BACKGROUND

Technical Field

10 The invention relates to modulators of the Mas-related G- protein coupled
receptor X4, to products containing the same, as well as to methods of their use and
preparation.

Description of the Related Art

Mas-related G protein receptors (MRGPRs) are a group of orphan receptors
15 with limited expression in very specialized tissues. Very little is known about the function
of most of these receptors. There are eight related receptors in this class expressed in
humans, only four of which have readily identifiable orthologs in other species (*i.e.*, MRGPR
D, E, F and G). The other four receptors (MRGPR X1, X2, X3 and X4) have no counterpart,
based on homology, in species other than human.

20 BRIEF SUMMARY

This invention is based, in part, on the identification that functionally in mice
MRGPR A1 corresponds, at least in part, to the human MRGPR X4. These receptors mediate
disorders including chronic itch (*e.g.*, pruritus), inflammation disorders, autoimmunity, skin
disorders, cardiovascular disease, lung inflammation/COPD, and adverse skin reactions to

drugs. More specifically, both MRGPR A1 and MRGPR X4 are expressed in sensory neurons, skin melanocytes, dendritic cells, polymorphonuclear cells, macrophages, bronchial epithelial cells, lung smooth muscle and dorsal root ganglia. It has now been identified that both MRGPR A1 and MRGPR X4 are receptors for (or sensitive to activation by) circulating

5 bilirubin and its metabolites, and thus are important for itch sensation in conditions of elevated bilirubin such as cholestatic pruritus. In addition, MRGPR X4 is activated by multiple additional components of bile including bile acids and metabolites thereof and heme metabolites including bilirubin and urobilin. Bile acids and bilirubin are highly elevated in cholestatic pruritus while urobilin, which is a potent mediator of itch induction in mouse

10 model, and thus may be important for itch sensation in conditions of elevated urobilin such as uremic pruritus. Thus, modulating MRGPR X4 allows for treatment of autoimmune diseases such as psoriasis, multiple sclerosis, Steven Johnson's Syndrome, and other chronic itch conditions as explained in more detail below.

Accordingly, in an embodiment, methods are provided for modulating a

15 MRGPR X4 by contacting the MRGPR X4 with an effective amount of a compound having the structure of Formula (I):

or a pharmaceutically acceptable isomer, racemate, hydrate, solvate, isotope, or salt thereof, wherein n , x , A, Q₁, Q₂, Z, R, R¹, R², R³, R⁴ and R⁵ are as defined below.

20 In another embodiment, methods are provided for treating a MRGPR X4 dependent condition by administering to a subject in need thereof an effective amount of a

compound having the structure of Formula (I), or a pharmaceutically acceptable isomer, racemate, hydrate, solvate, isotope, or salt thereof.

In more specific embodiments, the MRGPR X4 dependent condition is one or more of an itch associated condition, a pain associated condition, an inflammation-associated condition, or an autoimmune disorder.

In another embodiment, pharmaceutical compositions are provided comprising a compound having the structure of Formula (I), or a pharmaceutically acceptable isomer, racemate, hydrate, solvate, isotope, or salt thereof, in combination with a pharmaceutically acceptable excipient.

In another embodiment, compounds are provided having one or more of the structures disclosed herein, or a pharmaceutically acceptable isomer, racemate, hydrate, solvate, isotope, or salt thereof.

In further embodiments, prodrugs and/or metabolites of a compound having the structure of Formula (I) are also provided. In the case of prodrugs, a compound (*i.e.*, prodrug) may be administered to a subject which is then converted *in vivo* to a compound having the structure of Formula (I). In the case of metabolites, following administration to a subject of a compound having the structure of Formula (I) such compound may be converted *in vivo* to an active metabolite.

