

RETENTION MEMBER FOR CONNECTOR SYSTEM

This application claims priority to U.S. Patent Application No. 10/842,397 filed May 10, 2004, and U.S. Patent Application No. 60/492,901 filed August 6, 2003.

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] The subject matter disclosed in this patent application is related to the subject matter disclosed and claimed in U.S. patent application no. 10/634,547, filed on August 5, 2003, which is a continuation-in-part of U.S. patent application no. 10/294,966, filed on November 14, 2002, which is a continuation-in-part of U.S. patent nos. 6,652,318 and 6,692,272. The contents of each of the above-referenced U.S. patents and patent applications are herein incorporated by reference in their entireties.

FIELD OF THE INVENTION

[0002] The invention relates to electrical connectors. More particularly, the invention relates to a retention member for aligning and stabilizing lead assemblies in an electrical connector.

BACKGROUND OF THE INVENTION

[0003] Electrical connectors provide signal connections between electronic devices using signal contacts. Often, the signal contacts are so closely spaced that undesirable cross-talk occurs between nearby signal contacts. Cross-talk occurs when one signal contact induces electrical interference in a nearby signal contact thereby compromising signal integrity. With electronic device miniaturization and high speed electronic communications becoming more prevalent, the reduction of cross-talk becomes a significant factor in connector design.

[0004] Thus, as the speed of electronics increases, connectors are desired that are capable of high speed communications. Most connectors focus on shielding to reduce cross-talk, thereby allowing higher speed communication. However, focusing on shielding addresses only one aspect of communication speed.

[0005] Therefore, a need exists for a high speed electrical connector design that addresses high speed communications, beyond the use of shielding.

**WO 2005/018052
SUMMARY OF THE INVENTION****PCT/US2004/024691**

[0006] The invention provides a retention member for aligning and stabilizing one or more insert molded lead assemblies (IMLAs) in an electrical connector. The retention member provides for alignment and stability in the x-, y-, and z-directions. Embodiments of such a retention member are shown in connection with a right angle header connector. The retention member provides stability by maintaining the true positioning of the terminal ends of the contacts. The retention member is expandable in length, and may be sized and shaped to fit a single header assembly or multiple position configurations.

[0007] Additional features and advantages of the invention will be made apparent from the following detailed description of illustrative embodiments that proceeds with reference to the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

[0008] The foregoing summary, as well as the following detailed description of preferred embodiments, is better understood when read in conjunction with the appended drawings. For the purpose of illustrating the invention, there is shown in the drawings exemplary constructions of the invention; however, the invention is not limited to the specific methods and instrumentalities disclosed. In the drawings:

[0009] FIGs. 1A and 1B show a right angle header connector assembly including an exemplary retention member and exemplary housing in accordance with the present invention;

[0010] FIGs. 1C and 1D show exemplary protrusions in accordance with the present invention;

[0011] FIGs. 2A and 2B are side views of insert molded lead assemblies in accordance with the present invention;

[0012] FIGs. 3A-3D are isometric, side, front, and top views, respectively, of the retention member shown in FIGs. 1A and 1B;

[0013] FIG. 3E is a top view of an alternate embodiment of a retention member shown in FIGs. 1A and 1B;

[0014] FIGs. 4A and 4B depict a right angle header connector assembly including a another exemplary housing in accordance with the present invention; and

[0015] FIG. 5 depicts a right angle header connector assembly including another exemplary retention member in accordance with the present invention.

DETAILED DESCRIPTION OF ILLUSTRATIVE EMBODIMENTS

WO 2005/018052

PCT/US2004/024691

[0016] FIGs. 1A and 1B show a right angle header connector assembly 100 comprising an exemplary retention member 120 in accordance with the present invention. As shown, the header assembly 100 may comprise a plurality of insert molded lead assemblies (IMLAs) 102A, 102B, which are described in detail with respect to FIGs. 2A and 2B, respectively. According to an aspect of the invention, each IMLA 102A, 102B may be used, without modification, for single-ended signaling, differential signaling, or a combination of single-ended signaling and differential signaling.

[0017] Each IMLA 102A, 102B comprises a plurality of electrically conductive contacts 104, which are arranged in respective linear contact arrays. Though the header assembly 100 shown comprises ten IMLAs, it should be understood that a connector may include any number of IMLAs.

