BACKGROUND

[003] Cancer (e.g., tumor, neoplasm, metastases) is the second leading cause of death worldwide estimated to be responsible for about 10 million deaths each year. Many types of cancers are marked with mutations in one or more proteins involved in various signaling pathways leading to unregulated growth of cancerous cells. In some cases, about 25 to 30 percent (%) of tumors are known to harbor Rat sarcoma (Ras) mutations.

[004] Activated by guanine nucleotide exchange factors (GEFs), Ras in its GTP-bound state interacts with a number of effectors. Return to the inactive state is driven by GTPase-activating proteins (GAPs), which down-regulate active Ras by accelerating the weak intrinsic GTPase activity. For oncogenic Ras mutants, however, the GAP activity is impaired or greatly reduced, resulting in persistent activation, which drives the oncogenic Ras signaling through, e.g., the RAS-RAF-MEK-ERK and RAS-PI3K-PDK1-AKT pathways, both essential to cell survival and proliferation.

[005] The most-studied GEF for Ras is the protein Son of Sevenless (SOS) for which two human isoforms, SOS1 and SOS2, are known. SOS1 is a human homologue of the originally identified *Drosophila* protein Son of Sevenless. SOS1 has two binding sites for Ras proteins; a catalytic site that binds GDP-bound Ras proteins to promote guanine nucleotide exchange and an allosteric site that binds GTP-bound Ras to further promote activation of Ras proteins. Son of Sevenless 2 (SOS2) is a homolog of SOS1 in mammalian cells. Double SOS1 and SOS2 knockout leads to rapid lethality in adult mice (Baltanas et al., *Mol. Cell. Biol.*, 2013, 33(22):4562-78).

[006] Ras proteins have long been considered to be “undruggable”, due to, in part, high affinity to their substrate guanosine-5'-triphosphate (GTP) and/or their smooth surfaces without any obvious targeting region. A specific G12C Ras gene mutation has been identified as a druggable target to which a number of G12C specific inhibitors have been developed. However, such therapeutics are still of limited application, as the G12C mutation in Ras exhibits a much lower prevalence rate as compared to other known Ras mutations, including G12D and G12V. Drug resistance and lack of durability impose further limitations to such therapeutics.

SUMMARY

[007] In view of the foregoing, there remains a considerable need for a new design of therapeutics and diagnostics that can specifically inhibit Ras pathway signaling by, e.g., inhibiting a GEF such as a SOS protein. Such compositions and methods can be particularly useful for treating a variety of the diseases including, but not limited to, cancers and neoplasia conditions. The present disclosure addresses these needs, and provides additional advantages applicable for diagnosis, prognosis, and treatment for a wide diversity of diseases.

DETAILED DESCRIPTION

[046] Unless defined otherwise, all technical and scientific terms used herein have the same meaning as is commonly understood by one of skill in the art to which this disclosure belongs. In the event that there are a plurality of definitions for terms herein, those in this section prevail. All patents, patent applications, publications and published nucleotide and amino acid sequences (e.g., sequences available in GenBank or other databases) referred to herein are incorporated by reference. [064] It will be understood by those skilled in the art that substituents can themselves be substituted, if appropriate. Unless specifically stated as “unsubstituted”, references to chemical moieties herein are understood to include substituted variants. For example, reference to a “heteroaryl” group or moiety implicitly includes both substituted and unsubstituted variants.

[065] Where bivalent substituent groups are specified herein by their conventional chemical formulae, written from left to right, they are intended to encompass the isomer that would result from writing the structure from right to left, e.g., -CH₂O- is also intended to encompass -OCH₂-.

[066] “Optional” or “optionally” means that the subsequently described event or circumstances may or may not occur, and that the description includes instances where the event or circumstance occurs and instances in which it does not. For example, an “optionally substituted” group may be either unsubstituted or substituted.

[067] Compounds of the present disclosure also include crystalline and amorphous forms of those compounds, pharmaceutically acceptable salts, and active metabolites having the same type of activity, including, for example, polymorphs, pseudopolymorphs, solvates, hydrates, unsolvated polymorphs (including anhydrides), conformational polymorphs, amorphous forms of the compounds, and mixtures thereof.

[068] The compounds described herein may exhibit their natural isotopic abundance, or one or more of the atoms may be artificially enriched in a particular isotope having the same atomic number, but an atomic mass or mass number different from the atomic mass or mass number predominantly found in nature. All isotopic variations of the compounds of the present disclosure, whether radioactive or not, are encompassed within the scope of the present disclosure. For example, hydrogen has three naturally occurring isotopes, denoted ^1H (protium), ^2H (deuterium), and ^3H (tritium). Protium is the most abundant isotope of hydrogen in nature. Enriching for deuterium may afford certain therapeutic advantages, such as increased in vivo half-life and/or exposure, or may provide a compound useful for investigating in vivo routes of drug elimination and metabolism. Examples of isotopes that may be incorporated into compounds of the present disclosure include, but are not limited to, ^2H , ^3H , ^{13}C , ^{14}C , ^{15}N , ^{18}O , ^{17}O , ^{35}S , ^{36}Cl , and ^{18}F . Of particular interest are compound of Formula (I) enriched in tritium or carbon-14, which can be used, for example, in tissue distribution studies; compounds of the disclosure enriched in deuterium—especially at a site of metabolism—resulting, for example, in compounds having greater metabolic stability; and compounds of Formula (I) enriched in a positron emitting isotope, such as ^{11}C , ^{18}F , ^{15}O and ^{13}N , which can be used, for example, in Positron Emission Topography (PET) studies. Isotopically-enriched compounds may be prepared by conventional techniques well known to those skilled in the art.

[069] As used herein, the phrase “of the formula”, “having the formula” or “having the structure” is not intended to be limiting and is used in the same way that the term “comprising” is commonly used. For example, if one structure is depicted, it is understood that all stereoisomer and tautomer forms are encompassed, unless stated otherwise.

[070] Certain compounds described herein contain one or more asymmetric centers and can thus give rise to enantiomers, diastereomers, and other stereoisomeric forms, the asymmetric centers of which can be defined, in terms of absolute stereochemistry, as (R)- or (S)-. In some embodiments, in order to optimize the therapeutic activity of the compounds of the disclosure, e.g., to treat fibrosis, it may be desirable that the carbon atoms have a particular configuration (e.g., (R,R), (S,S), (S,R), or (R,S)) or are enriched in a stereoisomeric form having such configuration. The compounds of the disclosure may be provided as racemic mixtures. Accordingly, the disclosure relates to racemic mixtures, pure stereoisomers (e.g., enantiomers and diastereomers), stereoisomer-enriched mixtures, and the like, unless otherwise indicated. When a chemical structure is depicted herein without any stereochemistry, it is understood that all possible stereoisomers are encompassed by such structure. Similarly, when a particular stereoisomer is shown or named herein, it will be understood by those skilled in the art that minor amounts of other stereoisomers may be present in the compositions of the disclosure unless otherwise indicated, provided that the utility of the composition as a whole is not eliminated by the presence of such other isomers. Individual stereoisomers may be obtained by numerous methods that are known in the art, including preparation using chiral synthons or chiral reagents, resolution using chiral chromatography using a suitable chiral stationary phase or support, or by chemically converting them into diastereomers, separating the diastereoisomers by conventional means such as chromatography or recrystallization, then regenerating the original stereoisomer.

[071] Additionally, where applicable, all cis-trans or E/Z isomers (geometric isomers), tautomeric forms and topoisomeric forms of the compounds described herein are included with the scope of the disclosure unless

otherwise specified.

[072] The term “pharmaceutically acceptable” refers to a material that is not biologically or otherwise unacceptable when used in the subject compositions and methods. For example, the term “pharmaceutically acceptable carrier” refers to a material—such as an adjuvant, excipient, glidant, sweetening agent, diluent, preservative, dye, colorant, flavor enhancer, surfactant, wetting agent, dispersing agent, suspending agent, stabilizer, isotonic agent, solvent or emulsifier—that can be incorporated into a composition and administered to a patient without causing unacceptable biological effects or interacting in an unacceptable manner with other components of the composition. Such pharmaceutically acceptable materials typically have met the required standards of toxicological and manufacturing testing, and include those materials identified as suitable inactive ingredients by the U.S. Food and Drug Administration.

[073] The terms “salt” and “pharmaceutically acceptable salt” refer to a salt prepared from a base or an acid. Pharmaceutically acceptable salts are suitable for administration to a patient, such as a mammal (for example, salts having acceptable mammalian safety for a given dosage regime). Salts can be formed from inorganic bases, organic bases, inorganic acids and organic acids. In addition, when a compound contains both a basic moiety, such as an amine, pyridine or imidazole, and an acidic moiety, such as a carboxylic acid or tetrazole, zwitterions may be formed and are included within the term “salt” as used herein. Preferred pharmaceutically acceptable salts of the compounds described herein are pharmaceutically acceptable acid addition salts and pharmaceutically acceptable base addition salts.