5 DETAILED DESCRIPTION

As mentioned above, the invention relates to modulators of the MRGPR X4, to products containing the same, as well as to methods of their use and preparation. This invention is based, in part, on the identification that in mice MRGPR A1 functionally corresponds to the human MRGPR X4. These receptors mediate disorders including chronic and intermittent itch (*e.g.*, pruritus), inflammation disorders, autoimmunity, skin disorders, and adverse skin reactions to drugs and infectious diseases. More specifically, both MRGPR A1 and MRGPR X4 are expressed in sensory neurons and dorsal root ganglia. It has now been identified that both MRGPR A1 and MRGPR X4 are receptors for (or sensitive to activation by) circulating bilirubin and its metabolites, and thus are important for itch sensation in conditions of elevated bilirubin such as cholestatic pruritus and end-stage renal failure. In addition, MRGPR X4 is also activated by bile acids and metabolites thereof, which are also elevated in cholestatic pruritus. Furthermore, urobilin, an oxidative product of the heme metabolite urobilinogen solely excreted by the kidney, is a potent agonist of MRGPRX4 and pruritogen, and thus may be important for itch sensation in conditions of elevated urobilin such as uremic pruritus, kidney disease and end-stage renal failure. Thus, modulating MRGPR X4 allows for treatment of autoimmune diseases such as psoriasis, multiple sclerosis, Steven Johnson's Syndrome, atopic disorders such as atopic dermatitis and other chronic itch conditions as explained in more detail below.

MRGPRs appear to be sensory receptors that recognize their external environment to exogenous or endogenous signals/chemicals. These receptors likely respond to multiple chemical ligands/agonists. For example MRGPR X4 recognizes bilirubin, bile acids, and urobilin as agonist signals. In certain embodiments, molecules of this invention modulate MRGPR X4 by functioning as inverse agonists that are capable of blocking

multiple chemical entities, and/or as competitive antagonists that can specifically block individual ligands. In one embodiment, such modulations are selective against other MRGPRs, such as MRGPR X1, X2 and/or X3.

Accordingly, in one embodiment, methods for modulating a MRGPR X4 are provided comprising contacting the MRGPR X4 with an effective amount of compound having the structure of Formula (I):

In another embodiment, a carboxylic acid isostere may be cyclic and have one of the following structures:

“Isomer” is used herein to encompass all chiral, diastereomeric or racemic forms of a structure, unless a particular stereochemistry or isomeric form is specifically indicated. Such compounds can be enriched or resolved optical isomers at any or all asymmetric atoms as are apparent from the depictions, at any degree of enrichment. Both racemic and diastereomeric mixtures, as well as the individual optical isomers can be synthesized so as to be substantially free of their enantiomeric or diastereomeric partners, and these are all within the scope of certain embodiments of the invention. The isomers resulting from the presence of a chiral center comprise a pair of nonsuperimposable-isomers that are called “enantiomers.” Single enantiomers of a pure compound are optically active (*i.e.*, they are capable of rotating the plane of plane polarized light and designated *R* or *S*).

“Isolated optical isomer” means a compound which has been substantially purified from the corresponding optical isomer(s) of the same formula. For example, the isolated isomer may be at least about 80%, at least 80% or at least 85% pure by weight. In other embodiments, the isolated isomer is at least 90% pure or at least 98% pure, or at least 99% pure by weight.

“Substantially enantiomerically or diastereomerically” pure means a level of enantiomeric or diastereomeric enrichment of one enantiomer with respect to the other enantiomer or diastereomer of at least about 80%, and more specifically in excess of 80%, 85%, 90%, 95%, 98%, 99%, 99.5% or 99.9%.

The terms “racemate” and “racemic mixture” refer to an equal mixture of two enantiomers. A racemate is labeled “(±)” because it is not optically active (*i.e.*, will not rotate plane-polarized light in either direction since its constituent enantiomers cancel each other out). All compounds with an asterisk (*) adjacent to a tertiary or quaternary carbon are

optically active isomers, which may be purified from the respective racemate and/or synthesized by appropriate chiral synthesis.

A "hydrate" is a compound that exists in combination with water molecules. The combination can include water in stoichiometric quantities, such as a monohydrate or a dihydrate, or can include water in random amounts. As the term is used herein a "hydrate" refers to a solid form; that is, a compound in a water solution, while it may be hydrated, is not a hydrate as the term is used herein.

A "solvate" is similar to a hydrate except that a solvent other than water is present. For example, methanol or ethanol can form an "alcoholate", which can again be stoichiometric or non-stoichiometric. As the term is used herein a "solvate" refers to a solid form; that is, a compound in a solvent solution, while it may be solvated, is not a solvate as the term is used herein.

