COMPLIANT AND CROSSLINKABLE THERMAL INTERFACE MATERIALS

This application claims the benefit of U.S. utility application number 09/774466 incorporated herein by reference in its entirety.

G00002

Background

As electronic devices become smaller and operate at higher speeds, energy emitted in the form of heat increases dramatically. A popular practice in the industry is to use thermal grease, or grease-like materials, alone or on a carrier in such devices to transfer the excess heat dissipated across physical interfaces. Most common types of thermal interface materials are thermal greases, phase change materials, and elastomer tapes. Thermal greases or phase change materials have lower thermal resistance than elastomer tape because of the ability to be spread in very thin layers and provide intimate contact between adjacent surfaces. Typical thermal impedance values range between 0.6-1.6°C cm²/w.

A serious drawback of thermal grease is that thermal performance deteriorates significantly after thermal cycling, such as from -65°C to 150°C, or after power cycling when used in VLSI chips. It has been also found that the performance of these materials deteriorates when large deviations from surface planarity causes gaps to form between the mating surfaces in the electronic devices or when large gaps between mating surfaces are present for other reasons, such as manufacturing tolerances, etc. When the heat transferability of these materials breaks down, the performance of the electronic device in which they are used is adversely affected. The present invention provides a thermal interface material that is particularly suitable for use as an interface material in electronic devices.

Summary of the Invention

In accordance with the invention there is provided a compliant and crosslinkable material which comprises a silicone resin mixture, such as a mixture of vinyl silicone, vinyl Q resin, hydride functional siloxane and platinum-vinylsiloxane, a wetting enhancer and at least one thermally conductive filler. The compliant thermally conductive material has the

capability of enhancing heat dissipation in high power semiconductor devices and maintains stable thermal performance. It is not subject to interfacial delamination or phase separation during thermal-mechanical stresses or fluctuating power cycling of the electronic devices in which it is used.

The compliant and crosslinkable thermal interface material may be formulated by mixing the components together to produce a paste which may be applied by dispensing methods to any particular surface and cured at room temperature or elevated temperature. It can be also formulated as a highly compliant, cured, tacky elastomeric film or sheet for other interface applications where it can be preapplied, for example on heat sinks, or in any other interface situations.

The filler to be incorporated advantageously comprises at least one thermally conductive filler, such as silver, copper, aluminum, and alloys thereof; boron nitride, aluminum nitride, silver coated copper, silver coated aluminum and carbon fiber. It may be also additionally useful to incorporate antioxidants to reduce oxidation of the resins, wettability enhancing agents to promote wetting of surfaces, curing accelerators, such as would allow curing at room temperature, viscosity reducing agents to enhance dispersability and crosslinking aids. It is also often desirable to include substantially spherical particles of filler to limit the compressibility of the compliant material in interface applications, i.e. to limit or control the thickness.

It has been also found that thermal conductivity of resin systems, such as a combination of filler and the combined silicone resin mixture discussed above, can be especially improved by incorporating carbon micro fibers, with other fillers, into the system.

Detailed Description

A compliant and crosslinkable thermal interface material is formulated by combining a silicone resin mixture, such as a mixture of vinyl silicone, vinyl Q resin, hydride functional siloxane and platinum-vinylsiloxane, an organo-titanate wetting enhancer and at least one thermally conductive filler. More than one silicone resin mixture may be combined to produce a compliant and crosslinkable interface material. Silicone resin containing interface materials, with appropriate thermal fillers, exhibit a thermal capability of less than $0.5 \text{ cm}^2/\text{s}$

c/w. Unlike thermal grease, thermal performance of the material will not degrade after thermal cycling or flow cycling in IC devices because liquid silicone resins will cross link to form a soft gel upon heat activation. Moreover, when applied as an interface material it will not be "squeezed out" as thermal grease does in use and will not display interfacial delamination during thermal cycling. The new material can be provided as a dispensable liquid paste to be applied by dispensing methods and then cured as desired. It can also be provided as a highly compliant, cured, elastomer film or sheet for pre-application on interface surfaces, such as heat sinks. Advantageously, fillers with a thermal conductivity of greater than about 0.2, and preferably at least about 0.4, w/m°C will be used. Optimally, it is desired to have a filler of not less than about 1 w/m°C thermal conductivity. The compliant thermally conductive material enhances thermal dissipation of high power semiconductor devices. The paste may be formulated as a mixture of functional silicone resins and thermal fillers.

As used herein, the term "compliant" encompasses the property of a material that is yielding and formable at room temperature, as opposed to solid and unyielding at room temperature. As used herein, the term "crosslinkable" refers to those materials or compounds that are not yet crosslinked.

A vinyl Q resin is an activated cure specialty silicone rubber having the following base polymer structure:

Vinyl Q resins are also clear reinforcing additives for addition cure elastomers. Examples of vinyl Q resin dispersions that have at least 20% Q-resin are VQM-135 (DMS-V41 Base), VQM-146 (DMS-V46 Base), and VQX-221 (50% in xylene Base).

