STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH OR DEVELOPMENT

The research and development of the invention described below was not federally sponsored.

BACKGROUND

The term "opiate" has been used to designate pharmacologically active alkaloids derived from opium, e.g., morphine, codeine, and many semi-synthetic congeners of morphine. After the isolation of peptide compounds with morphine-like actions, the term opioid was introduced to refer generically to all drugs with morphine-like actions. Included among opioids are various peptides that exhibit morphine-like activity, such as endorphins, enkephalins and dynorphins. However, some sources use the term "opiate" in a generic sense, and in such contexts, opiate and opioid are interchangeable. Additionally, the term opioid has been used to refer to antagonists of morphine-like drugs as well as to characterize receptors or binding sites that combine with such agents.

Opioids are generally employed as analgesics, but they may have many other pharmacological effects as well. Morphine and related opioids produce certain of their major effects on the central nervous and digestive systems. The effects are diverse, including analgesia, drowsiness, mood changes, respiratory depression, dizziness, mental clouding, dysphoria, pruritus, increased pressure

in the biliary tract, decreased gastrointestinal motility, nausea, vomiting, and alterations of the endocrine and autonomic nervous systems.

When therapeutic doses of morphine are given to patients with pain, they report that the pain is less intense, less discomforting, or entirely gone. In addition to experiencing relief of distress, some patients experience euphoria. However, when morphine in a selected pain-relieving dose is given to a pain-free individual, the experience is not always pleasant; nausea is common, and vomiting may also occur. Drowsiness, inability to concentrate, difficulty in mentation, apathy, lessened physical activity, reduced visual acuity, and lethargy may ensue.

Two distinct classes of opioid molecules can bind opioid receptors: the opioid peptides (e.g., the enkephalins, dynorphins, and endorphins) and the alkaloid opiates (e.g., morphine, etorphine, diprenorphine and naloxone). Subsequent to the initial demonstration of opiate binding sites (Pert, C. B. and Snyder, S. H., Science (1973) 179:1011-1014), the differential pharmacological and physiological effects of both opioid peptide analogues and alkaloid opiates served to delineate multiple opioid receptors. Accordingly, three molecularly and pharmacologically distinct opioid receptor types have been described: delta, kappa and mu. Furthermore, each type is believed to have sub-types (Wollemann, M., J Neurochem (1990) 54:1095-1101; Lord, J. A., et al., Nature (1977) 267:495-499).

All three of these opioid receptor types appear to share the same functional mechanisms at a cellular level. For example, the opioid receptors cause inhibition of adenylate cyclase, and inhibition of neurotransmitter release via both potassium channel activation and inhibition of Ca^{2+} channels (Evans, C. J., In: Biological Basis of Substance Abuse, S. G. Korenman & J. D. Barchas, eds., Oxford University Press (in press); North, A. R., et al., Proc Natl Acad Sci USA (1990) 87:7025-29; Gross, R. A., et al., Proc Natl Acad Sci USA (1990) 87:7025-29; Sharma, S. K., et al., Proc Natl Acad Sci USA (1975) 72:3092-96). Although the functional mechanisms are the same, the behavioral manifestations of receptor-selective drugs differ greatly (Gilbert, P. E. & Martin,

W. R., J Pharmacol Exp Ther (1976) 198:66-82). Such differences may be attributable in part to the anatomical location of the different receptors.

Delta receptors have a more discrete distribution within the mammalian CNS than either mu or kappa receptors, with high concentrations in the amygdaloid complex, striatum, substantia nigra, olfactory bulb, olfactory tubercles, hippocampal formation, and the cerebral cortex (Mansour, A., et al., Trends in Neurosci (1988) 11:308-14). The rat cerebellum is remarkably devoid of opioid receptors including delta opioid receptors.

D. Delorme, E. Roberts and Z. Wei, World Patent WO/28275 (1998) discloses diaryl methylidenylpiperidines that are opioid analgesics, but does not disclose or suggest the compounds of the present invention.

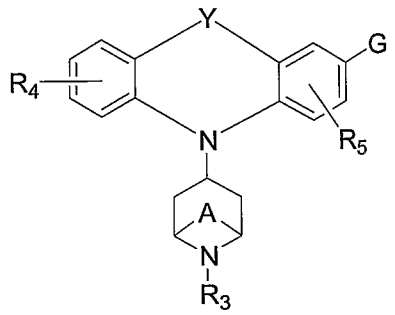

C. Kaiser, and others (J. Med. Chem. 1974, Volume 17, pages 57-61) disclose some piperidylidene derivatives of thioxanthenes, xanthenes, dibenoxepins and acridans that are neuroleptic agents. These authors, however, do not disclose or suggest either the structure or the activity of the compounds of the present invention.

British Patent GB 1128734 (1966) discloses derivatives of 6,11-dihydrodibenzo[b,e]oxepine that are anticholinergic, anti-convulsive, muscle-relaxing, sedating, diuretic, and/or vasoactive agents. These, agents, however, differ significantly from the compounds of the present invention both structurally and pharmacologically.

There is a continuing need for new delta opioid receptor modulators as analgesics. There is a further need for delta opioid receptor selective agonists as analgesics having reduced side effects. There is also a need for delta opioid receptor antagonists as immunosuppressants, antiinflammatory agents, agents for the treatment of neurological and psychiatric conditions, agents for the treatment of urological and reproductive conditions, medicaments for drug and alcohol abuse, agents for treating gastritis and diarrhea, cardiovascular agents and agents for the treatment of respiratory diseases, having reduced side effects.

In certain embodiments, the present invention provides compositions comprising the exo isomer of a compound of formula (I) wherein said composition is substantially free from the endo isomer

of said compound. In the present context, substantially free means less than 25 %, preferably less than 10 %, more preferably less than 5 %, even more preferably less than 2 % and even more preferably less than 1 % of the endo isomer.

In other embodiments, compositions of the present invention comprise a mixture of the exo and endo isomers of a compound of formula (I).

The compounds of the present invention may also be present in the form of pharmaceutically acceptable salts. For use in medicine, the salts of the compounds of this invention refer to non-toxic "pharmaceutically acceptable salts" (*Ref. International J. Pharm.*, **1986**, *33,* 201-217; *J. Pharm.Sci.*, **1997** (Jan), *66, 1,* 1). Other salts well known to those in the art may, however, be useful in the preparation of compounds according to this invention or of their pharmaceutically acceptable salts. Representative organic or inorganic acids include, but are not limited to, hydrochloric, hydrobromic, hydriodic, perchloric, sulfuric, nitric, phosphoric, acetic, propionic, glycolic, lactic, succinic, maleic, fumaric, malic, tartaric, citric, benzoic, mandelic, methanesulfonic, hydroxyethanesulfonic, benzenesulfonic, oxalic, pamoic, 2-naphthalenesulfonic, *p*-toluenesulfonic, cyclohexanesulfamic, salicylic, saccharinic or trifluoroacetic acid. Representative organic or inorganic bases include, but are not limited to, basic or cationic salts such as benzathine, chloroprocaine, choline, diethanolamine, ethylenediamine, meglumine, procaine, aluminum, calcium, lithium, magnesium, potassium, sodium and zinc.

The present invention includes within its scope prodrugs of the compounds of this invention. In general, such prodrugs will be functional derivatives of the compounds that are readily convertible *in vivo* into the required compound. Thus, in the methods of treatment of the present invention, the term "administering" shall encompass the treatment of the various disorders described with the compound specifically disclosed or with a compound which may not be specifically disclosed, but which converts to the

specified compound *in vivo* after administration to the patient. Conventional procedures for the selection and preparation of suitable prodrug derivatives are described, for example, in "Design of Prodrugs", ed. H. Bundgaard, Elsevier, 1985.