[074] “Pharmaceutically acceptable acid addition salt” refers to those salts which retain the biological effectiveness and properties of the free bases, which are not biologically or otherwise undesirable, and which are formed with inorganic acids such as hydrochloric acid, hydrobromic acid, sulfuric acid, nitric acid, phosphoric acid, hydroiodic acid, hydrofluoric acid, phosphorous acid, and the like. Also included are salts that are formed with organic acids such as aliphatic mono- and dicarboxylic acids, phenyl-substituted alkanolic acids, hydroxy alkanolic acids, alkanedioic acids, aromatic acids, aliphatic and aromatic sulfonic acids, etc., and include, for example, acetic acid, trifluoroacetic acid, propionic acid, glycolic acid, pyruvic acid, oxalic acid, maleic acid, malonic acid, succinic acid, fumaric acid, tartaric acid, citric acid, benzoic acid, cinnamic acid, mandelic acid, methanesulfonic acid, ethanesulfonic acid, p-toluenesulfonic acid, salicylic acid, and the like. Exemplary salts thus include sulfates, pyrosulfates, bisulfates, sulfites, bisulfites, nitrates, phosphates, monohydrogenphosphates, dihydrogenphosphates, metaphosphates, pyrophosphates, chlorides, bromides, iodides, acetates, trifluoroacetates, propionates, caprylates, isobutyrate, oxalates, malonates, succinate suberates, sebacates, fumarates, maleates, mandelates, benzoates, chlorobenzoates, methylbenzoates, dinitrobenzoates, phthalates, benzenesulfonates, toluenesulfonates, phenylacetates, citrates, lactates, malates, tartrates, methanesulfonates, and the like. Also contemplated are salts of amino acids, such as arginates, gluconates, and galacturonates (see, for example, Berge S.M. et al., “Pharmaceutical Salts,” *Journal of Pharmaceutical Science*, 66:1-19 (1997)). Acid addition salts of basic compounds are, in some embodiments, prepared by contacting the free base forms with a sufficient amount of the desired acid to produce the salt according to methods and techniques with which a skilled artisan is familiar.

[075] “Pharmaceutically acceptable base addition salt” refers to those salts that retain the biological effectiveness and properties of the free acids, which are not biologically or otherwise undesirable. These salts are prepared from addition of an inorganic base or an organic base to the free acid. Pharmaceutically acceptable base addition salts are, in some embodiments, formed with metals or amines, such as alkali and alkaline earth metals or organic amines. Salts derived from inorganic bases include, but are not limited to, sodium, potassium, lithium, ammonium, calcium,

magnesium, iron, zinc, copper, manganese, aluminum salts and the like. Salts derived from organic bases include, but are not limited to, salts of primary, secondary, and tertiary amines, substituted amines including naturally occurring substituted amines, cyclic amines and basic ion exchange resins, for example, isopropylamine, trimethylamine, diethylamine, triethylamine, tripropylamine, ethanolamine, diethanolamine, 2-dimethylaminoethanol, 2-diethylaminoethanol, dicyclohexylamine, lysine, arginine, histidine, caffeine, procaine, N,N-dibenzylethylenediamine, chloroprocaine, hydrabamine, choline, betaine, ethylenediamine, ethylenedianiline, N-methylglucamine, glucosamine, methylglucamine, theobromine, purines, piperazine, piperidine, N-ethylpiperidine, polyamine resins and the like. See Berge et al., *supra*.

[076] The term “effective amount” or “therapeutically effective amount” refers to the amount of an agent that is sufficient to effect beneficial or desired results. The therapeutically effective amount may vary depending upon one or more of: the subject and disease condition being treated, the weight and age of the subject, the severity of the disease condition, the manner of administration and the like, which can readily be determined by one of ordinary skill in the art. An effective amount of an active agent may be administered in a single dose or in multiple doses. A component may be described herein as having at least an effective amount, or at least an amount effective, such as that associated with a particular goal or purpose, such as any described herein. The term “effective amount” also applies to a dose that will provide an image for detection by an appropriate imaging method. The specific dose may vary depending on one or more of: the particular agent chosen, the dosing regimen to be followed, whether it is administered in combination with other compounds, timing of administration, the tissue to be imaged, and the physical delivery system in which it is carried.

[077] As used herein, “treating” or “treatment” refers to an approach for obtaining beneficial or desired results with respect to a disease, disorder, or medical condition (such as cancer) in a subject, including but not limited to the following: (a) preventing the disease or medical condition from occurring, e.g., preventing the reoccurrence of the disease or medical condition or prophylactic treatment of a subject that is pre-disposed to the disease or medical condition; (b) ameliorating the disease or medical condition, e.g., eliminating or causing regression of the disease or medical condition in a subject; (c) suppressing the disease or medical condition, e.g., slowing or arresting the development of the disease or medical condition in a subject; or (d) alleviating symptoms of the disease or medical condition in a subject. For example, “treating cancer” would include preventing cancer from occurring, ameliorating cancer, suppressing cancer, and alleviating the symptoms of cancer. Also, a therapeutic benefit is achieved with the eradication or amelioration of one or more of the physiological symptoms associated with the underlying disorder such that an improvement is observed in the subject, notwithstanding that the subject may still be afflicted with the underlying disorder.

[078] A “therapeutic effect”, as that term is used herein, encompasses a therapeutic benefit and/or prophylactic benefit as described above. A prophylactic effect includes delaying or eliminating the appearance of a disease or condition, delaying or eliminating the onset of symptoms of a disease or condition, slowing, halting, or reversing the progression of a disease or condition, or any combination thereof.

[079] The terms “antagonist” and “inhibitor” are used interchangeably, and they refer to a compound having the ability to inhibit a biological function (e.g., activity, expression, binding, protein-protein interaction) of a target protein (e.g., SOS1). Accordingly, the terms “antagonist” and “inhibitor” are defined in the context of the biological role of the target protein. While preferred antagonists herein specifically interact with (e.g., bind to) the target, compounds that inhibit a biological activity of the target protein by interacting with other members of the signal transduction pathway of which the target protein is a member are also specifically included within this definition.

[080] The term “selective inhibition” or “selectively inhibit” refers to the ability of a biologically active agent to preferentially reduce the target signaling activity as compared to off-target signaling activity, via direct or indirect interaction with the target.

[081] The terms “subject” and “patient” refer to an animal, such as a mammal, for example a human. The methods described herein can be useful in both human therapeutics and veterinary applications. In some embodiments, the subject is a mammal, such as a human. “Mammal” includes humans and both domestic animals such as laboratory animals and household pets (e.g., cats, dogs, swine, cattle, sheep, goats, horses, rabbits), and non-domestic animals such as wildlife and the like.

[082] The terms “therapeutic agent”, “therapeutic capable agent” or “treatment agent” are used interchangeably and refer to a molecule or compound that confers some beneficial effect upon administration to a subject. The beneficial effect includes enablement of diagnostic determinations; amelioration of a disease, symptom, disorder, or pathological condition; reducing or preventing the onset of a disease, symptom, disorder or condition; and generally counteracting a disease, symptom, disorder or pathological condition.

[083] The terms “polypeptide”, “peptide” and “protein” are used interchangeably herein to refer to polymers of amino acids of any length. The polymer may be linear or branched, it may comprise modified amino acids, and it may be interrupted by non-amino acids. The terms also encompass an amino acid polymer that has been modified; for example, disulfide bond formation, glycosylation, lipidation, acetylation, phosphorylation, or any other manipulation, such as conjugation with a labeling component. As used herein the term “amino acid” refers to either natural and/or unnatural or synthetic amino acids, including glycine and both the D or L optical isomers, and amino acid analogs and peptidomimetics.

[084] The terms “polynucleotide”, “nucleotide”, “nucleotide sequence”, “nucleic acid” and “oligonucleotide” are used interchangeably. They refer to a polymeric form of nucleotides of any length, either deoxyribonucleotides or ribonucleotides, or analogs thereof. Polynucleotides may have any three-dimensional structure, and may perform any function, known or unknown. The following are non-limiting examples of polynucleotides: coding or non-coding regions of a gene or gene fragment, loci (locus) defined from linkage analysis, exons, introns, messenger RNA (mRNA), transfer RNA, ribosomal RNA, short interfering RNA (siRNA), short-hairpin RNA (shRNA), micro-RNA (miRNA), ribozymes, cDNA, recombinant polynucleotides, branched polynucleotides, plasmids, vectors, isolated DNA of any sequence, isolated RNA of any sequence, nucleic acid probes, and primers. A polynucleotide may comprise one or more modified nucleotides, such as methylated nucleotides and nucleotide analogs, such as peptide nucleic acid (PNA), morpholino and locked nucleic acid (LNA), glycol nucleic acid (GNA), threose nucleic acid (TNA), 2'-fluoro, 2'-OMe, and phosphorothiolated DNA. If present, modifications to the nucleotide structure may be imparted before or after assembly of the polymer. The sequence of nucleotides may be interrupted by non-nucleotide components. A polynucleotide may be further modified after polymerization, such as by conjugation with a labeling component or other conjugation target.

