

Description

This invention relates to centrifugal compressors and to surge control methods for centrifugal compressors.

Surge conditions occur in a centrifugal compressor when the inlet flow is reduced to the extent that the compressor, at a given speed, can no longer pump against the existing pressure head. At this point, a momentary reversal of flow occurs along with a drop in pressure head. Normal compression resumes and the cycle repeats. This causes a pulsation and shock to the entire compressor and piping arrangement. If left uncontrolled, damage and danger to the compressor could result.

All centrifugal compressors are supplied with characteristic and setpoint curves defining zones of operation for the compressor. These compressor "maps" illustrate the surge area and the "stonewall" area of pumping limit of the turbomachinery. As shown in Figure 1A of the accompanying drawings, a compressor surge limit line is plotted against a discharge pressure versus flow rate relationship. Taking into account no changes in speed or inlet gas temperature, a surge control line can be plotted with this equation:

$$\text{Surge control line} = \% \text{ of control margin desired} \times \frac{\Delta P \text{ (pressure drop) across compressor}}{\Delta P \text{ (pressure drop) across inlet orifice}}$$

Three common forms of presently used surge control lines are shown in Figures 1A to 1C of the accompanying drawings. One position of the surge control line is parallel to the surge limit line (Figure 1A). To minimise recirculation, the surge control line should be set as close to the surge limit line as possible. Setting the control line with a slope less than that of the limit line (Figure 1B) can lead to excess recirculation at high pressures, and surge at low pressures during stopping and startup. The third method is to select a minimum safe volumetric flow, and set a vertical control line (Figure 1C). This can lead to excess recirculation at low pressures, and surge at high pressures. Many systems measure flow in the discharge without correcting for suction conditions. This gives maximum recirculation with minimum surge protection.

In the various surge controls, control is accomplished by opening a bypass valve around the compressor or blowing off gas to atmosphere to maintain minimum flow through the compressor. Since bypassing or blowing off gas wastes power, it is desirable to determine surge flow as accurately as possible to avoid bypassing fluid unnecessarily while maintaining safe operation. However, determining surge flow is often not a simple matter, but rather is a complex one. Surge conditions can be approached slowly or quickly and thus situations may occur when a normal surge control loop opening the bypass valve opens the bypass valve too slowly to prevent a surge condition. Known systems have used a second control loop for such emergency surge conditions to provide speedy and complete opening of the bypass valve. An example of such a control system having two separate control loops is disclosed in US Patent No. US-A-4 142 838.

Clearly, such known two mode control systems having two separate control loops are complicated, unstable, expensive, and required extensive coordination to properly switch between the two control loops. What is needed is a simple control loop arrangement which will provide control for both normal surge and emergency fast surge conditions.

US Patent No. US-A-4 139 328 represents the state of the art and discloses a turbo compressor having a surge control system. The system comprises a PI controller fed with a difference signal from a difference station. The difference signal is the difference ("control difference") between a signal indicative of compressor flow rate and a signal derived from a signal indicative of compressor discharge pressure by conversion in correspondence with a blowing off curve. The control difference is positive for permissible control differences, where the compressor operating point is to one side of the blowing off curve (and negative for non-permissible control differences, where the compressor operating point is on the other side of the blowing off curve). The PI controller controls a blowing off valve for controlling surging. To improve surging control, a non-linear transmission element is connected between the difference station and the PI controller. This results in non-linear amplification of the difference signal and therefore variation of the gain of the system. Specifically, the characteristic of the non-linear element is such that gain is increased if the control difference is negative. More specifically, the gain characteristic of the element comprises two straight lines, whose break falls within a negative quadrant whereby: small negative control differences (as may be caused by noisy signals) are negated up to a predetermined magnitude; and at greater (non-permissible) control difference the gain is increased to cause rapid opening of the blow off valve.

According to one aspect of the invention there is provided a centrifugal compressor having an adaptive gain surge control system, the system comprising:

a proportional and integral mode controller for controlling a bypass line of the centrifugal compressor, the controller having a variable gain;

characterised in that the system further comprises:

distance determining means for determining the distance, in terms of flow rate, between a surge control line established for the compressor on the basis of actual operating conditions and a surge line of the compressor;

control signal establishing means for establishing a control signal in response to the distance for changing the gain of the controller; and

bypass valve control means connected to the controller for varying the amount of bypass across the centrifugal compressor in response to the control signal;

- 5 the controller including an antiwindup adjustment to adjust the integral mode of the controller to shift the proportional band of the proportional mode of the controller to the same side of the control line that the measurement is on when the controller reaches its output limit so as thereby to prevent overshoot.