Where the compounds according to this invention have at least one chiral center, they may accordingly exist as enantiomers. Where the compounds possess two or more chiral centers, they may additionally exist as diastereomers. It is to be understood that all such isomers and mixtures thereof are encompassed within the scope of the present invention. Furthermore, some of the crystalline forms for the compounds may exist as polymorphs and as such are intended to be included in the present invention. In addition, some of the compounds may form solvates with water (i.e., hydrates) or common organic solvents, and such solvates are also intended to be encompassed within the scope of this invention.

Where the processes for the preparation of the compounds according to the invention give rise to mixture of stereoisomers, these isomers may be separated by conventional techniques such as preparative chromatography. The compounds may be prepared in racemic form, or individual enantiomers may be prepared either by enantiospecific synthesis or by resolution. The compounds may, for example, be resolved into their component enantiomers by standard techniques, such as the formation of diastereomeric pairs by salt formation with an optically active acid, such as (-)-di-p-toluoyl-d-tartaric acid and/or (+)-di-p-toluoyl-l-tartaric acid followed by fractional crystallization and regeneration of the free base. The compounds may also be resolved by formation of diastereomeric esters or amides, followed by chromatographic separation and removal of the chiral auxiliary. Alternatively, the compounds may be resolved using a chiral HPLC column.

During any of the processes for preparation of the compounds of the present invention, it may be necessary and/or desirable to protect sensitive or

reactive groups on any of the molecules concerned. This may be achieved by means of conventional protecting groups, such as those described in Protective Groups in Organic Chemistry, ed. J.F.W. McOmie, Plenum Press, 1973; and T.W. Greene & P.G.M. Wuts, Protective Groups in Organic Synthesis, John Wiley & Sons, 1991. The protecting groups may be removed at a convenient subsequent stage using methods known from the art.

Even though the compounds of the present invention (including their pharmaceutically, acceptable salts and pharmaceutically acceptable solvates) can be administered alone, they will generally be administered in admixture with a pharmaceutical carrier, excipient or diluent selected with regard to the intended route of administration and standard pharmaceutical or veterinary practice. Thus, the present invention is directed to pharmaceutical and veterinary compositions comprising compounds of Formula (I) and one or more pharmaceutically acceptable carriers, excipients or diluents.

By way of example, in the pharmaceutical and veterinary compositions of the present invention, the compounds of the present invention may be admixed with any suitable binder(s), lubricant(s), suspending agent(s), coating agent(s), and/or solubilising agent(s).

Tablets or capsules of the compounds may be administered singly or two or more at a time, as appropriate. It is also possible to administer the compounds in sustained release formulations.

Alternatively, the compounds of the general Formula (I) can be administered by inhalation or in the form of a suppository or pessary, or they may be applied topically in the form of a lotion, solution, cream, ointment or dusting powder. An alternative means of transdermal administration is by use of a skin patch. For example, they can be incorporated into a cream consisting of an aqueous emulsion of polyethylene glycols or liquid paraffin. They can also be incorporated, at a concentration of between 1 and 10% by weight, into an

ointment consisting of a white wax or white soft paraffin base together with such stabilizers and preservatives as may be required.

For some applications, preferably the compositions are administered orally in the form of tablets containing excipients such as starch or lactose, or in capsules or ovules either alone or in admixture with excipients, or in the form of elixirs, solutions or suspensions containing flavoring or coloring agents.

The compositions (as well as the compounds alone) can also be injected parenterally, for example intracavernosally, intravenously, intramuscularly or subcutaneously. In this case, the compositions will comprise a suitable carrier or diluent.

For parenteral administration, the compositions are best used in the form of a sterile aqueous solution which may contain other substances, for example enough salts or monosaccharides to make the solution isotonic with blood.

For buccal or sublingual administration the compositions may be administered in the form of tablets or lozenges which can be formulated in a conventional manner.

By way of further example, pharmaceutical and veterinary compositions containing one or more of the compounds of the invention described herein as the active ingredient can be prepared by intimately mixing the compound or compounds with a pharmaceutical carrier according to conventional pharmaceutical compounding techniques. The carrier may take a wide variety of forms depending upon the desired route of administration (e.g., oral, parenteral). Thus for liquid oral preparations such as suspensions, elixirs and solutions, suitable carriers and additives include water, glycols, oils, alcohols, flavoring agents, preservatives, stabilizers, coloring agents and the like; for solid oral preparations, such as powders, capsules and tablets, suitable carriers and additives include starches, sugars, diluents, granulating agents, lubricants,

binders, disintegrating agents and the like. Solid oral preparations may also be coated with substances such as sugars or be enteric-coated so as to modulate the major site of absorption. For parenteral administration, the carrier will usually consist of sterile water and other ingredients may be added to increase solubility or preservation. Injectable suspensions or solutions may also be prepared utilizing aqueous carriers along with appropriate additives.

Advantageously, compounds of the present invention may be administered in a single daily dose, or the total daily dosage may be administered in divided doses of two, three or four times daily. Furthermore, compounds for the present invention can be administered in intranasal form via topical use of suitable intranasal vehicles, or via transdermal skin patches well known to those skilled in that art. To be administered in the form of a transdermal delivery system, the dosage administration will, of course, be continuous rather than intermittent throughout the dosage regimen.

It is also apparent to one skilled in the art that the therapeutically effective dose for active compounds of the invention or a pharmaceutical composition thereof will vary according to the desired effect. Therefore, optimal dosages to be administered may be readily determined and will vary with the particular compound used, the mode of administration, the strength of the preparation, and the advancement of the disease condition. In addition, factors associated with the particular subject being treated, including subject age, weight, diet and time of administration, will result in the need to adjust the dose to an appropriate therapeutic level. The above dosages are thus exemplary of the average case. There can, of course, be individual instances where higher or lower dosage ranges are merited, and such are within the scope of this invention.

Compounds of this invention may be administered in any of the foregoing compositions and dosage regimens or by means of those compositions and

dosage regimens established in the art whenever use of the compounds of the invention as analgesics is required for a subject in need thereof.

The invention also provides a pharmaceutical or veterinary pack or kit comprising one or more containers filled with one or more of the ingredients of the pharmaceutical and veterinary compositions of the invention. Optionally associated with such container(s) can be a notice in the form prescribed by a governmental agency regulating the manufacture, use or sale of pharmaceuticals or biological products, which notice reflects approval by the agency of manufacture, use or sale for human administration.

The compounds of the present invention may be used to treat mild to severe pain in warm-blooded animals such as humans by administration of an analgesically effective dose. The dosage range would be from about 0.1 mg to about 15,000 mg, in particular from about 50 mg to about 3500 mg or, more particularly from about 100 mg to about 1000 mg of active ingredient in a regimen of about 1 to 4 times per day for an average (70 kg) human; although, it is apparent to one skilled in the art that the therapeutically effective amount for active compounds of the invention will vary as will the types of pain being treated.

For oral administration, a pharmaceutical composition is preferably provided in the form of tablets containing 0.01, 10.0, 50.0, 100, 150, 200, 250, and 500 milligrams of the active ingredient for the symptomatic adjustment of the dosage to the subject to be treated.

Examples of pain intended to be within the scope of the present invention include, but are not limited to, inflammatory pain, centrally mediated pain, peripherally mediated pain, visceral pain, structural or soft tissue injury related pain, progressive disease related pain, neuropathic pain and acute pain such as caused by acute injury, trauma or surgery and chronic pain such as headache and that caused by neuropathic conditions, post-stroke conditions,

cancer, and migraine.