[085] As used herein, “expression” refers to the process by which a polynucleotide is transcribed from a DNA template (such as into mRNA or other RNA transcript) and/or the process by which a transcribed mRNA is subsequently translated into peptides, polypeptides, or proteins. Transcripts and encoded polypeptides may be collectively referred to as “gene product.” If the polynucleotide is derived from genomic DNA, expression may include splicing of the mRNA in a eukaryotic cell.

[086] An “antigen” is a moiety or molecule that contains an epitope, and, as such, also specifically binds to an antibody. An “antigen binding unit” may be whole or a fragment (or fragments) of a full-length antibody, a

structural variant thereof, a functional variant thereof, or a combination thereof. A full-length antibody may be, for example, a monoclonal, recombinant, chimeric, deimmunized, humanized and human antibody. Examples of a fragment of a full-length antibody may include, but are not limited to, variable heavy (VH), variable light (VL), a heavy chain found in camelids, such as camels, llamas, and alpacas (VHH or V_HH), a heavy chain found in sharks (V-NAR domain), a single domain antibody (sdAb, e.g., “nanobody”) that comprises a single antigen-binding domain, Fv, Fd, Fab, Fab', F(ab')₂, and “r IgG” (or half antibody). Examples of modified fragments of antibodies may include, but are not limited to scFv, di-scFv or bi(s)-scFv, scFv-Fc, scFv-zipper, scFab, Fab₂, Fab₃, diabodies, single chain diabodies, tandem diabodies (Tandab's), tandem di-scFv, tandem tri-scFv, minibodies (e.g., (VH-VL-CH₃)₂, (scFv-CH₃)₂, ((scFv)₂-CH₃+CH₃), ((scFv)₂-CH₃) or (scFv-CH₃-scFv)₂), and multibodies (e.g., triabodies or tetrabodies).

[087] The term “antibody” and “antibodies” encompass any antigen binding units, including without limitation: monoclonal antibodies, human antibodies, humanized antibodies, camelised antibodies, chimeric antibodies, and any other epitope-binding fragments.

[088] “Prodrug” is meant to indicate a compound that may be converted under physiological conditions or by solvolysis to a biologically active compound described herein (e.g., a compound of Formula (I)). Thus, the term “prodrug” refers to a precursor of a biologically active compound that is pharmaceutically acceptable. In some aspects, a prodrug is inactive when administered to a subject but is converted *in vivo* to an active compound, for example, by hydrolysis. The prodrug compound often offers advantages of solubility, tissue compatibility or delayed release in a mammalian organism (see, e.g., Bundgard, H., *Design of Prodrugs* (1985), pp. 7-9, 21-24 (Elsevier, Amsterdam); Higuchi, T., et al., “Pro-drugs as Novel Delivery Systems,” (1987) A.C.S. Symposium Series, Vol. 14; and *Bioreversible Carriers in Drug Design*, ed. Edward B. Roche, American Pharmaceutical Association and Pergamon Press each of which is incorporated in full by reference herein). The term “prodrug” is also meant to include any covalently bonded carriers, which release the active compound *in vivo* when such prodrug is administered to a mammalian subject. Prodrugs of an active compound, as described herein, are typically prepared by modifying functional groups present in the active compound in such a way that the modifications are cleaved, either in routine manipulation or *in vivo*, to the parent active compound. Prodrugs include compounds wherein a hydroxy, amino or mercapto group is bonded to any group that, when the prodrug of the active compound is administered to a mammalian subject, cleaves to form a free hydroxy, free amino or free mercapto group, respectively. Examples of prodrugs include, but are not limited to, acetate, formate and benzoate derivatives of a hydroxy functional group, or acetamide, formamide and benzamide derivatives of an amine functional group in the active compound, and the like.

[089] The term “*in vivo*” refers to an event that takes place in a subject's body. The term “*ex vivo*” refers to an event that first takes place outside of the subject's body for a subsequent *in vivo* application into a subject's body. For example, an *ex vivo* preparation may involve preparation of cells outside of a subject's body for the purpose of introduction of the prepared cells into the same or a different subject's body. The term “*in vitro*” refers to an event that takes place outside of a subject's body. For example, an *in vitro* assay encompasses any assay run outside of a subject's body. *In vitro* assays encompass cell-based assays in which cells alive or dead are employed. *In vitro* assays also encompass a cell-free assay in which no intact cells are employed.

[090] The disclosure is also meant to encompass the *in vivo* metabolic products of the disclosed compounds. Such products may result from, for example, the oxidation, reduction, hydrolysis, amidation, esterification, and the like of the administered compound, primarily due to enzymatic processes. Accordingly, the disclosure includes

compounds produced by a process comprising administering a compound disclosed herein to a mammal for a period of time sufficient to yield a metabolic product thereof. Such products are typically identified by administering a radiolabeled compound of the disclosure in a detectable dose to an animal, such as rat, mouse, guinea pig, monkey, or to a human, allowing sufficient time for metabolism to occur, and isolating its conversion products from the urine, blood or other biological samples.

[091] The term “Ras” or “RAS” refers to a protein in the Rat sarcoma (Ras) superfamily of small GTPases, such as in the Ras subfamily. The Ras superfamily includes, but is not limited to, the Ras subfamily, Rho subfamily, Rab subfamily, Rap subfamily, Arf subfamily, Ran subfamily, Rheb subfamily, RGK subfamily, Rit subfamily, Miro subfamily, and Unclassified subfamily. In some embodiments, a Ras protein is selected from the group consisting of KRAS (K-Ras or K-ras or Kras), HRAS (or H-Ras), NRAS (or N-Ras), MRAS (or M-Ras), ERAS (or E-Ras), RRAS2 (or R-Ras2), RALA (or RalA), RALB (or RalB), RIT1, and any combination thereof, such as from KRAS, HRAS, NRAS, RALA, RALB, and any combination thereof.

In some embodiments, a mutation can be an introduced mutation, a naturally occurring mutation, or a non-naturally occurring mutation. In some embodiments, a mutation can be a substitution (e.g., a substituted amino acid), insertion (e.g., addition of one or more amino acids), or deletion (e.g., removal of one or more amino acids). In some embodiments, two or more mutations can be consecutive, non-consecutive, or a combination thereof. In some embodiments, a mutation can be present at any position of Ras. In some embodiments, a mutation can be present at position 12, 13, 62, 92, 95, or any combination thereof of Ras relative to SEQ ID No. 1 when optimally aligned. [183] The chemical entities described herein can be synthesized according to one or more illustrative schemes herein and/or techniques known in the art. Materials used herein are either commercially available or prepared by synthetic methods generally known in the art. These schemes are not limited to the compounds listed in the examples or by any particular substituents, which are employed for illustrative purposes. Although various steps are described and depicted in **Schemes 1-8** and **Examples 1-36**, the steps in some cases may be performed in a different order than the order shown in **Schemes 1-8** and **Examples 1-36**. Various modifications to these synthetic reaction schemes may be made and will be suggested to one skilled in the art having referred to the present disclosure. Numberings or R groups in each scheme typically have the same meanings as those defined elsewhere herein unless otherwise indicated.

[184] Unless specified to the contrary, the reactions described herein take place at atmospheric pressure, generally within a temperature range from -10 °C to 200 °C. Further, except as otherwise specified, reaction times and conditions are intended to be approximate, e.g., taking place at about atmospheric pressure within a temperature range of about -10 °C to about 110 °C over a period of about 1 to about 24 hours; reactions left to run overnight average a period of about 16 hours.

[185] In general, compounds of the disclosure may be prepared by the following reaction schemes:

Scheme 1

[186] In some embodiments, a compound of Formula 1e may be prepared according to Scheme 1. For example, heteroaryl amine 1b can be formed from chloride 1a via a nucleophilic aromatic substitution reaction. Substitution of the lactam can proceed under basic conditions to give diene 1c, which can undergo a cross metathesis reaction—such as Grubbs cross metathesis reaction—to form macrocycle 1d. Optionally, 1d may be subjected to one or more subsequent reactions, such as a hydrogenation reaction, to provide a compound of Formula 1e.

Scheme 2

[187] Similarly, in some embodiments, a compound of Formula 2e may be prepared according to Scheme 2. For example, heteroaryl amine 2b can be formed from chloride 2a via a nucleophilic aromatic substitution reaction. Substitution of the lactam can proceed under basic conditions to give diene 2c, which can undergo a cross metathesis reaction—such as Grubbs cross metathesis reaction—to form macrocycle 2d. Optionally, 2d may be subjected to one or more subsequent reactions, such as a hydrogenation reaction, to provide a compound of Formula 2e.

Scheme 3

[188] In some embodiments, a compound of Formula 3e may be prepared according to **Scheme 3**. For example, heteroaryl amine 3b can be formed from chloride 3a via a substitution reaction. Substitution of the lactam can give protected amine 3c. Hydrolysis of the ester can form carboxylic acid 3d, which can undergo deprotection and peptide coupling reactions to afford macrocycle of Formula 3e.

