

Description

This invention relates to press apparatus and tooling therefore used to convert the shells for self opening cans and the like. In particular the present invention relates to a press suitable for producing easy-

a rectangular bed
a corresponding rectangular slide driven by a crankshaft
vertical guide means attached to said bed and confining said slide to motion toward and away from said bed,

drive means connected to said slide to reciprocate said slide toward and away from said bed,
said press having a front and a back along the longer dimensions of said bed and slide and opposite sides along the shorter dimensions of said bed and slide;

conveyor means extending through said sides of said press and adapted to carry shells for processing into can ends,

upper and lower main tooling means supported on said slide and said bed respectively and located at the top and bottom of said conveyor means, said tooling means defining a plurality of stations (I—A. . . H & II—A. . . H),

first and second tab tooling means (35-T, 36-T) auxiliary to said main tooling means and also located on said bed and adapted to form opening tabs from a strip of metal stock fed theretinto in the front/back direction;

means for guiding a strip of stock into said tab tooling means;

means for guiding the completed tabs from said tab tooling means to one of said stations along said conveyor means for attachment to the shells.

Such a press is known from US—A—4 026 226. However, the tab tooling of this apparatus is at a different level than the main or end tooling, and operates 180 degrees-of-face with it. In addition, this document gives no hint for a particular arrangement of the tab and main tooling to achieve an improved balance of the forces acting on the bed and slide respectively.

Presses for can ends have been known for many years, and typically come in a range of sizes which are designated by tonnage, specifying the predetermined pressure that the press is designed to produce in consecutive pressing operations. However, a press of a given tonnage may in fact exceed its design limits for short periods of time during its operation. Also, the tooling for the press may be so designed that while momentary pressures exceed the designed tonnage, the pressure peaks are the result of the interaction of tooling in a minor part of the available bed-ram area of the press. However, continued such overloading may result in severe and/or premature wear, and to prevent such wear it is advisable to operate within design limits, and to seek optimum production through other means.

A sequence of preparing can ends, complete with scoring and attached tab for opening the end, is described in U.S.—A—3,366,086 (Fraze) issued 30 January 1968. This patent discloses the typical steps for creating the can end, creating the tab, making the integral rivet connection between the tab and the end, and passing the completed end to an apparatus where the can body is filled and the end is attached.

U.S.—A—3,470,837 issued 7 October 1969 and US—A—3,550,546 issued 29 December 1970 illustrate tooling and related apparatus for high production manufacturing of can ends in a typical single action press, where one completed end is discharged from the press for each complete press cycle. Typical of such designs, intermittently rotating carriers are provided, indexed step wise in coordination with the press cycle, to perform the sequence of operations in making the completed can end. Many such apparatus are in commercial use, and a typical press for that purpose is the Minster P-2 45 press, manufactured by Minster Machine Company, Minster, Ohio, U.S.A. Thus presses of this type are currently available on the used machinery market, thus the opportunity exists to modernize such existing single acting presses which, subject to replacement of bearings, drives, etc. are capable of many additional years of use.

More recently, there have been commercial installations of larger conversion presses wherein a two-lane conveyor belt extends front to back of the press, through in-line conversion tooling. Cooperating with the conveyor are up-stacker and down-stacker mechanisms located in front of and rearward of the slide, to carry a double lane of shells through the tooling in this press. The shells are received in circular apertures in the stainless steel conveyor belt, which is moved stepwise through the press in synchronism with the opening and closing of the tooling. To one side of this conveyor mechanism there is conventional in-line progressive tab tooling to form tabs from a metal strip which enters the press from one side.

Such presses provide two-out capacity, but the tooling is arranged in such fashion that the entire set of tab tooling is to one side of the center of the press, and a substantial off-center or asymmetric loading exists on the slide.

In view of the afore-mentioned prior art it is the object of the present invention to provide a modern balanced tooling for the production of can ends with a high degree of efficiency, and also to a design with such balanced type of tooling heretofor not achieved.

This object is achieved by a press as defined in the pre-characterising part of claim 1 which is characterized in that the rectangular slide is driven by an overhead crankshaft; said main tooling means and said tab tooling means are located symmetrically to a vertical plane extending from front to back of the press along the center line of the press bed such as to balance the loading on the bed and slide as the press

works progressively on shells located at each of the stations;

and said tab tooling means is closed and opened by said slide at the same time as said main tooling means.

Can end manufacturers are thus able to renovate existing capital equipment or to purchase new or innovated equipment having the improved manufacturing techniques.

The present invention provides apparatus which maximizes use of the design tonnage capacity for a particular press, and thus makes higher output available from new equipment, and also enables the renovation of existing presses, particularly single acting presses, within their design tonnage capabilities. The present invention also provides novel upper and lower tooling for a reciprocating press used to convert shells into easy opening can ends.

Particularly in presses used for production of self opening or easy-opening can ends, the material and the work has been arranged to flow from front to back of the press. This terminology is used with reference to a press having a rectangular bed and ram of substantially greater width than depth, and the front to back flow of the material in process is described with reference to motion generally transverse to the greater width dimension of the press.

In accordance with the here disclosed embodiment of the invention the shells being converted to ends, contrary to most previous arrangements, flow from side to side, or transversely to the depth dimension of the press. The depth dimension is sufficient that the path can be made wide enough to accommodate two working paths or lanes, side by side. A conveyor belt, having apertures for supporting the shells from which the ends are made, is mounted to extend width-wise of the press, for example from outside one side frame to outside the other side frame, carrying the parts in step-wise fashion through the press throat between the slide and the bed. The arrangement of the tooling is such that operations formed on the shells prior to attachment of the tabs, and operations performed in tab attaching and subsequent to such attachment, can be roughly divided into two equal series of steps or stations arranged on opposite sides of the center of the press.