Compounds of the present invention are also useful as immunosuppressants, antiinflammatory agents, agents for the treatment and prevention of neurological and psychiatric conditions, for instance, depression and Parkinson's disease, agents for the treatment of urological and reproductive conditions, for instance, urinary incontinence and premature ejaculation, medicaments for drug and alcohol abuse, agents for treating gastritis and diarrhea, cardiovascular agents and cardioprotective agents and agents for the treatment of respiratory diseases.

The compounds of the present invention are also useful in treating pain caused by osteoarthritis, rheumatoid arthritis, fibromyalgia, migraine, headache, toothache, burn, sunburn, snake bite (in particular, venomous snake bite), spider bite, insect sting, neurogenic bladder, benign prostatic hypertrophy, interstitial cystitis, rhinitis, contact dermatitis/hypersensitivity, itch, eczema, pharyngitis, mucositis, enteritis, cellulites, causalgia, sciatic neuritis, mandibular joint neuralgia, peripheral neuritis, polyneuritis, stump pain, phantom limb pain, post-operative ileus, cholecystitis, postmastectomy pain syndrome, oral neuropathic pain, Charcot's pain, reflex sympathetic dystrophy, Guillain-Barre syndrome, meralgia paresthetica, burning-mouth syndrome, post-herpetic neuralgia, trigeminal neuralgia, cluster headache, migraine headache, peripheral neuropathy, bilateral peripheral neuropathy, diabetic neuropathy, postherpetic neuralgia, trigeminal neuralgia, optic neuritis, postfebrile neuritis, migrating neuritis, segmental neuritis, Gombault's neuritis, neuronitis, cervicobrachial neuralgia, cranial neuralgia, geniculate neuralgia, glossopharyngial neuralgia, migrainous neuralgia, idiopathic neuralgia, intercostals neuralgia, mammary neuralgia, Morton's neuralgia, nasociliary neuralgia, occipital neuralgia, red neuralgia, Sluder's neuralgia, splenopalatine neuralgia, supraorbital neuralgia, vidian neuralgia, inflammatory bowel disease, irritable bowel syndrome, sinus headache, tension headache, labor, childbirth,

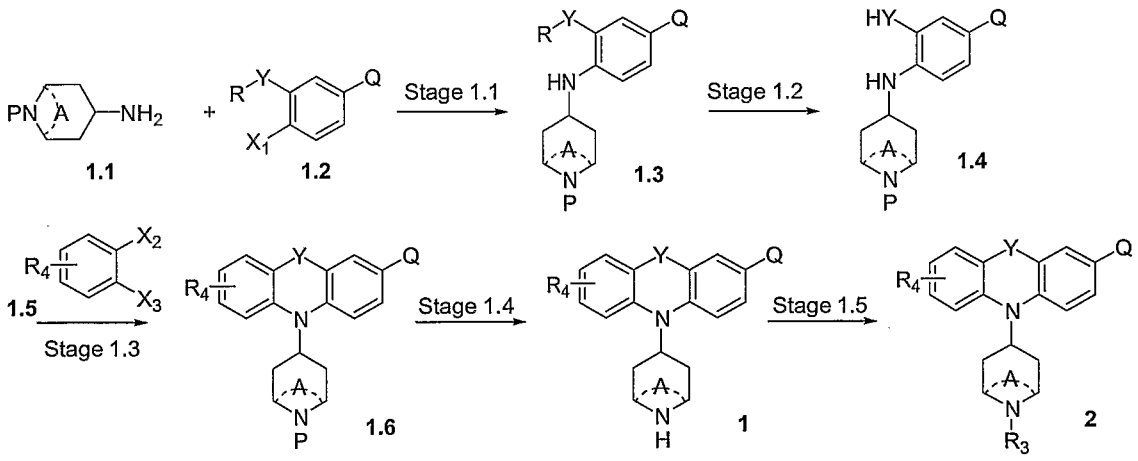

menstrual cramps, and cancer.

In regard to the use of the present compounds in treatment of the disases or conditions such as those listed above, a therapeutically effective dose can be determined by persons skilled in the art by the use of established animal models. Such a dose would likely fall in the range of from about 0.01 mg to about 15,000 mg of active ingredient administered 1 to 4 times per day for an average (70 kg) human.

GENERAL SYNTHETIC METHODS

Representative compounds of the present invention can be synthesized in accordance with the general synthetic methods described below and are illustrated in the schemes that follow. Since the schemes are an illustration, the invention should not be construed as being limited by the chemical reactions and conditions expressed. The preparation of the various starting materials used in the schemes is well within the skill of persons versed in the art.

Scheme 1

The preparation of compounds of this invention is illustrated in Schemes 1 through 11. The overall strategy in Scheme 1 is based on the synthesis of

appropriately substituted compounds of formula **1.4** (Y =O, S) that are condensed with an appropriately substituted compound of formula **1.5**. In compounds of formula **1.5**, X_2 and X_3 can each be a halogen atom, trifluoromethanesulfonyloxy or a nitro group. In stage 1.1, a bridged *N*1-protected 4-aminopiperidine **1.1** is condensed with a properly substituted *O*-protected phenol (Y=O) or thiophenol (Y=S) **1.2**. The protective group on the N1 nitrogen of **1.1** (represented as P) may include an alkanyl, alkenyl or aralkanyl group in which case they are the therapeutically useful products of this invention. The group P may also be trifluoromethylcarbonyl, alkoxycarbonyl or aralkoxycarbonyl. Bridge A may include $(CH_2)_2$ and $(CH_2)_3$. Useful phenol or thiophenol protective groups (R) include lower alkyl groups, benzyl, trialkylsilyl and the like. Appropriate substituents on the protected phenol or thiophenol in the 2-position (X_1) may include halogens and trifluoromethanesulfonyloxy. The Q group in the 5-position may be a substituent such as fluoro, chloro, bromo, cyano, iodo, carboxy, dialkylaminosulfonyl or trifluoromethanesulfonyloxy. Stage 1.2 includes deprotection of the phenol or thiophenol protective group. Such transformations may include the dealkylation of lower alkyl ethers to give their corresponding alcohols using reagents such as boron trihalides, or dealkylation of lower alkyl thioethers using reagents such as Na/NH_3. A benzyl protective group may be removed under conditions of hydrogenation in the presence of a transition metal such as palladium. Trialkylsilyl protective groups may be removed by treatment with a source of fluoride anion such as tetrabutyl ammonium fluoride, or by exposure to an inorganic acid such as aqueous hydrogen chloride and the like.

In stage 1.3, hydroxyaniline (Y=O) or thioaniline (Y=S) **1.4** may be condensed with an appropriately substituted benzene moiety **1.5**. Substituents X_2 and X_3 may include halogens, trifluoromethanesulfonyloxy, or a nitro group. Useful coupling conditions of the anilino nitrogen with a compound of formula **1.5** include palladium catalyzed condensations in the presence of a phosphine ligand such as $Pd_2(dba)_3$ and a base such as cesium carbonate. Coupling of

the hydroxy or thio moiety with the remaining substituted phenyl group may proceed using Ullmann type coupling conditions. In addition, the two steps described in stage 1.3 may be reversed with biaryl ether or biaryl thioether formation preceding the formation of the biaryl amine. Alternatively, the condensation between compounds of formula **1.4** and compounds of formula **1.5** to yield compounds of formula **1.6** in one step may be affected by treatment with an inorganic base such as potassium carbonate in a suitable solvent such as dimethyl formamide.

