

Abstract

METHOD AND DEVICE FOR DETERMINING A DEGREE OF GENE ASSOCIATION

The present application discloses a method and device for determining a degree of gene association. Through determining record data of target association record(s) of a disease description entry and a plurality of genes in each preset association database, inputting the record data into a preset entry-gene association matrix, and determining an association score of the disease description entry with respective to each of the plurality of genes in the preset association database, the degrees of association between the disease description entry and the plurality of genes can be rapidly obtained.