The tooling for the manufacture of the tabs from strip material is arranged approximately along the center of the press, extending front to back, and the tab forming progression is preferably arranged in about the same number of steps on opposite sides of the approximate center of the press. The complete tabs, still carried attached to the strip, are then looped back into the throat of the press to the station at which the tabs are attached, e.g. staked, to the partially completed ends.

Thus the primary object of the present invention is to provide a balanced design of tooling wherein the steps of forming the ends prior to and subsequent to tab attachment are divided side to side or width wise of the throat of the press, and the tab forming steps are divided into two sections essentially equal front to back along the center line of the press; to provide such a novel tooling system as a result of which the load imposed by such tooling on the slide and bed, and the rest of the press mechanism, is essentially equally distributed over the rectangular area of the cooperating slide and bed; and to provide a novel tooling system for easy open ends in which the resulting improved distribution of forces enables an optimum integrated load, as a result of which a press of nominally lower tonnage is capable of substantially higher output.

Other objects and advantages of the invention will be apparent from the following description, the accompanying drawings and the appended claims.

In order that the invention may be more readily understood, reference will now be made to the accompanying drawings, in which:

Figures 1 and 2 are front and side overall views of the press;

Figure 3 is a plan view of the conveyor belt and related parts of the press, taken generally along line 3—3 in Figure 4.

Figure 4 is an enlarged view of the rear of the press, showing details of indexing drives for the conveyor belt, the tab strip, the up-stacker and down-stacker mechanism;

Figure 5 is a view taken on line 5—5 in Figure 4 showing further detail of the strip indexing feed;

Figure 6 is a perspective type schematic diagram showing the arrangement of the tab forming and end forming paths in the press;

Figure 7 shows the successive steps performed by the end conversion tooling;

Figure 8 is a view showing the progressive steps in forming tabs from a strip of materials;

Figure 9 is an exploded perspective view of the tooling and supporting members;

Figure 10 is a plan view of one of the vacuum boxes associated with the lower tooling and located beneath the conveyor belt, and also showing the tab strip bridge across the end conversion tooling;

Figure 11 is a cross-sectional view of one of the end conversion tooling stations, showing the relation of the conveyor belt and the vacuum box;

Figure 12 is a detail plan view of the tab transfer and staking stations where tabs are joined to the ends;

Figure 13 is a plan view of the loading or down-stacker mechanism;

Figure 14 is a side view of the loading mechanism;

Figure 15 is an enlarged sectional view taken on line 15—15 of Figure 13;

Figure 16 is a plan view of the unloading or up-stacker mechanism;

Figure 17 is a side view of the unloading mechanism;

Figure 18 is an enlarged cross-sectional view showing details of the unloading mechanism; and

Figure 19 is a view showing the relationship of the bed, slide, tool mounting blocks and stop blocks to the tab strip bridge and the tab transfer station.

Press drive layout

Figures 1, 2 and 6 show, respectively, the overall configuration of a press in accordance with a preferred embodiment of the invention, and the general arrangement of the progressive tooling to work upon shells, form completed tabs from a strip of material, and attach these tabs to complete the manufacture or conversion of the shells into ends for cans and similar containers.

For purposes of this description the press illustrated in Figures 1, 2 and 3 is typical of a 45 ton single acting press, and includes a bed 10, side frames including uprights 12, 13, 14 and 15 surrounding side openings 16 and 17, and a crown 18 supported on the side frames. The crank 20 is rotatably supported in the crown, and has secured to it a flywheel 22, and is belt-driven by a drive motor 25 supported on top of the crown structure. The crank is connected to the slide 30 by a pair of connecting rods (not shown), and in conventional fashion cooperative upper and lower tooling sets indicated by the general reference numerals 35 and 36, are mounted on the slide and on the bed respectively. At the opposite side of the press from the flywheel, the crank 20 is fitted with a power take-off pulley 38.

Referring to Figures 3, 4 and 5, a belt 40 transfers power from the crank pulley 38 to a pulley 42 connected to drive a shaft 45 which is mounted in suitable bearings 46 supported outboard from the uprights or posts 14 and 15 which are part of the right hand side frame of the press (as viewed from the front). Shaft 45 is connected via a clutch 48 to a right angle intermittent drive unit 50, of conventional construction, which in turn is connected through an output clutch 52 to a shaft 53 supported in bearings 54 and carrying a drive drum 55 which is rotated in timed intermittent fashion, synchronized with the rotation of the crank 20, and therefore with the motion of the press slide 30. At the other (or left) side of the press, outboard of the side frame and posts 12, 13, an idler drum 57 is supported in suitable bearings 58, and extending between the drums 55 and 57 is a conveyor belt 60.

This belt is of the endless type, made preferably of material such as thin stainless steel, and is provided with two rows or paths of regularly spaced carrier openings 62. These openings are of a diameter such that the lip of a shell overlaps the edge of the openings, and thus shells deposited on the belt cover each of the openings and are carried by the belt through the tooling, in intermittent or step-wise fashion, synchronized to the operating strokes of the press. Shells to be converted are loaded onto belt 60 at the loading station indicated by general reference numeral 65 in Figure 3, and the shells, now converted into finished ends, are unloaded from belt 60 at the unloading station indicated by the general reference numeral 68. The loading and unloading mechanisms, described later in detail, are also referred to in the art, as a down-stacker mechanism and an up-stacker mechanism, referring to the manner in which these mechanisms remove single shells from the bottom of a supply stack thereof and place a single shell onto an opening in the belt, and at the discharge location, remove the finished ends and pass them upwardly into a stack thereof.