The regiochemical outcome of the condensation between compounds of formula **1.4** and compounds of formula **1.5** depends on the position of the R4 substituent in compounds of formula **1.5** and on the reaction conditions used for the condensation. An extensive review on this topic is available in the literature (see, for eample: 'The Smiles and Related Rearrangements of aromatic Systems' by W. E. Truce, E. M. Kreider, and W. W. Brand in Organic Reactions, 1970, Vol. 18, pp.99-215).

The protective group P can be removed to obtain secondary amines **1** as illustrated for Stage 1.4. These transformations may be carried out using certain acidic reagents such as hydrogen bromide or trimethylsilyl iodide. Phenoxazines (Y=O) or phenothiazines (Y=S) of type **1.6** bearing readily cleavable groups such as methyl, allyl or benzyl may be transformed into the aforementioned alkoxycarbonyl derivatives by treatment with alkanylchloroformates such as ethyl chloroformate or 1-chloroethyl chloroformate and thus serve as sources of phenoxazines and phenothiazines **1**. Phenoxazines or phenothiazines of type **1.6** bearing a trifluormethylcarbonyl group may be treated with potassium carbonate in an alcoholic solvent such as methanol to yield phenoxazines and phenothiazines **1.**

Finally the secondary amines **1** may be converted to a compound of formula **2** as shown in Stage 1.5. These transformations may be carried out by reductive alkylation using a carbonyl compound and a reducing agent such as sodium borohydride, sodium cyanoborohydride, sodium triacetoxyborohydride, or tetramethylammonium triacetoxyborohydride. They may also be carried out

by alkylation using an alkanyl, alkenyl or aralkyl halide and an organic or inorganic base.

The Q function in compounds **1** or **2** may be converted into group G, which may be $-C(Z)NR_1R_2$, an aryl substituent, or an appropriate heterocycle as defined herein, to give compounds of formula **I**. When the Q function is a halogen or trifluoromethanesulfonyloxy, it may be converted to an ester via alkoxycarbonylation using carbon monoxide, an aliphatic alcohol, a trialkanyl amine, and a palladium catalyst such as bis(triphenylphosphine) palladium(II)dichloride. Subsequently, when Q is an ester, the ester may be hydrolyzed to a carboxylic acid. The carboxylic acid may then be coupled with ammonia, a primary amine, or a secondary amine to form a primary, secondary or tertiary amide, respectively. Alternatively, the conversion of a carboxylic acid to an amide may be carried out via an acid chloride using thionyl chloride, oxalyl chloride, or the like, followed by a Schotten-Baumann reaction using ammonia or an amine in the presence of an alkali metal hydroxide. Alternatively, the conversion of a carboxylic acid to an amide may be carried out via the use of peptide coupling agents such as 1,3-dicyclohexylcarbondiimide (DCC), *O*-(7-azabenzotriazol-1-yl)-*N,N,N',N'*-tetramethyluronium hexafluorophosphate (HATU), *O*-benzotriazol-1-yl-*N,N,N',N'*-tetramethyluronium hexafluorophosphate (HBTU), or the like. Alternatively, the ester may be converted directly to the amide by the action of a dimethylaluminum amide.

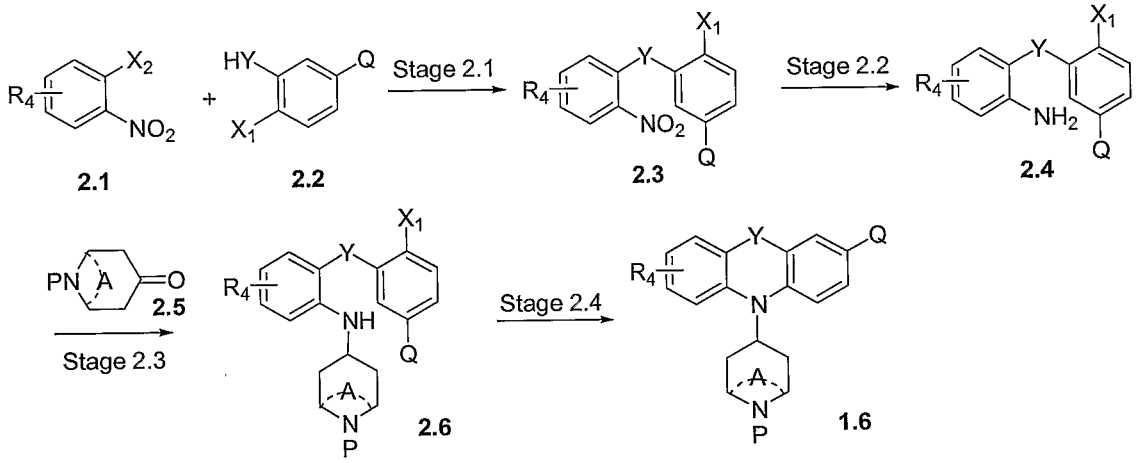

Alternatively, when the Q function is a halogen or trifluoromethanesulfonyloxy, it may be converted directly to an amide via aminocarbonylation using a carbon monoxide source such as molybdenum hexacarbonyl, an appropriate amine, and a palladium catalyst such as Hermann's catalyst.

Alternatively, one may effect the transformation of the group Q to a substituent G (wherein G is an amidino or heterocycle) by way of a nitrile. Synthesis of the nitrile may be accomplished by treatment of the compounds **1** or **2** (when Q is bromo or trifluoromethanesulfonyloxy) with $Zn(CN)_2$ and a

palladium catalyst such as $(Ph_3P)_4Pd$ or by treatment of the compounds **1** or **2** with CuCN at elevated temperatures. For the synthesis of amidino functional groups, the nitrile is treated with hydroxylamine under basic conditions to afford an oxime. Treatment of the oxime with a primary or secondary amine, CuCl, and an alkali metal carbonate under microwave irradiation in an alcoholic solvent provides the amidino compounds of the present invention. Microwave accelerated reactions may be performed using either a CEM Discover or a Personal Chemistry Smith Synthesizer microwave instrument. The oxime described above is instrumental in the preparation of compounds wherein G is a heterocycle. The oxime may be cyclized with a variety of electrophiles known to one versed in the art to give the heterocycles of the present invention. For instance, reaction of an oxime with CDI provides oxadiazolones, and treatment of the oxime with TCDI provides the corresponding oxadiazolethiones. Similarly, the treatment of the oxime with thionyl chloride in the presence of a tertiary amine gives oxathiadiazoles of the present invention.

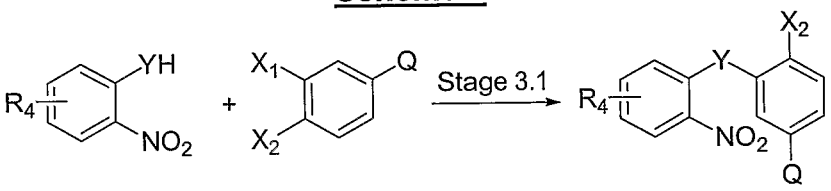

Alternatively, compounds where Q is a halogen atom or a trifluoromethanesulfonyloxy group may participate in transition metal-mediated coupling reactions such as Suzuki, Stille or Negishi chemistry.
Desired end products of the present invention may include chemical modifications at R_4. Such transformations may include the dealkylation of lower alkyl ethers to give the corresponding alcohols using reagents such as boron trihalides. Compounds where R_4 is a halogen atom may participate in transition metal-mediated coupling reactions such as Suzuki, Stille or Negishi chemistry.

