[2216] In embodiments, artificial intelligence modules 13404 may also include and/or provide access to a rules-based module 13428 that may be integrated into or be accessed by an intelligence service client 13324. In some embodiments, a rules-based module 13428 may be configured with programmatic logic that defines a set of rules and other conditions that trigger certain actions that may be performed in connection with an intelligence client. In embodiments, the rules-based module 13428 may be configured with programmatic logic that receives input and determines whether one or more rules are met based on the input. If a condition is met, the rules-based module 13428 determines an action to perform, which may be output to a requesting intelligence service client 13324. The data received by the rules-based engine may be received from an intelligence service inputs 13470 and/or may be requested from another module in artificial intelligence modules 13404, such as the machine vision module 13422, the neural network module 13414, the machine learning module 13412, and/or the like. For example, a rules-based module 13428 may receive classifications of objects in a field of view of a smart container from a machine vision system and/or sensor data from a lidar sensor of the smart container and, in response, may determine whether the smart container should continue in its path, change its course, or stop. In embodiments, the rules-based module 13428 may be configured to make other suitable rules-based decisions on behalf of a respective intelligence service client 13324, examples of which are discussed throughout the disclosure. In some embodiments, the rules-based engine may apply governance standards and/or analysis modules, which are described in greater detail below.

[2217] In embodiments, artificial intelligence modules 13404 interface with an intelligence service controller 13402, which is configured to determine a type of request issued by an intelligence service client 13324 and, in response, may determine a set of governance standards and/or analyses that are to be applied by the artificial intelligence modules 13404 when responding to the request. In embodiments, the intelligence service controller 13402 may include an analysis management module 13406, a set of analysis modules 13408, and a governance library 13410.

[2218] In embodiments, an intelligence service controller 13402 is configured to determine a type of request issued by an intelligence service client 13324 and, in response, may determine a set of governance standards and/or analyses that are to be applied by the artificial intelligence modules 13404 when responding to the request. In embodiments, the intelligence service controller 13402 may include an analysis management module 13406, a set of analysis modules

13408, and a governance library 13410. In embodiments, the analysis management module 13406 receives an artificial intelligence module 13404 request and determines the governance standards and/or analyses implicated by the request. In embodiments, the analysis management module 13406 may determine the governance standards that apply to the request based on the type of decision that was requested and/or whether certain analyses are to be performed with respect to the requested decision. For example, a request for a control decision that results in an intelligence service client 13324 performing an action may implicate a certain set of governance standards that apply, such as safety standards, legal standards, quality standards, or the like, and/or may implicate one or more analyses regarding the control decision, such as a risk analysis, a safety analysis, an engineering analysis, or the like.

[2219] In some embodiments, the analysis management module 13406 may determine the governance standards that apply to a decision request based on one or more conditions. Non-limiting examples of such conditions may include the type of decision that is requested, a geolocation in which a decision is being made, an environment that the decision will affect, current or predicted environment conditions of the environment and/or the like. In embodiments, the governance standards may be defined as a set of standards libraries stored in a governance library 13410. In embodiments, standards libraries may define conditions, thresholds, rules, recommendations, or other suitable parameters by which a decision may be analyzed. Examples of standards libraries may include a legal standards library, a regulatory standards library, a quality standards library, an engineering standards library, a safety standards library, a financial standards library, and/or other suitable types of standards libraries. In embodiments, the governance library 13410 may include an index that indexes certain standards defined in the respective standards library based on different conditions. Examples of conditions may be a jurisdiction or geographic areas to which certain standards apply, environmental conditions to which certain standards apply, device types to which certain standards apply, materials or products to which certain standards apply, and/or the like.

[2220] In some embodiments, the analysis management module 13406 may determine the appropriate set of standards that must be applied with respect to a particular decision and may provide the appropriate set of standards to the artificial intelligence modules 13404, such that the artificial intelligence modules 13404 leverages the implicated governance standards when determining a decision. In these embodiments, the artificial intelligence modules 13404 may be configured to apply the standards in the decision-making process, such that a decision output by the artificial intelligence modules 13404 is consistent with the implicated governance standards. It is appreciated that the standards libraries in the governance library may be defined by the platform provider, customers, and/or third parties. The standards may be government standards, industry standards, customer standards, or other suitable sources. In embodiments, each set of standards may include a set of conditions that implicate the respective set of standards, such that the conditions may be used to determine which standards to apply given a situation.