Scheme 4

[189] Similarly, in some embodiments, a compound of Formula 4e may be prepared according to **Scheme 4**. For example, heteroaryl amine 4b can be formed from chloride 4a via a substitution reaction. Substitution of the lactam can give protected amine 4c. Hydrolysis of the ester can form carboxylic acid 4d, which can undergo deprotection and peptide coupling reactions to afford a macrocycle of Formula 4e.

Scheme 5

[190] In some embodiments, a compound of Formula 5g may be prepared according to **Scheme 5**. For example, heteroaryl amine 3c can be formed by coupling chloride 5a with amine 5b. Oxidation of the alcohol can give

aldehyde **5d**, which can be followed with substitution of the phenol to give **5e**. Removal of the amine protecting group can afford **5f**, which can undergo a reductive amination to form a macrocycle of Formula **5g**.

Scheme 6

[191] In some embodiments, a compound of Formula **6f** may be prepared according to **Scheme 6**. For example, heteroaryl amine **6c** can be formed by coupling chloride **1a** with amine **6b**. Substitution of the phenol to olefin **6d** can be followed by installation of a second olefin to give diene **6e**. A cross metathesis reaction—such as Grubbs cross metathesis reaction—can be followed by hydrogenation of the resulting double bond to provide a macrocycle of Formula **6f**.

Scheme 7

[192] In some embodiments, a compound of Formula **7e** may be prepared according to **Scheme 7**. For example, heteroaryl amine **7b** can be formed by coupling chloride **7a** with amine **5b**. Substitution of the phenol can give **7c**. Ester hydrolysis and deprotection of the amine can give **7d**, which can be cyclized to form a macrocycle of Formula **7e** via a peptide coupling reaction.

Scheme 8

[193] In some embodiments, a compound of Formula **8g** may be prepared according to **Scheme 8**. For example, substitution of lactam **8a** with a suitable bromo dioxolane (**8b**) can give acetal **8c**. Nucleophilic aromatic substitution with amine **8d** can provide heteroaryl amine **8e**, which can be treated with a suitable acid, such as HCl, to remove the Boc protecting group and reveal the aldehyde. Finally, cyclization of **8f** can proceed via reductive amination conditions to give a macrocycle of Formula **8g**.

[194] In some embodiments, a compound of the present disclosure, for example, a compound of a formula given in **Table 1**, was synthesized according to one of the general routes outlined in **Schemes 1-8**, **Examples 1-36**, or by methods generally known in the art. In some embodiments, exemplary compounds may include, but are not limited to, a compound selected from **Table 1**, or a salt or solvate thereof.

[195] In some embodiments, the compounds of the present disclosure exhibit one or more functional characteristics described herein. For example, a subject compound is capable of reducing Ras signaling output. In some instances, a subject compound is capable of disrupting a Ras-SOS interaction, including disrupting interaction or binding between a mutant Kras (e.g., Kras G12C) and SOS1, or between a wildtype Kras and SOS1, thereby reducing Ras signaling output. In some embodiments, a subject compound binds specifically to a SOS protein, including SOS1. In some embodiments, the IC₅₀ of a subject compound (including those shown in Table 1) for a SOS protein is less than about 5 μ M, less than about 1 μ M, less than about 50 nM, less than about 10 nM, less than about 1 nM, less than about 0.5 nM, less than about 100 pM, or less than about 50 pM, as measured in an in vitro assay known in the art or exemplified herein.

[196] A reduction in Ras signaling output can be evidenced by one or more members of the following: (i) an increase in steady state level of GDP-bound Ras protein; (ii) a reduction in steady state level of GTP-bound Ras protein; (iii) a reduction of phosphorylated AKTs473, (iv) a reduction of phosphorylated ERKT202/y204, (v) a reduction of phosphorylated S6S235/236, (vi) reduction (e.g., inhibition) of cell growth of Ras-driven tumor cells (e.g., those derived from a tumor cell line disclosed herein), and (vii) an interference or disruption of the interaction or binding between a SOS protein (e.g., SOS1) with a Ras protein such as a wildtype or a mutant Ras. In some cases, the reduction in Ras signaling output can be evidenced by two, three, four, five, six, or all of (i)-(vii) above.

[197] It shall be understood that different aspects of the invention can be appreciated individually, collectively, or in combination with each other. Various aspects of the invention described herein may be applied to any of the particular applications disclosed herein. The compositions of matter including compounds of any formulae disclosed herein in the compounds section of the present disclosure may be utilized in the methods section including methods of use and production disclosed herein, or vice versa.

[214] In combination therapy, a compound provided herein and other anti-cancer agent(s) may be administered either simultaneously, concurrently or sequentially with no specific time limits, wherein such administration provides therapeutically effective levels of the two compounds in the body of the patient. In some embodiments, a compound of the present disclosure and another anti-cancer agent(s) are generally administered sequentially in any order by infusion or orally. The dosing regimen may vary depending upon the stage of the disease, physical fitness of the patient, safety profiles of the individual drugs, and tolerance of the individual drugs, as well as other criteria known to the attending physician and medical practitioner(s) administering the combination. The compound of the present invention and other anti-cancer agent(s) may be administered within minutes of each other, hours, days, or even weeks apart depending upon the particular cycle being used for treatment. [215] An antibiotic can be administered to a subject as part of a therapeutic regime. An antibiotic can be administered at a therapeutically effective dose. An antibiotic can kill or inhibit growth of bacteria. An antibiotic can be a broad spectrum antibiotic that can target a wide range of bacteria. Broad spectrum antibiotics, either a 3rd or 4th generation, can be cephalosporin or a quinolone. An antibiotic can also be a narrow spectrum antibiotic that can target specific types of bacteria. An antibiotic can target a bacterial cell wall such as penicillins and cephalosporins. An antibiotic can target a cellular membrane such as polymyxins. An antibiotic can interfere with essential bacterial enzymes such as antibiotics: rifamycins, lipiarmycins, quinolones, and sulfonamides. An antibiotic can also be a protein synthesis inhibitor such as macrolides, lincosamides, and tetracyclines. An antibiotic can also be a cyclic lipopeptide such as daptomycin, glycyclcyclines such as tigecycline, oxazolidinones such as linezolid, and lipiarmycins such as fidaxomicin. In some cases, an antibiotic can be 1st generation, 2nd generation, 3rd generation, 4th generation, or 5th generation. A first-generation antibiotic can have a narrow spectrum. Examples of 1st generation antibiotics can be penicillins (Penicillin G or Penicillin V), Cephalosporins (Cephazolin, Cephalothin,

Cephapirin, Cephaethin, Cephadrin, or Cephadroxin). In some cases, an antibiotic can be 2nd generation. 2nd generation antibiotics can be a penicillin (Amoxicillin or Ampicillin), Cephalosporin (Cefuroxime, Cephmandole, Cephoxitin, Cephaclor, Cephrozil, Loracarbef). A 3rd generation antibiotic can be penicillin (carbenicillin and ticarcillin) or cephalosporin (Cephixime, Cephtriaxone, Cephotaxime, Cephtizoxime, and Cephtazidime). An antibiotic can also be a 4th generation antibiotic. A 4th generation antibiotic can be Cephipime. An antibiotic can also be 5th generation. 5th generation antibiotics can be Cephtaroline or Cephtobiprole.

[216] In some cases, an anti-viral agent may be administered as part of a treatment regime. In some cases, a herpes virus prophylaxis can be administered to a subject as part of a treatment regime. A herpes virus prophylaxis can be valacyclovir (Valtrex). Valtrex can be used orally to prevent the occurrence of herpes virus infections in subjects with positive HSV serology. It can be supplied in 500 mg tablets. Valacyclovir can be administered at a therapeutically effective amount.

[217] In some cases, a treatment regime may be dosed according to a body weight of a subject. In subjects who are determined obese (BMI > 35) a practical weight may need to be utilized. BMI is calculated by: $BMI = \text{weight (kg)} / [\text{height (m)}]^2$. Body weight may be calculated for men as $50 \text{ kg} + 2.3 * (\text{number of inches over 60 inches})$ or for women $45.5 \text{ kg} + 2.3 * (\text{number of inches over 60 inches})$. An adjusted body weight may be calculated for subjects who are more than 20% of their ideal body weight. An adjusted body weight may be the sum of an ideal body weight + $(0.4 \times (\text{actual body weight} - \text{ideal body weight}))$. In some cases, a body surface area may be utilized to calculate a dosage. A body surface area (BSA) may be calculated by: $BSA (m^2) = \sqrt{\text{Height (cm)} * \text{Weight (kg)} / 3600}$.