[0018] The header assembly 100 includes an electrically insulating lead frame 108 through which the contacts 104 extend. Preferably, the lead frame 108 comprises a dielectric material such as a plastic. According to an aspect of the invention, the lead frame 108 is constructed from as little material as possible and the connector is air-filled to the extent possible. That is, the contacts 104 may be insulated from one another using air as a second dielectric. The use of air provides for a decrease in cross-talk and for a low-weight connector (as compared to a connector that uses a heavier dielectric material throughout, for example).

[0019] The contacts 104 comprise terminal ends 110 for engagement with a circuit board. Preferably, the terminal ends 110 are compliant terminal ends, though it should be understood that the terminals ends could be press-fit or any surface-mount or through-mount terminal ends, for example. The contacts also comprise mating ends 112 for engagement with complementary receptacle contacts. As shown, the connector 100 may also comprise a first embodiment housing 114. The housing 114 comprises a plurality of spaced apart dividing walls 114A, with each dividing wall defining a single notch 114B. The dividing walls 114A are spaced along the housing 114 and are spaced apart far enough to create an opening or slot ST that is large enough for the mating ends 112 of each IMLA 102A, 102B to pass through (approximately 0.9 mm or less, for example), and small enough to prevent the IMLAs 102A, 102B from moving in a first direction (e.g., in the negative x-direction shown in FIG. 1A, i.e., toward the housing 114). In a preferred embodiment, there may also be mechanical stops MS defined by each IMLA to prevent each IMLA from moving in the negative x-direction.

[0020] The housing 114 defines one or more notches 114B. Each notch 114B desirably receives a half taper or half ramp protrusion 114C on each IMLA 102A, 102B, so that the IMLAs 102A, 102B are locked in the opposite direction (e.g., the IMLAs are generally restrained

WO 2005/018052

PCT/US2004/024691

in the x-direction and the negative x-direction shown in FIG. 1A) after being inserted into the housing 114. For added reparability and strengthening, the protrusion 114C can be ramped in either or both of two directions, and thus may have a triangular 114C(1) or trapezoidal 114C(2) cross-section, as shown in FIGs. 1C and 1D, respectively. This design allows individual IMLAs 102A, 102B to be removed in the positive x-direction (i.e., away from the housing) after installation of the IMLA 102A, 102B.

[0021] The header assembly 100 also comprises a retention member 120 which provides for alignment and stability of the IMLAs 102A, 102B in the x-, y-, and z-directions. The retention member 120 provides stability by maintaining the true positioning of the terminal ends 110 of the contacts 104. The retention member 120 may have any length, and may be sized and shaped to fit a single header assembly or multiple position configurations. For example, the length L of the retention member 120 may correspond with the width W of a single header assembly, as shown, or may correspond to the combined width of a number of header assemblies disposed adjacent to one another.

[0022] An IMLA may have a thickness T of about 1.0 to 1.5 millimeters, for example. An IMLA spacing IS between adjacent IMLAs may be about 0.75 – 1.0 millimeters. Exemplary configurations include 150 position, for 1.0 inch slot centers, and 120 position, for 0.8 inch slot centers, all without interleaving shields. The IMLAs are stand-alone, which means that the IMLAs may be stacked into any centerline spacing desired for customer density or routing considerations. Examples include, but are not limited to, 2.0 mm, 2.5 mm, 3.0 mm, or 4.0 mm.

[0023] FIG. 2A is a side view of an IMLA 102A according to the invention. The IMLA 102A comprises a linear contact array of electrically conductive contacts 104, and a lead frame 108 through which the contacts 104 at least partially extend. The contacts 104 may be selectively designated as either ground or signal contacts.

[0024] For example, contacts a, b, d, e, g, h, j, k, m, and n may be defined to be signal contacts, while contacts c, f, i, l, and o may be defined to be ground contacts. In such a designation, signal contact pairs a-b, d-e, g-h, j-k, and m-n form differential signal pairs. Alternatively, contacts a, c, e, g, i, k, m, and o for example, may be defined to be signal contacts, while contacts b, d, f, h, j, l, and n may be defined to be ground contacts. In such a designation, signal contacts a, c, e, g, i, k, m, and o form single-ended signal conductors. In another designation, contacts a, c, e, g, h, j, k, m, and n, for example, may be defined to be signal contacts, while contacts b, d, f, i, l, and o may be defined to be ground contacts. In such a designation, signal contacts a, c, and e form single-ended signal conductors, and signal contact pairs g-h, j-k, and m-n form differential signal pairs. Again, it should be understood that, in

general, each of the contacts may thus be defined as either a signal contact or a ground contact depending on the requirements of the application.

