

Description

The present invention relates to a buckle for fastening a closure flap of a bag, a rucksack or the like, and also for fastening straps, belts or suspenders of a shoe, a boot, trousers, a skirt or the like.

Japanese Utility Model Laid-Open Publication 60-31809 discloses a buckle for fastening belts of a shoe which buckle comprises, as shown in Figures 4A and 4B of the accompanying drawings, interlocking male and female members A, B. The male member A has on its rear surface a pair of resilient legs C, C, each having on its outer side a stepped portion which is engageable with the edge D of an aperture in the female member B as the male member A is pressed against the female member B so as to force the legs C, C into the aperture from the front side of the female member B in a snap action. The female member B has a pair of resilient arms E, E having a pair of inwardly directed pushing portions F, F. When the two arms E, E are pressed toward each other, the pusher portions F, F pushes the legs C, C so as to resiliently bend the same inwardly, thereby bringing the stepped portions out of engagement with the edge D of the aperture.

Such prior buckle is disadvantageous in that since there is no means for protecting the arms E, E, the extent to which each of the arms E is movable laterally and perpendicularly to the general plane of the buckle is more than necessary. Further, such non-protected arms E, E tend to be broken when undue pulling forces are exerted on the arms, for example when a garment is caught by the arms.

The present invention seeks to provide a buckle in which male and female members are coupled together by forcing resilient legs of the male member into a central aperture in the female member from the front side of the female member, and in which a pair of resilient arms of a female member is kept from moving beyond a constant necessary extent and is hence prevented from being broken or otherwise damaged.

According to the present invention, there is provided a buckle comprising: a female member in the form of a case having in its top wall a central aperture; and a male member having a tongue-shaped presser having on its bottom side a pair of resilient legs, each having on its outer side at least one stepped portion resiliently engageable with an edge of said central aperture in said female member as said legs are forced into said central aperture in a snap action by pressing said presser against the front side of said female member; said female member having a pair of transversely spaced resilient arms each extending from a base near one end of said female member and having on its free end an inwardly extending pusher portion for pushing the respective leg of said male member so as to resiliently bend the latter inwardly, thereby bringing the stepped portion out of engagement with the edge of the central aperture, characterized in that said female member further has in its side walls a pair of side

slits and in its bottom wall a pair of transversely spaced restriction holes each of said arms extending into the respective side slit, and that each of the said arms has a projection extending into the respective hole of said bottom wall, the movement of each arm in a direction perpendicular to said female member being restricted within the side slit and the lateral or transversal movement of each arm being restricted within the respective hole.

Many other objects, advantages and additional features of the present invention will become manifest to those versed in the art upon making reference to the detailed description and the accompanying sheets of drawings in which a preferred structural embodiment incorporating the principle of the present invention is shown by way of illustrative example.

Figure 4A is a plan view of a buckle according to a prior art, showing male and female members in a coupled posture.

Figure 4B is a bottom view of Figure 4A.

The principle of the present invention is particularly useful when embodied in a buckle such as shown in Figures 3A through 3C.

The buckle comprises a male member (Figures 2A through 2D) 13 and a female member (Figures 1A through 1E) 1. Each of the male and female members 13, 1 is molded of a synthetic resin such as polyacetal, nylon or polypropylene.

As shown in Figure 1A through 1E, the female member 1 is generally in the form of a case having in its top wall a central aperture 2, in its side walls a pair of side slits 9, 9, and in its bottom wall a pair of transversely spaced restriction holes 11, 11. The female member 1 also has a pair of resilient arms 4, 4 each extending from a base 5 near one end (right end in Figures 1A through 1C) of the female member 1 into the respective side slit 9. As shown in Figures 1A and 1C, each arm 4 is restricted or narrowed in width at its midpor-

tion and has on its free end 6 a grip 8 projecting outwardly of the respective side slit 9. The restricted midportion of the arm 4 is resiliently bendable when the grip 8 is pushed inwardly for a purpose described below.

Each arm 4 also has on its free end 6 an inwardly extending pusher portion 7 for a purpose described below. A projection 10 extends from the pusher portion 7 perpendicularly to the general plane of the female member 1 into the respective hole 11. On the bottom side of the female member 1 there are three supports 12, 12, 12 adapted to be secured to a strap, a belt, a suspender or the like (hereinafter referred to as "strap") 24.

Most important, the extent to which each arm 4 is movable perpendicularly to the general plane of the female member 1 is restricted within the width of the respective side slit 9. The extent to which the projection 10 of each arm 4 is movable laterally or transversely of the female member 1 is restricted within the width of the respective hole 11; that is, the lateral movement of each arm 4 is restricted within the width of the respective hole 11.