The compositions may be presented in unit-dose or multi-dose containers, for example sealed ampoules and vials, and may be stored in powder form or in a freeze-dried (lyophilized) condition requiring only the addition of the sterile liquid carrier, for example, saline or sterile pyrogen-free water, immediately prior to use. Extemporaneous injection solutions and suspensions may be prepared from sterile powders, granules and tablets of the kind previously described.

[229] Pharmaceutical compositions for parenteral administration include aqueous and non-aqueous (oily) sterile injection solutions of the active compounds which may contain antioxidants, buffers, bacteriostats and solutes which render the formulation isotonic with the blood of the intended recipient; and aqueous and non-aqueous sterile suspensions which may include suspending agents and thickening agents. Suitable lipophilic solvents or vehicles include fatty oils such as sesame oil, or synthetic fatty acid esters, such as ethyl oleate or triglycerides, or liposomes. Aqueous injection suspensions may contain substances which increase the viscosity of the suspension, such as sodium carboxymethyl cellulose, sorbitol, or dextran. Optionally, the suspension may also contain suitable stabilizers or agents which increase the solubility of the compounds to allow for the preparation of highly concentrated solutions.

[230] Pharmaceutical compositions may also be formulated as a depot preparation. Such long-acting formulations may be administered by implantation (for example subcutaneously or intramuscularly) or by intramuscular injection. Thus, for example, the compounds may be formulated with suitable polymeric or hydrophobic materials (for example, as an emulsion in an acceptable oil) or ion exchange resins, or as sparingly soluble derivatives, for example, as a sparingly soluble salt.

[233] Unless noted otherwise, all materials, such as reagents, starting materials and solvents, were purchased from commercial suppliers, such as Sigma-Aldrich, VWR, and the like, and were used without further purification. Reactions were run under nitrogen atmosphere, unless noted otherwise. The progress of reactions was monitored by thin layer chromatography (TLC), analytical high performance liquid chromatography (anal. HPLC), and mass spectrometry, the details of which may be provided in specific examples.

[234] Reactions were worked up as described specifically in each preparation; commonly, reaction mixtures were purified by extraction and other purification methods such as temperature- and solvent-dependent crystallization, and precipitation. In addition, reaction mixtures were routinely purified by preparative HPLC, for example, using Microsorb C18 or Microsorb BDS column packings and conventional eluents. Progress of reactions was typically monitored by liquid chromatography mass spectrometry (LCMS). Characterization of isomers was typically done by Nuclear Overhauser effect spectroscopy (NOE). Characterization of reaction products was routinely carried out by mass spectrometry and/or ^1H -NMR spectroscopy. For NMR measurement, samples were dissolved in deuterated solvent (CD_3OD , CDCl_3 , or $\text{DMSO}-d_6$).

To a solution of **36-9** (200 mg, 0.44 mmol) in THF (10 mL) was added L-Selectride (0.88 mL, 2 eq., 1 M) at -70 °C. The solution was stirred at -70 °C for 60 mins, then quenched with saturated aqueous NH_4Cl . The solution was extracted by ethyl acetate (3x10 mL), dried over Na_2SO_4 , concentrated in vacuo and the residue was purified by prep-TLC to give **36-10** (170 mg) as a colorless oil. To a solution of **36-10** (200 mg, 0.087 mmol) in MeOH (2.8 mL) was added a solution of HCl/dioxane (4M, 0.7 mL) at room temperature. The reaction mixture was stirred for 2 hours, then treated with aqueous NaHCO_3 . The solution was concentrated and the resulting solution was extracted with ethyl acetate (3x10 mL). The combined organic layers were dried over Na_2SO_4 . After filtration, the solvent was removed to give **36-11** (150 mg) as a colorless oil. ESI-MS m/z : $(\text{M-Boc}+\text{H})^+ = 355.2$.

[525] Step K: Preparation of 4-(8-(5-(1,3-dioxolan-2-yl)pentyl)-4-chloro-7-oxo-7,8-dihydropyrido[2,3-d]pyrimidin-6-yl)tetrahydro-2H-thiopyran-4-carbonitrile 1,1-dioxide (**36-12**). [533] **Example 38:** Protein expression

[534] DNA expression constructs encoding one or more protein sequences of interest (e.g., Kras fragments thereof, mutant variants thereof, etc.) and its corresponding DNA sequences are optimized for expression in *E. coli* and synthesized by, for example, the GeneArt Technology at Life Technologies. In some cases, the protein sequences of interest are fused with a tag (e.g., glutathione S-transferase (GST), histidine (His), or any other affinity tags) to facilitate recombinant expression and purification of the protein of interest. Such tag can be cleaved subsequent to purification. Alternatively, such tag may remain intact to the protein of interest and may not interfere

with activities (e.g., target binding and/or phosphorylation) of the protein of interest

[535] A resulting expression construct is additionally encoded with (i) att-site sequences at the 5' and 3' ends for subcloning into various destination vectors using, for example, the Gateway Technology, as well as (ii) a Tobacco Etch Virus (TEV) protease site for proteolytic cleavage of one or more tag sequences. The applied destination vectors can be a pET vector series from Novagen (e.g., with ampicillin resistance gene), which provides an N-terminal fusion of a GST-tag to the integrated gene of interest and/or a pET vector series (e.g., with ampicillin resistance gene), which provides a N-terminal fusion of a HIS-tag to the integrated gene. To generate the final expression vectors, the expression construct of the protein of interest is cloned into any of the applied destination vectors. The expression vectors are transformed into E. coli strain, e.g., BL21 (DE3). Cultivation of the transformed strains for expression is performed in 10 L and 1 L fermenter. The cultures are grown, for example, in Terrific Broth media (MP Biomedicals, Kat. #1 13045032) with 200 µg/mL ampicillin at a temperature of 37 °C to a density of 0.6 (OD600), shifted to a temperature of ~27 °C (for K-Ras expression vectors) induced for expression with 100 mM IPTG, and further cultivated for 24 hours. After cultivation, the transformed E. coli cells are harvested by centrifugation and the resulting pellet is suspended in a lysis buffer, as provided below, and lysed by passing three-times through a high pressure device. The lysate is centrifuged (49000g, 45 min, 4 °C) and the supernatant is used for further purification.

[536] Example 39: Ras protein Purification

[537] A Ras (e.g., K-Ras wildtype or a mutant such as K-Ras G12D, K-Ras G12V or K-Ras G12C) construct or a variant thereof is tagged with GST. E. coli culture from a 10L fermenter is lysed in lysis buffer (50 mM Tris HCl 7.5, 500 mM NaCl, 1 mM DTT, 0.5% CHAPS, Complete Protease Inhibitor Cocktail-(Roche)). As a first chromatography step, the centrifuged lysate is incubated with 50 mL Glutathione Agarose 4B (Macherey-Nagel; 745500.100) in a spinner flask (16 h, 100). The Glutathione Agarose 4B loaded with protein is transferred to a chromatography column connected to a chromatography system, e.g., an Akta chromatography system. The column is washed with wash buffer (50 mM Tris HCl 7.5, 500 mM NaCl, 1 mM DTT) and the bound protein is eluted with elution buffer (50 mM Tris HCl 7.5, 500 mM NaCl, 1 mM DTT, 15 mM Glutathione). The main fractions of the elution peak (monitored by OD280) are pooled. For further purification by size-exclusion chromatography, the above eluate volume is applied to a column Superdex 200 HR prep grade (GE Healthcare) and the resulting peak fractions of the eluted fusion protein are collected. Native mass spectrometry analyses of the final purified protein construct can be performed to assess its homogeneous load with GDP.

[538] Example 40: SOS purification

[539] A SOS construct or a variant thereof is His10-tagged (SEQ ID NO. 6). E. coli cultures are induced in a fermenter, harvested, and lysed in lysis buffer, for example, in 25 mM Tris HCl 7.5, 500 mM NaCl, 20 mM Imidazol, Complete EDTA-free (Roche)). For immobilized metal ion affinity chromatography (IMAC), the centrifuged lysate (50,000 x g, 45 min, 40) is incubated with 30 mL Ni-NTA (Macherey-Nagel; #745400.100) in a spinner flask (16 h, 40) and subsequently transferred to a chromatography column connected to a chromatography system, e.g., an Akta chromatography system. The column is rinsed with wash buffer, e.g., in 25 mM Tris HCl 7.5, 500 mM NaCl, 20 mM Imidazol and the bound protein is eluted with a linear gradient (0-100%) of elution buffer (25 mM Tris HCl 7.5, 500 mM NaCl, 300 mM Imidazol). The main fractions of the elution peak (monitored by OD280) containing homogenous His10-hSOS is pooled.

[540] Example 41: Ras-SOS interaction assay

[541] The ability of any compound of the present disclosure to reduce a Ras protein signaling output by, e.g.,

interfering or disrupting interaction (or binding) between SOS1 and a Ras protein can be assessed in vitro. For example, the equilibrium interaction of human SOS1 (hSOS1) with human wildtype Kras or K-Ras mutant (e.g., hK-Ras G12C mutant, or hK-Ras G12C) can be assessed as a proxy or an indication for a subject compound's ability to inhibit SOS. Detection of such interaction is achieved by measuring homogenous time-resolved fluorescence resonance energy transfer (HTRF) from (i) a fluorescence resonance energy transfer (FRET) donor (e.g., antiGST-Europium) that is bound to GST-tagged K-Ras G12C to (ii) a FRET acceptor (e.g., anti-6His-XL665) bound to a His-tagged hSOS1.