"Isotope" refers to atoms with the same number of protons but a different number of neutrons, and an isotope of a compound of Formula (I) includes any such compound wherein one or more atoms are replaced by an isotope of that atom. For example, carbon 12, the most common form of carbon, has six protons and six neutrons, whereas carbon 13 has six protons and seven neutrons, and carbon 14 has six protons and eight neutrons. Hydrogen has two stable isotopes, deuterium (one proton and one neutron) and tritium (one proton and two neutrons). While fluorine has a number of isotopes, fluorine-19 is longest-lived. Thus, an isotope of a compound having the structure of Formula (I) includes, but not limited to, compounds of Formula (I) wherein one or more carbon 12 atoms are replaced by carbon-13 and/or carbon-14 atoms, wherein one or more hydrogen atoms are replaced with deuterium and/or tritium, and/or wherein one or more fluorine atoms are replaced by fluorine-19.

"Salt" generally refers to an organic compound, such as a carboxylic acid or an amine, in ionic form, in combination with a counter ion. For example, salts formed between acids in their anionic form and cations are referred to as "acid addition salts". Conversely, salts formed between bases in the cationic form and anions are referred to as "base addition salts."

The term "pharmaceutically acceptable" refers an agent that has been approved for human consumption and is generally non-toxic. For example, the term "pharmaceutically acceptable salt" refers to nontoxic inorganic or organic acid and/or base addition salts (see, e.g., Lit *et al.*, Salt Selection for Basic Drugs, *Int. J. Pharm.*, **33**, 201-217, 5 1986) (incorporated by reference herein).

Pharmaceutically acceptable base addition salts of compounds of the invention include, for example, metallic salts including alkali metal, alkaline earth metal, and transition metal salts such as, for example, calcium, magnesium, potassium, sodium, and zinc salts. Pharmaceutically acceptable base addition salts also include organic salts made 10 from basic amines such as, for example, *N,N*-dibenzylethylenediamine, chlorprocaine, choline, diethanolamine, ethylenediamine, meglumine (N-methylglucamine), and procaine.

Pharmaceutically acceptable acid addition salts may be prepared from an inorganic acid or from an organic acid. Examples of inorganic acids include hydrochloric, hydrobromic, hydriodic, nitric, carbonic, sulfuric, and phosphoric acids. Appropriate organic 15 acids may be selected from aliphatic, cycloaliphatic, aromatic, aromatic aliphatic, heterocyclic, carboxylic, and sulfonic classes of organic acids, examples of which include formic, acetic, propionic, succinic, glycolic, gluconic, lactic, malic, tartaric, citric, ascorbic, glucuronic, maleic, fumaric, pyruvic, aspartic, glutamic, benzoic, anthranilic, 4-hydroxybenzoic, phenylacetic, mandelic, hippuric, malonic, oxalic, embonic (pamoic), 20 methanesulfonic, ethanesulfonic, benzenesulfonic, panthothenic, trifluoromethanesulfonic, 2-hydroxyethanesulfonic, *p*-toluenesulfonic, sulfanilic, cyclohexylaminosulfonic, stearic, alginic, β -hydroxybutyric, salicylic, -galactaric, and galacturonic acid.

Although pharmaceutically unacceptable salts are not generally useful as medicaments, such salts may be useful, for example as intermediates in the synthesis of 25 compounds having the structure of Formula I, for example in their purification by recrystallization.

In another embodiment, a method of treating a subject having a MRGPR X4 dependent condition is provided, the method comprising administering to the subject a pharmaceutically effective amount of a compound having the structure of Formula (I):

and wherein each occurrence of carbocycle or heterocycle is substituted with 0, 1, 2 or 3 substituents individually selected from halogen, oxo, halo, alkyl, haloalkyl,

As used herein, the phrase “MRGPR X4 dependent condition” means a condition where the activation, over sensitization, or desensitization of MRGPR X4 by a natural or synthetic ligand initiates, mediates, sustains, or augments a pathological condition.
15 For example, it is known that some itch or pain sensations are caused by elevated bilirubin and its metabolites or bile acids in patients suffering from pruritus, atopic or other autoimmune or inflammatory diseases. It has been found that MRGPR X4 is sensitive to (or activated by) bilirubin and its metabolites, including urobilin, or bile acids. Without limited by theory, it is to be understood that by modulating MRGPR X4, the itch or pain sensations
20 can be eased.