For example, a contemplated silicone resin mixture could be formed as follows:

Component	% by weight	Note/Function
Vinyl silicone	75 (70-97 range)	Vinyl terminated siloxane
Vinyl Q Resin	20 (0-25 range)	Reinforcing additive
Hydride functional siloxane	5 (3-10 range)	Crosslinker
Platinum -vinylsiloxane	20-200 ppm	Catalyst

The resin mixture can be cured at either at room temperature or elevated temperature to form a compliant elastomer. The reaction is via hydrosilylation (addition cure) of vinyl functional siloxanes by hydride functional siloxanes in the presence of a catalyst, such as platinum complexes or nickel complexes. Preferred platinum catalysts are SIP6830.0, SIP6832.0, and platinum-vinylsiloxane.

Contemplated examples of vinyl silicone include vinyl terminated polydimethyl siloxanes that have a molecular weight of about 10000 to 50000. Contemplated examples of hydride functional siloxane include methylhydrosiloxane-dimethylsiloxane copolymers that have a molecular weight about 500 to 5000. Physical properties can be varied from a very soft gel material at a very low crosslink density to tough elastomer network of higher crosslink density.

Thermal filler particles to be dispersed in the resin mixture should advantageously have a high thermal conductivity. Suitable filler materials include silver, copper, aluminum, and alloys thereof; boron nitride, aluminum spheres, aluminum nitride, silver coated copper, silver coated aluminum and carbon fibers. Combinations of boron nitride and silver or boron nitride and silver/copper also provide enhanced thermal conductivity. Boron nitride in amounts of at least 20 wt. %, aluminum spheres in amounts of at least 70 wt. %, and silver in amounts of at least about 60 wt. % are particularly useful.

Of special efficacy is a filler comprising a particular form of carbon fiber referred to as "vapor grown carbon fiber" (VGCF) such as is available from Applied Sciences, Inc., Cedarville, Ohio. VGCF, or "carbon micro fibers", are a highly graphitized type by heat treatment (thermal conductivity = 1900 w/m°C). Addition of about 0.5 wt. % carbon micro

fibers provides significantly increased thermal conductivity. Such fibers are available in varying lengths and diameters; namely, 1 mm to tens of centimeters in length and from under 0.1 to over 100 μm in diameter. One useful form has a diameter of not greater than about 1 μm and a length of about 50 to 100 μm , and possess a thermal conductivity of about two or three times greater than with other common carbon fibers having diameters greater than 5 μm .

It is difficult to incorporate large amounts of VGCF in resin systems such as the silicone resin mixture discussed above. When carbon micro fibers, e.g. (about 1 μm , or less, are added to the resins they do not mix well because the need to incorporate a large amount of fiber relative to the amount of the resins for beneficial improvement thermal conductivity. However, we have found that relative large amounts of carbon micro fibers can be added to resin systems that have relatively large amounts of other fillers. A greater amount of carbon micro fibers can be added to the resin when added with other fibers than can be added alone to the polymer, thus providing a greater benefit with respect to improving thermal conductivity of the thermal interface material. Desirably, the ratio of carbon micro fibers to polymer is in the range of 0.05 to 0.50 by weight.

It is also advantageous to incorporate substantially spherical filler particles to maximize packing density. Additionally, substantially spherical shapes or the like will also provide some control of the thickness during compaction. Dispersion of filler particles can be facilitated by addition of functional organo metallic coupling agents or wetting agents, such as organosilane, organotitanate, organozirconium, etc. Typical particle sizes useful for fillers in the resin material may be in the range of about 1-20 μm with a maximum of about 100 μm . Antioxidants may be added to inhibit oxidation and thermal degradation of the resin mixture gel. Typical useful antioxidants include Irganox 1076, a phenol type of Irganox 565, an amine type, (at 0.01% to about 1 wt.%), available from Ciba Giegy of Hawthorne, New York.

To illustrate the invention, a number of examples were prepared by mixing the components described in Examples A through F below. The examples shown include one or more of the optional additions, e.g., antioxidant, or wettability enhancer. The amounts of such additions may vary but, generally, they may be usefully present in the following approximate amounts (in wt. %): filler up to 95% of total (filler plus resins); wettability enhancer 0.1 to 5% (of total); adhesion promoters 0.01 to 1% (of total) and antioxidant 0.01 to 1% (of total). It

should be noted the addition at least about 0.5% carbon fiber significantly increases thermal conductivity. The examples also show various physico-chemical measurements for the contemplated mixtures.

