

Transmission system with adaptive channel encoder and decoder.

The present invention relates to a transmission system comprising a transmitter coupled via a transmission channel to a receiver, in which the transmitter comprises a channel encoder for encoding source symbols into coded symbols, and in which the receiver comprises a source decoder for deriving reconstructed source symbols from the coded symbols received from the transmission channel, the transmission system comprising coding property setting means for setting at least one coding property of the channel encoder and the channel decoder.

The present invention also relates to a transmitter and a receiver for use in such a transmission system. The invention further relates to a transmission method.

Such transmission systems can be used in applications where the quality of the transmission channel shows considerable variations. To enable a virtual error free transmission over such a transmission channel, in the transmitter the source symbols are encoded using a channel encoder according a code which has error correcting and/or error detecting capabilities. In the receiver the source symbols are reconstructed by a channel decoder. Useful codes can include convolutional codes and several types of block codes such as Reed-Solomon codes. Also a combination of a convolutional code with a block code is often used.

The ratio between the number of source symbols and the number of channel symbols of such a code is called the rate of the code. The error correction capabilities of such a code depend heavily on the rate of the code. In case of a transmission channel with a strongly varying transmission quality the rate of the used channel code should be chosen to obtain virtually error free transmission at the worst channel conditions. This leads to a loss of useful transmission capacity when the transmission quality is high.

To prevent this loss of transmission capacity, the transmission system can set the at least one coding property e.g. the rate of the channel encoder, in dependence on the transmission quality. It is further observed that it can be desirable to set the coding property of the channel encoder and decoder in dependence of the type of source symbols to be transmitted. E.g. the transmission of data signals representing computer files, requires bit error rates below 10^{-10} , and the transmission of digitized speech signal may require bit error rates only below 10^{-4} .

The problem to be solved by the present invention is how to inform the receiver of a change of the at least one property of the channel encoder, in order to be able to decode it.

To solve this problem the transmission system according to the present invention is characterized in that the transmitter comprises a further channel encoder for
5 obtaining an encoded coding property from the at least one coding property, in that the transmitter is arranged for transmitting the encoded coding property to the receiver, in that the receiver comprises a further channel decoder for obtaining the at least one coding property from the encoded coding property, and in that the receiver is arranged for setting the at least one
10 coding property of the channel decoder according to the at least one coding property.

By using a separate channel for transmitting the at least one coding property, it is obtained that the transmission of this coding property does not depend on the (main) channel coding scheme which might fail under rapidly changing channel conditions. Because in general the amount of information needed to communicate the at least one coding property is very small,
15 a very strong error correcting coding scheme can be used in the further channel encoder.

An embodiment of the invention is characterized in that that the further channel encoder comprises a block encoder, and in that the further channel decoder comprises a block decoder.

The use of a combination of a block encoder and a block decoder enables an
20 easy decoding, in particular when the amount of information to be transmitted is low.

A further embodiment of the present invention is characterized in that the encoded symbols are arranged in frames, and in that the transmitter is arranged for splitting the encoded coding property into at least two parts, and for transmitting said at least two parts in subsequent frames.

25 By splitting the encoded coding property in at least two parts which are transmitted in subsequent frames, it becomes possible to choose longer codewords in order to obtain a further increased error correcting capability.

A still further embodiment of the present invention is characterized in that the transmission system comprises transmission quality determining means for deriving a
30 transmission quality measure from the channel decoder in the receiver, and means for transmitting via a further transmission channel the quality measure to the transmitter.

By using a return link from the receiver to the transmitter, it becomes easy to obtain a transmission quality at the transmitter. In a similar way, it is also possible to use transmission quality dependent channel encoding on a full duplex link.

The present invention will now be explained with reference to the drawing figures.

Fig. 1 shows a transmission system according to the invention.

Fig. 2 shows a frame structure use in the transmission system according to Fig.

5 1.

The transmission system according to Fig. 1, comprises three important elements being the TRAU (Transcoder and Rate Adapter Unit) 2, the BTS (Base Transceiver Station) 4 and the Mobile Station 6. The TRAU 2 is coupled to the BTS 4 via the A-bis interface 8. The BTS 4 is coupled to the Mobile Unit 6 via an Air Interface 10.