The power takeoff shaft 45 also is fitted with a pulley 70 that is connected via belt 72 to a further shaft 75 extending across the rear of the press bed. This shaft in actuality comprises several sections, the first of which 75a is supported in bearings 77 and has a pulley 78 thereon driven by belt 72. The pulley 79 immediately above pulley 78 is an adjustable idler for the purpose of keeping proper tension in belt 72. Shaft section 75a is connected through coupling 81 to the input of a right angle gear drive unit 80, and through that unit and a further coupling 82 to the shaft section 75b. A further coupling 84 (Figure 4) is connected to the right angle output of gear box 80, to drive a shaft 85 which is supported in depending bearing amounts 87. The shaft 85 drives a pair of pulleys 88, and also drives an eccentric 90. The purpose of these driven items is explained hereafter.

Shaft section 75b is connected by a further coupling 92 (Figures 3 and 4) to another shaft section 75c which is supported in suitable bearings 94, and this shaft section in turn drives a final shaft section 75d through an overload friction-type clutch 95. The final shaft section 75d is supported in bearings 97 below and rearward of the discharge station 68, and a pulley 98 and belt 99 provide power to that station.

Tooling layout

Figures 3, 6, 8 and 9 illustrate details of the unique upper and lower tooling sets 35, 36 which are provided in accordance with a preferred embodiment of the invention. With reference to Figure 3 and Figure 9, the lower tooling set includes a subplate 100 upon which is secured a die shoe 102. The subplate is secured to the press bed by suitable fasteners (not shown) including precision locating pins in 104 and bushings 105 (Figure 8) and are dimensioned to fit centrally between the side frames of the press, between and below the side openings 16 and 17. The subplate and die shoe at opposite sides have the same general rectangular end configuration, but at the center the subplate includes outwardly extending parts or extensions 100a both frontward and backward of the bed, while the die shoe is provided with niches 102a in generally corresponding locations.

The punch holder plate 105 is fastened to the bottom surface of the slide 30 and corresponds in outline shape to the subplate 100. The die shoe and the punch holder plate are provided with cooperating stop blocks 108 which provide limits for the close position of the tooling (in known manner) and the punch holder plate is fitted with four guide rods 110 arranged generally near the four corners of the rectangular parts of the tooling, and extending downward into receiving posts or sockets 112 fitted to the die shoe and

including suitable precision ball bearing guides (not shown) which assure the necessary high accuracy of interfit between the upper (punch) and lower (die) tooling parts.

Conventional end conversion tooling is mounted on the die shoe, defining a plurality of stations arranged in two lanes, corresponding to the lanes of conveyor 60. Corresponding upper or punch tooling is mounted to the underside of the punch holder plate 105, thus shells placed in the apertures of the conveyor are carried progressively to the succeeding stations of the end conversion tooling by each step-wise movement of the conveyor. The end converting path thus defined extends from side to side of the press and the end conversion stations are laid out on the die shoe and punch holder plate in such fashion that they are generally symmetrically disposed with respect to the side to side and front to back center lines of the press, thereby equilibrating to a considerable extent the forces not heretofore achieved on the bed and slide.

In similar fashion, the subplate 100 and the punch holder plate 105 are fitted with tab forming tooling 35-T and 36-T which extends transversely of the end conversion tooling, in a direction generally front to back of the press, such tab conversion tooling being divided into first and second parts each of which consists of cooperating punch and die members, and which are supported on the extensions 100a and 105a of the subplate and punch holder plate respectively. Because of the height of the tab conversion dies, these are mounted to the subplate and fitted within the niches 102a of the die shoe 102. The path defined by the tab forming tooling is located on the front-back center line of the press, thereby also equilibrating the reaction forces on the slide and bed produced by operation of the tab forming tooling.

Referring to Figures 3, 6 and 7, the end conversion tooling stations are disposed in lanes I and II and are identified as:

	bubble stations	I—A and II—A
	idle stations	I—B and II—B
25	button station	I—C and II—C
	forming station	I—D and II—D
	idle station	tab die bridge
	score station	I—E and II—E
	lettering station	I—F and II—F
30	transfer/stake station	I—G and II—G
	doming station	I—H and II—H

Figure 7 shows, with a series of progressive views of an end from which the idle station is omitted, the conventional operations performed at those stations. Details of the individual punches and dies are not shown since these will vary with any particular installation, and they are not necessary for an understanding of the present invention.

Figure 8 shows the progressive steps in forming tabs from a strip 115 of suitable material, such as aluminum, which is fed from a supply roll 116 (Figure 2) along the tab forming path and then through the transfer/stake stations I—G and II—G. The tab forming tooling extends to the front and back of the end conversion tooling, as mentioned, and the completed tabs remain attached to the strip as it is looped back to the transfer/stake station (see Figures 3, 6, 10 and 19). There the tabs are removed from the strip, attached to the ends, and the remainder of the strip proceeds to scrap collection. Again, details of the tab forming tooling are not shown since they will vary with the type of end being made, and they are not necessary for an understanding of the invention.

Referring to Figures 10 and 19, in the end conversion tooling, at the point where the tab forming tooling intersects with it, there is provided a bridge 120 which receives the strip of partially formed tabs and carries them across the end conversion tooling into the remainder of the tab tooling located to the front side of the conveyor. The bridge consists of a bottom plate 121 with a front to back extending slot 122, and a cover 124 fitted to the strip and secured by suitable fasteners to its sides, whereby the slot 122 provides a closed passageway for a strip of material (later described) from which tabs are being formed.

Thus, as particularly shown in Figures 3 and 6, the stations of the end conversion tooling, along with the conveyor, define a side-to-side end conversion path, while the tab forming tooling defines a tab forming path in a front-back direction that is transverse to and crosses the end conversion path, then loops back to carry the tabs into the transfer/stake station. The symmetrical relationship of the tooling to the bed and slide can be observed in Figure 3, by comparing the outline of the tooling subplate 100 to the side frame uprights 12—15 within which the slide reciprocates. The reaction forces on the slide and bed during closing and working of the tooling are distributed in approximately uniform fashion over the area of the slide and the underlying bed. This permits maximizing the loading on the press and enables two-out production of ends in a press typically having a rated capacity of forty-five tons (U.S.).

