air is introduced to the server cooling room 500; the hot air ejected from the servers is circulated back to the mixing chamber 518 and the cooling module 502. In another mode, outside cool air is introduced to the server cooling room 500. The ceiling dampers 514 are open while the dampers 512 on the mixing chamber are closed. Outside cool air passes through the cooling module 502 and enters cold row encapsulation structure 506.

In one embodiment, the ceiling dampers 514 are closed and the dampers 512 on the mixing chamber are open. Part of the hot air ejected by the servers is exhausted outside of the server cooling room 500 through the one or more ceiling exhaust fans 516; part of the hot air enters the mixing chamber 518 through the open dampers 512. The hot air inside the mixing chamber is drawn to the cooling module 502 and exchanges heat with the cooling coils 504. Cold air then enters the cold row encapsulation structure 506 through gravity and lower air pressure inside the interior space of the cold row encapsulation structure 506.

In another embodiment, the ceiling dampers 514 are open and the dampers 512 on the mixing chamber are closed. The outside cool air enters the mixing chamber 518 through the open dampers 514, passes through the cooling module 504, and sinks to the interior space of the cold row encapsulation structure 506.

5 In some embodiments, the opening and closing of the dampers 512 and 514 may be controlled by a temperature control unit. When the outside temperature reaches an appropriate level, the temperature control unit opens up the ceiling dampers 514 to allow outside air to enter the room and closes the dampers 512 on the mixing chamber to prevent hot air ejected from the server from entering the mixing
10 chamber. When the outside temperature is too hot for the server cooling room 500, the temperature control unit closes the ceiling dampers 514 to prevent introducing hot outside air indoors, and opens up the dampers 512 to allow hot air ejected from the servers back to the mixing chamber. Utilizing outside natural cool air significantly reduces energy consumption of data centers, as it reduces the need to cool the liquid
15 circulating through the cooling module 100. In some embodiments, the opening and closing of the dampers 512 and 514, and the operation of the ceiling exhaust fans 516 are all controlled by an electronic device such as a temperature control unit that monitors the temperature inside and outside the server cooling room and operates the dampers and the fans to achieve optimal efficiency in cooling the room.

20 Depending on the location of the data center, humidity of the outside cool air may vary. When the humidity of the outside cool air is low, the outside air may have to be conditioned so that the humidity level meets the requirement for reliable operation of the servers. Although server manufacturers have significantly relaxed the requirement on humidity for reliable operation of the server equipment, the
25 appropriate humidity of ambient air inside a data center server cooling room still is important to the performance and reliability of the equipment in a data center. In some embodiments, one or more humidifiers may be installed in the mixing chamber 518 to condition the humidity of the air passing through the mixing chamber.

FIG. 6 illustrates an example cooling system with one or more hookup clips
30 606 that connect the top crossbar extending horizontally across and proximal to an upper edge of the server rack port and the top crossbar of the server rack. In FIG. 6, the cooling module 600 is placed on top of the cold row encapsulation structure 612 which comprises a server rack port configured to engage a rack. When one or more server racks 614 are engaged in the server rack port, the cold row encapsulation

structure's top crossbar 602 is engaged with one or more top crossbars 604 of the server racks 614. The one or more hookup clips 606 are used to quickly secure the top crossbars of the one or more server racks 614 with the top crossbar of the cold row encapsulation structure 612. Similarly, the cold row encapsulation structure's
5 bottom crossbar 618 may be engaged with the bottom crossbars 620 of the server racks. The one or more hookup clips 616 are used to quickly secure the bottom crossbars of the one or more server racks 614 with the bottom crossbar of the cold row encapsulation structure 612.

In some embodiments, a hookup clip may have a U-shaped profile. The U-
10 shaped hookup clip may be used as a clasp to secure two crossbars. On one side of the U-shaped hookup clip, one or more pin members 608 may be tightened to fasten the hookup clip and secure the connection. The pin members 608 may be metal bolts. The hookup clip 606 may be made of metal such as steel. The width of the hookup clip may be commensurate with the combined width of the top or bottom crossbar of
15 the cold row encapsulation structure and the top or bottom crossbar of a server rack. The hookup clip provides a quick and easy mechanism for securing a server rack with the cold row encapsulation structure.