Scheme 2

Scheme 2 outlines an alternative approach to the synthesis of phenoxazines (Y=O) or phenothiazines (Y=S) **1.6.** In this scheme, an appropriately substituted phenol (Y=O) or thiophenol (Y=S) of type **2.2** is reacted with an appropriately substituted benzene moiety **2.1** in the presence of a base, such as potassium carbonate or sodium hydroxide in an organic solvent, such as dimethyl formamide, dimethyl acetamide, dimethyl sulfoxide or the like as shown in stage 2.1. Appropriate substituents X_1 and X_2 in this scheme may include halogens and trifluoromethanesulfonyloxy. In stage 2.2, the nitro functionality is reduced to the corresponding amine. This reduction can be accomplished via treatment with tin(II) chloride in an alcoholic solvent such as ethanol. Stage 2.3 depicts the conversion of primary aniline **2.4** to secondary aniline **2.6**, which can be accomplished via reductive alkylation using a carbonyl compound **2.5** and a reducing agent such as sodium borohydride, sodium cyanoborohydride, sodium triacetoxyborohydride, or tetramethylammonium triacetoxyborohydride. Stage 2.4 depicts formation of compounds of formula **1.6**, which can be accomplished by treatment of secondary aniline **2.6** with an appropriate base such as potassium carbonate.

Appropriate X_1, X_2 and X_3 substituents may include halogens and trifluoromethanesulfonyloxy. Palladium catalyzed condensation of biaryl ethers or biaryl thioethers **4.1** with bridged *N*1-protected 4-

aminopiperidines **1.1** in the presence of a phosphine ligand such as $Pd_2(dba)_3$ and a base such as cesium carbonate is shown in stage 4.2 may result in the formation of phenoxazines or phenothiazines **1.6**.

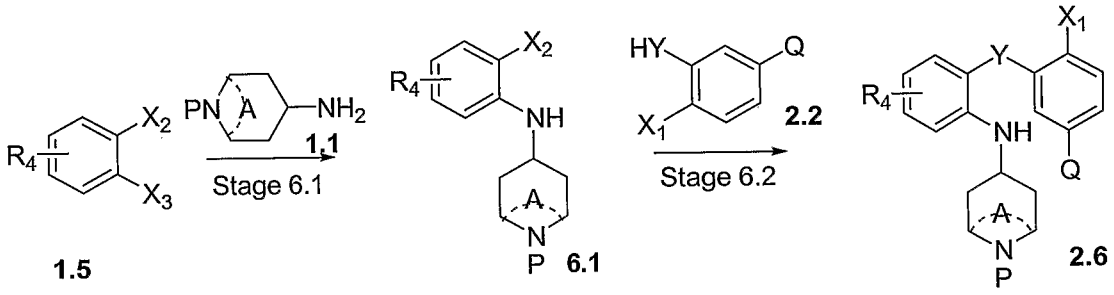

Scheme 5

5.1 **3.2** **4.1**

An alternative approach to the synthesis of intermediate **4.1** is depicted in Scheme 5 and is based on the reaction of appropriately substituted phenols (Y=O) or thiophenols (Y=S) **5.1** with an appropriately substituted benzene moiety **3.2** under Ullmann type coupling conditions (stage 5.1). Substituents X_1, X_2, and X_3 may include halogens or trifluoromethanesulfonyloxy.

Scheme 6

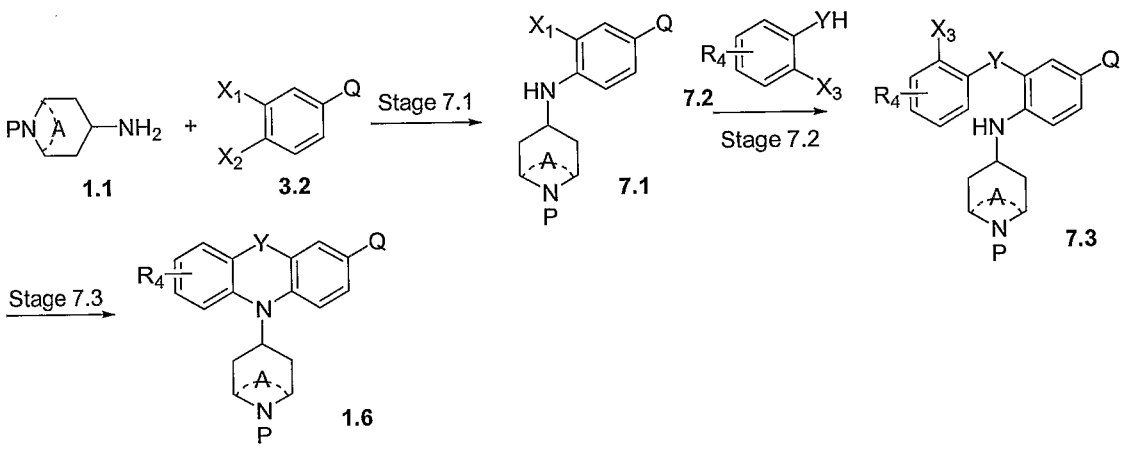

1.5 **6.1** **2.6**

Scheme 6 illustrates an alternative approach to the synthesis of intermediates **2.6**. An appropriately substituted compound of formula **1.5** may be reacted with bridged *N*1-protected 4-aminopiperidines **1.1** in the presence of a palladium catalyst such as $Pd_2(dba)_3$, a phosphine ligand and a base such as cesium carbonate as shown in stage 6.1. Appropriate X_1 and X_2 substituents may include halogens and trifluoromethanesulfonyloxy. Compounds of formula **6.1** may then be reacted with appropriately substituted phenols (Y=O) or

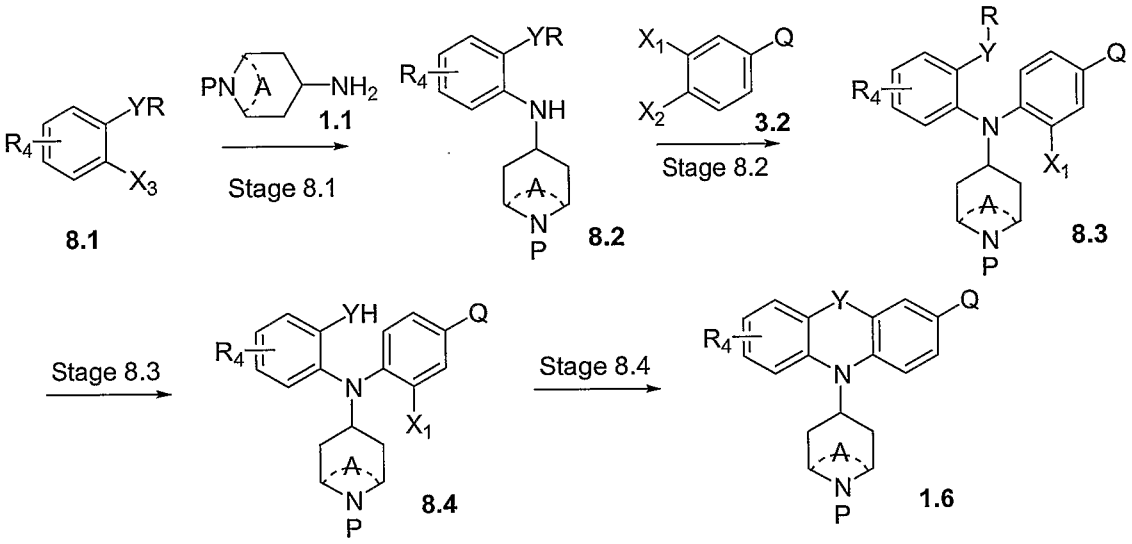

thiophenols (Y=S) **2.2** under Ullmann type coupling conditions to yield anilines **2.6** as shown in stage 6.2.