To retain the shells in position on conveyor 60, as they are located at the successive end conversion stations, the die (lower) parts of the end conversion tooling are located in vacuum boxes 130, which are shown in outline form in Figure 3 and in greater detail in Figures 10 and 11. These comprise a lower generally rectangular frame 132 bolted to die shoe 102, and an upper frame 133 bolted to the lower frame. At each station the upper frame has circular openings 134 which surround the dies, and support rails 135 are bolted to the upper frame, extending along the end conversion path and providing support, at both

sides and the center, to the underside of conveyor 60. A top plate 137 is bolted to upper frame 133 and is provided with circular openings 138 corresponding to openings 134.

The top plate thus also functions as a cover for the vacuum box, encloses the center and side edges of the conveyor, and the openings provide passage for the upper (punch) end conversion tools. When the interior of the boxes 130 is connected to a source of vacuum (not shown) and shells or partially converted ends rest in each of the carrier openings 62, the rails 135 together with the transverse end parts of upper frame 133 provide a moving seal over which the stainless steel conveyor belt slides, and the vacuum holds the ends firmly on the belt.

Shell feed/end discharge

The shell feeding mechanism 65, sometimes referred to as a downstacker, has been mentioned earlier with respect to its general function, and its location on the press (Figure 3). Additional details of a suitable mechanism are shown in Figures 13, 14 and 15. This mechanism is per se known, but a brief description of it is desirable to appreciate its function in the present invention.

There are two mechanisms, each designated by the general reference numeral 145, one each of which is mounted over the conveyor lanes I and II. For simplification only one will be described. The base plate 147 holds both mechanisms, and is mounted over conveyor 60, outside of the left side frame (Figure 3). A bottom plate 148, to which the base plate is bolted, includes a vacuum chamber 150 to which a vacuum hose fitting 151 is attached. Plates 147 and 148 are recessed (Figure 15) to define a shallow passageway 153 receiving the conveyor belt 60.

Above chamber 150 there is a circular feed opening 155, of a diameter just large enough to pass the shells S which descend from a stack thereof contained within three guide rods 156. The lowermost shell S has its lip supported on the feeding threads of three feed screws 158, spaced around opening 155 such that 360° rotation of these screws will carry the lowermost shell from the stack and deposit the shell in a belt carrier opening 62 located beneath the feed opening 155.

The power and timing for the feed screw rotation is derived from belt 99, which is driven from power take-off shaft section 75d as earlier described. Belt 99 wraps over and drives pulleys 159 which are fixed to short feeder-shafts 160 that are supported in suitable bearing blocks above the base plate 147. Bevel gear sets 162 transfer power to vertical shafts 163 which are mounted in suitable bushing (Figure 15) in circular top plates 164. Pinions 165, on the shafts 163, mesh with internal gears 167, and pinions 168 on the feed screws 158 are driven from the internal gears through idler gears 169. Thus, by proper selection of pulley sizes and gear sizes, teeth numbers, and ratios, the intermittent rotation of the shaft 75 is translated into 360° rotations of feed screws 158, and a single shell is deposited in a carrier opening 62 as those openings halt under the feed opening 155.

At the other side of the press, beyond the right side frame opening 17 (Figure 3) the unloading or upstacker mechanism 68 is mounted above and below the conveyor belt 60. Figures 16, 17 and 18 show details of this mechanism, which also is per se known.

The first power takeoff shaft 75a has an eccentric or cam 170 thereon (Figures 3 & 17) which is coupled to oscillate a rod 171. The end of rod 171 is pinned to a rocker arm 172 which is supported by a bearing mounted stub shaft 173. The rocker arm includes a set of parallel arms 174 which straddle a piston carrier block 175, and fasten to the block through a cross-pin 176.

The mechanisms on the block 175 are duplicated for each unloading station in lanes I and II, hence only one mechanism is hereafter described. The block has a recess 178 which receives an extension 179 of a primary piston 180 that is reciprocally retained in a sleeve 182. This sleeve is mounted within a boss 183 on a sub-plate 185, which in turn is bolted to the lower plate 187 of the mechanism. An upper plate 188 is fastened to, and cooperates with, the lower plate 187 to define a passageway 190 for the upper flight of conveyor 60, on which are carried the finished ends; one of these is shown at E, being removed from the conveyor.

The upper end of primary piston 180 extends, in its fully raised position (shown in Figures 17 and 18) into an opening 192 formed into lower plate 187 and receiving the upper edge of boss 183. In this position, however, the top of the primary piston 180 is below the conveyor passageway 190.

The center of piston 180 has a central bore 195, an upper cavity 196 in its head, and a counterbore 197 therebetween in which is fastened a gland member 198. A secondary piston 200 is supported in the gland and has a lower head 201, with an O-ring seal 202, slidable in bore 195. A secondary head 205 is secured to the top of piston 200 by a machine screw 206, and is sized to fit within cavity 196 on top of gland member 198.

The upper surface of head 205 is designed to engage an end E, as shown, and lift the end from the conveyor, thrusting it upward into a receiver opening 210 within the base plate 212 of the upstacker storage. A plurality of laterally sliding fingers 215 extend inward of opening 210, at its interface with plate 188. These fingers are urged inward by a garter spring 216, and the fingers will yield to the pressure of the flange on an upwardly thrust end E, to capture the end at the bottom of a stack thereof formed in opening 210. The stack of ends can rise through a corresponding opening in top plate 217, and into magazines defined by upwardly extending rods 218 (Figures 16 and 17).