In some embodiments, the MRGPR X4 dependent condition is a condition that is caused by the activation of MRGPR X4 by a bile acid. As used herein, the term “bile acid” includes primary bile acids (e.g., cholic acid, chenodeoxycholic acid), conjugated bile acids, also referred to as bile salts (e.g., taurocholic acid, glycocholic acid,
25 taurochenodeoxycholic acid, glycochenodeoxycholic acid), secondary bile acids (e.g., deoxycholic acid, lithocholic acid), and bile acid analogs. In some embodiments, a bile acid analog is a farnesoid X-receptor (FXR) agonist. Thus, the compounds of the present disclosure may be used for treating an MRGPR X4 dependent condition caused by activation of MRGPR X4 by a bile acid and that would benefit from modulating MRGPR X4.

In some embodiments, the MRGPR X4 dependent condition is an itch associated condition, a pain associated condition, an autoimmune condition, or an autoimmune or inflammatory disorder.

As used herein, the phrase “itch associated condition” means pruritus
5 (including acute and chronic pruritus) associated with any condition. The itch sensation can originate, *e.g.*, from the peripheral nervous system (*e.g.*, dermal or neuropathic itch) or from the central nervous system (*e.g.*, neuropathic, neurogenic or psychogenic itch). Thus, in one embodiment, the method of present invention is provided to treat an itch associated condition, such as chronic itch; cholestatic pruritus; contact dermatitis; Allergic blepharitis;

In other embodiments, prodrugs and/or metabolites of compounds of Formula (I), as well as Formulas (II) through (XXIV), are provided.

- 5 Thus, in one embodiment, prodrugs of a compound of the invention are provided, which upon administration to a subject, undergo chemical conversion by metabolic or other physiological processes to become active pharmacological substances. Conversion by metabolic or other physiological processes includes, without limitation, enzymatic (*e.g.*, specific enzymatically catalyzed) and non-enzymatic (*e.g.*, general or specific acid or base
- 10 induced) chemical transformation of the prodrug into the active pharmacological substance. In general, such prodrugs will be functional derivatives of a compound of the invention which are readily convertible *in vivo* into a compound of the invention. Conventional procedures for the selection and preparation of suitable prodrug derivatives are described, for example, in *Design of Prodrugs*, ed. H. Bundgaard, Elsevier, 1985.

Accordingly, a “prodrug” is a substance that, upon administration to a subject, is converted *in vivo* by the action of biochemicals within the subject’s body, such as enzymes, to an active pharmaceutical ingredient. Examples of prodrugs include esters of carboxylic acid groups, which can be hydrolyzed by endogenous esterases as are found in the
5 bloodstream of humans and other mammals. In one embodiment, substances are provided that can be administered to a subject which are then converted within the subject’s body to provide a compound having the structure of Formula (I), or any of Formulas (II) through (XXIV).

In this regard, prodrugs of carboxylic acids are typically esters and amides,
10 which can readily be made from the corresponding carboxylic acid by known techniques. For example, in one embodiment, prodrugs may be generated by converting the carboxylic acid moiety of the compounds of Formula (I) through (VII) and (XVI) through (XXIV) to an ester functional group: including, alkyl esters such as methyl, ethyl, isopropyl and n-butyl esters; aryl esters such as phenyl and indanyl esters; double esters such as (acyloxy)alkyl or
15 [(alkoxycarbonyl)oxy]methyl esters; and cyclic carbonates such as (oxodioxolyl)methyl esters. In another embodiment, the carboxylic acid moiety may incorporate a carbamoylmethyl, aminoalkyl, or amidoalkyl moiety to provide carbamoylmethyl, aminoalkyl and amidoalkyl esters, respectively. In yet another embodiment, the carboxylic acid moiety can incorporate esters of acylglycerols and bis(acyl-amino)propan-2-ols. In a
20 further embodiment, the carboxylic acid moiety can incorporate amide groups, including N-hydroxyamide, N-acylsulfonamides and N-acylsulfonylureas.