As shown in Figures 2A through 2C, the male member 1 includes an attachment 15 and a tongue-shaped presser 14 pivotally mounted on the attachment 15 by means of pins 16, 16. The attachment 15 has on its bottom side a pair of supports 20, 20 adapted to be secured to another strap 22 (Figure 3B).

The presser 14 has on its bottom side a pair of resilient legs 17, 17 each having on its outer side a pair of stepped portions 19, 19 (Figures 2B through 2D). The stepped portions 19, 19, 19, 19 are resiliently engageable with the edge 3 of the central aperture 2 in the female member 1 as the legs 17, 17 are forced into the central aperture 2 (as shown in Figures 3A through 3C) in a snap action by pressing the presser 14 against the front side of the female member 1. Each leg 17 also has a pair of sloping surfaces 18, 18 (Figure 2D) contiguous to the respective stepped portions 19, 19 which surfaces aid in inserting the leg 17 smoothly into the central aperture 11. Each leg 17 additionally has a slit 17a (Figure 2D) which causes an increased degree of resilience of the leg 17.

As shown in Figure 3B, the removal of the straps 22, 25 from the supports 20 of the male member 13 and from the supports 12 of the female member 1 is prevented by a pair of retainer plates 23, 25, respectively.

With the male and female members 13, 1 in a coupled posture (Figures 3A through 3C), when the opposed arms 4, 4 are pressed inwardly toward each other, the pusher portions 7, 7 pushes the legs 17, 17 so as to resiliently bend the latter inwardly, thereby bringing the stepped portions 19, 19, 19, 19 out of engagement with the edge 3 of the central aperture 2. At that time, the extent to which each arm 4 is moved perpendicularly to the general plane of the female member 1 and hence of the buckle, is restricted within the

width (height in Figures 3B and 3C) of the respective side slit 9. Further, the extent to which the projection 10 of each arm 4 is moved laterally or transversely of the female member 1, is restricted within the width of the respective hole 11; that is, the lateral movement of each arm 4 is restricted within the width of the respective hole 11.

With the stepped portions 19 of the two legs 17, 17 out of engagement with the edge 3 of the central aperture 2, as the presser 14 is pivotally moved clockwise in Figure 3B about the aligned pins 16 by pulling the distal end 21 of the presser 14 upwardly the two legs 17, 17 are released from the central aperture 2 in the female member 1. Thus the male and female members 13, 1 have been uncoupled.

According to the present invention, partly because the movement of each arm 4 in a direction perpendicular to the general plane of the female member 1 is restricted within the width of the respective side slit 9, and partly because the lateral or transverse movement of each arm 4 is restricted within the width of the respective hole 11, the arm 4 is prevented from being broken or otherwise damaged even when undue stress is exerted on the arm 4.

Claims

1. A buckle comprising: a female member (1) in the form of a case having in its top wall a central aperture (2); and a male member (13) having a tongue-shaped presser (14) having on its bottom side a pair of resilient legs (17), (17) each having on its outer side at least one stepped portion (19) resiliently engageable with an edge (3) of said central aperture (2) in said female member (1) as said legs (17), (17) are forced into said central aperture (2) in a snap action by pressing said presser (14) against the front side of said female member (1); said female member (1) having a pair of transversely spaced resilient arms (4), (4) each extending from a base (5) near one end of said female member (1) and having on its free end (6) an inwardly extending pusher portion (7) for pushing the respective leg (17) of said male member (13) so as to resiliently bend the latter inwardly, thereby bringing the stepped portion (19) out of engagement with the edge (3) of the central aperture (2), characterized in that said female member (1) further has in its side walls a pair of side slits (9), (9) and in its bottom wall a pair of transversely spaced restriction holes (11), (11), each of said arms (4) extending into the respective side slit (9), and that each of said arms (4) has a projection (10) extending into the respective hole (11) of said bottom wall, the movement of each arm (4) in a direction perpendicular to said female member (1) being restricted within the side slit (9) and the lateral or transversal movement of each arm (4) being restricted within the respective hole (11).

2. A buckle according to claim 1, wherein each of said legs (17) having a slit (17a).

tion and has on its free end 6 a grip 8 projecting outwardly of the respective side slit 9. The restricted midportion of the arm 4 is resiliently bendable when the grip 8 is pushed inwardly for a purpose described below.

Each arm 4 also has on its free end 6 an inwardly extending pusher portion 7 for a purpose described below. A projection 10 extends from the pusher portion 7 perpendicularly to the general plane of the female member 1 into the respective hole 11. On the bottom side of the female member 1 there are three supports 12, 12, 12 adapted to be secured to a strap, a belt, a suspender or the like (hereinafter referred to as "strap") 24.

