

METHOD OF SYNTHESIS OF PYRROLE AMIDES

Background of the Invention

5 Field of the Invention

This invention relates a method for synthesis of novel fused pyrrolocarboxamides which selectively bind to GABA_A receptors. This invention also relates to chemical intermediates for synthesis of such compounds. Compounds which bind to GABA_A receptors are useful in treating anxiety, sleep and seizure disorders, and overdoses of benzodiazepine-type drugs, and enhancing alertness.

10 Description of the Related Art

γ -Aminobutyric acid (GABA) is regarded as one of the major inhibitory amino acid transmitters in the mammalian brain. Over 30 years have elapsed since its presence in the brain was demonstrated (Roberts & Frankel, J. Biol. Chem 187: 55-63, 1950; Udenfriend, J. Biol. Chem. 187: 65-69, 1950). Since that time, an enormous amount of effort has been devoted to implicating GABA in the etiology of seizure disorders, sleep, anxiety and cognition (Tallman and Gallager, Ann. Rev. Neuroscience 8: 21-44, 1985). Widely, although unequally, distributed through the mammalian brain, GABA is said to be a transmitter at approximately 30% of the synapses in the brain. In most regions of the brain, GABA is associated with local inhibitory neurons and only in two regions is GABA associated with longer projections. GABA mediates many of its actions through a complex of proteins localized both on cell bodies and nerve endings; these are called GABA_A receptors. Postsynaptic responses to GABA are mediated through alterations in chloride conductance that generally, although not invariably, lead to hyperpolarization of the cell. Recent investigations have indicated that the complex of proteins associated with postsynaptic GABA responses is a major site of action for a number of structurally unrelated compounds capable of modifying postsynaptic responses to GABA. Depending on the mode of interaction, these compounds are capable of producing a spectrum of activities (either sedative, anxiolytic, and anticonvulsant, or wakefulness, seizures, and anxiety).

1,4-Benzodiazepines continue to be among the most widely used drugs in the world. Principal among the benzodiazepines marketed are chlordiazepoxide, diazepam, flurazepam, and triazolam. These compounds are widely used as anxiolytics, sedative-hypnotics, muscle relaxants, and anticonvulsants. A number of

these compounds are extremely potent drugs; such potency indicates a site of action with a high affinity and specificity for individual receptors. Early electrophysiological studies indicated that a major action of benzodiazepines was enhancement of GABAergic inhibition. The benzodiazepines were capable of enhancing presynaptic inhibition of a monosynaptic ventral root reflex, a GABA-mediated event (Schmidt et al., 1967, Arch. Exp. Path. Pharmacol. 258: 69-82). All subsequent electrophysiological studies (reviewed in Tallman et al. 1980, Science 207: 274-81, Haefley et al., 1981, Handb. Exptl. Pharmacol. 33: 95-102) have generally confirmed this finding, and by the mid-1970s, there was a general consensus among electrophysiologists that the benzodiazepines could enhance the actions of GABA.

With the discovery of the "receptor" for the benzodiazepines and the subsequent definition of the nature of the interaction between GABA and the benzodiazepines, it appears that the behaviorally important interactions of the benzodiazepines with different neurotransmitter systems are due in a large part to the enhanced ability of GABA itself to modify these systems. Each modified system, in turn, may be associated with the expression of a behavior.

Studies on the mechanistic nature of these interactions depended on the demonstration of a high-affinity benzodiazepine binding site (receptor). Such a receptor is present in the CNS of all vertebrates phylogenetically newer than the bony fishes (Squires & Braestrup 1977, Nature 166: 732-34, Mohler & Okada, 1977, Science 198: 854-51, Mohler & Okada, 1977, Br.J.Psychiatry 133: 261-68). By using tritiated diazepam, and a variety of other compounds, it has been demonstrated that these benzodiazepine binding sites fulfill many of the criteria of pharmacological receptors; binding to these sites *in vitro* is rapid, reversible, stereospecific, and saturable. More importantly, highly significant correlations have been shown between the ability of benzodiazepines to displace diazepam from its binding site and activity in a number of animal behavioral tests predictive of benzodiazepine potency (Braestrup & Squires 1978, Br. J. Psychiatry 133: 261-68). The average therapeutic doses of these drugs in man also correlate with receptor potency (Tallman et al. 1980, Science 207: 274-281).