[2221] In some embodiments, the analysis management module 13406 may determine one or more analyses that are to be performed with respect to a particular decision and may provide

corresponding analysis modules 13408 that perform those analyses to the artificial intelligence modules 13404, such that the artificial intelligence modules 13404 leverage the corresponding analysis modules 13408 to analyze a decision before outputting the decision to the requesting client. In embodiments, the analysis modules 13408 may include modules that are configured to perform specific analyses with respect to certain types of decisions, whereby the respective modules are executed by a processing system that hosts the instance of the intelligence service 13004. Non-limiting examples of analysis modules 13408 may include risk analysis module(s), security analysis module(s), decision tree analysis module(s), ethics analysis module(s), failure mode and effects (FMEA) analysis module(s), hazard analysis module(s), quality analysis module(s), safety analysis module(s), regulatory analysis module(s), legal analysis module(s), and/or other suitable analysis modules.

[2222] In some embodiments, the analysis management module 13406 is configured to determine which types of analyses to perform based on the type of decision that was requested by an intelligence service client 13324. In some of these embodiments, the analysis management module 13406 may include an index or other suitable mechanism that identifies a set of analysis modules 13408 based on a requested decision type. In these embodiments, the analysis management module 13406 may receive the decision type and may determine a set of analysis modules 13408 that are to be executed based on the decision type. Additionally, or alternatively, one or more governance standards may define when a particular analysis is to be performed. For example, the engineering standards may define what scenarios necessitate an FMEA analysis. In this example, the engineering standards may have been implicated by a request for a particular type of decision and the engineering standards may define scenarios when an FMEA analysis is to be performed. In this example, artificial intelligence modules 13404 may execute a safety analysis module and/or a risk analysis module and may determine an alternative decision if the action would violate a legal standard or a safety standard. In response to analyzing a proposed decision, artificial intelligence modules 13404 may selectively output the proposed condition based on the results of the executed analyses. If a decision is allowed, artificial intelligence modules 13404 may output the decision to the requesting intelligence service client 13324. If the proposed configuration is flagged by one or more of the analyses, artificial intelligence modules 13404 may determine an alternative decision and execute the analyses with respect to the alternate proposed decision until a conforming decision is obtained.

[2223] It is noted here that in some embodiments, one or more analysis modules 13408 may themselves be defined in a standard, and one or more relevant standards used together may comprise a particular analysis. For example, the applicable safety standard may call for a risk analysis that can use one or more allowable methods. In this example, an ISO standard for overall process and documentation, and an ASTM standard for a narrowly defined procedure may be employed to complete the risk analysis required by the safety governance standard.

[2224] As mentioned, the foregoing framework of an intelligence service 13004 may be applied and/or leveraged at various levels of a value chain. For example, in some embodiments, a platform level intelligence system may be configured with the entire capabilities of the

intelligence service 13004, and certain configurations of the intelligence service 13004 may be provisioned for respective value chain entities. Furthermore, in some embodiments, an intelligence service client 13324, such as the smart container system 13000, may be configured to escalate an intelligence system task to a higher-level value chain entity (e.g., edge-level or the platform-level) when the intelligence service client 13324 cannot perform the task autonomously. It is noted that in some embodiments, an intelligence service controller 13402 may direct intelligence tasks to a lower-level component. Furthermore, in some implementations, an intelligence service 13004 may be configured to output default actions when a decision cannot be reached by the intelligence service 13004 and/or a higher or lower-level intelligence system. In some of these implementations, the default decisions may be defined in a rule and/or in a standards library.

[2225] In embodiments, a "set" of machine-learned models may include a set with multiple members. In embodiments, a "set" of machine-learned models may include hybrids of different types of models (e.g., hybrids of RNN and CNN).

[2226] In one example, a set of machine-learned models may be used for smart container predictive maintenance. In this example, the intelligence service 13004 may receive order data, historical order data, maintenance data, weather data, and/or video feed from sensors inside a smart container for the user device 13094 and may generate a set of feature vectors based on the received data. The intelligence service 13004 may input the feature vectors into machine-learned models trained (e.g., using a combination of simulation data and real-world data) to predict when a particular smart container will require maintenance, such as based on a training data set of outcomes. In embodiments, the intelligence service 13004 may include an input set of training data representing predictions or the probability of required maintenance by a set of human experts and/or by other systems or models.