Referring to Figure 18, the chamber 195 in the primary piston is connected via passages 220 to a flexible hose 222. Similarly, the space between gland members 198 and the top of lower head 201 is

connected via passages 224 to a flexible hose 225. Air (or other fluid) under pressure can be applied to one of these hoses and evacuated from the other, under control of a suitable valve shown schematically at 227 (Figure 17).

This causes the secondary piston 200 to rise to its active position as shown in Figure 18, or to retract to an inactive position within cavity 196. In the active position each stroke of the pistons will lift ends from conveyor 60 and thrust the ends into the receiver openings of the magazines. If the secondary piston is retracted, and the ends on the conveyor will not be touched, and the next increment of conveyor movement will carry them past the discharge mechanism 68.

In the preferred embodiment of the invention, acceptable finished ends are thrust up into the stacks, while detected unacceptable ends are carried to and discharged over drum 55. This arrangement can readily be reversed, however, merely by having suitable fault detectors (not shown) actuate the valve 227 in the opposite fashion. In such case only rejected ends will be raised into the magazines, and acceptable ends can discharge over drum 55 into any suitable collection device.

Tab tooling and attachment

As previously mentioned the tabs T (Figure 8) are formed from a strip 115 of aluminum or like material, supplied from a roll 116 and directed along the tab forming path which is transverse to the end conversion path and generally along the transverse center line of the press (see Figures 3 and 10). This strip is advanced through the tab forming tooling and the bridge 120 over the conversion tooling, forms a reverse loop 230 (Figures 2, 3 and 6), passes back through the guide 232 (Figure 19) into the stations I—G, II—G, and the remaining scrap strip is cut into suitable pieces and discharged.

Figures 4 and 5 show the incremental strip feeding mechanisms 235A and 235B which are driven in incremental fashion from belts 88. These feeding mechanisms are identical and commercially available from Ferguson Machine Co. under the name Camtrol roll feed. Essentially, these mechanisms receive intermittent rotary input from the power take-off shaft 75, gear box 80, and belts 88, and provide intermittent rotary feed output to feed rollers 236, between which the strip 115 is threaded. Pressure adjustment devices 237 control the pressure of the rollers 236 against the strip. Thus, strip 115 is withdrawn from roll 116 by the mechanism 235A, passes through the tab forming tooling and transfer/stake station, and discharges through a guillotine cutter 240. The cutter or chopper is driven by a rocker arm 241 and connecting rod 242 which is reciprocated by a cam 243 mounted to the end of shaft 85.

The strip 115 is thereby fed in push-pull fashion through the looped path shown in Figure 6. Two lanes of tabs T—I and T—II are formed in the strip, through the steps shown and noted in Figure 8. These tabs remain attached to the strip at the connection Tc, and are carried around the loop into the transfer/stake station I—G and II—G. It will be noted that center lines of the two tab lanes align with the centers of the ends located at the station; these centers are indicated by crosses on Figure 10.

In known manner, the rivet holes in the tabs located at this station are thus aligned with the button or rivet on the ends, and as the connections Tc are severed, the tabs are set onto the ends. Complete closing of the tooling finishes the attachment by staking the rivets to form the well-known integral rivet attachment between the tabs and ends. After the next tooling station operation (H) the end conversion is complete and the ends proceed to the unloading mechanism. The remainder of the strip 115 proceeds to the cutter 240, where the strip is cut into short lengths as it is fed incrementally. These scrap lengths can be suitably collected for reclaiming, in known fashion.

While the method herein described, and the form of apparatus for carrying this method into effect, constitute preferred embodiments of this invention, it is to be understood that the invention is not limited to this precise method and form of apparatus, and that changes may be made in either without departing from the scope of the invention, as is defined in the appended claims.

Claims

1. A press suitable for producing easy-open ends for cans and the like, said press having
 - a rectangular bed (10)
 - a corresponding rectangular slide (30) driven by a crankshaft (20)
 - vertical guide means (12, 13, 14, 15) attached to said bed and confining said slide to motion toward and away from said bed,
 - drive (20, 22, 25) means connected to said slide to reciprocate said slide toward and away from said bed,
 - said press having a front and a back along the longer dimensions of said bed and slide and opposite sides along the shorter dimensions of said bed and slide;
 - conveyor means (60) extending through said sides of said press and adapted to carry shells for processing into can ends,
 - upper and lower main tooling means (35, 36) supported on said slide and said bed respectively and located at the top and bottom of said conveyor means, said tooling means defining a plurality of stations (I—A . . . H & II—A . . . H),
 - first and second tab tooling means (35-T, 36-T) auxiliary to said main tooling means and also located

connected via passages 224 to a flexible hose 225. Air (or other fluid) under pressure can be applied to one of these hoses and evacuated from the other, under control of a suitable valve shown schematically at 227 (Figure 17).

This causes the secondary piston 200 to rise to its active position as shown in Figure 18, or to retract to an inactive position within cavity 196. In the active position each stroke of the pistons will lift ends from conveyor 60 and thrust the ends into the receiver openings of the magazines. If the secondary piston is retracted, and the ends on the conveyor will not be touched, and the next increment of conveyor movement will carry them past the discharge mechanism 68.

In the preferred embodiment of the invention, acceptable finished ends are thrust up into the stacks, while detected unacceptable ends are carried to and discharged over drum 55. This arrangement can readily be reversed, however, merely by having suitable fault detectors (not shown) actuate the valve 227 in the opposite fashion. In such case only rejected ends will be raised into the magazines, and acceptable ends can discharge over drum 55 into any suitable collection device.

Tab tooling and attachment

As previously mentioned the tabs T (Figure 8) are formed from a strip 115 of aluminum or like material, supplied from a roll 116 and directed along the tab forming path which is transverse to the end conversion path and generally along the transverse center line of the press (see Figures 3 and 10). This strip is advanced through the tab forming tooling and the bridge 120 over the conversion tooling, forms a reverse loop 230 (Figures 2, 3 and 6), passes back through the guide 232 (Figure 19) into the stations I—G, II—G, and the remaining scrap strip is cut into suitable pieces and discharged.