[542] The assay buffer can contain 5 mM HEPES pH 7.4, 150 mM NaCl, 10 mM EDTA, 1 mM DTT, 0.05% BSA, 0.0025% (v/v) Igepal and 100 mM KF. A Ras working solution is prepared in assay buffer containing typically 10 nM of the protein construct (e.g., GST-tagged hK-Ras G12C) and 2 nM of the FRET donor (e.g., antiGST-Eu(K) from Cisbio, France). A SOS1 working solution is prepared in assay buffer containing typically 10 nM of the protein construct (e.g., His-hSOS1) and 10 nM of the FRET acceptor (e.g., anti-6His-XL665 from Cisbio, France). An inhibitor control solution is prepared in assay buffer containing 10 nM of the FRET acceptor without the SOS1 protein.

[543] A fixed reaction mixture with or without test compound is transferred into a 384-well plate. Ras working solution is added to all wells of the test plate. SOS1 working solution is added to all wells except for those that are subsequently filled with the inhibitor control solution. After approximately 60 min incubation, the fluorescence is measured with a M1000Pro plate reader (Tecan) using HTRF detection (excitation 337 nm, emission 1: 620nm, emission 2: 665nm). Compounds are tested in duplicate at different concentrations (for example, 10 μ M, 2.5 μ M, 0.63 μ M, 0.16 μ M, 0.04 μ M, 0.01 μ M test compound). The ratiometric data (i.e., emission 2 divided by emission 1) is used to calculate IC₅₀ values against SOS1 using GraphPad Prism (GraphPad software).

[544] **Table 2** below shows the resulting IC₅₀ values of the compounds exemplified in Table 1 against SOS1 using the Ras-SOS interaction assay as described above, wherein K-Ras G13D is utilized. The results demonstrate that compounds disclosed herein are capable of reducing Ras protein signaling by inhibiting SOS1-mediated signaling. Many of the exemplified compounds are potent SOS1 inhibitors, exhibiting an IC₅₀ value against SOS1 less than about 500 nM, 400 nM, 300 nM, 200 nM, 100 nM, 80nM, 60 nM, 50 nM, 40 nM, 30 nM, 20 nM, or even less than 10 nM. For example, compounds 54, 61, 101, 120, 138, 159, 166, 167, 168, 170, 171, 173, 174, 175, 176, 209, 210, 211, 212, and 213 exhibit IC₅₀ values less than 50 nM, 40 nM, 30 nM, 20 nM, or 10 nM.

[545] **Table 2** shows the resulting IC₅₀ values of selected compounds against SOS1 using the Ras-SOS interaction assay described herein. Compound numbers correspond to the numbers and structures provided in **Table 1** and **Examples 1-36**. IC₅₀ values were not determined for compounds of **Table 1** that are not listed in **Table 2**.

[547] **Example 42:** ERK phosphorylation assay

[548] An ERK phosphorylation assay is used to examine the potency with which compounds disclosed herein inhibit the SOS1-mediated signaling and hence Ras signaling output in a Kras mutant cancer cell line. MIA PaCa-2 cells (ATCC CRL-1420) expressing K-Ras G12C are grown in DMEM/Ham's F12 medium supplemented with 10% fetal calf serum, glutamine and ~2.5% horse serum. Alternatively, other cell lines with aberrant Ras signaling output can be utilized. Non-limiting exemplary cell lines include NCI-H358 and H1975. Cells are plated in 96-well plates at a concentration of 40,000 cells/well and allowed to attach for at least 8 hours. Following, diluted solutions of test inhibitor compounds are added to the cell culture. After ~2 hours of incubation, the medium is removed and lysis buffer from AlphaLISA® SureFire® Ultra™ p-ERK 1/2 (Thr202/Tyr204) assay kit (Perkin Elmer ALSU-PERK-A10K) is added to the cells. The plate is agitated for 10 min at room temperature and 10 µL of the lysate is transferred to a 384-well Optiplate™ (Perkin Elmer) for assay. Thereafter ~5 µL of Acceptor Mix from the p-ERK AlphaLISA assay kit is added to wells and the plate is sealed with adhesive film. The samples are incubated for one hour at room temperature. Following, 5 µL of Donor Mix is added to the wells and plate is re-sealed with adhesive film and incubated for one hour at room temperature. The plate is then read on a multimode microplate reader (e.g., SPARK® Tecan) equipped with Alpha detection module. The data can be fitted to four-parameter dose-response curve using Prism version 9 (GraphPad) to calculate an IC₅₀ for the inhibition of ERK phosphorylation. Certain

compounds disclosed herein when assessed in this ERK phosphorylation assay exhibited IC₅₀ values less than about 1 μ M, about 500 nM, about 200 nM, about 100 nM, or 50 nM.

[549] Example 43: Ras-SOS cellular growth inhibition assay

[550] The ability of any compound of the present disclosure to inhibit SOS1-mediated signaling and hence Ras protein signaling can be demonstrated by inhibiting growth of a given Kras mutant cell line.

[551] Growth of cells with K-Ras G12C mutation: MIA PaCa-2 (ATCC CRL-1420) and NCI-H1792 (ATCC CRL-5895) cell lines comprise a G12C mutation and can be used to assess Ras cellular signaling in vitro, e.g., in response to a subject compound of the present disclosure. This cellular assay can also be used to discern selective inhibition of subject compounds against certain types of Kras mutants, e.g., more potent inhibition against Kras G12D relative to Kras G12C mutant, by using MIA PaCa-2 (G12C driven tumor cell line) as a comparison. Cell culture medium (comprising, for example, MIA PaCa-2 cells) is prepared with DMEM/Ham's F12 (e.g., with stable Glutamine, 10% FCS, and 2.5% Horse Serum). NCI-H1792 culture medium is prepared with RPMI 1640 (e.g., with stable Glutamine) and 10% FCS. A CellTiter-Glo (CTG) luminescent based assay (Promega) is used to assess growth of the cells, as a measurement of the ability of the compounds herein to inhibit Ras signaling in the cells. The cells (e.g., 800-1200 per well) are seeded in their respective culture medium in standard tissue culture-treated ultra-low attachment surface 96-well format plates (Corning Costar #3474). The day after plating, cells are treated with a dilution series (e.g., a 9 point 3-fold dilution series) of the compounds herein (e.g., approximately 125 μ L final volume per well). Cell viability can be monitored (e.g., approximately 5 days later) according to the manufacturer's recommended instructions, where the CellTiter-Glo reagent is added (e.g., approximately 65 μ L), vigorously mixed, covered, and placed on a plate shaker (e.g., approximately for 20 min) to ensure sufficient cell lysis prior to assessment of luminescent signal. The IC₅₀ values are determined using the four-parameter fit. The resulting IC₅₀ value is a measurement of the ability of the compounds herein to reduce cell growth of Ras-driven cells as representative tumor cells. Many of the exemplified compounds are potent SOS1 inhibitors, inhibiting SOS1-mediated signaling, capable of reducing cell growth with an IC₅₀ value less than about 1 μ M, 500 nM, 400 nM, 300 nM, 200 nM, 100 nM, 80 nM, 60 nM, 50 nM, 40 nM, 30 nM, 20 nM, 10 nM or even less. For example, compounds 6, 9, 54, 61, 101, 120, 167, 170, 171, 173, 174, and 175 exhibit IC₅₀ values less than about 1 μ M, 500 nM, 400 nM, 300 nM, 200 nM, 100 nM, 80 nM, 60 nM, 50 nM, 40 nM, 30 nM, 20 nM, or even less than 10 nM, in inhibiting MIA PaCa-2 cell growth. The results demonstrate that the subject compounds are effective in inhibiting growth of tumor cells including cells comprising one or more Kras mutations, e.g., Ras-driven tumor cells carrying a Kras G12C mutation.

[552] Example 44: EGFR-SOS cellular inhibition assay

[553] The ability of any compound of the present disclosure to inhibit SOS1-mediated signaling and hence Ras protein signaling can be demonstrated by inhibiting growth of a given EGFR mutant cell line.