[2227] In yet another example, a set of machine-learned models may be used to predict the traffic at a container terminal at a given point in time. In this example, the intelligence service 13004 may receive historical container terminal traffic data, maritime data, news data, and weather data and may generate feature vectors based on the received data. In embodiments, feature vectors may include other data, such as data characterizing container terminal layout elements upon which traffic may depend. The intelligence service 13004 may input the feature vectors into machine-learned models trained (e.g., using a combination simulation data and real-world data) to predict the traffic at a container terminal.

[2228] In another example, a set of machine-learned models may be used to detect illicit and/or illegal items being shipped. In this example, the intelligence service 13004 may receive order data, shipper data, historical cargo data, and/or video feed and other sensor data from sensors disposed inside of a smart container and may generate feature vectors based on the received data. The intelligence service 13004 may input the feature vectors into machine-learned models trained (e.g., using a combination of simulation data and real-world data) to detect illicit and/or illegal items. In embodiments, detection of illicit and/or illegal items may involve a set of distinct models that are respectively trained based on training data sets and/or feature vector

inputs that are specific to jurisdictional factors, including laws or regulations (e.g., training with awareness of legality), cultural factors (e.g., where whether the item is considered illicit varies based on cultural norms, and the like. In embodiments, training may include providing, such as through human experts, information about alternative terminology, or the like, that shippers or other users may employ to describe illegal or illicit items (such as when shippers or other users describe the cargo to be shipped in an order), such as code words, euphemisms, or the like. In embodiments, a model may be trained to provide a word cloud, cluster of words, or other features, such as to facilitate recognition of illegal or illicit items and/or recognition of words, images, or other elements used to characterize them. As one non-limiting example, a self-organizing map (SOM) may be employed to generate a mapping of entities, such as mapping entities, classes, objects, workflows, or the like to jurisdictions, to topics, to each other, or the like. Additionally, or alternatively, the machine-learned models may be configured to identify container contents.

[2229] In another example, a set of machine-learned models may be used to provide decision support related to the pricing of one or more freight storage and/or transportation services (e.g., services that require the use of a smart container). For example, the intelligence service 13004 may receive data from various sources described throughout this document and the documents incorporated by reference herein and may generate a set of feature vectors based on the received data. The intelligence service 13004 may input the feature vectors into machine-learned models trained (e.g., using a combination of simulation data and real-world data) to provide decision support related to the pricing of one or more services, such as based on a training data set of outcomes. In embodiments, the intelligence service 13004 may include an input set of training data representing decision support related to service pricing by a set of human experts and/or by other systems or models. Data sources used to produce the set of feature vectors, may include, but are not limited to, order data, demand data, supply data, cost data, volatility data, pricing pattern data, order size data, order volume data, geographic trading data, maritime data, trucking fleet data, railway data, traffic data, weather data, social media sites, external data (such as news involving smart containers or shipping or the like), and many others.

[2230] In another example, a set of machine-learned models may be used to provide decision support related to loading and/or unloading cargo. The intelligence service 13004 may receive order data (optionally including weight data, volume data, cargo description data, destination location, or the like) and/or video feed from sensors disposed outside the smart container and/or within the smart container and may generate a set of feature vectors based on the received data. The intelligence service 13004 may input the set of feature vectors into a machine-learned model trained (e.g., using a combination of simulation data and real-world data) to provide decision support related to cargo loading and/or unloading. For example, the machine-learned model could be configured to provide decision support about the order in which specific cargo is loaded and/or unloaded, the clustering of cargo, the configuration of cargo within the smart container, or the like. In embodiments, a model or set of models may be trained by an expert in the loading and/or unloading of cargo.

[2231] In yet another example, a set of machine-learned models may be used to determine regulatory compliance of a shipment. For example, the intelligence service 13004 may receive data from various sources described throughout this document and the documents incorporated by reference herein and may generate a set of feature vectors based on the received data. The intelligence service 13004 may input the feature vectors into machine-learned models trained to determine regulatory compliance. As one non-limiting example, regulatory compliance may include compliance with regulations that require documentation confirming customs duties are paid. In embodiments, relating to such an example, a machine-learned model may parse documentation, commercial invoices, and the like, such as to find verification of the required tariff payments.