According to another aspect of the invention there is provided a method of controlling normal and emergency surge in a centrifugal compressor having a bypass valve controlled by a variable gain controller, the method being characterised by the steps of:

10 measuring an offset, in terms of flow rate, of a surge line of the compressor from a surge control line established for the compressor according to a function of pressure differentials across an orifice in an inlet to the compressor and across the compressors, respectively;

15 establishing a controller gain control signal which is a function of the offset of the surge control line from the surge line; and

using the controller gain control signal to vary the gain of the controller according to the offset of the surge control line from the surge line for normal surge conditions and to provide additional gain to the controller at a predetermined value of the offset for emergency surge conditions.

A preferred surge control system for a centrifugal compressor described hereinbelow provides surge control for both normal and fast acting emergency surge conditions using the same single control loop, the control system being operative to initiate normal low gain surge control and emergency anti-surge action by increasing the gain of a controller in the single control loop to quickly and fully open a bypass valve during fast acting emergency surge conditions.

The preferred control system operates on a two mode principle. A usual mode of bypass valve operation is utilised for slow upsets or normal surge conditions. Slow upsets can be counteracted through a normal modulating control of a single control loop at a first gain factor thereby offsetting the surge condition at maximum efficiency energy usage by limiting the amount of bypass flow through a relief valve. The second mode of operation is an emergency mode. The emergency mode comes into play during a fast upset or emergency surge condition. A controller will offset such a fast upset by changing the controller to a high gain factor to provide a step function command to the relief valve to quickly and completely open. By stepping open the relief valve, efficiency is sacrificed for maintaining protection of the compressor.

The response of the controller of the preferred system to input conditions depends upon the proportional control mode bandwidth and integral action rate of an integral mode of the controller. These parameters influence the stability of the control system. Decreasing the proportional band, or increasing the integral action rate, increases the speed of the controller's response; but, past a certain point, system stability will be disturbed. All closed-loop control systems have a stability limit.

This stability limit along with the two types of surge upsets previously mentioned give rise to the need for two different modes of antisurge control operation. When the control system is operating in the normal surge mode, the control system is maintained within the stability range of the controller by setting the gain of the controller at a low level. When the control system reaches an emergency surge condition, control system stability is sacrificed to achieving protection for the compressor and the gain of the controller is driven beyond normal stable operation limits.

In view of the foregoing it will be seen that the preferred system comprises a single loop control system that will control both normal and emergency surge conditions. Further, the preferred system comprises a single loop surge control system having a variable gain controller whose gain is determined by the intensity of the surge condition.

The invention will now be further described, by way of illustrative and non-limiting example, with reference to the accompanying drawings, in which:

50 Figures 1A to 1C are a series of three curves showing known compressor surge control lines;

Figure 2 is a schematic view of a compressor using a surge control system embodying the present invention;

Figure 3 is a schematic view of the surge control system of Figure 2;

55 Figure 4 is a curve of compressor discharge pressure versus flow rate showing the relationship of a surge control line to a compressor surge line; and

Figure 5 is an illustration of an adaptive gain factor G shown as a function of a variable d .

Figure 2 of the drawings shows a parallel compressor system 10 having a reciprocating compressor 12 parallel connected to a centrifugal compressor 14 used to provide an output pressure at an output line 16. The reciprocating compressor 12 acts as a base load machine, which can operate normally in one of two different capacities; 50% and 100% of its output pressure. This change of capacity from 100% to 50% initiates a surge condition in the compressor 14 and forms the basis of the advance warning system for a surge control system 18. The change in capacity may, for example, be initiated by a manual/automatic control system 20.

65 The centrifugal compressor 14 acts as a booster in the parallel arrangement, and because it is a dynamic machine (as opposed to a positive displacement machine like the reciprocating compressor 12) it

has the potential of surging because of the decrease in flow.

With particular reference to Figure 3, the surge control system 18 is schematically depicted in SAMA Standard RC22-11-1966 notation with the symbols applicable to mechanical, pneumatic, or electronic control systems.

Measured variables $\% \Delta P_o$ and $\% \Delta P_c$ represent, respectively, the pressure differential across an orifice 22 in an inlet line 24 of the centrifugal compressor 14 and the pressure differential across the centrifugal compressor 14. These variables are measured by respective pressure transmitters and are inputted into a function generator 26 which develops an output at a line 28 representative of a surge control line 30 which is substantially parallel to and at a predetermined distance d (or d_{scl}) to the right of a compressor surge line 32, as is shown in Figure 4.

A multiplying station 34 multiplies the surge control line outputted along the line 28 with the measured speed S_r of the centrifugal compressor 14 outputted along a line 29, thus locating an intersection 36 of a particular compressor rotation speed point N_r and the surge control line 30.