As used herein, a “metabolite” is a compound that, following administration to a subject, is converted within the body of the subject to yield an active substance. Such conversion often involves hydrolysis, phosphorylation and/or oxidation/reduction processes,
25 and may be mediated by any number of enzymes (*e.g.*, esterases, phosphatases, cytochrome P450, and the like), as well by different environments within the body (*e.g.*, changes in pH).

In one embodiment, compounds of Formula (I), as well as Formulas (II) through (XXII), as applicable, are modified to encompass metabolites of the parent compound. In another embodiment, compounds of Formula (I), as well as Formulas (II)

through (XXII), are modified to have the “A-ring” carboxylic acid of Formula (I) derivatized with carbohydrate or amino acid compounds. In a further embodiment, the A-ring carboxylic acid moiety is derivatized with glucuronic acid or the amino acid glycine to give compounds of Formulas (XXV) and (XXVI), respectively:

5

In certain embodiments, the invention provides a pharmaceutical composition comprising a compound of any one of Formulas (I) through (XIV) together with at least one pharmaceutically acceptable carrier, diluent, or excipient. For example, the active compound will usually be mixed with a carrier, or diluted by a carrier, or enclosed within a carrier which can be in the form of an ampoule, capsule, sachet, paper, or other container. When the active compound is mixed with a carrier, or when the carrier serves as a diluent, it can be solid, semi-solid, or liquid material that acts as a vehicle, excipient, or medium for the active compound. The active compound can be adsorbed on a granular solid carrier, for example contained in a sachet. Some examples of suitable carriers are water, salt solutions, alcohols, polyethylene glycols, polyhydroxyethoxylated castor oil, peanut oil, olive oil, gelatin, lactose, terra alba, sucrose, dextrin, magnesium carbonate, sugar, cyclodextrin, amylose, magnesium stearate, talc, gelatin, agar, pectin, acacia, stearic acid, or lower alkyl ethers of cellulose, silicic acid, fatty acids, fatty acid amines, fatty acid monoglycerides and diglycerides, pentaerythritol fatty acid esters, polyoxyethylene, hydroxymethylcellulose, and polyvinylpyrrolidone. Similarly, the carrier or diluent can include any sustained release

material known in the art, such as glyceryl monostearate or glyceryl distearate, alone or mixed with a wax.

5 pharmaceutically acceptable isomer, racemate, hydrate, solvate, isotope or salt thereof, formulated with a pharmaceutically acceptable carrier, which can also include other additives, and manufactured or sold with the approval of a governmental regulatory agency as part of a therapeutic regimen for the treatment of disease in a mammal. Pharmaceutical compositions can be formulated, for example, for oral administration in unit dosage form
10 (*e.g.*, a tablet, capsule, caplet, gelcap, or syrup); for topical administration (*e.g.*, as a cream, gel, lotion, or ointment); for intravenous administration (*e.g.*, as a sterile solution free of particulate emboli and in a solvent system suitable for intravenous use); or in any other formulation described herein. Conventional procedures and ingredients for the selection and preparation of suitable formulations are described, for example, in *Remington: The Science*
15 *and Practice of Pharmacy*, 21st Ed., Gennaro, Ed., Lippencott Williams & Wilkins (2005) and in The United States Pharmacopeia: The National Formulary (USP 36 NF31), published in 2013.

For example, reactions may be carried out in any suitable solvent, or other reagents to perform the transformation(s) necessary. Generally, suitable solvents are protic or aprotic solvents which are substantially non-reactive with the reactants, the intermediates or products at the temperatures at which
5 the reactions are carried out (*i.e.*, temperatures which may range from the freezing to boiling temperatures). A given reaction may be carried out in one solvent or a mixture of more than one solvent. The compounds and intermediates produced according to the methods of the invention may require purification. Purification of organic compounds is well known to a person skilled in the art and there may be several ways of purifying the same compound. In some cases, no purification may be
15 necessary. In some cases, the compounds may be purified by crystallization. In some cases, impurities may be stirred out using a suitable solvent. In some cases, the compounds may be purified by chromatography, particularly flash column chromatography, using purpose-made or prepacked silica gel cartridges and eluents such as gradients of solvents such as heptane, ether, ethyl acetate, acetonitrile, ethanol and the like. In some cases, the compounds