[2232] In another example, a set of machine-learned models may be used to categorize or classify cargo. For example, the intelligence service 13004 may receive data from various sources described throughout this document and the documents incorporated by reference herein and may generate a set of feature vectors based on the received data. The intelligence service 13004 may input the set of feature vectors into a machine-learned model trained (e.g., using a combination of simulation data and real-world data) to categorize cargo, such as based on a training data set of outcomes. In embodiments, the intelligence service 13004 may include an input set of training data representing categorizations or classifications of cargo by a set of human experts and/or by other systems or models. Data sources and feature vectors used for categorization or classification of cargo may include shipping data of the many types described herein, shipper profile data, as well as external data sources that may assist with classification or categorization of cargo. Such artificial intelligence systems used for classification, in the present example and other examples described herein, may include a recurrent neural network (including a gated recurrent neural network), a convolutional neural network, a combination of a recurrent neural network and a convolutional neural network, or other type of neural network or combination or hybrid of types of neural network described herein or in the documents incorporated by reference herein.

[2233] In another example, a set of machine-learned models may be used to optimize smart container design. For example, the intelligence service 13004 may receive data from various sources described throughout this document and the documents incorporated by reference herein and may generate a set of feature vectors based on the received data. The intelligence service 13004 may input the feature vectors into machine-learned models trained (e.g., using a combination of simulation data and real-world data) to optimize the design of the smart container, such as based on a training data set of outcomes. In embodiments, the intelligence service 13004 may include an input set of training data representing smart container optimization by a set of human experts and/or by other systems or models. Data sources and feature vectors used for optimization of marketplace efficiency may include shipping data of the many types described herein that may assist with smart container design optimization. Such artificial intelligence systems used for optimization, in the present example and other examples described herein, may include a recurrent neural network (including a gated recurrent neural

network), a convolutional neural network, a combination of a recurrent neural network and a convolutional neural network, or other type of neural network or combination or hybrid of types of neural network described herein or in the documents incorporated by reference herein. In embodiments, the smart container design may be optimized for cost, carbon emissions, speed, efficiency, performance, performance in specific environments (e.g., optimized to operate in arctic conditions), carrying capacity, safety, and the like.

[2234] In another example, a set of machine-learned models may be used to optimize a smart container route. For example, the intelligence service 13004 may receive data from various sources described throughout this document and the documents incorporated by reference herein and may generate a set of feature vectors based on the received data. The intelligence service 13004 may input the feature vectors into machine-learned models trained (e.g., using a combination of simulation data and real-world data) to optimize the smart container route, such as based on a training data set of outcomes. In embodiments, the intelligence service 13004 may include an input set of training data representing marketplace profitability optimization by a set of human experts and/or by other systems or models. Data sources and feature vectors used for optimization of the smart container route may include shipping data of the many types described herein that may assist with the smart container route optimization, including historical route data, order data, weather data, maritime data, traffic data, truck fleet data, railway data, news data, or the like.

[2235] The foregoing examples are non-limiting examples and the intelligence service 13004 may be used for any other suitable AI/machine-learning related tasks that are performed with respect to smart containers and shipping environments.

[2236] In embodiments, a security system 13046 includes a framework that may be implemented at various levels of the disclosed systems. In these embodiments, instances of the security system 13046 may be implemented at the system-level, at the fleet- or team-level, or individual-level. For example, at the system-level, the security system 13046 may provide security-related functionality on behalf of the system 13000 and/or with respect to any communications and/or other interactions with smart container operating units. In embodiments, a security system 13046 implemented at the fleet-level or team-level, whereby the security-system may be configured to provide security-related functionality on behalf of the smart container team or fleet and/or with respect to communications and/or other interactions with smart containers in the team or fleet. In embodiments, a security system 13046 implemented at the smart container-level may be configured to provide security-related functionality on behalf of the smart container and/or with respect to communications and/or other interactions with other smart containers, smart container teams, and/or the system 13000.