The point 36 defines a certain flow rate of the centrifugal compressor 14 which is outputted along a line 38 and compared in a difference station 40 with an actual measured compressor flow rate F_r supplied along a line 42 to the difference station 40.

An output from the difference station 40 is provided along a line 44 to a proportional and integral action controller 46 having a predetermined set point which will then control a final control element 48, namely a bypass valve controlling the amount of bypass in a bypass line 50, to stop a surge condition by allowing the inlet line 24 of the starved centrifugal compressor 14 to utilise outlet fluid from the centrifugal compressor 14 from an inlet line 52.

The remaining circuitry is an adaptive gain control module 54 which is utilised to develop a gain factor, according to which additional gain is inputted along a line 56 to the proportional and integral action controller 46 in proportion to the varying size of a disturbance sensed along a line 58 to provide the bypass valve 48 with a stepping open action.

The symbols used here have the following meanings:

ΔP_o = the pressure differential across the inlet orifice (Pa or inches of water)

ΔP_c = the pressure differential across the centrifugal compressor (Pa or lbf/in² (PSI))

K = a constant which represents the compressor surge line characteristics of a particular compressor

f_o = calibrated span of the inlet orifice pressure transmitter (e.g. 0—3.5 kPa or 0—14 inches of water produces 0—100% input) (%)

f_c = calibrated span of the centrifugal compressor differential pressure transmitter (e.g. 0—2.76 MPa or 0—400 lbf/in² produces 0—100% output) (%)

d = offset from the surge line expressed as a percentage of the maximum value of P_o (e.g. for an offset of 0.35 kPa or 1.4 inches of water when P_o maximum = 3.5 kPa or 14 inches of water, $d = 10\%$) (%)

G = Gain factor (dimensionless) of the proportional and integral controller.

It is well known that the compressor surge line may be expressed as follows:

$$(\Delta P_c / \Delta P_o) = K \quad (1)$$

or:

$$\Delta P_c - K \Delta P_o = 0 \quad (2)$$

Similarly:

$$\frac{\Delta P_c}{f_c} - K' \frac{\Delta P_o}{f_o} = 0 \quad (3)$$

where:

$$K' = (f_o / f_c) K \quad (4)$$

Defining:

$$\% \Delta P_c = \frac{\Delta P_c}{f_c} \quad (5)$$

and

$$\% \Delta P_o = \frac{\Delta P_o}{f_o} \quad (6)$$

and substituting into Equation (3) yields:

$$\% \Delta P_c - K' \% \Delta P_o = 0 \quad (7)$$

Similarly, the equation for a line parallel to the compressor surge line but offset horizontally from the compressor surge line by some value d may be expressed as:

$$\% \Delta P_c - K' \% \Delta P_o = -dK' \quad (8)$$

or

$$d = \frac{\% \Delta P_c}{K'} + \% \Delta P_o \quad (9)$$

EP 0 175 445 B1

Note that when the value of d in Equation (9) is equal to zero, Equation (9) is equivalent to Equation (7), which defined the compressor surge line.

For different values of d (i.e. $d_1, d_2, \dots, d_i$), a family of lines parallel to the surge line will be generated. If d was limited to a single specific value, e.g. 10%, the line generated is normally referred to as the surge control line as shown in Figure 4 at 30.

Based on empirical testing of various compressor arrangements, an optimum gain factor G can be determined for each value of d , as seen in Figure 5. The values of G will typically be 4 to 12 for d equal to between 0 to 40%, but the exact values are dependent on the specific compressors, combination of compressors, and piping arrangement used.

In operation, the measured variable $\% \Delta P_o$ and the constant K' are inputted into a dividing station which develops an output at a line 62. The measured variable $\% \Delta P_o$ and the output at the line 62 are then inputted to a summing station 64 which develops an output at the line 58 representative of d as defined by Equation (9).

A function generator 66 is set up to produce a predetermined value for G for each value of d sensed along the line 58, as may best be seen in Figure 5 which shows how G varies with d in accordance with the function $f(d_x)$ on which the function generator 66 operates. A normal or stable system gain factor G is used in normal modulating control (slow upset). But, as the value of d approaches a set level (fast upset), additional gain is inputted along a line 68 to a tuning block 70 which interfaces with the proportional and integral action controller 46 which, in turn, provides the bypass valve 48 with a stepping open action.

The proportional-plus-integral controller 46 has an antiwindup feature. The antiwindup feature is necessary due to the nature of the proportional and integral functions. Normally, the centrifugal compressor 14 operates in an area some distance from the surge control line 30, resulting in an offset between the measurement and the set point of the controller. As a result, the output signal winds up to its low limit.