10 A main signal being here a speech signal to be transmitted to the Mobile Unit 6, is applied to a speech encoder 12. A first output of the speech encoder 12 carrying an encoded speech signal, also referred to as source symbols, is coupled to a channel encoder 14 via the A-bis interface 8. A second output of the speech encoder 12, carrying a background noise level indicator B_D is coupled to an input of a system controller 16. A first output of the system
15 controller 16 carrying a coding property, being here a downlink rate assignment signal R_D is coupled to the speech encoder 12 and, via the A-bis interface, to coding property setting means 15 in the channel encoder 14 and to a further channel encoder being here a block coder 18. A second output of the system controller 16 carrying an uplink rate assignment signal R_U is coupled to a second input of the channel encoder 14. The two-bit rate assignment signal R_U is
20 transmitted bit by bit over two subsequent frames. The rate assignment signals R_D and R_U constitute a request to operate the downlink and the uplink transmission system on a coding property represented by R_D and R_U respectively.

It is observed that the value of R_D transmitted to the mobile station 6 can be overruled by the coding property sequencing means 13 which can force a predetermined
25 sequence of coding properties, as represented by the rate assignment signal R_U , onto the block encoder 18 the channel encoder 14 and the speech encoder 13. This predetermined sequence can be used for conveying additional information to the mobile station 6, without needing additional space in the transmission frame. It is possible that more than one predetermined sequence of coding properties is used. Each of the predetermined sequences of coding properties corresponds
30 to a different auxiliary signal value.

The system controller 16 receives from the A-bis interface quality measures Q_U and Q_D indicating the quality of the air interface 10 (radio channel) for the uplink and the

downlink. The quality measure Q_U is compared with a plurality of threshold levels, and the result of this comparison is used by the system controller 16 to divide the available channel capacity between the speech encoder 36 and the channel encoder 38 of the uplink. The signal Q_D is filtered by low pass filter 22 and is subsequently compared with a plurality of threshold values.

- 5 The result of the comparison is used to divide the available channel capacity between the speech encoder 12 and the channel encoder 14. For the uplink and the downlink four different combinations of the division of the channel capacity between the speech encoder 12 and the channel encoder 14 are possible. These possibilities are presented in the table below.

R_X	$R_{\text{SPEECH}}(\text{kbit/s})$	R_{CHANNEL}	$R_{\text{TOTAL}}(\text{kbit/s})$
0	5.5	$\frac{1}{4}$	22.8
1	8.1	$\frac{3}{8}$	22.8
2	9.3	$\frac{3}{7}$	22.8
3	11.1	$\frac{1}{2}$	22.8
0	5.5	$\frac{1}{2}$	11.4
1	7.0	$\frac{5}{8}$	11.4
2	8.1	$\frac{3}{4}$	11.4
3	9.3	$\frac{6}{7}$	11.4

10

Table 1

- From Table 1 it can be seen that the bitrate allocated to the speech encoder 12 and the rate of the channel encoder increases with the channel quality. This is possible because at better channel conditions the channel encoder can provide the required transmission quality (Frame Error Rate) using a lower bitrate. The bitrate saved by the larger rate of the channel encoder is exploited by allocating it to the speech encoder 12 in order to obtain a better speech quality. It is observed that the coding property is here the rate of the channel encoder 14. The coding property setting means 15 are arranged for setting the rate of the channel encoder 14 according to the coding property supplied by the system controller 16.

20

Under bad channel conditions the channel encoder needs to have a lower rate in order to be able to provide the required transmission quality. The channel encoder will be a variable rate convolutional encoder which encodes the output bits of the speech encoder 12 to

which an 8 bit CRC is added. The variable rate can be obtained by using different convolutional codes having a different basic rate or by using puncturing of a convolutional code with a fixed basic rate. Preferably a combination of these methods is used.

In Table 2 presented below the properties of the convolutional codes given in

5 Table 1 are presented. All these convolutional codes have a value v equal to 5.

Pol/Rate	1/2	1/4	3/4	3/7	3/8	5/8	6/7
G ₁ =43							000002
G ₂ =45				003		00020	
G ₃ =47			001		301	01000	
G ₄ =51		4				00002	101000
G ₅ =53				202			
G ₆ =55		3					
G ₇ =57	2			020	230		
G ₈ =61			002				
G ₉ =65	1		110		022	02000	000001
G ₁₀ =66							
G ₁₁ =67		2					000010
G ₁₂ =71				001			
G ₁₃ =73					010		
G ₁₄ =75				110	100	10000	000100
G ₁₅ =77		1				00111	010000

Table 2

In Table 2 the values G_i represent the generator polynomials. The generator polynomials G(n) are defined according to:

$$G_i(D) = g_0 \oplus g_1 \cdot D \oplus \dots \oplus g_{n-1} \cdot D^{n-1} \oplus g_n \cdot D^n \quad (A)$$

In (1) $\oplus$ is a modulo-2 addition. i is the octal representation of the sequence $g_0, g_1, \dots, g_{n-1}, g_n$.