Figures 4 and 5 show the incremental strip feeding mechanisms 235A and 235B which are driven in incremental fashion from belts 88. These feeding mechanisms are identical and commercially available from Ferguson Machine Co. under the name Camtrol roll feed. Essentially, these mechanisms receive intermittent rotary input from the power take-off shaft 75, gear box 80, and belts 88, and provide intermittent rotary feed output to feed rollers 236, between which the strip 115 is threaded. Pressure adjustment devices 237 control the pressure of the rollers 236 against the strip. Thus, strip 115 is withdrawn from roll 116 by the mechanism 235A, passes through the tab forming tooling and transfer/stake station, and discharges through a guillotine cutter 240. The cutter or chopper is driven by a rocker arm 241 and connecting rod 242 which is reciprocated by a cam 243 mounted to the end of shaft 85.

The strip 115 is thereby fed in push-pull fashion through the looped path shown in Figure 6. Two lanes of tabs T—I and T—II are formed in the strip, through the steps shown and noted in Figure 8. These tabs remain attached to the strip at the connection Tc, and are carried around the loop into the transfer/stake station I—G and II—G. It will be noted that center lines of the two tab lanes align with the centers of the ends located at the station; these centers are indicated by crosses on Figure 10.

In known manner, the rivet holes in the tabs located at this station are thus aligned with the button or rivet on the ends, and as the connections Tc are severed, the tabs are set onto the ends. Complete closing of the tooling finishes the attachment by staking the rivets to form the well-known integral rivet attachment between the tabs and ends. After the next tooling station operation (H) the end conversion is complete and the ends proceed to the unloading mechanism. The remainder of the strip 115 proceeds to the cutter 240, where the strip is cut into short lengths as it is fed incrementally. These scrap lengths can be suitably collected for reclaiming, in known fashion.

While the method herein described, and the form of apparatus for carrying this method into effect, constitute preferred embodiments of this invention, it is to be understood that the invention is not limited to this precise method and form of apparatus, and that changes may be made in either without departing from the scope of the invention, as is defined in the appended claims.

Claims

1. A press suitable for producing easy-open ends for cans and the like, said press having
 - a rectangular bed (10)
 - a corresponding rectangular slide (30) driven by a crankshaft (20)
 - vertical guide means (12, 13, 14, 15) attached to said bed and confining said slide to motion toward and away from said bed,
 - drive (20, 22, 25) means connected to said slide to reciprocate said slide toward and away from said bed,
 - said press having a front and a back along the longer dimensions of said bed and slide and opposite sides along the shorter dimensions of said bed and slide;
 - conveyor means (60) extending through said sides of said press and adapted to carry shells for processing into can ends,
 - upper and lower main tooling means (35, 36) supported on said slide and said bed respectively and located at the top and bottom of said conveyor means, said tooling means defining a plurality of stations (I—A. . . H & II—A. . . H),
 - first and second tab tooling means (35-T, 36-T) auxiliary to said main tooling means and also located

on said bed and adapted to form opening tabs from a strip of metal stock fed thereinto in the front/back direction;

means for guiding a strip (115) of stock into said tab tooling means;

means (232) for guiding the completed tabs from said tab tooling means to one of said stations along said conveyor means for attachment to the shells characterised in that

the rectangular slide (30) is driven by an overhead crankshaft;

said main tooling means (35, 36) and said tab tooling means (35-T, 36-T) are located symmetrically to a vertical plane extending from front to back of the press along the center line of the press bed such as to balance the loading on the bed and slide as the press works progressively on shells located at each of the stations;

and said tab tooling means is closed and opened by said slide at the same time as said main tooling means.

2. Apparatus as defined in claim 1, wherein the crankshaft (20) extends from side to side across the top of the press, said main tooling means (35, 36) and said tab tooling means (35-T, 36-T) are located symmetrically to a vertical plane extending from side to side through the press and through the crankshaft.

3. Apparatus as defined in claim 2, wherein said tab tooling means is provided with a gap bridging said main tooling means, and means (120) guiding the partially completed tab strip across said gap.

4. Apparatus as defined in claim 1, including means on said conveyor means defining carriers (62) for shells moving along separate parallel lanes through said main tooling means.

5. Apparatus as defined in claim 4, wherein said stations of said main tooling means are distributed symmetrically over the area of said bed and slide to maximize usage of the rated tonnage of the press.

6. Tooling for use in a press for converting ends for cans and the like, comprising conveyor means (60) extending sideways through the press and adapted to carry shells for processing into can ends along an end converting path, upper and lower main tooling means (35, 36) located along the end converting path at the top and bottom of said conveyor means and defining a plurality of stations on opposite sides of the centre of the tooling means for working progressively on shells moved by said conveyor means along the end converting path, first and second tab forming tooling means (35-T, 36-T) auxiliary to said main tooling means in which tab forming tooling means opening tabs are formed from a strip of metal stock fed thereinto, said tab forming tooling means (35-T, 36-T) extending transversely of said conveyor means (60) and defining a tab forming path which bridges the end converting path means for guiding a strip of stock (115) through said tab tooling means, and means (232) for guiding the strip with completed tabs from said tab forming tooling means to one of the stations of the end converting path for removal from the strip and attachment to the shells, characterized in that said tab forming tooling means (35-T, 36-T) consists of first and second parts (35-T, 36-T) mounted respectively above and below the converting path, said tab forming tooling means being arranged along the front to back centre-line of the main tooling means (35, 36).

