ABSTRACT

**METHOD AND SYSTEM FOR WEBSITE VERIFICATION**

A computer-implemented method is proposed for website verification. The method comprises: storing registration records for legitimate websites in a verification register; receiving, from a website to be verified, a user-initiated verification request; responsive to the user-initiated verification request, checking that the website to be verified is in the verification register; generating and transmitting a dynamic code for display on the website if the website to be verified is in the verification register; and responsive to a user entering the dynamic code into a verification module, retrieving details of the website from the verification register and transmitting the details of the website to the user for checking against the website to be verified.