Scheme 7

Scheme 7 illustrates an alternative approach to the synthesis of phenoxazines (Y=O) or phenothiazines (Y=S) **1.6**. Condensation of appropriately substituted compounds of formula **3.2** with bridged *N*1-protected 4-aminopiperidines **1.1** may result in formation of intermediate **7.1** as shown in stage 7.1. Appropriate X_1, X_2, and X_3 substituents may include halogens and trifluoromethanesulfonyloxy. Reaction of compounds **7.1** with appropriately substituted phenol (Y=O) or thiophenols (Y=S) **7.2** under Ullmann like coupling conditions may result in formation of compounds **7.3** as shown in stage 7.2. Finally, ring closure of compounds **7.4** may be accomplished in the presence of a palladium catalyst such as $Pd_2(dba)_3$, a phosphine ligand such as 4,5-bis(diphenylphosphino)-9,9-dimethylxanthene (xant phos) and a base such as potassium tert-butoxide or cesium carbonate as shown in stage 7.3.

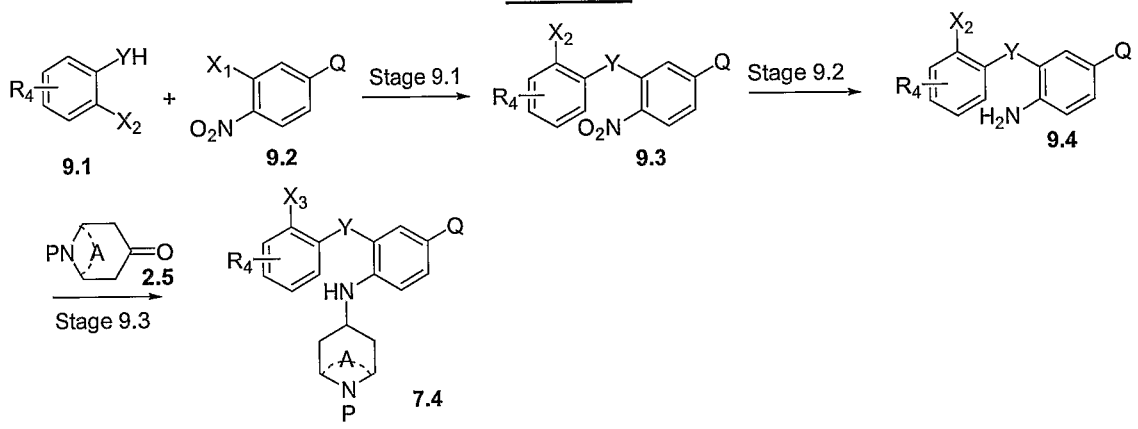

Scheme 8

Scheme 8 illustrates an alternative synthesis of phenoxazines (Y=O) or phenothiazines (Y=S) **1.6** and is based on an Ullmann-like coupling of bridged *N*1-protected 4-aminopiperidines **1.1** with appropriately substituted and protected phenols (Y=O) or thiophenols (Y=S) **8.1** as shown in stage 8.1. Useful phenol or thiophenol protective groups for compounds **8.1** include lower alkyl groups, benzyl, trialkylsilyl and the like. Appropriate X_1, X_2, and X_3 substituents may include halogens and trifluoromethanesulfonyloxy. The resulting compounds **8.2** may be condensed with appropriately functionalized benzene compounds **3.2** to yield diarylanilines **8.3**. Stage 8.3 includes deprotection of the phenol or thiophenol protective group. Such transformations may include the dealkylation of lower alkyl ethers to give their corresponding alcohols using reagents such as boron trihalides or the dealkylation of the alkyl thioethers using Na/NH_3. A benzyl protective group may be removed under conditions of hydrogenation in the presence of a transition metal such as palladium. Trialkylsilyl protective groups may be removed by treatment with a source of fluoride anion such as tetrabutyl ammonium fluoride, or by exposure to an inorganic acid such as aqueous hydrogen chloride and the like. Finally, ring closure of compounds **8.3** to phenoxazines or phenothiazines **1.6** may be accomplished via an Ullmann type

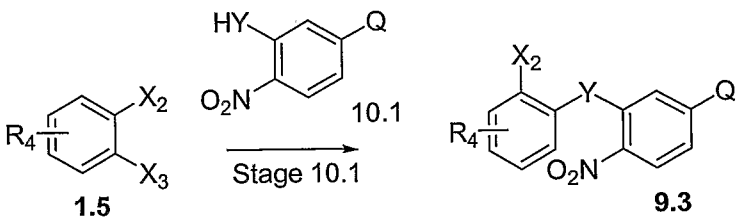

transformation as shown in stage 8.4.

Scheme 9

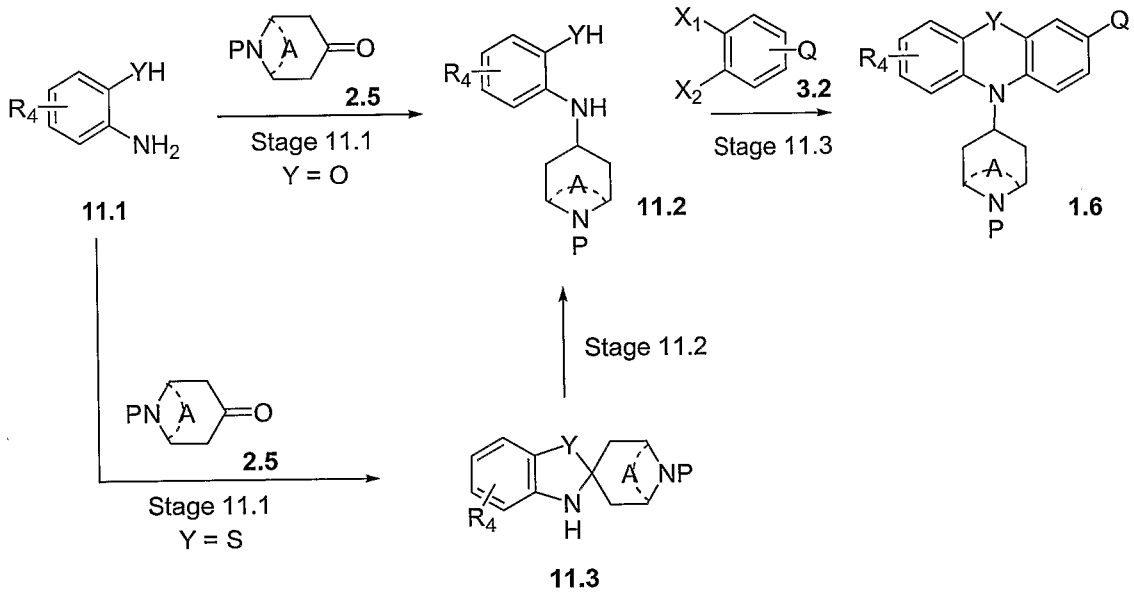

Scheme 9 illustrates another synthetic approach to compounds **7.4**. Displacement of X_1 in appropriately substituted compounds of formula **9.2** with appropriately substituted compounds of formula **9.1** as shown in stage 9.1 may lead to biaryl ethers (Y=O) and biarylthioethers (Y=S) **9.3**. Appropriate X_1 and X_2 substituents may include halogens and trifluoromethanesulfonyloxy. Reduction of compounds **9.3** to amines **9.4** as shown in stage 9.2 may be accomplished using tin(II) chloride in an alcoholic solvent such as ethanol. Stage 9.3 depicts the conversion of primary anilines **9.4** to secondary anilines **7.4** and can be accomplished via reductive alkylation using a carbonyl compounds **2.5** and a reducing agent such as sodium borohydride, sodium cyanoborohydride, sodium triacetoxyborohydride, or tetramethylammonium triacetoxyborohydride.