Most important, the extent to which each arm 4 is movable perpendicularly to the general plane of the female member 1 is restricted within the width of the respective side slit 9. The extent to which the projection 10 of each arm 4 is movable laterally or transversely of the female member 1 is restricted within the width of the respective hole 11; that is, the lateral movement of each arm 4 is restricted within the width of the respective hole 11.

As shown in Figures 2A through 2C, the male member 1 includes an attachment 15 and a tongue-shaped presser 14 pivotally mounted on the attachment 15 by means of pins 16, 16. The attachment 15 has on its bottom side a pair of supports 20, 20 adapted to be secured to another strap 22 (Figure 3B).

The presser 14 has on its bottom side a pair of resilient legs 17, 17 each having on its outer side a pair of stepped portions 19, 19 (Figures 2B through 2D). The stepped portions 19, 19, 19 are resiliently engageable with the edge 3 of the central aperture 2 in the female member 1 as the legs 17, 17 are forced into the central aperture 2 (as shown in Figures 3A through 3C) in a snap action by pressing the presser 14 against the front side of the female member 1. Each leg 17 also has a pair of sloping surfaces 18, 18 (Figure 2D) contiguous to the respective stepped portions 19, 19 which surfaces aid in inserting the leg 17 smoothly into the central aperture 11. Each leg 17 additionally has a slit 17a (Figure 2D) which causes an increased degree of resilience of the leg 17.

As shown in Figure 3B, the removal of the straps 22, 25 from the supports 20 of the male member 13 and from the supports 12 of the female member 1 is prevented by a pair of retainer plates 23, 25, respectively.

With the male and female members 13, 1 in a coupled posture (Figures 3A through 3C), when the opposed arms 4, 4 are pressed inwardly toward each other, the pusher portions 7, 7 pushes the legs 17, 17 so as to resiliently bend the latter inwardly, thereby bringing the stepped portions 19, 19, 19 out of engagement with the edge 3 of the central aperture 2. At that time, the extent to which each arm 4 is moved perpendicularly to the general plane of the female member 1 and hence of the buckle, is restricted within the

width (height in Figures 3B and 3C) of the respective side slit 9. Further, the extent to which the projection 10 of each arm 4 is moved laterally or transversely of the female member 1, is restricted within the width of the respective hole 11; that is, the lateral movement of each arm 4 is restricted within the width of the respective hole 11.

With the stepped portions 19 of the two legs 17, 17 out of engagement with the edge 3 of the central aperture 2, as the presser 14 is pivotally moved clockwise in Figure 3B about the aligned pins 16 by pulling the distal end 21 of the presser 14 upwardly the two legs 17, 17 are released from the central aperture 2 in the female member 1. Thus the male and female members 13, 1 have been uncoupled.

According to the present invention, partly because the movement of each arm 4 in a direction perpendicular to the general plane of the female member 1 is restricted within the width of the respective side slit 9, and partly because the lateral or transverse movement of each arm 4 is restricted within the width of the respective hole 11, the arm 4 is prevented from being broken or otherwise damaged even when undue stress is exerted on the arm 4.

Claims

1. A buckle comprising: a female member (1) in the form of a case having in its top wall a central aperture (2); and a male member (13) having a tongue-shaped presser (14) having on its bottom side a pair of resilient legs (17), (17) each having on its outer side at least one stepped portion (19) resiliently engageable with an edge (3) of said central aperture (2) in said female member (1) as said legs (17), (17) are forced into said central aperture (2) in a snap action by pressing said presser (14) against the front side of said female member (1); said female member (1) having a pair of transversely spaced resilient arms (4), (4) each extending from a base (5) near one end of said female member (1) and having on its free end (6) an inwardly extending pusher portion (7) for pushing the respective leg (17) of said male member (13) so as to resiliently bend the latter inwardly, thereby bringing the stepped portion (19) out of engagement with the edge (3) of the central aperture (2), characterized in that said female member (1) further has in its side walls a pair of side slits (9), (9) and in its bottom wall a pair of transversely spaced restriction holes (11), (11), each of said arms (4) extending into the respective side slit (9), and that each of said arms (4) has a projection (10) extending into the respective hole (11) of said bottom wall, the movement of each arm (4) in a direction perpendicular to said female member (1) being restricted within the side slit (9) and the lateral or transversal movement of each arm (4) being restricted within the respective hole (11).

2. A buckle according to claim 1, wherein each of said legs (17) having a slit (17a).

3. A buckle according to claim 1 or 2, wherein said male member (13) also includes an attachment (15), said tongue-shaped presser (14) being pivotally mounted on said attachment (15).