[2237] In embodiments, a security system 13046 may include an autonomous adaptive security module, an autonomous non-adaptive security module, and/or a manual security module. An autonomous adaptive security module may be configured to request intelligence tasks from intelligence service 13004, whereby an adaptive security module leverages the artificial intelligence modules of an intelligence service 13004 to assess a security risk and determine an

action based on an output of the intelligence service 13004. For example, the adaptive security module of a smart container fleet may monitor one or more conditions associated with the smart container fleet by receiving data from a set of data sources, such as monitoring a route for potentially dangerous conditions based on a set of data sources (e.g., weather data, video feeds, sensor data from the smart containers and/or environment, input from individual smart containers, and/or the like). In response to receiving the data, the adaptive security module may request an assessment (e.g., a classification) of an environment from the intelligence service 13004 regarding the security of the environment. In response, the intelligence service 13004 may provide one or more classifications that indicate an assessment of the environment. The adaptive security module may then determine whether the assessment necessitates an action to be taken, and if so, what particular action to take. In some of these embodiments, the adaptive security module may use a rules-based approach to determine whether the assessment necessitates an action and, if so, what action to take. Additionally, or alternatively, the adaptive security module may leverage a neural network that is trained to an action to recommend given a set of features (e.g., classifications, sensor readings from one or more smart containers, locations of smart containers, objects detected in the environment and locations thereof, and/or any other relevant features). In these embodiments, the neural network module 13414 may receive the features from the adaptive security module and/or a set of intelligence service inputs 13470 and may output a proposed action given the set of features. In some of these embodiments, an intelligence service controller 13402 of the intelligence service 13004 may allow or override decisions made by the artificial intelligence modules 13404. For instance, the analysis modules 13408 may perform dynamic risk analyses and/or static risk analyses. Examples of dynamic risk analysis may include, but are not limited to, real-time data driven analyses (e.g., current weather patterns, current regulatory environment, current container port events, and/or the like) and/or risk analyses specific to a particular freight storage and/or transportation service order (e.g., contractual risks, environmental risks, safety liabilities, monetary liabilities, and/or the like). Examples of static risk analyses may include, but are not limited to, operational risks and/or regulatory/compliance risks.

[2238] In embodiments, the autonomous adaptive security module may operate in an isolated manner (e.g., without communication with external devices or systems) or in a connected manner (e.g., with communication with external devices or systems).

[2239] In embodiments, the security system 13046 may include an autonomous non-adaptive security module. In embodiments, the autonomous non-adaptive security module is configured to make security related decisions on behalf of a client autonomously (e.g., without human intervention). In embodiments, a non-adaptive security module performs logic-based security-related actions (e.g., risk mitigation actions) in response to detecting one or more specific sets of conditions. For example, a non-adaptive security module may be configured to, in response to detecting a specific set of conditions, trigger actions, such actions as, locking a smart container, locking the digital twin of a smart container, shutting off smart container power, stopping a movement of the smart container, initiating charging, sounding an alarm or siren, triggering a

strobe or light, sending a notification to another device or system, self-destructing, or the like. In embodiments, the non-adaptive security module responds to risks that are more easily diagnosable, such as overheating conditions, moving or being taken out of a geofenced area, detected internal leaks, low power conditions, low fluid levels, and/or the like.

[2240] In embodiments, the security system 13046 may include a manual security module. In embodiments, the manual security module is configured to allow a user to make decisions regarding security-related actions. In some of these embodiments, the manual security module is configured to receive a notification of an assessed risk (e.g., from the adaptive security module, the non-adaptive security module, from an intelligence service client 13324, or the like). In these embodiments, the human user may interface with the manual security module via a human interface, which may be provided via a user device (e.g., mobile device, tablet, computing device, or the like).

[2241] In embodiments, the fleet management system 13002 may utilize the features and capabilities of the smart container system 13000 to facilitate substantially optimized utilization of fleet resources by anticipating fleet resource needs and preparing those resources in advance of anticipated use. In embodiments, resource need anticipation may include coordinating maintenance activities with shipment scheduling to ensure that preventable interruptions due to lack of maintenance are prevented. Additionally, or alternatively, resource need anticipation may be based on alignment of detected fleet resource use with information that supports, among other things, anticipation of freight storage and/or transportation service orders. In embodiments, factors such as weather pattern forecasting, time of year, location, and/or the like may influence the likelihood of certain freight storage and/or transportation service orders. For example, high freight volumes are likely during peak shipping season, from August to October, whereas freight volumes are likely to be low during the start of the year, from January to March. Example implementations for generating fleet need predictions and addressing those predictions follow the discussion of the components of the fleet management system 13002 and those of the related smart container system 13000. As previously discussed, example components of the smart container system 13000 may include a communication management system 13010, the remote-control system 13012, and a human interface system 13038.