Certain fused pyrrolicarboxamides which are useful as GABA brain receptor ligands are disclosed in United States Patent 5,484,944 which is hereby incorporated by reference. These compounds may be prepared by the scheme shown below.

Detailed Description of the Invention

10

The method of this invention is illustrated by the scheme shown below.

15

wherein Ar, R^1 , R^2 and n are as defined above.

Compounds of formula II are readily prepared by reacting the appropriate 1,3-diketone with halo pyruvic acid ester, preferably ethylbromopyruvate as described in U.S. Patent No. 5,484,944 and general procedure A of Example 1 of the present invention.

Compound I is prepared from compound II by converting the carboxylic acid group of compound I to the mixed acid anhydride and thence to the carboxanilide by reaction of the acid anhydride with the selected aniline in the presence of base. The reaction is preferably carried out in a reaction inert solvent at a reduced temperature
5 without isolation of the intermediate acid anhydride.

Any acid chloride or anhydride may be used to form the mixed acid anhydride, ethylchloroformate is a preferred reagent.

The above-reaction is illustrated in general procedure B of Example 1 below.

Conversion of compound I to the final product (compound III) is accomplished
10 by reaction of compound I with an ammonium salt in a reaction inert solvent at an elevated temperature adequate to insure reaction in a reasonable period of time. Any polar reaction inert solvent is suitable; n-methyl pyrrolidine is preferred. Ammonium acetate is a convenient source of ammonium ion.

This procedure is illustrated in general procedure C of Example I below.

20 apparent to those skilled in the art of organic synthesis as well as the conditions necessary to attach and remove such groups.

The invention is illustrated further by the following examples which are not to be construed as limiting the invention in scope or spirit to the specific procedures described in them.

Example 15 **4-Oxo-5,6,7,8-tetrahydro-4H-cyclohepta[b]furan-3-carboxylic acid**

General Procedure A (diketone to furan carboxylic acid):

Cycloheptane-1,3-dione (22.1 g, 174 mmol) was dissolved in 176 mL of isopropanol and cooled to 0 °C. Ethyl bromopyruvate (21.9 mL, 174 mmol) was added, followed by K_2CO_3 (24.2 g, 175 mmol). The solution was then allowed to warm to room temperature and stirred for 16 hours. 220 mL of water were added, and the solution was extracted with four 110 mL portions of dichloromethane. The combined organic extracts were then washed with brine, and concentrated to provide an orange-brown oil. 220 mL of 1 N H_2SO_4 was then added, and the solution warmed in an 85 °C oil bath for 16 hours. After cooling to room temperature, the solution was extracted with two 220 mL portions of dichloromethane. The combined organic extracts were washed with brine, and concentrated to provide 37.2 g of a tan solid. This crude product was then granulated with 170 mL of methyl t-butyl ether, warming nearly to reflux for 30 min, followed by stirring at room temperature for 16 hours. Filtration provided the product as an off-white solid, 14.6 g (75 mmol, 43% yield from the diketone).

4-Oxo-5,6,7,8-tetrahydro-4H-cyclohepta[b]furan-3-carboxylic acid (2-fluoro-4-methoxy-phenyl)-amide

General Procedure B (furan carboxylic acid to furan carboxamide):

- 5 A solution of furan acid from Procedure A (7.65 g, 39.4 mmol) was dissolved in 80 mL dichloromethane and cooled to 0 °C. Triethylamine (7.1 mL, 51 mmol) was added, followed by ethyl chloroformate (4.5 mL, 47 mmol). After 20 min, 2-fluoro-4-methoxyaniline (5.56 g, 39.4 mmol) was added in several small portions. The
10 solution was allowed to warm to room temperature and stirred for 5 hours. The reaction mixture was worked up by diluting with dichloromethane, washing with brine, and drying over MgSO₄. Filtration and concentration provided 15.0 g of an off-white solid, which was granulated with 100 mL of methyl t-butyl ether for 16 hours. Filtration then provided 11.71 g of product (36.9 mmol, 94% yield) as a tan-white