[0025] In each of the designations described above in connection with IMLA 102A, contacts f and l are ground contacts. It should be understood that it may be desirable, though not necessary, for ground contacts to extend further than signal contacts so that the ground contacts make contact before the signal contacts do. Thus, the system may be brought to ground before the signal contacts mate. Because contacts f and l are ground contacts in either designation, the terminal ends of ground contacts f and l may be extended beyond the terminal ends of the other contacts so that the ground contacts g and m mate before any of the signal contacts mate and, still, the IMLA can support either designation without modification.

[0026] FIG. 2B is a side view of an IMLA 102B that comprises a linear contact array of electrically conductive contacts 104, and a lead frame 108 through which the contacts 104 at least partially extend. Again, the contacts 104 may be selectively designated as either ground or signal contacts.

[0027] For example, contacts b, c, e, f, h, i, k, l, n, and o may be defined to be signal contacts, while contacts a, d, g, j, and m may be defined to be ground contacts. In such a designation, signal contact pairs b-c, e-f, h-i, k-l, and n-o form differential signal pairs. Alternatively, contacts b, d, f, h, j, l, and n, for example, may be defined to be signal contacts, while contacts a, c, e, g, i, k, m, and o may be defined to be ground contacts. In such a designation, signal contacts b, d, f, h, j, l, and n form single-ended signal conductors. In another designation, contacts b, c, e, f, h, j, l, and n, for example, may be defined to be signal contacts, while contacts a, d, g, i, k, m, and o may be defined to be ground contacts. In such a designation, signal contact pairs b-c and e-f form differential signal pairs, and signal contacts h, j, l, and n form single-ended signal conductors. It should be understood that, in general, each of the contacts may thus be defined as either a signal contact or a ground contact depending on the requirements of the application.

[0028] In each of the designations described above in connection with IMLA 102B, contacts g and m are ground contacts, the terminal ends of which may extend beyond the terminal ends of the other contacts so that the ground contacts g and m mate before any of the signal contacts mate.

[0029] Also, though the IMLAs shown in FIGs. 2A and 2B are shown to include fifteen contacts each, it should be understood that an IMLA may include any desired number of contacts. For example, IMLAs having twelve or nine contacts are also contemplated. A connector according to the invention, therefore, may include any number of contacts.

WO 2005/018052

PCT/US2004/024691

[0030] Each IMLA 102A, 102B comprises an arm portion 150 having a button end 152. As will be described in detail below, the arm portion 150 may be configured such that the retention member 120 may fit snugly between the arm portion 150 and a first face 156 of the IMLA 102. The arm portion 150 may be further configured such that a second face 154 of the IMLA 102 may rest on top of the retention member 120. Thus, the IMLA 102 may be designed such that the arm portion 150 straddles the retention member 120. An example is shown in FIG. 4A, where the arm portion 150 of the IMLA 102 extends over the retention member 120. However, as shown in FIG. 1A, for example, the button end 152 acts to push or bias the retainer 120 in the negative x-direction (toward the housing 114).

[0031] FIGs. 3A-3D provide isometric, side, front, and top views, respectively, of a retention member according to the invention. As shown, the retention member 120 may be formed, by molding for example, as a single piece of material. The material may be an electrically insulating material, such as a plastic, for example. As an example, the retention member may have a height H of about 14 mm, a length L of about 20 mm, and a depth D of about 2-5 mm. The retention member shown is adapted to retain ten IMLAs in a single connector. Thus, the retention member shown has a length L that corresponds to the typical width of a connector comprising ten IMLAs.

[0032] The retention member 120 comprises a wall portion 122 having a first side 122A and a second side 122B. When secured to the connector, the first side 122A of the wall portion 122 abuts the IMLAs. Thus, the wall portion 122 prevents the IMLAs from moving in the x-direction (as shown in FIG. 1A, for example). As described above, the arm portion 150 of each IMLA straddles the top 122T of the wall portion 122. The end 152 of the arm portion 150 abuts the second side 122B of the wall portion 122 of the retention member 120.