[554] Growth of cells with EGFR T790M L858R double mutation: The NCI-H1975 (ATCC CRL-5908) cell line comprises an EGFR T790M L858R double mutation and can be used to assess EGFR cellular signaling in vitro, e.g., in response to a subject compound of the present disclosure. NCI-H1975 culture medium is prepared with RPMI 1640 (e.g., with stable Glutamine) and 10% FCS. A CellTiter-Glo (CTG) luminescent based assay (Promega) is used to assess growth of the cells, as a measurement of the ability of the compounds herein to inhibit EGFR signaling in the cells. The cells (e.g., 800-1200 per well) are seeded in their respective culture medium in standard tissue culture-treated ultra-low attachment surface 96-well format plates (Corning Costar #3474). The day after plating, cells are treated with a dilution series (e.g., a 9 point 3-fold dilution series) of the compounds herein (e.g.,

approximately 125 μ L final volume per well). Cell viability can be monitored (e.g., approximately 5 days later) according to the manufacturer's recommended instructions, where the CellTiter-Glo reagent is added (e.g., approximately 65 μ L), vigorously mixed, covered, and placed on a plate shaker (e.g., approximately for 20 min) to ensure sufficient cell lysis prior to assessment of luminescent signal. The IC₅₀ values are determined using the four-parameter fit. The resulting IC₅₀ value is a measurement of the ability of the compounds herein to reduce growth of EGFR-driven tumor cells. See **Table 4**. Many of the exemplified compounds are potent SOS1 inhibitors, capable of reducing cell growth with an IC₅₀ value less than about 1 μ M, 500 nM, 400 nM, 300 nM, 200 nM, 100 nM, 80 nM, 60 nM, 50 nM, 40 nM, 30 nM, 20 nM, or even less than 10 nM. For example, compounds 6, 54, 61, 101, 120, 159, 167, 170, 171, 173, 174, 175, 176, 209, 210, 211, 212, and 213 exhibit IC₅₀ values less than 500 nM, 400 nM, 300 nM, 200 nM, 100 nM, 80 nM, 60 nM, 50 nM, 40 nM, 30 nM, 20 nM, or even less than 10 nM, in inhibiting growth of an NCI-H1975 (ATCC CRL-5908) cell line comprising an EGFR T790M L858R double mutation.

[555] **Table 4** shows the resulting IC₅₀ values of selected compounds against SOS1 using the cell proliferation assays described herein. Compound numbers correspond to the numbers and structures provided in **Table 1** and **Examples 1-36**. IC₅₀ values were not determined for compounds of **Table 1** that are not listed in **Table 4**.

[556] **Example 45:** In vivo Ras inhibition and synergistic reduction of tumor growth in a Ras-driven model

[557] The in vivo reduction in Ras signaling output by a subject compound alone and synergistic reduction of tumor growth in combination with another therapeutic agent are determined in a mouse tumor xenograft model.

[558] Xenograft with K-Ras G12C mutation: In an example, tumor xenografts are established by administration of tumor cells with K-Ras G12C mutation (e.g., MIA PaCa-2 cells) into mice, e.g., injection of the tumor cells into the right flanks of female BomTacNMRI-Foxn1nu mice with an age between 6 to 8 weeks. In case of the subcutaneous (s.c.) MIA PaCa-2 xenograft mouse models, MIA PaCa-2 cells are grown in cell culture flasks in appropriate medium. Cultures are incubated at 37 °C and 5% CO₂ in a humidified atmosphere, with medium change or subcultivation performed 2-3 times a week. For injection, the cultured tumor cells are mixed with PBS including 5% FCS and Matrigel in a 1:1 ratio. About 0.5x10⁷ cells in a volume of 100 μ L is injected s.c. in each mouse to establish tumors. Mice are randomized into treatment groups of 6-10 mice, once tumors reach a desirable size (e.g., between about 88 to about 504 mm³, or between about 103 to about 377 mm³). Treatment with a subject compound of the present disclosure or with a control (e.g., vehicle control) may start on the day of randomization and can be continued until end of the study (e.g., 18 days). The test samples are administered intragastrically using a gavage

needle at an application volume of 10 mL/kg in a volume of 10 mL/kg per mouse daily twice with a 6h difference.

[559] Mice are housed under standardized conditions at 21.5 ± 1.5 °C and $55 \pm 10\%$ humidity. Standardized irradiated diet and autoclaved tap water is provided ad libitum. In some cases, tags (e.g., ear tags, microchips implanted subcutaneously under isoflurane anesthesia) are used to identify each mouse. The tumor diameter is measured two or three times a week with a caliper. The volume of each tumor (in mm³) is calculated according to the formula “tumor volume = (π * length * width²) / 6.” To monitor side effects of treatment, mice are inspected daily for abnormalities and body weight is determined, e.g., daily. Animals are sacrificed at the end of the study. Animals with necrotic tumors or tumor sizes exceeding 1500 mm³ are sacrificed early during the study for ethical reasons. A compound disclosed herein inhibited tumor growth alone at an appropriate dose, and further synergistically inhibited tumor growth when administered in conjunction with a KRAS G12C inhibitor.

[560] **Example 46: Metabolic (Microsomal) Stability Assay**

[561] The metabolic stability of a test compound is assayed at 37 °C using pooled liver microsomes (mouse or human liver microsomes). An aliquot of 10 µL of 50 µM test compound is mixed with 490 µL of 0.611 mg/mL liver microsomes, and then, 50 µL of the mixtures are dispensed to the 96 well tubes and warmed at 37 °C for 10 minutes. The reactions are initiated by adding 50 µL of the pre-warmed NADPH regeneration system solution (add 1.2 µL solution, 240 µL solution B, mix with 10.56 mL KPBS) and then incubated at 37 °C. The final incubation solution contains 100 mM potassium phosphate (pH 7.4), 1.3 mM NADP⁺, 3.3 mM glucose 6-phosphate, 0.4 Unit/mL of glucose 6-phosphate dehydrogenase, 3.3 mM magnesium chloride, 0.3 mg/mL liver microsomes and 0.5 µM test article. After 0, 15, 30 and 60 minutes in a shaking incubator, the reactions are terminated by adding 100 µL of acetonitrile containing 200 nM buspirone as an internal standard. All incubations are conducted in duplicate. Plates are vortexed vigorously by using Fisher Scientific microplate vortex mixer (Henry Troemner, US). Samples are then centrifuged at 3500 rpm for 10 minutes (4 °C) using Sorvall Legend XRT Centrifuge (Thermo Scientific, GE). Supernatants (40 µL) are transferred into clean 96-deep well plates. Each well is added with 160 µL of ultrapure water (Milli-Q, Millipore Corporation) with 0.1% (v/v) formic acid (Fisher Chemical), mixed thoroughly and subjected to LC/MS/MS analysis in MRM positive ionization mode.

[562] All the samples are measured using a mass spectrometer (QTrap 5500 quadrupole/ion trap) coupled with a Shimadzu HPLC system. The HPLC system consists of a Shimadzu series degasser, binary quaternary gradient pumps, column heater coupled to an autosampler, and a Phenomenex Gemini-NX, C18, 3.0 µm or Phenomenex Lunar, C8, 5.0 µm HPLC column (Phenomenex, Torrance, CA), and elute with a mobile phase gradient consisting of Solution A (0.1% formic acid water) and Solution B (0.1% formic acid acetonitrile). The column temperature is maintained at 40 °C. All the analytes are detected with positive-mode electrospray ionization (ES⁺).

[563] The half-life for the metabolic degradation of the test compound is calculated by plotting the time-course disappearance of the test compound during the incubation with liver microsomes. Each plot is fitted to a first-order equation for the elimination of the test compound (% remaining compound) versus time using non-linear regression (Equation 1).

Equation 1:

$$\frac{C_t}{C_0} = e^{-kt}$$

where C_t is the mean relative substrate concentration at time t and C_0 is the initial concentration (0.5 µM) at time 0. Note that the area ratio of the substrate peak to an internal standard peak is proportional to the analyte concentration and is used for regression analysis to derive a value of k .

[564] The half-life $t_{1/2}$ for metabolic (microsome) stability is derived from the test compound elimination constant k using Equation 2 below.

Equation 2:

$$t_{1/2} = \frac{0.693}{k}$$

[565] **Example 47:** CYP2C19 Inhibition Assay

[566] Some xenobiotics can inhibit cytochrome P450 (CYP) enzyme function, which alters their ability to metabolize drugs. Administration of a CYP inhibitor with a drug whose clearance is dependent on CYP metabolism can result in increased plasma concentrations of this concomitant drug, leading to potential toxicity. The inhibition of CYP2C19 by a test compound is assayed in human liver microsomes using S-Mephenytoin as a CYP2C19 substrate. The stock solution of the test compound or known CYP2C19 inhibitor as a positive control (10 mM) is diluted with KPBS to 40 μ M. In a similar way, the stock solutions of the human liver microsomes and S-Mephenytoin are diluted with KPBS buffer. The pre-incubations are started by incubating a plate containing 25 μ L human liver microsomes (final concentration of 0.2 mg/mL), 25 μ L NADPH-generating system, and a 25 μ L test compound (final concentration 10 μ M) or the positive control for 30 min at 37 ± 1 °C. After the pre-incubation, 25 μ L S-Mephenytoin (final concentration 200 μ M) is added and incubated another 12 minutes at 37 ± 1 °C for substrate metabolism. The reactions are terminated by addition of 100 μ L of ice-cold acetonitrile containing an internal standard (buspirone). Precipitated proteins are removed by centrifugation at 3500 rpm for 10 minutes at 4 °C (Allegra 25R, Beckman Co. Fullerton, CA) and then an aliquot of the supernatant is transferred to an assay plate.

