

DEMOLISHING METHOD

ABSTRACT

The present invention provides a demolishing method that can demolish a concrete member ideally. When demolishing a belt-like planned demolishing region (3) of a pressure resistant plate (105), first, opening sections (5) ranging the overall width of the planned demolishing region (3) are formed at intervals in a lengthwise direction of the planned demolishing region (3). Next, a step in which pressure is applied from fracturing holes (25) that are perforated at intermediate regions (13) between the opening sections (5) and the concrete member is pushed out toward the opening sections (5) to break the concrete member is repeated so that the concrete member at the intermediate regions (13) is split from each side of the opening section (5) sequentially.