Antiwindup adjusts the integral loading to shift the proportional band to the same side of the control line that the measurement is on when the controller reaches its output limit. Then, if the control line is approached rapidly, the measurement enters the proportional band and control starts before the value reaches the control line. Thus, overshoot is eliminated.

Derivative control is not used because it can open the anti-surge valve far from the surge line and can cause system oscillations. Rapid oscillations in flow, even in the safe operating zone, can cause the valve to open because of the characteristics of the derivative response.

Claims

1. A centrifugal compressor having an adaptive gain surge control system, the system comprising: a proportional and integral mode controller (46) for controlling a bypass line (50) of the centrifugal compressor (14), the controller (46) having a variable gain (G); characterised in that the system further comprises:

distance determining means (60, 64) for determining the distance (d), in terms of flow rate, between a surge control line (30) established for the compressor (14) on the basis of actual operating conditions and a surge line (32) of the compressor (14);

control signal establishing means (66, 70) for establishing a control signal in response to the distance (d) for changing the gain (G) of the controller (46); and

bypass valve control means connected to the controller (46) for varying the amount of bypass across the centrifugal compressor (14) in response to the control signal;

the controller (46) including an antiwindup adjustment to adjust the integral mode of the controller to shift the proportional band of the proportional mode of the controller to the same side of the control line (30) that the measurement is on when the controller reaches its output limit so as thereby to prevent overshoot.

2. A compressor according to Claim 1, wherein the control signal establishing means (66, 70) includes a function generator (66) for establishing a controller gain signal as a function of the distance (d).

3. A compressor according to Claim 1 or Claim 2, wherein the controller (46) is only a proportional and integral function controller, the controller having no derivative mode in order to prevent system oscillation.

4. A compressor according to Claim 1, Claim 2 or Claim 3, wherein the distance determining means (60, 64) is operative to determine the distance (d) from a first signal indicative of the pressure differential ($\% \Delta P_o$) across an orifice (22) in an inlet line (24) of the centrifugal compressor (14) and a second signal ($\% \Delta P_c$) indicative of the pressure differential across the centrifugal compressor (14).

5. A compressor according to Claim 4, wherein the distance determining means (60, 64) comprises a dividing station (60) operative to divide said second signal by a constant (K') and a summing station (64) for adding the result of said division to said first signal.

6. A compressor according to Claim 4 or Claim 5, wherein the system comprises a function generator (26) responsive to said first and second signals to establish an output representative of the surge control line (30), a multiplying station (34) operative to multiply the output representative of the surge control line by a signal indicative of the speed (S_r) of the centrifugal compressor (14), and a difference station (40) operative to produce a difference signal representing the difference between an output of the multiplying station (34)

Note that when the value of d in Equation (9) is equal to zero, Equation (9) is equivalent to Equation (7), which defined the compressor surge line.

For different values of d (i.e. $d_1, d_2, \dots, d_i$), a family of lines parallel to the surge line will be generated. If d was limited to a single specific value, e.g. 10%, the line generated is normally referred to as the surge control line as shown in Figure 4 at 30.

Based on empirical testing of various compressor arrangements, an optimum gain factor G can be determined for each value of d , as seen in Figure 5. The values of G will typically be 4 to 12 for d equal to between 0 to 40%, but the exact values are dependent on the specific compressors, combination of compressors, and piping arrangement used.

In operation, the measured variable $\% \Delta P_o$ and the constant K' are inputted into a dividing station 60 which develops an output at a line 62. The measured variable $\% \Delta P_o$ and the output at the line 62 are then inputted to a summing station 64 which develops an output at the line 58 representative of d as defined by Equation (9).

A function generator 66 is set up to produce a predetermined value for G for each value of d sensed along the line 58, as may best be seen in Figure 5 which shows how G varies with d in accordance with the function $f(d_i)$ on which the function generator 66 operates. A normal or stable system gain factor G is used in normal modulating control (slow upset). But, as the value of d approaches a set level (fast upset), additional gain is inputted along a line 68 to a tuning block 70 which interfaces with the proportional and integral action controller 46 which, in turn, provides the bypass valve 48 with a stepping open action.

The proportional-plus-integral controller 46 has an antiwindup feature. The antiwindup feature is necessary due to the nature of the proportional and integral functions. Normally, the centrifugal compressor 14 operates in an area some distance from the surge control line 30, resulting in an offset between the measurement and the set point of the controller. As a result, the output signal winds up to its low limit.

Antiwindup adjusts the integral loading to shift the proportional band to the same side of the control line that the measurement is on when the controller reaches its output limit. Then, if the control line is approached rapidly, the measurement enters the proportional band and control starts before the value reaches the control line. Thus, overshoot is eliminated.