Patentansprüche

1. Schnalle, umfassend ein Aufnahmeteil (1) in Form eines Gehäuses, das in seiner Oberwand eine zentrale Öffnung (2) aufweist; und ein Einsteckteil (13) mit einem zungenförmigen Drücker (14), der an seiner Unterseite zwei elastische Schenkel (17, 17) aufweist, die jeweils an ihrer Außenseite mindestens einen abgestuften Bereich (19) haben, der mit einer Kante (3) der zentralen Öffnung (2) des Aufnahmeteils (1) elastisch in Eingriff bringbar ist, wenn die Schenkel (17, 17) mit einer Federwirkung in die zentrale Öffnung (2) hineingedrückt werden, indem der Drücker (14) gegen die Vorderseite des Aufnahmeteils (1) gedrückt wird; wobei das Aufnahmeteil (1) zwei im Querabstand angeordnete federnde Arme (4, 4) hat, die jeweils von einer Basis (5) nahe einem Ende des Aufnahmeteils (1) ausgehen und die an ihrem freien Ende (6) einen nach innen ragenden Schubbereich (7) haben, um den entsprechenden Schenkel (17) des Einsteckteils (13) federnd nach innen auszulenken, um dadurch den abgestuften Bereich (19) mit der Kante (3) der zentralen Öffnung (2) außer Eingriff zu bringen, dadurch gekennzeichnet, daß das Aufnahmeteil (1) ferner in seinen Seitenwänden zwei seitliche Schlitz (9, 9) und in seiner Bodenwand zwei im Querabstand angeordnete Begrenzungsöffnungen (11, 11) aufweist, wobei sich jeder der besagten Arme (4) in den zugeordneten seitlichen Schlitz (9) hinein erstreckt, und daß jeder dieser Arme (4) einen in die betreffende Öffnung (11) der Bodenwand hineinragenden Vorsprung (10) hat, wobei die Bewegung jedes Arms (4) rechtwinklig zu dem Aufnahmeteil (1) in dem seitlichen Schlitz (9) und die seitliche oder quergerichtete Bewegung jedes Arms (4) in der betreffenden Öffnung (2) begrenzt ist.

2. Schnalle nach Anspruch 1, wobei jeder Schenkel (17) einen Schlitz (17a) hat.

3. Schnalle nach Anspruch 1 oder 2, wobei das Einsteckteil (13) ferner eine Befestigung (15) umfaßt, wobei der zungenförmige Drücker (14) an dieser Befestigung (15) angelenkt ist.

Revendications

1. Bouclé comportant: un élément femelle (1) sous la forme d'un boîtier ayant dans sa paroi supérieure une ouverture centrale (2); et un élément mâle (13) ayant un dispositif de pression (14) en forme de langue ayant sur son côté inférieur une paire de pattes élastiques (17), (17), ayant chacune sur sa face extérieure au moins une partie étagée (19) pouvant être engrenée de façon élastique avec un bord (3) de ladite ouverture centrale (2) dans ledit élément femelle (1) lorsque lesdites pattes (17), (17) sont forcées dans ladite ouverture centrale (2) dans une action d'encliquetage en pressant ledit dispositif presseur (14) contre le côté ayant dudit élément femelle (1); ledit élément femelle (1) ayant une paire de bras élastiques (4), (4) espacés de façon transversale s'étendant chacun à partir d'une base (5) voisine d'une extrémité dudit élément femelle (1) et ayant sur son extrémité libre (6) une partie (7) de poussée s'étendant vers l'intérieur pour pousser la patte respective (17) dudit élément mâle (13) de façon à plier élastiquement cette dernière vers l'intérieur, afin d'amener par conséquent la partie étagée (19) hors d'engrènement par rapport au bord (3) d'ouverture centrale (2), caractérisée en ce que ledit élément femelle (1) possède de plus dans ses parois latérales une paire de fentes latérales (9), (9) et dans sa paroi inférieure une paire de trous (11), (11) d'étrangement espacés transversalement, chacun desdits bras (4) s'étendant dans la fente latérale respective (9), et en ce que chacun desdits bras (4) a une saillie (10) s'étendant dans le trou respectif (11) de ladite paroi inférieure, le déplacement de chaque bras (4) dans une direction perpendiculaire audit élément femelle (1) étant restreint à l'intérieur de la fente latérale (9) et le déplacement latéral ou transversal de chaque bras (4) étant restreint à l'intérieur du trou respectif (11).

2. Boucle selon la revendication 1, dans laquelle chacune desdites pattes (17) a une fente (17a).

3. Boucle selon la revendication 1 ou 2, dans laquelle chaque élément mâle (13) comporte également une fixation (15), ledit dispositif presseur (14) en forme de langue étant monté de façon à pouvoir pivoter sur ladite fixation (15).