FIG. 7 illustrates an example hookup clip securing two crossbars. The U-
shaped hookup clip 704 is used to secure crossbar 700 and crossbar 702. In some
20 embodiments, crossbar 700 may be a top crossbar of a cold row encapsulation structure and crossbar 702 may be a top crossbar of a server rack which is engaged in a server rack port of the cold row encapsulation structure. The crossbars 700 and 702 may be made of metal such as steel. The width of the hookup clip 704 may be commensurate with the combined width of the crossbar 700 and crossbar 702. Two
25 pin members 706 on the hookup clip may comprise metal bolts that can be tightened through two sockets to secure the connection of the crossbar 700 and 702. In some embodiments, more than two pin members may be used on a hookup clip.

FIG. 8 illustrates an example hookup clip securing two crossbars. The U-
shaped hookup clip 804 is used to secure crossbar 800 and crossbar 802. In some
30 embodiments, crossbar 800 may be a bottom crossbar of a cold row encapsulation structure and crossbar 802 may be a bottom crossbar of a server rack which is engaged in a server rack port of the cold row encapsulation structure. The crossbars 800 and 802 may be made of metal such as steel. The width of the hookup clip 804 may be commensurate with the combined width of the crossbar 800 and crossbar 802.

Two pin members 806 on the hookup clip may comprise metal bolts that can be tightened through two sockets to secure the connection of the crossbar 800 and 802. In some embodiments, more than two pin members may be used on a hookup clip.

The present invention has been explained with reference to specific
5 embodiments. For example, while embodiments of the present invention have been described with reference to specific components and configurations, those skilled in the art will appreciate that different combination of components and configurations may also be used. Other embodiments will be evident to those of ordinary skill in the art. It is therefore not intended that the present invention be limited, except as
10 indicated by the appended claims.

CLAIMS

What is claimed is:

1. A server cooling system, comprising
 - an enclosure defining an interior space and comprising a rack port configured
 - 5 to engage a rack, the enclosure further comprising a top crossbar extending horizontally across and proximal to an upper edge of the rack port and a bottom crossbar extending horizontally across and proximal to a lower edge of the rack port;
 - a cooling and mixing module operative to supply cooling air to the interior space defined by the enclosure;
 - 10 a rack including a crossbar and one or more rack-mounted units installed in the rack, wherein the rack is engaged in the rack port such that respective front faces of the one or more rack-mounted units interface with the interior space defined by the enclosure;
 - one or more cooling fans operative to draw air from the interior space through
 - 15 the respective front faces of the one or more rack-mounted units and expel heated air from the one or more rack-mounted units; and
 - a hookup clip securing the crossbar of the rack to the top or bottom crossbar of the enclosure.
- 20 2. The server cooling system of claim 1 wherein the hookup clip has a U-shaped profile and comprises:
 - one or more pin members;
 - a clasp member further comprising one or more sockets for receiving the pin members, wherein the clasp member secures the crossbar of the rack to the top
 - 25 or bottom crossbar of the enclosure through the pin members in the sockets.
3. The server cooling system of claim 1, wherein the rack port is configured to substantially conform to an outer periphery of one or more racks.
- 30 4. The server cooling system of claim 3, wherein the rack port can be substantially sealed when attached to the racks.

5. The server cooling system of claim 4, wherein the rack port comprises a gasket configured to substantially seal the one or more racks with the rack port.

6. The server cooling system of claim 1, wherein the cooling and mixing module

5 further comprises

one or more integrated coils adaptive to cool ambient air within the cooling module;

one or more integrated dampers adaptive to adjust the flow of air in and out of the cooling module;

10 a control unit operative to control operation of the integrated dampers.

7. The server cooling system of claim 6, wherein liquid is used inside the integrated coils to cool ambient air.

15 8. The server cooling system of claim 6, wherein the integrated dampers are controlled by a temperature control unit.

9. The server cooling system of claim 1, wherein the rack port comprises one or more racks on which one or more servers is placed.

20

10. A server cooling system, comprising

an enclosure defining an interior space and comprising a rack port configured to engage a rack, the enclosure further comprising a top crossbar extending horizontally across and proximal to an upper edge of the rack port and a bottom

25 crossbar extending horizontally across and proximal to a lower edge of the rack port;

a cooling and mixing module operative to supply cooling air to the interior space defined by the enclosure;

a rack including one or more crossbars and one or more rack-mounted units installed in the rack, wherein the rack is engaged in the rack port such that respective front faces of the one or more rack-mounted units interface with the interior space defined by the enclosure;

30 one or more cooling fans operative to draw air from the interior space through the respective front faces of the one or more rack-mounted units and expel heated air from the one or more rack-mounted units; and

one or more hookup clips securing the one or more crossbars of the rack to the top or bottom crossbars of the enclosure.