Purification methods as described herein may provide compounds of the present invention which possess a sufficiently basic or acidic functionality in the form of a salt, such as, in the case of a compound of the present invention which is sufficiently basic, a trifluoroacetate or formate salt, or, in the case of a compound of the present invention which
25 is sufficiently acidic, an ammonium salt. A salt of this type can either be transformed into its free base or free acid form, respectively, by various methods known to a person skilled in the art, or be used as salts in subsequent biological assays. It is to be understood that the specific form of a compound of the present invention as isolated and as described herein is

not necessarily the only form in which said compound can be applied to a biological assay in order to quantify the specific biological activity.

Chemical names were generated using the ChemDraw naming software (Version 17.0.0.206) by PerkinElmer Informatics, Inc. In some cases, generally accepted
5 names of commercially available reagents were used in place of names generated by the naming software.

Step 1-1. Synthesis of methyl 3-((4-chloro-2-(trifluoromethyl)phenoxy)methyl)benzoate (Compound 1-0)

To a stirring solution of methyl 3-(bromomethyl)benzoate (150 mg, 655 μmol) in MeCN (3 mL) were added 2-methyl-4-(trifluoromethyl)phenol (115 mg, 655 μmol) and K_2CO_3 (118 mg, 0.85 mmol). The reaction mixture was heated at 60°C for 3h then cooled to room temperature and diluted with H_2O (3 mL). The aqueous layer was extracted with Et_2O (2 x 6 mL) and EA (1 X 6 mL) and the combined organic layers were dried (Na_2SO_4), filtered, concentrated and purified by SiO_2 chromatography (EA/hexanes) to afford 203 mg (77.4%) of methyl 3-((2-methyl-4-(trifluoromethyl)phenoxy)methyl)benzoate (Compound 1-0) as a white solid. LCMS-ESI (m/z) calculated for $\text{C}_{17}\text{H}_{15}\text{F}_3\text{O}_3$: 324.3; found 346.1 $[\text{M}+\text{Na}]^+$, t_{R} = 6.68 min (Method 1).

Synthesis of Compound 65-1

Scheme 65

15 Reagents: (i) Na₂CO₃, DMF; (ii) Fe, HCl, MeOH

Step 65-1. Synthesis of 2-chloro-1-((3-nitrobenzyl)oxy)-4-(trifluoromethyl)benzene (INT 65-1)

5 Into a 250 mL flask were added 1-(bromomethyl)-3-nitrobenzene (1.0g, 4.37 mmol), 2-chloro-4-(trifluoromethyl)phenol (858 mg, 4.37 mmol), Na₂CO₃ (1.39g, 13 mmol) and DMF (50 mL). After stirring at 50 °C for 18h, the reaction was quenched with H₂O and extracted into EA. The organic layers were dried (Na₂SO₄), concentrated and purified by SiO₂ chromatography (EA/Hexane) to provide 1.0 g (69%) of 2-chloro-1-((3-nitrobenzyl)oxy)-4-(trifluoromethyl) benzene (INT 65-1). LCMS-ESI no mass observed, t_R = 5.66 min (Method 11).

Step 65-2. Synthesis of 3-((2-chloro-4-(trifluoromethyl)phenoxy)methyl)aniline (Compound 65-1)

15 INT 65-1 (1.0g, 3.02 mmol) was dissolved in MeOH (10 mL) and excess 2N HCl and Fe powder (210 mg, 3.77 mmol) were added. The reaction mixture was heated to 80 °C for 18 h, filtered through Celite, concentrated, and purified over SiO₂, (EA/hexane).

20 The resulting material was further purified by reverse- phase chromatography (MeOH/H₂O with 0.1% formic acid) to provide 800 mg (60%) of 3-((2-chloro-4-(trifluoromethyl)phenoxy)methyl)aniline (Compound 65-1). LCMS-ESI (m/z) calculated for C₁₄H₁₁ClF₃NO: 301.05; found 302.1 (M+H)⁺, t_R = 2 min (Method 11).

