

FLAT DATA ROUTING CHAIN

ABSTRACT

A routing server may receive a request to establish a connection from an originating node to a terminating node. The routing server may determine a route for the connection based on data in the request. Determining the route may comprise selecting at least two of the originating node, at least one virtual node, and the at least one terminating node. The originating node and/or at least one virtual node may establish at least one rule for routing data therethrough. The routing server may establish the connection between the originating node and the at least one terminating node. The routing server may route the data between the originating node and the at least one terminating node according to the at least one rule.