Patentansprüche

1. Für die Herstellung von leicht zu öffnenden Stirnflächen von Dosen und dergleichen geeignete Presse mit

einem rechteckigen Bett (10),

einem entsprechenden rechteckigen Schlitten (30), welche durch eine Kurbelwelle (20) angetrieben wird,

einer vertikalen Führungseinrichtung (12, 13, 14, 15), welche an dem Bett angebracht ist und den Schlitten darauf begrenzt, sich in Richtung auf das Bett zu und von diesem weg zu bewegen,

einer Antriebseinrichtung (20, 22, 25), welche mit dem Schlitten verbunden ist, um den Schlitten in Richtung auf das Bett zu und von diesem weg hin- und herzubewegen,

wobei die Presse eine Front und eine Rückseite entlang der längeren Abmessungen des Bettes und des Schlittens sowie gegenüberliegende Seiten entlang der kürzeren Abmessungen des Bettes und des Schlittens hat,

und eine Transporteinrichtung (60) sich durch die genannten Seiten der Presse hindurch erstreckt und dafür ausgelegt ist, Rohlinge für die Verarbeitung zu Dosenstirnseiten zu tragen,

oberen und unteren Hauptwerkzeugen (35, 36), welche an dem Schlitten bzw. an dem Bett gehalten sind und über bzw. unter der Transporteinrichtung angeordnet sind, wobei die Hauptwerkzeuge eine Mehrzahl von Stationen (I—A...H und II—A...H) definieren,

ersten und zweiten Laschenwerkzeugen (35-T, 36-T), die hilfsweise zu den Hauptwerkzeugen vorgesehen sind und ebenfalls auf dem Bett angeordnet und so ausgelegt sind, daß sie Öffnungslaschen aus einem in der Vorwärts-/Rückwärtsrichtung zugeführten Metallstreifenmaterial bilden,

einer Einrichtung zum Führen eines Streifens (115) aus einem Vorratsmaterial zu den Laschenwerkzeugen,

einer Einrichtung (232) zum Führen der vervollständigten Laschen von den Laschenwerkzeugen zu einer der Stationen entlang der Transporteinrichtung für die Anbringung an den Rohlingen bzw. Deckeln, dadurch gekennzeichnet, daß

der rechtwinklige Schlitten (30) durch eine oben liegende Kurbelwelle angetrieben wird,

die Hauptwerkzeuge (35, 36) und die Laschenwerkzeuge (35-T, 36-T) symmetrisch bezüglich einer

vertikalen Ebene angeordnet sind, die sich von der Front zur Rückseite der Presse entlang der Mittellinie des Bettes der Presse erstreckt, um so die Belastung des Bettes und des Schlittens auszubalancieren, während die Presse die Rohlinge, welche an jeder der Stationen angeordnet sind, zunehmend bearbeitet, und daß die Laschenwerkzeuge durch den Schlitten zur selben Zeit wie die Hauptwerkzeuge geschlossen und geöffnet werden.

2. Vorrichtung nach Anspruch 1, wobei die Kurbelwelle (20) sich von einer Seite zur anderen Seite über die Oberseite der Presse erstreckt und wobei die Hauptwerkzeuge (35, 36) und die Laschenwerkzeuge (35-T, 36-T) symmetrisch bezüglich einer vertikalen Ebene angeordnet sind, die sich von einer Seite zur anderen durch die Presse und durch die Kurbelwelle erstreckt.

3. Vorrichtung nach Anspruch 2, wobei die Laschenwerkzeuge mit einer Lücke versehen sind, welche die Hauptwerkzeuge überbrückt, sowie mit einer Einrichtung (120), welche den teilweise vervollständigten Laschenstreifen über die Lücke hinwegführt.

4. Vorrichtung nach Anspruch 1, einschließlich einer Einrichtung auf der Transporteinrichtung, welche Träger (62) für Rohlinge bzw. Deckel definiert, die sich entlang getrennter paralleler Bahnen durch die Hauptwerkzeuge bewegen.

5. Vorrichtung nach Anspruch 4, wobei die Stationen der Hauptwerkzeuge symmetrisch über die Fläche des Bettes und des Schlittens verteilt sind, um die nominelle Tonnage (Druckkraft) der Presse maximal auszunutzen.

6. Werkzeug für die Verwendung in einer Presse zum Umformen der Stirnseiten für Dosen und dergleichen, mit einer Transporteinrichtung (60), welche sich seitlich durch die Presse hindurch erstreckt und so ausgelegt ist, daß sie Rohlinge zum Verarbeiten zu Dosenstirnseiten bzw. Dosendeckeln entlang eines Deckelumformweges trägt, oberen und unteren Hauptwerkzeugen (35, 36), welche entlang des Deckelumformweges an der Oberseite und am Boden der Transporteinrichtung angeordnet sind und eine Mehrzahl von Stationen auf gegenüberliegenden Seiten des Zentrums der Werkzeuge definieren, um die Rohlinge, welche von der Transporteinrichtung entlang des Deckelumformweges transportiert werden, zunehmend zu bearbeiten, ersten und zweiten Laschenformwerkzeugen (35-T, 36-T), welche hilfsweise zu den Hauptwerkzeugen vorgesehen sind und in welchen Öffnungslaschen aus einem dahin zugeführten Streifen eines Metallmaterials gebildet werden, wobei die Laschenformwerkzeuge (35-T, 36-T) sich quer zu der Transporteinrichtung (60) erstrecken und einen Laschenformweg bilden, der den Deckelumformweg überbrückt, einer Einrichtung zum Führen eines Streifenmaterials (115) durch die Laschenwerkzeuge und einer Einrichtung (232) zum Führen des Streifens mit vervollständigten Laschen von den Laschenformwerkzeugen zu einer der Stationen des Deckelumformweges für die Abnahme von dem Streifen und das Anbringen an den Rohlingen, dadurch gekennzeichnet, daß die Laschenformwerkzeuge (35-T, 36-T) aus ersten und zweiten Teilen (35-T, 36-T) bestehen, welche über bzw. unter dem Umformweg montiert sind, wobei die Laschenformwerkzeuge entlang der Mittellinie von der Front zur Rückseite der Hauptwerkzeuge (35, 36) angeordnet sind.