Derivative control is not used because it can open the anti-surge valve far from the surge line and can cause system oscillations. Rapid oscillations in flow, even in the safe operating zone, can cause the valve to open because of the characteristics of the derivative response.

Claims

1. A centrifugal compressor having an adaptive gain surge control system, the system comprising: a proportional and integral mode controller (46) for controlling a bypass line (50) of the centrifugal compressor (14), the controller (46) having a variable gain (G); characterised in that the system further comprises: distance determining means (60, 64) for determining the distance (d), in terms of flow rate, between a surge control line (30) established for the compressor (14) on the basis of actual operating conditions and a surge line (32) of the compressor (14); control signal establishing means (66, 70) for establishing a control signal in response to the distance (d) for changing the gain (G) of the controller (46); and bypass valve control means connected to the controller (46) for varying the amount of bypass across the centrifugal compressor (14) in response to the control signal; the controller (46) including an antiwindup adjustment to adjust the integral mode of the controller to shift the proportional band of the proportional mode of the controller to the same side of the control line (30) that the measurement is on when the controller reaches its output limit so as thereby to prevent overshoot.
2. A compressor according to Claim 1, wherein the control signal establishing means (66, 70) includes a function generator (66) for establishing a controller gain signal as a function of the distance (d).
3. A compressor according to Claim 1 or Claim 2, wherein the controller (46) is only a proportional and integral function controller, the controller having no derivative mode in order to prevent system oscillation.
4. A compressor according to Claim 1, Claim 2 or Claim 3, wherein the distance determining means (60, 64) is operative to determine the distance (d) from a first signal indicative of the pressure differential ($\% \Delta P_o$) across an orifice (22) in an inlet line (24) of the centrifugal compressor (14) and a second signal ($\% \Delta P_c$) indicative of the pressure differential across the centrifugal compressor (14).
5. A compressor according to Claim 4, wherein the distance determining means (60, 64) comprises a dividing station (60) operative to divide said second signal by a constant (K') and a summing station (64) for adding the result of said division to said first signal.
6. A compressor according to Claim 4 or Claim 5, wherein the system comprises a function generator (26) responsive to said first and second signals to establish an output representative of the surge control line (30), a multiplying station (34) operative to multiply the output representative of the surge control line by a signal indicative of the speed (S_T) of the centrifugal compressor (14), and a difference station (40) operative to produce a difference signal representing the difference between an output of the multiplying station (34)

and a signal indicative of the flow rate (F_T) of the centrifugal compressor (14), the proportional and integral mode controller (46) being connected to receive said difference signal.

7. A method of controlling normal and emergency surge in a centrifugal compressor (14) having a bypass valve (48) controlled by a variable gain controller (46), the method being characterised by the steps of:

measuring (60, 64) an offset (d), in terms of flow rate, of a surge line (32) of the compressor (14) from a surge control line (30) established for the compressor according to a function of pressure differentials ($\% \Delta P_o$, $\% \Delta P_c$) across an orifice (22) in an inlet to the compressor (14) and across the compressor, respectively;

establishing (66) a controller gain control signal which is a function of the offset (d) of the surge control line (30) from the surge line (32); and

using the controller gain control signal to vary the gain (G) of the controller (46) according to the offset (d) of the surge control line (30) from the surge line (32) for normal surge conditions and to provide additional gain to the controller at a predetermined value of the offset (d) for emergency surge conditions.

8. A method according to Claim 7, wherein the bypass valve (48) controls the flow of fluid in a bypass path (50) across the centrifugal compressor (14), the method comprising controlling opening of the valve (48) in accordance with the gain (G) of the controller (46) and providing a stepping open action to the valve (48) according to the additional gain of the controller.

9. A method according to Claim 6 or Claim 7, wherein said pressure differentials ($\% \Delta P_o$, $\% \Delta P_c$) comprise the pressure differential $\% \Delta P_o$ across an orifice (22) in an inlet line (24) of the centrifugal compressor (14) and the pressure differential $\% \Delta P_c$ across the centrifugal compressor (14).

10. A method according to Claim 9, wherein the offset (d) is measured by generating signals indicative of the pressure differentials $\% \Delta P_o$ and $\% \Delta P_c$ by a constant (K'), and adding the result of the division to the signal indicative of the pressure differential $\% \Delta P_o$.

11. A method according to Claim 9 or Claim 10, wherein an output representative of the surge control line (30) is established as a function of the pressure differentials $\% \Delta P_o$ and $\% \Delta P_c$, the signal representative of the surge control line is multiplied by a signal indicative of the speed (S_T) of the centrifugal compressor, and a difference signal representing the difference between the result of said multiplication and a signal representative of the flow rate (F_T) of the centrifugal compressor is supplied to the variable gain controller (46).