[0033] The retention member 120 comprises a plurality of protrusions, or nubs, 124 disposed along and extending from the first side 112A of the wall portion 122. The nubs 124 are sized, shaped, and located such that the nubs 124 form a plurality of channels 126. Each channel 126 has a channel spacing CS, which is the distance between adjacent nubs 124 in a given row of nubs 124. The channel spacing CS is chosen such that an IMLA may be received and fit snugly within each channel 126 between adjacent nubs 124. The nubs 124 serve to align the IMLAs truly in the z-direction, and prevent the IMLAs from significantly moving in the y-direction (as shown in FIG. 1A, for example). A rib RB can also be added to the second side 122B of each IMLA to help prevent movement of the IMLAs in the negative z-direction. The button end 152 of arm portion 150 of each IMLA preferably snap fits over a corresponding rib RB.

WO 2005/018052

PCT/US2004/024691

[0034] Each nub 124 has a width w , length l , and depth d . The width w of each nub 124 is desirably chosen to provide the desired channel spacing CS . In an example embodiment, the width w of each nub is approximately 1 mm, and the channel spacing CS is the same size or slightly larger than the width of each IMLA, so that a clearance fit is obtained between the IMLAs and the retainer. However, other suitable connection methods are also contemplated, such as a dovetail fit between the IMLAs and the retainer. The depth d of each nub 124 is desirably chosen to provide sufficient resistance in the y -direction to keep the IMLA from moving in the y -direction. In an example embodiment, the nub depth d is approximately 1 mm. The length l of each nub 124 is desirably chosen to minimize the amount of material required to form the retention member 120, yet still provide the desired stabilization and alignment of IMLAs. In an example embodiment, the nub length l is approximately 1 mm. It should be understood, however, that the nubs 124 may have any width w , length l , and depth d desired for a particular application.

[0035] Minimizing the amount of material in the retention member 120 contributes to minimizing the weight of the connector. For example, as shown, each nub 124 may have a rounded end 124e, shown in FIG. 3E, which serves to reduce the weight of the retention member 120, as well as to facilitate engagement of the retention member 120 with the IMLAs. Though two rows of nubs 124 are shown, it should be understood that a single row of nubs 124 may suffice, or that more than two rows of nubs 124 may be employed.

[0036] The retention member 120 also comprises a plurality of seats 128 disposed along and extending from the first side 122A of the wall portion 122. The IMLAs preferably pass between seats 128. Thus, the retention member 120 prevents the IMLAs from moving in the z -direction (as shown in FIG. 1A, for example). The seats 128 are configured to have a seat spacing SS between them, as shown in FIG. 3C, for example. The seat spacing SS may be smaller than the channel spacing CS , as shown, to provide compliance with IMLAs that have a lead frame 108 that does not have a uniform thickness in the area of the seats 128.

[0037] The second side 122B of an exemplary retention member 120 preferably comprises a shoulder 130, a pair of grooves 132, 134, and a foot portion 136, as shown in FIG. 3B, for example.

[0038] FIGs. 4A and 4B depict an exemplary retention member 120 as part of a right angle header connector assembly including an exemplary housing 300 according to the invention. The housing 300 is similar to the housing 114 described above, and comprises a plurality of spaced apart dividing walls 300A, each of which may include one or more notches 300B(1), 300B(2). The dividing walls 300A are desirably spaced apart far enough to create an

WO 2005/018052

PCT/US2004/024691

opening between them that is large enough for the mating ends 112 of each IMLA 102A, 102B to pass through (e.g., approximately 0.9mm or less), and small enough to prevent the IMLAs 102A, 102B from moving in the x-direction (i.e., toward the housing 300).

[0039] Each notch 300B(1), 300B(2) receives a half taper or half ramp protrusion 300C on each IMLA 102A, 102B, so that the IMLAs 102A, 102B are locked in the negative x-direction (i.e., away from the housing 300) after being inserted into the housing 300. For added reparability and strengthening, the protrusion 300C can be ramped in either or both of two directions, and thus may have a triangular or trapezoidal cross-section, as described above. This design allows individual IMLAs 102A, 102B to be removed in the negative x-direction (i.e., away from the housing 300) after installation of the IMLAs 102A, 102B.

