IMAGE DISPLAY APPARATUS FOR SIMULTANEOUS DISPLAY OF PLURAL IMAGES

ABSTRACT

An image display apparatus such as a television receiver has a frame memory for storing video signals. The image display apparatus displays a combination of main and auxiliary images on a display raster based on the video signals stored in the frame memory. Specifically, the image display apparatus displays a plurality of auxiliary images surrounded by respective frames, and responsive to a control signal from a remote control unit, for example, individually changes the manner in which the frames are displayed respectively around the auxiliary images. For example, the colour of the frame displayed around one of the auxiliary images is changed when that one auxiliary image is selected.