Patentansprüche

1. Zentrifugalverdichter mit einem Pumpregelsystem mit anpassungsfähiger Verstärkung, wobei das System aufweist:

einen Regler (46) mit proportionaler und integraler Betriebsart, um eine Bypass-Leitung (50) des Zentrifugalverdichters (14) zu steuern, wobei der Regler (46) eine variable Verstärkung (G) hat, dadurch gekennzeichnet, daß das System weiterhin aufweist:

eine Abstandsbestimmungseinrichtung (60, 64), um den Abstand (d) zwischen einer Pumpregel­linie (30), welche für den Verdichter (14) auf der Basis der tatsächlichen Betriebsbedingungen bereitgestellt ist, und einer Pumplinie (32) des Verdichters (14), in Einheiten der Durchströmungsrate zu bestimmen,

eine Steuersignalbereitstellungseinrichtung (66, 70), um ein Steuersignal unter Ansprechen auf den Abstand (d) bereitzustellen, um die Verstärkung (G) des Reglers (46) zu ändern, und

eine Bypassventilsteuerung, welche mit dem Regler (46) verbunden ist, um die Menge des Bypass-Stromes an dem Zentrifugalverdichter (14) vorbei unter Ansprechen auf das Regelsignal zu verändern, wobei der Regler (46) eine Einstelleinrichtung gegen das Überschießen aufweist, um den Integralteil des Reglers so einzustellen, daß das Proportionalband des Proportionalteiles des Reglers in eben die Richtung der Regellinie (30) zu verschieben, auf welcher sich die Messung befindet, wenn der Regler seinen Ausgabegrenzwert erreicht, um damit ein Überschießen zu verhindern.

2. Verdichter nach Anspruch 1, wobei die Regelsignalbereitstellungseinrichtung (66, 70) einen Funktionsgenerator (66) aufweist zum Bereitstellen eines Verstärkungssignales für den Regler als Funktion des Abstandes (d).

3. Verdichter nach Anspruch 1 oder 2, wobei der Regler (46) lediglich ein Proportional- und Integralregler ist, wobei der Regler keinen Differentialteil aufweist, um Systemschwingungen zu vermeiden.

4. Verdichter nach Anspruch 1, 2 oder 3, wobei die Abstandsbestimmungseinrichtung (60, 64) so betreibbar ist, daß sie den Abstand (d) aus einem ersten Signal, welches eine Anzeige der Druckdifferenz ($\% \Delta P_o$) über einer Blendenöffnung (22) in einer Einlaßleitung (24) des Zentrifugalverdichters (14) und aus einem zweiten Signal ($\% \Delta P_c$) bestimmt, welches eine Anzeige für die Druckdifferenz über den Zentrifugalverdichter (14) ist.

5. Verdichter nach Anspruch 4, wobei die Abstandsbestimmungseinrichtung (60, 64) eine Dividierstation (60) aufweist, die so betreibbar ist, daß sie das zweite Signal durch eine Konstante (K') dividiert, und eine Summierstation (64) aufweist, um das Ergebnis dieser Division mit dem ersten Signal zu addieren.

6. Verdichter nach Anspruch 4 oder 5, wobei das System einen Funktionsgenerator (26) aufweist, der

auf die ersten und zweiten Signale anspricht, um einen Ausgangswert bereitzustellen, der die Pumpregellinie (30) repräsentiert, eine Multiplizierstation (34) aufweist, welche so betreibbar ist, daß sie den Ausgangswert der die Pumpregellinie repräsentiert, mit einem Signal multipliziert, welches eine Anzeige für die Geschwindigkeit (S_T) des Zentrifugalverdichters (14) ist, und eine Differenzstation (40) aufweist, welche so betreibbar ist, daß sie ein Differenzsignal erzeugt, welches der Differenz zwischen einem Ausgangswert der Multiplizierstation (34) und einem Signal ist, welches eine Anzeige für die Durchströmungsrate (F_T) des Zentrifugalverdichters (14) ist, wobei der Proportional- und Integralregler (46) so angeschlossen ist, daß er das Differenzsignal empfängt.