Revendications

1. Presse convenant à la production d'extrémités aisées à ouvrir pour des boîtes et analogues, ladite presse comportant
 - un bâti rectangulaire (10),
 - un coulisseau rectangulaire correspondant (30) entraîné par un vilebrequin (20),
 - des moyens verticaux (12, 13, 14, 15) de guidage reliés audit bâti et confinant ledit coulisseau à un mouvement le rapprochant et l'éloignant dudit bâti,
 - des moyens d'entraînement (20, 22, 25) reliés audit coulisseau pour lui faire exécuter un mouvement alternatif le rapprochant et l'éloignant dudit bâti,
 - ladite presse comportant un devant et un dos le long des grandes dimensions desdits bâti et coulisseau et des côtés opposés le long des courtes dimensions desdits bâti et coulisseau;
 - des moyens transporteurs (60) s'étendant à travers lesdits côtés de ladite presse et conçus pour porter des douilles à traiter pour former des extrémités de boîtes,
 - des moyens d'outillage principaux supérieur et inférieur (35, 36) supportés par ledit coulisseau et ledit bâti, respectivement, et situés sur le dessus et sur le dessous desdits moyens transporteurs, lesdits moyens d'outillage définissant plusieurs postes (I—A. . H & II—A. . H),
 - des premier et second moyens d'outillage (35-T, 36-T) pour languettes, auxiliaires auxdits moyens d'outillage principaux et également situés sur ledit bâti et conçus pour former des languettes d'ouverture à partir d'une bande de métal de base introduite dans les moyens d'outillage dans la direction devant/dos;
 - des moyens destinés à guider une bande (115) de matière de base dans lesdits moyens d'outillage pour languettes;
 - des moyens (232) destinés à guider les languettes achevées à partir desdits moyens d'outillage pour languettes vers l'un desdits postes le long desdits moyens transporteurs pour une fixation aux douilles, caractérisée en ce que
 - le coulisseau rectangulaire (30) est entraîné par un vilebrequin supérieur;
 - lesdits moyens d'outillage principaux (35, 36) et lesdits moyens d'outillage pour languettes (35-T, 36-T) sont disposés symétriquement par rapport à un plan vertical s'étendant du devant jusqu'au dos de la

presse le long de l'axe central du bâti de la presse afin d'équilibrer la charge s'exerçant sur le bâti et le coulisseau pendant que la presse travaille progressivement sur des douilles disposées dans chacun des postes;

et lesdits moyens d'outillage pour languettes sont fermés et ouverts par ledit coulisseau en même temps que lesdits moyens d'outillage principaux.

2. Appareil selon la revendication 1, dans lequel le vilebrequin (20) s'étend d'un côté à l'autre en travers du haut de la presse, lesdits moyens d'outillage principaux (35, 36) et lesdits moyens d'outillage pour languettes (35-T, 36-T) sont disposés symétriquement par rapport à un plan vertical s'étendant d'un côté à l'autre à travers la presse et passant par le vilebrequin.

3. Appareil selon la revendication 2, dans lequel lesdits moyens d'outillage pour languettes présentent un intervalle traversant lesdits moyens d'outillage principaux, et des moyens (120) guidant la bande de languettes partiellement achevées à travers ledit intervalle.

4. Appareil selon la revendication 1, comprenant des moyens situés sur lesdits moyens transporteurs et définissant des supports (62) pour des douilles se déplaçant suivant des files parallèles séparées à travers lesdits moyens d'outillage principaux.

5. Appareil selon la revendication 4, dans lequel lesdits postes desdits moyens d'outillage principaux sont distribués symétriquement sur l'étendue desdits bâti et coulisseau pour maximiser l'utilisation du tonnage étalonné de la presse.

6. Outillage à utiliser dans une presse pour transformer des extrémités pour boîtes et analogues, comprenant des moyens transporteurs (60) s'étendant latéralement à travers la presse et conçus pour porter des douilles à traiter pour former des extrémités de boîtes le long d'un trajet de transformation d'extrémités, des moyens d'outillage principaux supérieur et inférieur (35, 36) disposés le long du trajet de transformation d'extrémités sur le dessus et le dessous desdits moyens transporteurs et définissant plusieurs postes sur des côtés opposés du centre des moyens d'outillage pour travailler progressivement des douilles déplacées par lesdits moyens transporteurs le long du trajet de transformation d'extrémités, des premier et second moyens d'outillage (35-T, 36-T) pour la formation de languettes, auxiliaires auxdits moyens d'outillage principaux, moyens d'outillage de formation de languettes dans lesquels des languettes d'ouverture sont formées à partir d'une bande de métal de base avancée dans ces moyens, lesdits moyens d'outillage (35-T, 36-T) de formation de languettes s'étendant transversalement auxdits moyens transporteurs (60) et définissant un trajet de formation de languettes qui franchit le trajet de transformation des extrémités, des moyens destinés à guider une bande de matière de base (115) à travers lesdits moyens d'outillage pour languettes, et des moyens (232) destinés à guider la bande, avec les languettes achevées, desdits moyens d'outillage de formation de languettes vers l'un des postes du trajet de transformation d'extrémités pour les enlever de la bande et les fixer aux douilles, caractérisé en ce que lesdits moyens d'outillage (35-T, 36-T) de formation de languettes comprennent des première et seconde parties (35-T, 36-T) montées respectivement au-dessus et au-dessous du trajet de transformation, lesdits moyens d'outillage de formation de languettes étant agencés le long de l'axe central d'avant en arrière des moyens d'outillage principaux (35, 36).