[567] All the samples are determined by a mass spectrometer (QTrap 5500 quadrupole/ion trap) coupled with a Shimadzu HPLC system, following the manufacturer's instructions. The metabolism of S-Mephenytoin in human liver microsomes is monitored by LC/MS/MS as representative of CYP2C19 inhibitory activity. The amount of metabolite formed is assessed by the peak area ratio (metabolite/IS) and % inhibition at 10 μ M is expressed as a percentage of the metabolite signal reduced compared to the control (i.e. an incubation that contained no inhibitor and represented 100% enzyme activity): % inhibition = $(1 - A/B) \times 100\%$, where A is the metabolite peak area ratio formed in the presence of test compound or inhibitor at 10 μ M and B is the metabolite peak area ratio formed without test compound or inhibitor in the incubation.

[568] **Example 48:** Mouse and Human Protein Binding Assay to Assess Free Drug Concentration

[569] The assay is to determine the plasma protein binding of the test compound in the plasma of human and animal species using a Rapid Equilibrium Dialysis (RED) device for equilibrium dialysis and LC-MS/MS for sample analysis. Test compound is spiked in. The stock solution of the test compound is prepared at 5 mM concentration. One μ L of 5 mM working solution into 1000 μ L plasma. The final concentration is 5 μ M. The spiked plasma is placed on a rocker and gently agitated for approximately 20 minutes. A volume of 300 μ L of the plasma sample containing 5 μ M test compound from each species is added to designate RED device donor chambers followed by addition of 500 μ L of potassium phosphate buffer to the corresponding receiver chambers in duplicate. The RED device is then sealed with sealing tape and shaken at 150 RPM for 4 hours at 37 °C. Post-dialysis donor and receiver compartment samples are prepared for LC-MS/MS analysis, including spiking samples with an internal standard for the bioanalytical analysis. Warfarin and propranolol are purchased from Sigma-Aldrich (St. Louis, MO), and used as positive controls for low and high plasma protein binding, respectively.

[570] All the samples are analyzed using an Agilent Technologies 6430 Triple Quad LC/MS system. The HPLC system consisted of Agilent 1290 Infinity Liquid Chromatograph coupled to an autosampler (Agilent 1290 Infinity

LC Injector HTC), and a Phenomenex Gemini-NX, C18, 3.0 μm or Phenomenex Lunar, C8, 5.0 μm HPLC column (Phenomenex, Torrance, CA), and are eluted with a mobile phase gradient consisting of Solution A (0.1% formic acid water) and Solution B (0.1% formic acid acetonitrile). The column temperature is maintained at 40 $^{\circ}\text{C}$. All the analytes are detected with positive-mode electrospray ionization (ES+). The percentage of the test compound bound to plasma is calculated following Equation 3 and 4.

Equation 3

$$\% \text{ Free test compound} = \frac{\text{Peak ratio} \left(\frac{\text{test compound}}{\text{Internal standard}} \right)_{\text{receiver compartment}}}{\text{Peak ratio} \left(\frac{\text{test compound}}{\text{Internal standard}} \right)_{\text{donor compartment}}} * 100$$

Equation 4

$$\% \text{ Plasma protein bound test compound} = 100 - \% \text{ Free test compound}$$

[571] **Example 49:** hERG (automated patch-clamp) Assay

[572] The human ether-a-go-go related gene (hERG) encodes the voltage gated potassium channel in the heart (IKr) which is involved in cardiac repolarization. Inhibition of the hERG causes QT interval prolongation and can lead to potential fatal events in humans. It is thus important to assess hERG inhibition early in drug discovery. A hERG automated patch-clamp assay is done using a hERG CHO-K1 cell line using an incubation time of 5 min. The degree of hERG inhibition (%) is obtained by measuring the tail current amplitude, which is induced by a one second test pulse to -40 mV after a two second pulse to +20 mV, before and after drug incubation (the difference current is normalized to control and multiplied by 100 to obtain the percent of inhibition). The percent hERG inhibition is measured in the presence of 10 μM test compound.

[573] **Example 50:** Rat Oral Exposure (%F)

[574] A pharmacokinetic profile for a test compound is assessed by single dosing in jugular vein cannulated male Sprague-Dawley rats. Animal weights are typically over 200 grams, and animals are allowed to acclimate to their new environment for at least 3 days prior to the initiation of any studies. One set of animals is dosed intravenous (IV) with test compound, 2 mg/kg in 20% HP-beta-CD or 20% Captisol, pH adjusted to ~5-6 by citric acid. IV dosing solution concentration is 0.4 mg/mL test compound. Time of blood sampling is 5 minutes, 15 minutes, 30 minutes, 90 minutes, 360 minutes, and 24 hours following IV dosing. Another set of animals is dosed oral (po) with test compound, 10 mg/kg in 20% HP-beta-CD or 20% Captisol, pH adjusted to ~3-4 by citric acid. Oral dosing solution concentration is 1 mg/mL test compound. Time of blood sampling is 15 minutes, 30 minutes, 90 minutes, 180 minutes, 360 minutes and 24 hours following oral (po) dosing. Blood samples (~0.1 mL/sample) are collected via jugular catheter and placed in tubes containing EDTA-K2 and stored on ice until centrifuged. The blood samples are centrifuged at approximately 6800g for 6 minutes at 2-8 $^{\circ}\text{C}$ and the resulting plasma is separated and stored frozen at approximately -80 $^{\circ}\text{C}$.

[575] All the plasma samples are analyzed using an Agilent Technologies 6430 Triple Quad LC/MS system, following the manufacturer instructions. All the analytes are detected with positive-mode electrospray ionization (ES+). A standard curve for each test compound is generated and used to measure test compound concentrations in the rat plasma samples. Based on the time course sampling, an area under the curve is calculated for the oral dose group and the intravenous dose group. Percentage rat bioavailability is calculated based on equation 5.

Equation 5

$$\% F (\text{rat}) = \frac{\text{AUC}_{\text{po}} * \text{Dose}_{\text{IV}}}{\text{AUC}_{\text{IV}} * \text{Dose}_{\text{po}}}, \text{ where } F \text{ is bioavailability, } \text{AUC}_{\text{po}} \text{ is area under curve of oral drug, } \text{AUC}_{\text{IV}} \text{ is area under curve of intravenous drug, } \text{Dose}_{\text{IV}} \text{ is the intravenous dose and } \text{Dose}_{\text{po}} \text{ is the oral dose.}$$

[576] **Example 51:** Kinase selectivity assay

[577] Eurofins DiscoverX (USA) commercially offers measurement on its KINOMEScan scanEDGE™ 97Panel comprising of 97 potential kinase off-targets. The KINOMEScan™ screening platform employs an active site-directed competition binding assay to quantitatively measure interactions between test compounds and kinases. Test compound is screened at 10 μM, and results for primary screen binding interactions are reported as ‘Percent control’, where lower numbers indicate stronger binding to a kinase being examined.

$$\text{Percent control} = \left(\frac{\text{test compound signal} - \text{positive control signal}}{\text{negative control signal} - \text{positive control signal}} \right) * 100$$

where the negative control = DMSO (100%Ctrl) and the positive control = control compound (0%Ctrl).

[578] **Example 52:** Mouse Oral Exposure (%F)

One set of animals is dosed intravenous (IV) with test compound, 2 mg/kg in 20% HP-beta-CD or 20% Captisol, pH adjusted to ~5-6 by citric acid at 10 mL/kg. Time of blood sampling is 5 minutes, 15 minutes, 30 minutes, 90 minutes, 360 minutes, and 24 hours following IV dosing. Another set of animals is dosed oral (po) with test compound, 10 mg/kg in 20% HP-beta-CD or 20% Captisol, pH adjusted to ~3-4 by citric acid at 10 mg/mL. Oral dosing solution concentration is 1 mg/mL test compound and 10 mL/kg. Time of blood sampling is 15 minutes, 30 minutes, 90 minutes, 180 minutes, 360 minutes and 24 hours following oral (po) dosing. Blood samples (~0.1 mL/sample) are collected via submandibular facial vein and placed in tubes containing EDTA-K2 and stored on ice until centrifuged. The blood samples are centrifuged at approximately 6800g for 6 minutes at 2-8 °C and the resulting plasma is separated and stored frozen at approximately -80 °C.

[580] Plasma samples are analyzed using an Agilent Technologies 6430 Triple Quad LC/MS system, following the manufacturer instructions. All the analytes are detected with positive-mode electrospray ionization (ES+). A standard curve for each test compound is generated and used to measure test compound concentrations in the mouse plasma samples. Based on the time course sampling, an area under the curve is calculated for the oral dose group and the intravenous dose group. Percentage mouse bioavailability is calculated based on equation 6.

Equation 6