7. Verfahren zum Steuern des normalen sowie des Notpumpens in einem Zentrifugalverdichter (14), welcher ein Bypass-Ventil (48) hat, das durch einen Regler (46) mit variabler Verstärkung geregelt wird, wobei das Verfahren gekennzeichnet ist durch die Schritte:

Messen (60, 64) einer Verschiebung (d) einer Pumplinie (32) des Verdichters bezüglich einer Pumpregellinie (30), die für den Verdichter entsprechend einer Funktion der Druckdifferenzen ($\% \Delta P_o$, $\% \Delta P_e$) über einer Blende (22) in einer Einlaßleitung zu dem Verdichter (14) hin bzw. über den Verdichter bereitgestellt ist, und zwar in Einheiten der Durchströmungsrate,

Bereitstellen (66) eines Steuersignals für die Reglerv Verstärkung, welches eine Funktion der Verschiebung (d) der Pumpsteuerlinie (30) von der Pumplinie (32) ist, und

Verwenden des Steuersignals für die Verstärkungsregelung, um die Verstärkung (G) des Reglers (46) entsprechend der Verschiebung (d) der Pumpregellinie (30) von der Pumplinie (32) für normale Pumpbedingungen zu verändern und um eine zusätzliche Verstärkung für den Regler bei einem bestimmten Wert der Verschiebung (d) für Notpumpbedingungen vorzusehen.

8. Verfahren nach Anspruch 7, wobei das Bypass-Ventil (48) den Fluidstrom in einem Bypass-Weg (50) an dem Zentrifugalverdichter (14) vorbei regelt, wobei das Verfahren aufweist: Regeln des Öffnens des Ventiles (48) entsprechend der Verstärkung (G) des Reglers (46) und Bereitstellen eines stufenweisen Öffnungsvorganges für das Ventil (48) entsprechend der zusätzlich Verstärkung des Reglers.

9. Verfahren nach Anspruch 7 oder 8, wobei die Druckdifferenziale ($\% \Delta P_o$, $\% \Delta P_e$) den Druckunterschied bzw. das Druckdifferential $\% \Delta P_o$ über einer Blende (22) in einer Einlaßleitung (24) des Zentrifugalverdichters (14) sowie den Druckunterschied bzw. das Druckdifferential $\% \Delta P_e$ über den Zentrifugalverdichter (14) hinweg aufweisen.

10. Verfahren nach Anspruch 9, wobei die Verschiebung (d) gemessen wird durch das Erzeugen von Signalen, welche die Druckdifferenziale $\% \Delta P_o$ und $\% \Delta P_e$ erzeugen, das Signal, welches eine Anzeige für das Druckdifferential $\% \Delta P_o$ ist, durch eine Konstante (K') dividiert (60) wird, und das Ergebnis der Division zu dem Signal addiert wird, welches eine Anzeige für das Druckdifferential $\% \Delta P_o$ ist.

11. Verfahren nach Anspruch 9 oder 10, wobei ein Ausgangswert, der die Pumpregellinie (30) repräsentiert, als Funktion der Druckdifferenziale $\% \Delta P_o$ und $\% \Delta P_e$ bereitgestellt wird, das Signal, welches die Pumpregellinie repräsentiert, mit einem Signal multipliziert wird, welches eine Anzeige für die Geschwindigkeit (S_T) des Zentrifugalverdichters ist, und ein Differenzsignal, welches die Differenz zwischen dem Ergebnis dieser Multiplikation und einem Signal ist, das der Strömungsrate (F_T) zu dem Zentrifugalverdichter entspricht, dem Regler (46) mit variabler Verstärkung zugeführt wird.

Revendications

1. Compresseur centrifuge comportant un système de contrôle de pompe à gain adaptatif, le système comprenant:

un régulateur de mode intégral et proportionnel (46) pour contrôler une ligne de dérivation (50) du compresseur centrifuge (14), le régulateur (46) comportant un gain variable (G);

caractérisé en ce que le système comprend en outre:

un moyen d'évaluation de distance (60, 64) pour déterminer la distance (d), en termes de débit, entre une ligne de contrôle de pompe (30) établie pour le compresseur (14) sur la base de conditions de fonctionnement réelles et une ligne de pompe (32) du compresseur (14);

un moyen d'établissement de signal de commande (66, 70) pour établir un signal de commande de réponse à la distance (d) pour changer le gain (G) du régulateur (46); et

un moyen de contrôle de vanne de dérivation relié au régulateur (46) pour faire varier l'importance de la dérivation dans le compresseur centrifuge (14) en réponse au signal de commande;

le régulateur (46) comprenant un réglage d'antiremontage pour ajuster le mode intégral du régulateur afin de faire passer la bande proportionnelle du mode proportionnel du régulateur sur le même côté de la ligne de contrôle (30) que celui de la mesure lorsque le régulateur atteint sa limite de sortie afin d'empêcher un dépassement.

2. Compresseur selon la revendication 1, dans lequel le moyen d'établissement de signal de commande (66, 70) comprend un générateur de fonctions (66) pour établir un signal de gain du régulateur comme fonction de la distance (d).