For each of the different codes the generator polynomials used in it, are indicated by a number in the corresponding cell. The number in the corresponding cell indicates for which of the source symbols, the corresponding generator polynomial is taken into account. Furthermore said number indicates the position of the coded symbol derived by using said polynomial in the sequence of source symbols. Each digit indicates the position in the sequence of channel symbols, of the channel symbol derived by using the indicated generator polynomial. For the rate 1/2 code, the generator polynomials 57 and 65 are used. For each source symbol first

the channel symbol calculated according to polynomial 65 is transmitted, and secondly the channel symbol according to generator polynomial 57 is transmitted. In a similar way the polynomials to be used for determining the channel symbols for the rate 1/4 code can be determined from Table 3. The other codes are punctured convolutional codes. If a digit in the table is equal to 0, it means that the corresponding generator polynomial is not used for said particular source symbol. From Table 2 can be seen that some of the generator polynomials are not used for each of the source symbols. It is observed that the sequences of numbers in the table are continued periodically for sequences of input symbols longer than 1, 3, 5 or 6 respectively.

It is observed that Table 1 gives the values of the bitrate of the speech encoder 12 and the rate of the channel encoder 14 for a full rate channel and a half rate channel. The decision about which channel is used is taken by the system operator, and is signaled to the TRAU 2, the BTS 4 and the Mobile Station 6, by means of an out of band control signal, which can be transmitted on a separate control channel. 16. To the channel encoder 14 also the signal R_U is applied.

The block coder 18 is present to encode the selected rate R_D for transmission to the Mobile Station 6. This rate R_D is encoded in a separate encoder for two reasons. The first reason is that it is desirable to inform the channel decoder 28 in the mobile station of a new rate R_D before data encoded according to said rate arrives at the channel decoder 28. A second reason is that it is desired that the value R_D is better protected against transmission errors than it is possible with the channel encoder 14. To enhance the error correcting properties of the encoded R_D value even more, the codewords are split in two parts which are transmitted in separate frames. This splitting of the codewords allows longer codewords to be chosen, resulting in further improved error correcting capabilities.

The block coder 18 encodes the coding property R_D which is represented by two bits into an encoded coding property encoded according to a block code with codewords of 16 bits if a full rate channel is used. If a half rate channel is used, a block code with codewords of 8 bits are used to encode the coding property. The codewords used are presented below in Table 3 and Table 4.

R _D [1]	R _D [2]	C ₀	C ₁	C ₂	C ₃	C ₄	C ₅	C ₆	C ₇
0	0	0	0	0	0	0	0	0	0
0	1	0	0	1	1	1	1	0	1
1	0	1	1	0	1	0	0	1	1
1	1	1	1	1	0	1	1	1	0

Table 3 : Half Rate Channel

5

R _D [1]	R _D [2]	C ₀	C ₁	C ₂	C ₃	C ₄	C ₅	C ₆	C ₇	C ₈	C ₉	C ₁₀	C ₁₁	C ₁₂	C ₁₃	C ₁₄	C ₁₅
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
0	1	0	0	1	1	1	1	0	1	0	0	1	1	1	1	0	1
1	0	1	1	0	1	0	0	1	1	1	1	0	1	0	0	1	1
1	1	1	1	1	0	1	1	1	0	1	1	1	0	1	1	1	0

Table 4 : Full Rate Channel

From Table 3 and Table 4, it can be seen that the codewords used for a full rate channel are obtained by repeating the codewords used for a half rate channel, resulting in improved error correcting properties. In a half-rate channel, the symbols C₀ to C₃ are transmitted in a first frame, and the bits C₄ to C₇ are transmitted in a subsequent frame. In a full-rate channel, the symbols C₀ to C₇ are transmitted in a first frame, and the bits C₈ to C₁₅ are transmitted in a subsequent frame.