[0040] The exemplary housing 300 desirably allows for IMLAs to be attached to the housing 300 in a staggered pattern. For example, one protrusion 300C can engage a first notch 300B(1) and a protrusion 300C on a neighboring IMLA can engage a second notch 300B(2). This arrangement increases stability of the overall connector.

[0041] FIG. 5 shows an alternate embodiment of a retaining member 400 according to the invention. The retaining member 400 is generally in the form of a strip 410 that snap fits into recesses 420 defined by a backbone of each IMLA. Spaced apart spacing members 430 extend approximately 1-2 mm, for example, between the individual IMLAs. The length of the strip 410 and the number of spacing members 430 is desirably dependent on the number of IMLAs. In the example shown in FIG. 5, the overall length SL of the strip 410 may be approximately 19 mm, and the overall length L of each spacing member may be approximately 9 mm.

[0042] While the present invention has been described in connection with the preferred embodiments of the various figures, it is to be understood that other similar embodiments may be used or modifications and additions may be made to the described embodiments for performing the same function of the present invention without deviating therefrom. Therefore, the present invention should not be limited to any single embodiment, but rather should be construed in breadth and scope in accordance with the appended claims.

What is claimed:

1. An electrical connector comprising:
a connector housing;
a lead assembly comprising a mating end that extends into the housing in a mating direction; and
a lead assembly retainer comprising a plurality of retention surfaces that prevent the lead assembly from moving in at least one direction, wherein
the lead assembly further comprises a biasing member that biases the retainer in the mating direction.
2. The electrical connector of claim 1, wherein the lead assembly further comprises an arm portion that extends over the retainer and prevents the lead assembly from moving in the mating direction relative to adjacent lead assemblies of the electrical connector.
3. The electrical connector of claim 1, wherein the retainer prevents the lead assembly from moving in a direction opposite the mating direction.
4. The electrical connector of claim 1, wherein the connector housing comprises a mechanical stop, and the lead assembly abuts the mechanical stop such that the mechanical stop prevents the lead assembly from moving in the mating direction.
5. The electrical connector of claim 1, wherein the connector housing comprises first and second dividing walls, the lead assembly is disposed between the dividing walls, and the dividing walls are spaced apart by a distance that is small enough to prevent the lead assembly from moving in the mating direction.
6. The electrical connector of claim 5, wherein at least one of said first and second dividing walls comprises a notch, and the lead assembly comprises a protrusion that is

received into the notch and prevents the lead assembly from moving in a direction opposite the mating direction.

7. The electrical connector of claim 6, wherein the protrusion has a ramped configuration.

8. The electrical connector of claim 6, wherein the protrusion has a triangular cross-section.

9. The electrical connector of claim 6, wherein the protrusion has a trapezoidal cross-section.

10. An electrical connector comprising:

a connector housing comprising first and second dividing walls, each said dividing wall defining a respective notch, said notches disposed in a staggered relationship to one another;

a first lead assembly received in the connector housing in a mating direction, the first lead assembly comprising a first protrusion that is received into the notch in the first dividing wall and prevents the first lead assembly from moving in a direction opposite the mating direction; and

a second lead assembly comprising a second protrusion that is received into the notch in the second dividing wall and prevents the second lead assembly from moving in a direction opposite the mating direction.

11. The electrical connector of claim 10, wherein the dividing walls are spaced apart by a distance that is small enough to prevent the first lead assembly from moving in the mating direction.

12. The electrical connector of claim 10, wherein the first protrusion has a ramped configuration.

13. The electrical connector of claim 10, wherein the first protrusion has a triangular cross-section.

14. The electrical connector of claim 10, wherein the first protrusion has a trapezoidal cross-section.

15. The electrical connector of claim 10, wherein the first protrusion has a rounded end.

16. An electrical connector, comprising:

a connector housing;

a lead assembly comprising a mating end that extends into the housing in a mating direction and a tab that extends from the lead assembly in a direction opposite from the mating direction;

a retainer for retaining the lead assembly in the electrical connector, the retainer comprising a wall portion having a first side and an opposite second side, wherein the lead assembly is positioned adjacent to the first side of the retainer and the tab extends over the opposite second side of the retainer.

17. The electrical connector of claim 16, wherein the tab is resilient.