[2242] In embodiments, the communication management system 13010 is configured to enable communication (e.g., efficient and/or high speed communication) among system elements, such as the fleet management system 13002 and its elements as described herein, the intelligence service 13004 and its elements as described herein, external data sources 13036, third party systems (e.g., via an Internet and the like), smart container operating units, support systems and equipment, transportation resources (e.g., container ships, trucks, rail, or the like), human fleet resources, and the like. The communication management system 13010 may include or provide access to one or more communication network types, such as wired, wireless and the like that may support various data protocols, such as Internet Protocol (IP) and the like. The communication management system may include or have access to intelligence services (e.g., via the fleet intelligence system resources described herein) that manage and control portions of

the smart container fleet management system infrastructure associated with communication to ensure, for example: timely delivery of data collected by deployed smart container operating units to critical computation, analysis and/or data storage resources; prioritized delivery of smart container configuration and operational instructions; and the like. In fleet resource management and control embodiments, the communication management system 13010 may prioritize fleet security system communications use of fleet communication resources over communications among fleet intelligence system components to support a high degree of security and integrity of fleet resources. The communication management system 13010 may provide and manage access to networking, including network system 13202 that connects at least the smart container system 13000 with external systems, deployed smart container operating units, and other network-connectable elements (e.g., fleet edge devices and the like).

[2243] In embodiments, capabilities of the communication management system 13010 may include contextual specification, and/or adaptation of smart container system communication resources (e.g., networks, radio systems, data communication devices, such as routers, and the like) based on, among other things, an order execution plan, plan definitions, task definitions, smart container operating unit configurations, real-time job status, and the like. The communication management system 13010 adaptation of fleet communication resources may be impacted by a range of real-world conditions (e.g., weather, atmospheric conditions, container port traffic, container port and other facility structures, environment (e.g., land-to-submerged, subterranean), and the like). In embodiments, the communication management system 13010 may glean context from a freight storage and/or transportation service order that may facilitate anticipating a need for types of adaptation during order execution. As an example of freight storage and/or transportation service order context-based communication adaptation, a job may initiate at sea level, and then include actions by subterranean teams. Communication resources suitable for use in these different task environments that are configured by the fleet configuration system during job configuration activities may be adaptively controlled by the communication management system 13010 for the respective teams of smart containers as a job progresses through the exemplary environments.

[2244] Freight storage and/or transportation service order criteria may directly call for isolated operation. Alternatively, circumstances of the freight storage and/or transportation service order may favor isolated operation (e.g., operation within a foreign jurisdiction and the like). Communication resources for the requested service may be adapted accordingly. As an example, communication among a team of fleet resources assigned to co-locate when performing a job (e.g., co-locating to an origin location) may be configured by the fleet configuration system with additional encryption or with a radio frequency that defies conventional detection that the communication management system may facilitate activating when required by the freight storage and/or transportation service order (e.g., as noted above when the team enters a foreign jurisdiction). In this further embodiment of fleet resource configuration, the communication management system 13010 may detect and control communication resources (e.g., smart container operating unit radio interfaces, communication infrastructure that is proximal to

isolated smart container operating units and the like) to enforce such a fleet configuration. Yet further consideration for isolated operation may include adaptable isolation communication protocols, such as permitting only use of low energy near-field communication conditionally based on deployment context, such as an expected location of team smart containers, such as when multiple smart container operating units are expected to be nearby. The communication management system 13010 may assist the fleet configuration system with fleet configuration, such as configuring smart container operating units, selection of smart container units that meet a freight storage and/or transportation service order communication requirement, configuration and designation of deployment of fleet communication resources (e.g., co-locating an inter-smart container operating unit repeater device with the team), and other fleet and smart container configuration considerations. In an example of such fleet configuration assistance, a freight storage and/or transportation service order may indicate a preference to use specific smart container operating units. The fleet configuration system may query the communication control system regarding adaptation capabilities (e.g., of the communication management system and/or certain fleet communication resources) to support the preferred smart container operating units.

