

ABSTRACT

A method and server for processing transactions between clients of a subscriber entity and a non-subscriber entity are provided. The method comprises: receiving, from a sender entity server, a request for a transaction between the sender entity and a client of a recipient entity; in response to the recipient entity being the non-subscriber entity; transmitting a first portion of the client's ID to a first anonymizing entity server for generating a first anonymized portion; transmitting a second portion of the client's ID to a second anonymizing entity server for generating a second anonymized portion; combining the first and second portions, thereby generating the client's anonymized ID; determining, based on the client's anonymized ID, a client's evaluation score of the client of the recipient entity; and in response to the client's evaluation score being greater than a predetermined threshold, allowing the request for the transaction between the sender and recipient entities.