The outputs of the channel encoder 14 and the block encoder 18 are transmitted in time division multiplex over the air interface 10. It is however also possible to use CDMA for transmitting the several signals over the air interface 10. In the Mobile Station 6, the signal received from the air interface 10 is applied to a channel decoder 28 and to a further channel decoder being here a block decoder 26. The block decoder 26 is arranged for deriving the coding

property represented by the R_D bits by decoding the encoded coding property represented by codeword $C_0 \cdots C_N$, in which N is 7 for the half rate channel and N is 15 for the full rate channel.

The block decoder 26 is arranged for calculating the correlation between the
 5 four possible codewords and its input signal. This is done in two passes because the codewords are transmitted in parts in two subsequent frames. After the input signal corresponding to the first part of the codeword has been received, the correlation value between the first parts of the possible codewords and the input value are calculated and stored. When in the subsequent frame, the input signal corresponding to the second part of the codeword is received, the correlation
 10 value between the second parts of the possible codewords and the input signal are calculated and added to the previously stored correlation value, in order to obtain the final correlation values. The value of R_D corresponding to the codeword having the largest correlation value with the total input signal, is selected as the received codeword representing the coding property, and is passed to the output of the block decoder 26. The output of the block decoder 26 is connected to a
 15 control input of the property setting means in the channel decoder 28 and to a control input of the speech decoder 30 for setting the rate of the channel decoder 28 and the bitrate of the speech decoder 30 to a value corresponding to the signal R_D .

The channel decoder 28 decodes its input signal, and presents at a first output an encoded speech signal to an input of a speech decoder 30.

20 The channel decoder 28 presents at a second output a signal BFI (Bad Frame Indicator) indicating an incorrect reception of a frame. This BFI signal is obtained by calculating a checksum over a part of the signal decoded by a convolutional decoder in the channel decoder 28, and by comparing the calculated checksum with the value of the checksum received from the air interface 10.

25 The speech decoder 30 is arranged for deriving a replica of the speech signal of the speech encoder 12 from the output signal of the channel decoder 20. In case a BFI signal is received from the channel decoder 28, the speech decoder 30 is arranged for deriving a speech signal based on the previously received parameters corresponding to the previous frame. If a plurality of subsequent frames are indicated as bad frame, the speech decoder 30 can be arranged
 30 for muting its output signal.

The channel decoder 28 provides at a third output the decoded signal R_U . The signal R_U represents a coding property being here a bitrate setting of the uplink. Per frame the signal R_U comprises 1 bit (the RQI bit). In a deformatter 34 the two bits received in subsequent

frames are combined in a bitrate setting R_U' for the uplink which is represented by two bits. This bitrate setting R_U' which selects one of the possibilities according to Table 1 to be used for the uplink is applied to a control input of a speech encoder 36, to a control input of a channel encoder 38, and to an input of a further channel encoder being here a block encoder 40. If the channel decoder 20 signals a bad frame by issuing a BFI signal, the decoded signal R_U is not used for setting the uplink rate, because it is regarded as unreliable

The channel decoder 28 provides at a fourth output a quality measure MMD_d . This measure MMD can easily be derived when a Viterbi decoder is used in the channel decoder. This quality measure is filtered in the processing unit 32 according to a first order filter. For the output signal of the filter in the processing unit 32 can be written:

$$MMD'[n] = (1 - \alpha) \cdot MMD[n] + \alpha \cdot MMD'[n-1] \quad (B)$$

After the bitrate setting of the channel decoder 28 has been changed in response to a changed value of R_D , the value of $MMD'[n-1]$ is set to a typical value corresponding to the long time average of the filtered MMD for the newly set bitrate and for a typical downlink channel quality. This is done to reduce transient phenomena when switching between different values of the bitrate.

The output signal of the filter is quantized with 2 bits to a quality indicator Q_D . The quality indicator Q_D is applied to a second input of the channel encoder 38. The 2 bit quality indicator Q_D is transmitted once each two frames using one bit position in each frame.

A speech signal applied to the speech encoder 36 in the mobile station 6 is encoded and passed to the channel encoder 38. The channel encoder 38 calculates a CRC value over its input bits, adds the CRC value to its input bits, and encodes the combination of input bits and CRC value according to the convolutional code selected by the signal R_U' from Table 1.

The block encoder 40 encodes the signal R_U' represented by two bits according to Table 3 or Table 4 dependent on whether a half-rate channel or a full-rate channel is used.

Also here only half a codeword is transmitted in a frame.