Preparation I

Preparation of cycloheptane-1,3-dione:

5

1-(Trimethylsiloxy)-cyclopentene: A 1 L round bottom flask was charged with cyclopentanone (50.7 g, 0.603 mol) and DMF (250 mL). Triethylamine was added (200 mL, 1.45 mol), followed by dropwise addition of TMSCl (91 mL, 0.72 mol) over 5 min. The solution was then warmed to reflux (90 °C) for 26 h. After cooling to ambient temperature, the mixture was transferred to a separatory funnel, rinsing with 500 mL of hexanes. The solution was washed with water (3 portions of 100 mL each), brine (100 mL), then concentrated to give 110 g of a dark orange oil. ¹H nmr analysis showed the desired product, plus 10-15% of triethylamine. This material was used in the next reaction without further purification.

7,7-Dichloro-1-(trimethylsiloxy)-bicyclo[3.2.0]heptan-6-one: The crude TMS enol ether (2) (0.60 mol) was dissolved in 950 mL of hexanes in a 2 L round bottom flask. Triethylamine (100 mL, 0.72 mol) was added, followed by dichloroacetyl chloride (58 mL, 0.60 mol) as a solution in 450 mL hexanes, dropwise over 2 h. The solution was then stirred at ambient temperature overnight. The reaction mixture was then filtered through fritted glass, rinsing with several 50 mL portions of hexane. The clear solution was concentrated in vacuo to provide 128 g (80% over 2 steps) of product as a dark brown oil. This material was homogeneous by GC/MS and ¹H nmr, save traces of Et₃N and DMF, and was used directly in the next reaction.

Cycloheptane-1,3-dione (1): Dichlorocyclobutanone 3 (128 g, 0.48 mol) was dissolved in 520 mL of 1:1 isopropanol-water in a 2 L, 3-neck flask with an overhead stirrer. Zinc granules (126 g, 1.9 mol, -30+100 mesh) were added in one portion. After 60 min at room temperature, 130 mL of AcOH plus 260 mL of water were added dropwise via addition funnel (ca. 4 mL are added initially, followed by a 10 min hold to check for exotherms; 20 mL were then added, followed by another 10 min hold; once

any exotherm has abated, the remaining acid solution was added dropwise; the entire addition takes 1.5-2 h). After 16 h, the mixture was transferred to a separatory funnel, decanting away from most of the zinc (several small isopropanol rinses were used). The isopropanol-AcOH-water mixture was then extracted with 5 portions of toluene (250 mL each), which are combined and concentrated to provide 51.7 g of product as a dark, orange-brown oil (85% crude mass balance, ca. 85% pure by ^1H nmr). This material is suitable for subsequent reactions, or can be purified by distillation, which provided 29.4 g (0.23 mol, 49% yield) of product as a clear, colorless oil (b.p. 65-75 °C at 1.2 mm). Its spectral properties (^1H nmr, GC/MS) were identical to samples prepared by the oxymercuration route of Chandrasekaran (*Synthetic Communications* 1984, 14, 339-345).

Preparation II

Preparation of 2-fluoro-4-methoxyaniline:

1-(2-Fluoro-4-iodo-phenyl)-2,5-dimethyl-1H-pyrrole: A 500 mL round bottom flask was charged with 2-fluoro-4-iodoaniline (53.3 g, 220 mmol), toluene (250 mL), TsOH·H₂O (0.43 g, 2.3 mmol, 1 mol%), and acetonylacetone (30.8 g, 270 mmol, 1.2 eq). The solution was warmed to reflux under Dean-Stark conditions for 1 h, at which point GC/MS and TLC analysis indicate complete conversion to the pyrrole. The solution is cooled to room temperature, washed with aqueous NaHCO₃, dried over MgSO₄, filtered, and concentrated to provide a dark brown oil which crystallized upon standing (crude yield = 72.8 g, 103% of theory). This material was homogeneous by HPLC and ^1H nmr, and was suitable for use in the next reaction. An analytical sample was prepared by dissolving in 210 mL of hot hexanes, cooling, then concentrating to 50% of the original volume. Cooling in an ice bath with rapid stirring provided 35.5 g (49% recovery) of a brown, granular solid (m.p. 68-70 °C). ^1H NMR