3. Compresseur selon la revendication 1 ou 2, dans lequel le régulateur (46) n'est qu'un régulateur à fonction proportionnelle et intégrale, le régulateur ne comportant pas de mode de dérivation afin d'empêcher une oscillation du système.

4. Compresseur selon la revendication 1, 2 ou 3, dans lequel le moyen d'évaluation de distance (60, 64)

est apte à déterminer la distance (d) à partir d'un premier signal indiquant le différentiel de pression ($\% \Delta P_o$) dans un orifice (22) dans une ligne d'entrée (24) du compresseur centrifuge (14) et d'un second signal ($\% \Delta P_e$) indiquant le différentiel de pression dans le compresseur centrifuge (14).

5. Compresseur selon la revendication 4, dans lequel le moyen d'évaluation de distance (60, 64) comprend un poste de division (60) apte à diviser ledit second signal par une constante (K') et un poste d'addition (64) pour ajouter le résultat de ladite division audit premier signal.

6. Compresseur selon la revendication 4 ou 5, dans lequel le système comprend un générateur de fonctions (26) répondant auxdits premier et second signaux pour établir une sortie représentative de la ligne de contrôle de pompage (30), un poste de multiplication (34) apte à multiplier la sortie représentative de la ligne de contrôle de pompage par un signal indiquant la vitesse (S_T) du compresseur centrifuge (14), et un poste différentiel (40) apte à produire un signal différentiel représentant la différence entre une sortie du poste de multiplication (34) et un signal indiquant le débit (F_T) du compresseur centrifuge (14), le régulateur à mode proportionnel et intégral (46) étant raccordé pour recevoir ledit signal différentiel.

7. Procédé de contrôle de pompage normal et urgent dans un compresseur centrifuge (14) comportant une vanne de dérivation (48) commandée par un régulateur à gain variable (46), le procédé étant caractérisé par les phases de:

mesure (60, 64) d'un décalage (d), en termes de débit, d'une ligne de pompage (32) du compresseur (14) à partir d'une ligne de contrôle de pompage (30) établie pour le compresseur selon une fonction de différentiels de pression ($\% \Delta P_o$, $\% \Delta P_e$) dans un orifice (22) à une entrée vers le compresseur (14) et dans le compresseur, respectivement;

établissement (66) d'un signal de commande de gain du régulateur qui constitue une fonction du décalage (d) de la ligne de contrôle de pompage (30) à partir de la ligne de pompage (32); et

utilisation du signal de commande de gain du régulateur pour faire varier le gain (G) du régulateur (46) en fonction du décalage (d) de la ligne de contrôle de pompage (30) à partir de la ligne de pompage (32) pour des conditions de pompage normal et pour fournir un gain supplémentaire au régulateur à une valeur prédéterminée du décalage (d) pour des conditions de pompage d'urgence.

8. Procédé selon la revendication 7, dans lequel la vanne de dérivation (48) contrôle le flux de fluide dans une ligne de dérivation (50) dans le compresseur centrifuge (14), le procédé comprenant le contrôle de l'ouverture de la vanne (48) selon le gain (G) du régulateur (46) et la fourniture à la vanne (48) d'une action d'ouverture échelonnée selon le gain supplémentaire du régulateur.

9. Procédé selon la revendication 6 ou 7, dans lequel lesdits différentiels de pression ($\% \Delta P_o$, $\% \Delta P_e$) comprennent le différentiel de pression $\% \Delta P_o$ dans un orifice (22) dans une ligne d'entrée (24) du compresseur centrifuge (14) et le différentiel de pression $\% \Delta P_e$ dans le compresseur centrifuge (14).

10. Procédé selon la revendication 9, dans lequel le décalage (d) est mesuré en produisant des signaux indiquant les différentiels de pression $\% \Delta P_o$ et $\% \Delta P_e$, en divisant (60) le signal indiquant le différentiel de pression $\% \Delta P_e$ par une constante (K'), et en ajoutant le résultat de la division au signal indiquant le différentiel de pression $\% \Delta P_o$.

11. Procédé selon la revendication 9 ou 10, dans lequel une sortie représentative de la ligne de contrôle de pompage (30) est établie comme fonction des différentiels de pression $\% \Delta P_o$ et $\% \Delta P_e$, le signal représentatif de la ligne de contrôle de pompage est multiplié par un signal indiquant la vitesse (S_T) du compresseur centrifuge, et un signal différentiel représentant la différence entre le résultat de ladite multiplication et un signal représentatif du débit (F_T) du compresseur centrifuge est fourni au régulateur à gain variable (46).