EXAMPLE 66

MRGPRX4 Activity

HEK cells stably transfected to express human MRGPR X4 were maintained in an incubator at 37° C with 5% CO₂ and grown in DMEM media with 10% fetal bovine serum (FBS) and 1% each of sodium pyruvate, Glutamax, penicillin /streptomycin, and Geneticin. HEK cells stably transfected to express mouse MRGPR A1 were maintained in the same incubator and grown in DMEM media with 10% FBS, 1% each of sodium pyruvate, Glutamax, penicillin /streptomycin, Geneticin, and 2.2 mg/mL Hygromycin.

Cells were plated in a 384-well assay plate at 20,000 cells per well in 12 µL of Opti-MEM and kept in an incubator overnight. On the day of the assay, compounds solubilized at 10 mM in DMSO were added as a 10-point curve (10 uM final top concentration with 1:3 serial dilutions) using a Tecan D300E digital dispenser. Agonists were diluted in assay buffer (final concentrations of 5.7 mM Tris-HCl, 43 mM NaCl, 50 mM LiCl, pH= 8) and 2 µL of the appropriate agonist are added to each well. Final concentrations of agonists were 10 µM bilirubin, 20 µM deoxycholic acid, or 100 µM conjugated bilirubin (obtained from Lee Biosolutions, catalog # 910-12). Final concentrations of DMSO were kept consistent across the plate. Plates were incubated in the dark for 1 h at 37 °C and then for 30 minutes at room temperature. IP-1 standards and HTRF detection reagents were added according to the IP-One – Gq Kit purchased from Cisbio (part number 62IPAPEJ) and incubated in the dark for 1 h at room temperature. The plate was read on a Molecular Devices SpectraMax iD5 plate reader. The HTRF ratio was calculated from the raw data and graphed using GraphPad Prism to calculate an IC₅₀ value for each compound.

Activity data for selected MRGPR X4 antagonists (versus 10 µM Bilirubin agonist) are displayed in Table 66A. The activity ranges are denoted as follows: “++++” denotes antagonist activity <100 nM; “++++” denotes antagonist activity between 100 and 500 nM; “+++” denotes activity between 500 and 1000 nM; “++” denotes activity between 1000 and 2500 nM; and “+” denotes activity >2500 nM.

Mouse Pharmacokinetics Studies

Compounds were formulated in 5% DMSO, 5% Solutol, and 90% phosphate buffered saline at a concentration of 5 mg/mL, and typically appeared as a fine homogenous suspension. Male C57BL/6 mice (n=3 / compound) were administered a 50 mg/kg dose of each compound by oral gavage under a non-fasted condition. Blood samples were collected

10

via the saphenous vein onto K2-EDTA at 0.25, 0.5, 1, 2, 4, 8 and 24 hours after dosing, and plasma was prepared and stored at $\leq 60^{\circ}\text{C}$ until analysis. Plasma sample preparation for analysis was done by protein precipitation using acetonitrile (including Celecoxib as an internal standard) followed by centrifugation. Compound concentrations were determined

5 in extracted plasma using LC-MS/MS relative to an 8 point standard curve covering the 1 to 3000 ng/mL range. Non-compartmental analysis using Phoenix WinNonlin was used to estimate pharmacokinetic parameters including area under the curve, clearance, and half-life. The administered dose was confirmed by analysis of residual dosing material by UPLC-UV

10 relative to a single point calibration sample. The results of these studies are presented in Table 67.

EXAMPLE 68

Urobilin is a Potent MRGPRX4 Agonist and Pruritogen

Plasma urobilin is an oxidative product of the heme metabolite urobilinogen. Urobilinogen is a by-product of bilirubin reduction in the intestines. Some of urobilinogen
5 remains in the large intestine, where it is converted to stercobilin. Some urobilinogen is reabsorbed into the bloodstream and delivered to the kidney, where it is oxidized to urobilin upon exposure to air.

