

ABSTRACT OF THE DISCLOSURE

To provide a water flush toilet in which good eddy flows may be formed on a basin surface to wash the basin surface rear portion over a wide range in a good condition without using a distributor, the flushing water is caused to flow from a flushing water port 2 of a rear portion top surface through a central water passage 3 to a basin surface rear portion 6b, and to flow through an outer water passage 4 to form eddy flows to a basin surface front portion 6a. The central water passage 3 is formed so that its inlet 3a is narrowed and is opened more widely into a sector-shape toward the basin surface rear portion 6b.