Thermal Paste Examples

Component	A	B	C	D	E	F
Silicone resin mixture	25	20	24.8	19.8	16	12
Epoxy silane			0.1	0.1	0.1	0.1
Silanol terminated vinylsiloxane			0.1	0.1	0.1	0.1
Organo-titanate					3.8	3.8
Aluminum spheres	75	80	75	80	80	84
Viscosity (Pa.s)	80	275	78	280	85	180
Adhesive strength (psi)	100	45	250	180	160	250
Modulus at 25C (Mpa)	20	35	22	30	14	28
Thermal Impedance (cm²C/w)	0.44	0.55	0.40	0.50	0.28	0.25
Thermal Conductivity (w/mC)	1.8	1.5	1.8	1.5	3.0	3.2

Epoxy silane and silanol terminated vinyl siloxane are adhesion promoting additives. Organo-titanate acts a wetting enhancer to reduce paste viscosity and to increase filler loading. The organo-titanate used was isopropyl triisostearyl titanate. General structure of organo-titanate is RO-Ti(OXRY) where RO is a hydrolyzable group, X and Y are binder functional groups. Aluminum spheres have particle sizes in the range of 1-20 um.

Thus, specific embodiments and applications of compliant and crosslinkable thermal interface materials have been disclosed. It should be apparent, however, to those skilled in the art that many more modifications besides those already described are possible without departing from the inventive concepts herein. The inventive subject matter, therefore, is not to be restricted except in the spirit of the appended claims. Moreover, in interpreting both the specification and the claims, all terms should be interpreted in the broadest possible manner consistent with the context. In particular, the terms "comprises" and "comprising" should be interpreted as referring to elements, components, or steps in a non-exclusive manner,

indicating that the referenced elements, components, or steps may be present, or utilized, or combined with other elements, components, or steps that are not expressly referenced.

We claim:

1. A compliant and crosslinkable material useful as an interface material for electronic devices comprising at least one silicone resin mixture, at least one wetting enhancer and at least one thermally conductive filler.
2. The compliant and crosslinkable material of claim 1 wherein the at least one silicone resin mixture comprises a vinyl terminated siloxane, a reinforcing additive, a crosslinker and a catalyst.
3. The compliant and crosslinkable material of claim 2, wherein the vinyl terminated siloxane is vinyl silicone.
4. The compliant and crosslinkable material of claim 2, wherein the reinforcing additive is vinyl Q resin.
5. The compliant and crosslinkable material of claim 2, wherein the crosslinker comprises a hydride functional siloxane.
6. The compliant and crosslinkable material of claim 2, wherein the catalyst comprises a platinum complex.
7. The compliant and crosslinkable material of claim 6, wherein the platinum complex is a platinum-vinylsiloxane compound.
8. The compliant and crosslinkable material of claim 1, wherein the wetting enhancer comprises an organo-titanite compound.
9. A compliant and crosslinkable material according to claim 1 wherein said filler comprises at least one of silver, copper, aluminum, and alloys thereof; boron nitride, aluminum nitride, aluminum spheres, silver coated copper, silver coated aluminum, and carbon fibers; and mixtures thereof.
10. A compliant and crosslinkable material according to claim 9 further comprising carbon micro fibers in addition to at least one other filler.

11. A compliant and crosslinkable material according to claim 1 wherein said filler comprises said carbon micro fibers and at least one other filler comprising silver, copper, aluminum, and alloys thereof; boron nitride, aluminum nitride, silver coated copper, silver coated aluminum, and carbon fibers; and mixtures thereof.
12. A compliant and crosslinkable material according to claim 1 wherein at least one portion of said filler comprises substantially spherical particles.
13. A compliant and crosslinkable material according to claim 1 further comprising an antioxidant.
14. A compliant and crosslinkable material according to claim 7 wherein said antioxidant is present in an amount of 0.01 to 1 wt. %.
15. A dispensable paste of a compliant and crosslinkable material useful as an interface material for electronic devices comprising at least one silicone resin mixture, at least one wetting enhancer and at least one thermally conductive filler.
16. A sheet or film of a compliant and crosslinkable material useful as an interface material for electronic devices comprising at least one silicone resin mixture, at least one wetting enhancer and at least one thermally conductive filler.
17. A method of making a compliant and crosslinkable material comprising combining at least one silicone resin mixture with at least one wetting enhancer and at least one thermally conductive filler.
18. A method according to claim 17 further comprising formulating a dispensable paste of said material.
19. A method according to claim 17 further comprising molding said material as a sheet or film capable of being cut to size and applied as an interface between components in an electronic device.
20. A method of increasing the thermal conductivity of a polymer comprising incorporating therein carbon micro fibers and at least one thermally conductive filler.

21. A method according to claim 20 wherein said carbon micro fiber is present in an amount of at least about 0.5 wt.%, or in a ratio of carbon micro fibers to polymer of at least 0.05.
22. A method according to claim 21 further comprising additionally incorporating a filler comprising at least one of silver, copper, aluminum, and alloys thereof; boron nitride, aluminum nitride, silver coated copper, silver coated aluminum, and carbon fibers; and mixtures thereof.