(CDCl₃): d 7.43 (t, J = 27 Hz, 2H), 7.13 (t, J = 20 Hz, 1H), 5.94 (s, 2H), 2.02 (s, 6H); ¹³C NMR (CDCl₃) d 158.3 (d, J = 254 Hz), 131.6, 128.9, 127.8 (d, J = 3 Hz), 122.0, 120.3 (d, J = 23 Hz), 106.4, 12.4; MS (EI): m/z 268 (100).

- 5 **1-(2-Fluoro-4-methoxy-phenyl)-2,5-dimethyl-1H-pyrrole:** The crude product from the previous reaction (1-(2-fluoro-4-iodo-phenyl)-2,5-dimethyl-1H-pyrrole, 70.0 g, 222 mmol) was dissolved in 230 mL of MeOH and 70 mL of DMF. To this solution was added NaOMe (35.9 g, 666 mmol, 3.0 eq) and CuCl (3.3 g, 31 mmol, 15 mol%). The resulting mixture was warmed to reflux for 4 h. After cooling to room temperature, isopropyl ether (IPE) (500 mL), 5% aqueous NH₄Cl (220 mL), and water (350 mL)
- 10 were added, and the mixture was stirred overnight. The mixture was then filtered through celite, the layers were separated, and the aqueous layer extracted with 350 mL of IPE. The combined organic extracts were then washed with 10% aqueous NH₄OH (200 mL), and passed through a pad of silica gel (100 g). Concentration provided a brown oil, which crystallized upon standing (45.2 g, 93% yield).
- 15 Recrystallization from 135 mL of hot hexane provided 30.1 g (62% yield) of product as a brown solid, m.p. 67-69 °C. ¹H NMR (CDCl₃): d 7.12 (t, J = 8 Hz, 1H), 6.75 (d, J = 8 Hz, 1H), 6.73 (s, 1H), 5.89 (s, 2H), 3.82 (s, 3H), 1.97 (s, 6H); ¹³C NMR (CDCl₃) (9 of 10 lines observed) d 159.1 (d, J = 260 Hz), 130.7, 129.5, 109.9 (d, J = 3 Hz), 106.0, 105.6, 102.3 (d, J = 25 Hz), 55.7, 12.4; MS (EI): m/z 219 (100).
- 20 **2-Fluoro-4-methoxyaniline:** A 2 L round bottom flask is charged with 1-(2-fluoro-4-methoxy-phenyl)-2,5-dimethyl-1H-pyrrole (60.0 g, 271 mmol), H₂NOH·HCl (188 g, 2.71 mol, 10 eq), EtOH (600 mL), water (300 mL), and Et₃N (76 mL, 0.54 mol), then warmed to reflux for 16 h. After cooling to room temperature, the reaction mixture is slowly poured into 1.7 L of ice-cold 1 N HCl, and washed with two 500 mL portions of
- 25 IPE. The aqueous phase was then brought to pH 10 by careful addition of 6 N NaOH, and extracted with two 500 mL portions of IPE. The organic extracts were concentrated to provide an oily solid, which was filtered, rinsing with additional IPE (the solid was not related to the aniline product by ¹H nmr analysis, and is presumably some acetonylacetone related by-product of the deprotection). Further
- 30 concentration of the IPE solution provided a brown oil (36 g, 98% yield), which was recrystallized from 200 mL of hot IPE, to provide 26.8 g (70% yield) of 2-fluoro-4-methoxyaniline 1 as a brown solid, m.p. 46-47 °C (lit. 47-48 °C). Spectral data (¹H

nmr, mass spec) were identical to samples prepared by the literature method (*Aust. J. Chem.* 1972, 25, 2621-2629).