Scheme 10

Scheme 10 illustrates another synthetic approach to compounds **9.3**. For construction of diaryl ethers (Y=O) and diaryl thioethers (Y=S) **9.3**, appropriately substituted 2-hydroxynitrobenzenes or 2-thionitrobenzenes **10.1** may be caused to react with appropriately substituted compounds of formula **1.5** under Ullmann type conditions as shown in stage 10.1. Appropriate X_2 and X_3 substituents may include halogens and trifluoromethanesulfonyloxy.

Scheme 11

Scheme 11 illustrates another synthetic approach to compounds **1.6**. Stage 11.1 depicts the conversion of appropriately substituted 2-hydroxyanilines (Y=O) **11.1** to compounds **11.2** (Y=O), which can be accomplished via reductive alkylation using a carbonyl compound **2.5** and a reducing agent such as sodium borohydride, sodium cyanoborohydride, sodium triacetoxyborohydride, or tetramethylammonium triacetoxyborohydride. Appropriately substituted 2-hydroxyanilines **11.2** may be caused to react with an appropriately substituted benzene **3.2** under Ullmann type conditions or under basic conditions such as potassium carbonate in DMF (when X_1= NO_2) as shown in stage 11.3 to yield compounds of formula **1.6**. Appropriate X_1 and

X_2 substituents may include halogens, trifluoromethanesulfonyloxy, and a nitro group.

The regiochemical outcome of the condensation of compounds of formula **11.2** with compounds of formula **3.2** depends on the position of the Q substituent in compounds of formula **3.2** and on the reaction conditions used for the condensation. An extensive review on this topic is available in the literature (see, for eample: 'The Smiles and Related Rearrangements of aromatic Systems' by W. E. Truce, E. M. Kreider, and W. W. Brand in Organic Reactions, 1970, Vol. 18, pp.99-215).

In compounds of formula **11.1** where Y is sulfur, an intermediate spiro compound of formula **11.3** may be formed. Compounds of formula **11.3** may be converted to compounds of formula **11.2** (Y = S) by treatment with a hydride reagent such as lithium aluminum hydride or sodium borohydride.

In the above Schemes 1 through 11, the Q function of compounds **2** may be converted into group G, which may be $-C(Z)NR_1R_2$, an aryl substituent, or an appropriate heterocycle as defined herein, to give compounds of formula **3**. When the Q function of compounds **2** is a halogen or trifluoromethanesulfonyloxy, it may be converted to an ester via alkoxycarbonylation using carbon monoxide, an aliphatic alcohol, a trialkanyl amine, and a palladium catalyst such as bis(triphenylphosphine) palladium(II)dichloride. Subsequently, when Q is an ester, the ester may be hydrolyzed to a carboxylic acid. The carboxylic acid may then be coupled with ammonia, a primary amine, or a secondary amine to form a primary, secondary or tertiary amide, respectively. Alternatively, the conversion of a carboxylic acid to an amide may be carried out via an acid chloride using thionyl chloride, oxalyl chloride, or the like, followed by a Schotten-Baumann reaction using ammonia or an amine in the presence of an alkali metal hydroxide. Alternatively, the conversion of a carboxylic acid to an amide may be carried out via the use of peptide coupling agents such as 1,3-dicyclohexylcarbondiimide (DCC), *O*-(7-azabenzotriazol-1-yl)-*N,N,N',N'*-

tetramethyluronium hexafluorophosphate (HATU), *O*-benzotriazol-1-yl-*N,N,N',N'*-tetramethyluronium hexafluorophosphate (HBTU), or the like. Alternatively, the ester may be converted directly to the amide by the action of a dimethylaluminum amide.

Instead of proceeding to compounds **3** *via* an ester, one may effect the transformation of the group Q to a substituent G (wherein G is an amidino or heterocycle) by way of a nitrile. Synthesis of the nitrile may be accomplished by treatment of the compounds **2** (when Q is bromo or trifluoromethanesulfonyloxy) with $Zn(CN)_2$ and a palladium catalyst such as $(Ph_3P)_4Pd$ or by treatment of the compounds **2** with CuCN at elevated temperatures. For the synthesis of amidino functional groups, the nitrile is treated with hydroxylamine under basic conditions to afford an oxime. Treatment of the oxime with a primary or secondary amine, CuCl, and an alkali metal carbonate under microwave irradiation in an alcoholic solvent provides the amidino compounds of the present invention. Microwave accelerated reactions may be performed using either a CEM Discover or a Personal Chemistry Smith Synthesizer microwave instrument. The oxime described above is instrumental in the preparation of compounds wherein G is a heterocycle. The oxime may be cyclized with a variety of electrophiles known to one versed in the art to give the heterocycles of the present invention. For instance, reaction of an oxime with CDI provides oxadiazolones, and treatment of the oxime with TCDI provides the corresponding oxadiazolethiones. Similarly, the treatment of the oxime with thionyl chloride in the presence of a tertiary amine gives oxathiadiazoles of the present invention.

An aryl substituent may be installed in place of the functional group Q by coupling compounds **2** (when Q is bromo or trifluoromethanesulfonyloxy) with a suitably substituted arylboronic acid in the presence of a palladium catalyst and an alkali metal carbonate.

Desired end products of the present invention may include chemical modifications at R_4. Such transformations may include the dealkylation of lower alkyl ethers to give their corresponding alcohols, using reagents such as

boron trihalides. Compounds where R_4 is a halogen atom may participate in transition metal-mediated coupling reactions such as Suzuki, Stille or Negishi chemistry.

It is generally preferred that the respective product of each process step be separated from other components of the reaction mixture and subjected to purification before its use as a starting material in a subsequent step. Separation techniques typically include evaporation, extraction, precipitation and filtration. Purification techniques typically include column chromatography (Still, W. C. et. al., *J. Org. Chem.* 1978, *43*, 2921), thin-layer chromatography, crystallization and distillation. The structures of the final products, intermediates and starting materials are confirmed by spectroscopic, spectrometric and analytical methods including nuclear magnetic resonance (NMR), mass spectrometry (MS) and liquid chromatography (HPLC). In the descriptions for the preparation of compounds of this invention, ethyl ether, tetrahydrofuran and dioxane are common examples of an ethereal solvent; benzene, toluene, hexanes and heptanes are typical hydrocarbon solvents and dichloromethane and dichloroethane are representative halogenated hydrocarbon solvents. In those cases where the product is isolated as the acid addition salt the free base may be obtained by techniques known to those skilled in the art. In those cases in which the product is isolated as an acid addition salt, the salt may contain one or more equivalents of the acid. Enantiomers of the compounds of the present invention may be separated using chiral HPLC.

Representative compounds of the present invention can be synthesized in accordance with the general synthetic methods described above and are illustrated more particularly in the schemes that follow. Since the schemes are illustrations, the invention should not be construed as being limited by the chemical reactions and conditions expressed. The preparation of the various starting materials used in the schemes is well within the skill of persons versed in the art.