The output signals of the channel encoder 38 and the block encoder 40 in the mobile station 6 are transmitted via the air interface 10 to the BTS 4. In the BTS 4, the block coded signal R_U' is decoded by a further channel decoder being here a block decoder 42. The operation of the block decoder 42 is the same as the operation of the block decoder 26. At the output of the block decoder 42 a decoded coding property represented by a signal R_U'' is

available. This decoded signal R_U is applied to a control input of coding property setting means in a channel decoder 44 and is passed, via the A-bis interface, to a control input of a speech decoder 48.

In the BTS 4, the signals from the channel encoder 38, received via the air interface 10, are applied to the channel decoder 44. The channel decoder 44 decodes its input signals, and passes the decoded signals via the A-bis interface 8 to the TRAU 2. The channel decoder 44 provides a quality measure MMD_u representing the transmission quality of the uplink to a processing unit 46. The processing unit 46 performs a filter operation similar to that performed in the processing unit 32 and 22. Subsequently the result of the filter operation is quantized in two bits and transmitted via the A-bis interface 8 to the TRAU 2.

In the system controller 16, a decision unit 20 determines the bitrate setting R_U to be used for the uplink from the quality measure Q_U . Under normal circumstances, the part of the channel capacity allocated to the speech coder will increase with increasing channel quality. The rate R_U is transmitted once per two frames.

The signal Q_D received from the channel decoder 44 is passed to a processing unit 22 in the system controller 16. In the processing unit 22, the bits representing Q_D received in two subsequent frames are assembled, and the signal Q_D is filtered by a first order low-pass filter, having similar properties as the low pass filter in the processing unit 32.

The filtered signal Q_D is compared with two threshold values which depend on the actual value of the downlink rate R_D . If the filtered signal Q_D falls below the lowest of said threshold value, the signal quality is too low for the rate R_D , and the processing unit switches to a rate which is one step lower than the present rate. If the filtered signal Q_D exceeds the highest of said threshold values, the signal quality is too high for the rate R_D , and the processing unit switches to a rate which is one step higher than the present rate. The decision taking about the uplink rate R_U is similar as the decision taking about the downlink rate R_D .

Again, under normal circumstances, the part of the channel capacity allocated to the speech coder will increase with increasing channel quality. Under special circumstances the signal R_D can also be used to transmit a reconfiguration signal to the mobile station. This reconfiguration signal can e.g. indicate that a different speech encoding/decoding and or channel coding/decoding algorithm should be used. This reconfiguration signal can be encoded using a special predetermined sequence of R_D signals. This special predetermined sequence of R_D signals

is recognised by an escape sequence decoder 31 in the mobile station, which is arranged for issuing a reconfiguration signal to the effected devices when a predetermined (escape) sequence has been detected. The escape sequence decoder 30 can comprise a shift register in which subsequent values of R_D are clocked. By comparing the content of the shift register with the predetermined sequences, it can easily be detected when an escape sequence is received, and which of the possible escape sequences is received..

An output signal of the channel decoder 44, representing the encoded speech signal, is transmitted via the A-Bis interface to the TRAU 2. In the TRAU 2, the encoded speech signal is applied to the speech decoder 48. A signal BFI at the output of the channel decoder 44, indicating the detecting of a CRC error, is passed to the speech decoder 48 via the A-Bis interface 8. The speech decoder 48 is arranged for deriving a replica of the speech signal of the speech encoder 36 from the output signal of the channel decoder 44. In case a BFI signal is received from the channel decoder 44, the speech decoder 48 is arranged for deriving a speech signal based on the previously received signal corresponding to the previous frame, in the same way as is done by the speech decoder 30. If a plurality of subsequent frames are indicated as bad frame, the speech decoder 48 can be arranged for performing more advanced error concealment procedures.

Fig. 2 shows the frame format used in a transmission system according to the invention. The speech encoder 12 or 36 provides a group 60 of C-bits which should be protected against transmission errors, and a group 64 of U-bits which do not have to be protected against transmission errors. The further sequence comprises the U-bits. The decision unit 20 and the processing unit 32 provide one bit RQI 62 per frame for signalling purposes as explained above.

The above combination of bits is applied to the channel encoder 14 or 38 which first calculates a CRC over the combination of the RQI bit and the C-bits, and appends 8 CRC bits behind the C-bits 60 and the RQI bit 62. The U-bits are not involved with the calculation of the CRC bits. The combination 66 of the C-bits 60 and the RQI bit 62 and the CRC bits 68 are encoded according to a convolutional code into a coded sequence 70. The encoded symbols comprise the coded sequence 70. The U-bits remain unchanged.

