

ABSTRACT

HALOGEN LAMP

In a halogen lamp, the halogen bulb (28) is supported in the housing (12) so that it slides in the axial direction and is pushed outward by at least one spring (42). The bulb is held in a rear position inside the housing (12) by a clamping ring (18), which is mounted on the housing. By removing the clamping ring (18) from the housing (12), the halogen bulb (28) is automatically pushed out into a position defined by stops (44), where it can be easily gripped by hand and replaced if desired. The bulb can be pushed back to its rear position just as easily by placing the clamping ring (18) back in position. (Figure 2)