Rat Brain Delta Opioid Receptor Binding Assay

Procedure: Male, Wistar rats (150-250 g, VAF, Charles River, Kingston, NY) were killed by CO_2, and their brains were removed and placed immediately in ice cold Tris HCl buffer (50 mM, pH 7.4). The forebrains were separated from the remainder of the brain by a coronal transection, beginning dorsally at the colliculi and passing ventrally through the midbrain-pontine junction. After dissection, the forebrains were homogenized in Tris buffer in a Teflon®-glass homogenizer. The homogenate was diluted to a concentration of 1 g of forebrain tissue per 80 mL Tris and centrifuged at 39,000 x g for 10 min. The pellet was resuspended in the same volume of Tris buffer containing 5 mM $MgCl_2$ with several brief pulses from a Polytron homogenizer. This particulate preparation was used for the delta opioid binding assays. Following incubation with the delta selective peptide ligand ~4 nM [^{3}H]DPDPE or 0.15 nM [^{3}H]naltrindole at 25°C for 2.5 h in a 96-well plate with total volume of 1 mL, the plate contents were filtered through Wallac filtermat B sheets on a Tomtec 96-well harvester. The filters were rinsed three times with 2 mL of 10 mM

HEPES (pH 7.4), and dried in a 650 W microwave oven for 1.75 min twice. To each sample area 2 X 50 µL of Betaplate Scint scintillation fluid (LKB) was added and the radioactivity quantified on a LKB (Wallac) 1205 BetaPlate liquid scintillation counter.

Analysis: The data from the scintillation counter were used to calculate either the % inhibition compared to control binding (when only a single concentration of test compound was evaluated) or a K_i value (when a range of concentrations was tested). Percent inhibition was calculated as: [(total dpm-test compound dpm)/(total dpm-nonspecific dpm)]*100. Kd and Ki values were calculated using GraphPad PRISM data analysis program.

Rat Brain Mu Opioid Receptor Binding Assay

Procedure: Male, Wistar rats (150-250 g, VAF, Charles River, Kingston, NY) were killed by CO_2, and their brains were removed and placed immediately in ice cold Tris HCl buffer (50 mM, pH 7.4). The forebrains were separated from the remainder of the brain by a coronal transection, beginning dorsally at the colliculi and passing ventrally through the midbrain-pontine junction. After dissection, the forebrains were homogenized in Tris buffer in a Teflon®-glass homogenizer. The homogenate was diluted to a concentration of 1 g of forebrain tissue per 80 mL Tris and centrifuged at 39,000 x g for 10 min. The pellet was resuspended in the same volume of Tris buffer containing 5 mM $MgCl_2$ with several brief pulses from a Polytron homogenizer. This particulate preparation was used for the delta opioid binding assays. Following incubation with the mu selective peptide ligand, ~0.8 nM [^{3}H]DAMGO, at 25°C for 2.5 h in a 96-well plate with total assay volume of 1 mL, the plate contents were filtered through Wallac filtermat B sheets on a Tomtec 96-well harvester. The filters were rinsed three times with 2 mL of 10 mM HEPES (pH 7.4), and dried in a 650 W microwave oven for 1.75 min twice. To each sample area 2 X 40 µL of Betaplate Scint scintillation fluid (LKB) was added and the radioactivity quantifed on a LKB (Wallac) 1205 BetaPlate liquid scintillation counter.

Analysis: The data from the scintillation counter were used to calculate either the % inhibition compared to control binding (when only a single concentration of test compound was evaluated) or a K_i value (when a range of concentrations tested). Percent inhibition was calculated as: [(total dpm-test compound dpm)/(total dpm-nonspecific dpm)]*100. Kd and Ki values were calculated using GraphPad PRISM data analysis program.

[^{35}S]GTPγS Binding Assay in NG108-15 Cell Membranes (delta opioid)

Methods: NG108-15 cell membranes can be purchased from Applied Cell Sciences (Rockville, MD). 8 mg/mL of membrane protein suspended in 10 mM TRIS-HCl pH 7.2, 2 mM EDTA, 10% sucrose. Membranes can be maintained at 4-8 °C. A 1 mL volume of membranes can be added into 10 mL cold binding assay buffer. The assay buffer contained 50 mM Tris, pH 7.6, 5 mM $MgCl_2$, 100 mM NaCl, 1 mM DTT and 1 mM EGTA. The membrane suspension can be homogenized twice with a Polytron, and centrifuged at 3000 rpm for 10 min. The supernatant can be then centrifuged at 18,000 rpm for 20 min. Ten mL assay buffer can be added into the pellet containing tube. The pellet and buffer can be mixed with a Polytron.

Incubation procedure: The pellet membranes (75 µg/mL) can be preincubated with SPA (10 mg/mL) at 25°C for 45 min in the assay buffer. The SPA (5 mg/mL) coupled with membranes (37.5 µg/mL) can then be incubated with 0.1 nM [^{35}S] GTPγS in the same Tris buffer containing 100 µM GDP in total volume of 200 µL. Increasing concentrations of receptor agonists can be used to stimulate [^{35}S]- GTP□S binding. The basal binding can be tested in the absence of agonists and non-specific binding can be tested in the presence of 10 µM unlabeled GTPγS. The data can be analyzed on a Packard Top Count.

DATA

% of Basal = (stimulated - non specific)*100/(basal - non specific).

EC_{50} value values can be calculated using GraphPad Prism.

[^{35}S]GTPγS Binding Assays in CHO-hMOR Cell Membranes

Methods: CHO-hMOR cell membranes can be purchased from Receptor Biology, Inc. (Baltimore, MD). About 10 mg/mL of membrane protein can be suspended in 10 mM TRIS-HCl pH 7.2, 2 mM EDTA, 10% sucrose, and the suspension kept on ice. A 1mL volume of membranes can be added to 15 mL cold binding assay buffer containing 50 mM HEPES, pH 7.6, 5 mM $MgCl_2$, 100 mM NaCl, 1 mM DTT and 1 mM EDTA. The membrane suspension can be homogenized with a Polytron and centrifuged at 3,000 rpm for 10 min. The supernatant can then be centrifuged at 18,000 rpm for 20 min. The pellet can be resuspended in 10 mL assay buffer with a Polytron. The membranes can be preincubated with wheat germ agglutinin coated SPA beads (Amersham) at 25 °C for 45 min in the assay buffer. The SPA bead (5 mg/mL) coupled membranes (10 µg/mL) can be then incubated with 0.5 nM [^{35}S]GTPγS in the assay buffer. The basal binding can be that taking place in the absence of added test compound; this unmodulated binding can be considered as 100%, with agonist stimulated binding rising to levels significantly above this value. A range of concentrations of receptor agonist can be used to stimulate [^{35}S]GTPγS binding. Both basal and non-specific binding can be tested in the absence of agonist; non-specific binding determination included 10 µM unlabeled GTPγS.

Compounds can be tested for function as antagonists by evaluating their potential to inhibit agonist-stimulated GTPγS binding. Radioactivity can be quantified on a Packard TopCount. The following parameters can be calculated:

$$\% \text{ stimulation} = \frac{(\text{test compound cpm} - \text{non-specific cpm})}{(\text{basal cpm} - \text{non-specific cpm})} \times 100$$

$$\% \text{ inhibition} = \frac{(\% \text{ stimulation by 1 } \mu\text{M DAMGO} - \% \text{ stimulation by test compound})}{(\% \text{ stimulation by 1 } \mu\text{M DAMGO} - 100)} \times 100$$

EC_{50} values can be calculated using GraphPad Prism.