The number of bits in the combination 66 depends on the rate of the convolutional encoder and the type of channel used, as is presented below in Table 5.

#bits/rate	1/2	1/4	3/4	3/7	3/8	5/8	6/7
Full rate	217	109		189	165		

Half rate	105		159			125	174
-----------	-----	--	-----	--	--	-----	-----

Table 5

The two R_A bits which represent the coding property are encoded in codewords 74, which represent the encoded coding property, according the code displayed in Table 3 or 4, dependent on the available transmission capacity (half rate or full rate). This encoding is only performed once in two frames. The codewords 74 are split in two parts 76 and 78 and transmitted in the present frame and the subsequent frame.

Claims

1. Transmission system comprising a transmitter coupled via a transmission channel to a receiver, in which the transmitter comprises a channel encoder for encoding source symbols into coded symbols, and in which the receiver comprises a source decoder for deriving reconstructed source symbols from the coded symbols received from the transmission channel,
5 the transmission system comprising coding property setting means for setting at least one coding property of the channel encoder and the channel decoder, characterized in that the transmitter comprises a further channel encoder for obtaining an encoded coding property from the at least one coding property, in that the transmitter is arranged for transmitting the encoded coding property to the receiver, in that the receiver comprises a further channel decoder for obtaining the
10 at least one coding property from the encoded coding property, and in that the receiver is arranged for setting the at least one coding property of the channel decoder according to the at least one coding property.
2. Transmission system according to claim 1, characterized in that the further
15 channel encoder comprises a block encoder, and in that the further channel decoder comprises a block decoder.
3. Transmission system according to claim 1 or 2, characterized in that the
20 encoded symbols are arranged in frames, and in that the transmitter is arranged for splitting the encoded coding property into at least two parts, and for transmitting said at least two parts in subsequent frames.
4. Transmission system according to one of the previous claims, characterized in
25 that the transmission system comprises transmission quality determining means for deriving a transmission quality measure from the channel decoder in the receiver, and means for transmitting via a further transmission channel the quality measure to the transmitter.
5. Transmitter comprising a channel encoder for encoding source symbols into coded symbols and property setting means for setting at least one coding property of the channel

encoder characterized in that the transmitter comprises a further channel encoder for obtaining an encoded coding property from the at least one coding property, and in that the transmitter is arranged for transmitting the encoded coding property.

5 6. Receiver comprising a source decoder for deriving reconstructed source symbols from received coded symbols, and coding property setting means for setting at least one coding property of the channel decoder characterized in that the receiver comprises a further channel decoder for obtaining at least one coding property from an received encoded coding property, and in that the receiver is arranged for setting the at least one coding property of the
10 channel decoder according to the at least one coding property.

7. Integrated circuit comprising a channel encoder for encoding source symbols into coded symbols and property setting means for setting at least one coding property of the channel encoder characterized in that the integrated circuit comprises a further channel encoder
15 for obtaining an encoded coding property from the at least one coding property, and in that the integrated circuit is arranged for transmitting the encoded coding property.

8. Integrated circuit comprising a source decoder for deriving reconstructed source symbols from received coded symbols, and coding property setting means for setting at
20 least one coding property of the channel decoder characterized in that the integrated circuit comprises a further channel decoder for obtaining at least one coding property from an received encoded coding property, and in that the integrated circuit is arranged for setting the at least one coding property of the channel decoder according to the at least one coding property.

25 9. Transmission method comprising encoding source symbols into encoded symbols and transmitting the encoded symbols via a transmission channel, receiving encoded symbols from the transmission channel, deriving reconstructed source symbols from the encoded symbols received from the transmission channel and setting at least one coding property of the channel encoder and the channel decoder, characterized in that the method further comprises
30 obtaining an encoded coding property from the at least one coding property, transmitting the encoded coding property via the transmission channel, receiving the encoded coding property from the transmission channel, obtaining the at least one coding property from the encoded coding property, and setting the at least one coding property of the channel decoder according to the at least one coding property.

10. Method comprising encoding source symbols into coded symbols and setting at least one coding property, characterized in that the method comprises obtaining an encoded coding property from the at least one coding property, and in that the method comprises
- 5 transmitting the encoded coding property.
11. Method comprising deriving reconstructed source symbols from received coded symbols, and setting at least one coding property characterized in that the method comprises obtaining at least one coding property from an received encoded coding property, and
- 10 in that the method comprises setting the at least one coding property of the channel decoder according to the at least one coding property.