Metabolites of heme (bilirubin, biliverdin, urobilin, urobilinogen, and stercobilin) were analyzed for *in vitro* activation of MRGPRX4. Cells were plated in a 384-
10 well assay plate at 20,000 cells per well in 12 μ L of Opti-MEM and kept in an incubator overnight. On the day of the assay, different agonists solubilized at 10 mM in 0.1% NaOH were added as a 10-point curve (10 mM final top concentration with 1:3 serial dilutions) using a Tecan D300E digital dispenser. Agonists were diluted in assay buffer (final concentrations of 5.7 mM Tris-HCl, 43 mM NaCl, 50 mM LiCl, pH= 8) and 2 μ L of the
15 appropriate agonist are added to each well. Plates were incubated in the dark for 1 h at 37 °C and then for 30 minutes at room temperature. IP-1 standards and HTRF detection reagents were added according to the IP-One – Gq Kit purchased from Cisbio (part number 62IPAPEJ) and incubated in the dark for 1 h at room temperature. The plate was read on a Molecular Devices SpectraMax iD5 plate reader. The HTRF ratio was calculated from the
20 raw data and graphed using GraphPad Prism to calculate an IC₅₀ value for each compound.

The results of this study are shown in FIG. 1. Urobilin was shown to be at least 10-fold more efficacious at activating MRGPRX4 than bilirubin.

The ability of urobilin to induce itch in wild type mice was also tested. Typical mouse itch studies occurred as follows: C57B6J male mice were multiple- housed
25 in a normal light cycle (6am on; 6pm off) under temperature and humidity-controlled conditions. The mice were handled and habituated to test chambers before testing, then placed in individual SCLABA test chambers. After 20 minutes, the mice were dosed PO with vehicle (saline, pH 7-8). After 30 minutes, the pruritogen of study (100mL in saline) or saline is given subcutaneously (SC) on the neck on the midline behind the ears. Video was

recorded from the first pruritogen injection for 30 minutes using the SCLABA system. Scratching bouts were scored from SCLABA thumbnails using 12/45/85/100 waveform criteria. Group sizes were typically 9-10 animals per group.

As shown in FIG. 2A, urobilin induced scratch response in mice in a dose dependent manner. Itch induction of urobilin was also compared to deoxycholic acid agonist and bilirubin agonist. As shown in FIG. 2B, urobilin is a potent inducer of scratch response in mice.

EXAMPLE 69

Bilirubin and Urobilin Can Be Degraded by Light,

Reducing Their Agonist Activity on MRGPRX4

Bilirubin and Urobilin are agonists of MRGPRX4 that have been demonstrated to be active pruritogens. Light therapy has been shown to reduce itch in cholestatic pruritis patients, which has been attributed to light-induced decomposition or chemical modification of bilirubin. To further explore the contribution of light degradation toward the reduction of MRGPRX4 agonism, bilirubin and urobilin were pre-treated with different lighting and their activities were measured.

Stock solutions of both bilirubin and urobilin were made at 210 μ M in 0.1N NaOH (aq). Samples were stored either at room temperature in the dark, in a -20°C freezer in the dark, room temperature on the countertop under normal, lab lighting conditions, or at room temperature under a 400 nm blue-light lamp (similar to medical lamps used for treating jaundice). Samples were evaluated after 24 hours and the percent remaining of urobilin and bilirubin, relative to a time zero standard, were determined by measurement of the degradation of the analyte contained in the samples as determined by tandem mass spectroscopy (LC MS/MS). The samples (at 24 h) were also evaluated for their ability to agonize MRGPRX4.

After 24h, the freezer stock showed the highest amount of bilirubin remaining (44% of time zero), whereas all other conditions (room temperature dark, room temperature lab light, and room temperature blue light) did not have any detectable bilirubin remaining.

(Figure 3A). All samples that were stored at room temperature (dark, room light and blue light) showed significantly decreased agonist activity relative to the frozen sample. (Figure 3B)

Urobilin exhibited more stability than bilirubin, but degradation was still observed for all conditions. After 24 h, the sample stored in the dark had the highest remaining amount of urobilin relative to the time zero measurement (40%), while the freezer sample in the dark only had 21% remaining. The room temperature sample under ambient lighting had 34% remaining, but the room temperature sample under blue light had no detectable urobilin remaining, indicating a higher vulnerability to that wavelength of light. (Figure 4A) The blue-light sample demonstrated very little agonist activity relative to the other three groups that were examined (room temp dark, frozen dark, and room temp light), corresponding to the measured remaining urobilin in those samples. (Figure 4B)