[2245] In an example of communication management adaptability capabilities for supporting diverse smart container operating unit communication configurations, the communication management system 13010 may support a first team of smart container operating units performing operations in using a different radio frequency for wireless communication than a second team of smart container operating units that are performing operations in the same radio signal range as the first team of smart container operating units; thereby mitigating the likelihood of cross-radio interference. Further, the communication management system 13010 may provide for reliable communication through use of redundancy, such as through dual radio systems, automatic channel selection (e.g., local networking, cellular networking, mesh networking, long range satellite networking, and the like). Fleet communication resources may include smart container operating units acting as network elements, such as when smart container operating units are configured into one or more mesh networks and the like. Smart container operating units may facilitate communication in other ways, including visually, such as through use of light sources (e.g., Morse code or binary transmissions), physical gestures, infrared signals, ant-based trails, and the like. Auditory communications among smart containers (e.g., non-human language encoded audio signaling), ultrasound and other auditory-based techniques may be rendered as a form of communication among smart containers. Much like how co-located smart containers on different teams may use different radio frequency signals, co-located smart containers may use different auditory signaling to assist in communication clarity among team members.

[2246] In embodiments, the communication management system 13010 may be constructed as a plurality of independent communication systems that are configured to meet at least a corresponding portion of fleet communication needs. In an example, the communication management system 13010 may be constructed with a first communication system for communicating among elements within the fleet management system 13002 (or any other fleet

system, system, module, team, fleet segment and the like), and with a second communication system for communication among intelligence service 13004 elements (or any other portion of the fleet system that can be separated from the first communication system), so that disruption of any individual communication system may be isolated from other system communication systems, thereby reducing impact of communication problems throughout the system. Further in this example, the fleet management system 13002 and its constituent elements (e.g., job configuration system 13018, and the like) may continue to communicate through the first communication system and indeed perform all pertinent fleet operation functions (including communication with remotely deployed fleet smart container operating units and the like) even though access to intelligence service 13004 elements, such as a machine learning system, may be compromised due to problems with the second communication system serving the intelligence service 13004. Further, the communication management system 13010 may include security features that effect isolation and shunning of systems, sub-systems, system elements, communication systems, and other system resources that appear to be compromised due to malware or the like. Other independent communication systems include smart container-to-smart container communication systems, robot-to-smart container communication systems, human-to-smart container communication systems, emergency response communication systems, and the like. Yet further independent communication systems may be based on aspects, such as confidentiality of information (e.g., negotiations between a fleet management provider and a shipper), fleet operations oversight and the like. In embodiments, the communication management system 13010 may be constructed to provide role-based (or the like) access to different communication systems. For example, a fleet operations executive may be granted concurrent access to smart container operating units allocated to different jobs for performing fleet supervisory functions.

[2247] In addition to and/or instead of separated communication systems, the communication management system 13010 may provide for redundancy (multi-frequency radios, and the like) to address exception conditions that may cause network compromise, may require overriding operational communication channels for emergency use, and the like.

[2248] In embodiments, the communication management system 13010 may provide fleet resource-specific (e.g., individual smart container operating unit) secure communication so that two fleet resources (e.g., two smart container operating units, a smart container operating unit and a fleet monitoring system, and the like) may communicate securely. The communication management system 13010 may further provide broadcast capabilities to support notification, update, alert, and other services. Broadcast capabilities may be fleet-wide (e.g., a notice to all fleet resources to observe daylight savings time), team-specific (e.g., an update to all team members regarding role changes of team members), job-specific (e.g., an alert to fleet resources assigned to a job, which may include a plurality of smart container teams, that the job is put on hold), fleet resource type-specific to address issues that concern certain types of fleet resources (e.g., such as smart container operating units), fleet support units, location-specific units (e.g., all units within a foreign jurisdiction), and the like.

[2249] In embodiments, the communication management system 13010 may use or manage job-specific communications elements together with other fleet management system features or services including, without limitation, the security system 13046, the network system 13202, and various resources including Artificial Intelligence (AI) chipsets, data encoders, communication spectrum frequencies, and the like. The communication management system 13010 may work together with the security system 13046, such as by providing secure high-up-time access to fleet and associated communication resources. As an example, a security system 13046 may utilize a portion of configured communication channels (e.g., wired inter-computer links, wireless networks, and the like) that may be reserved by the communication management system for security use. The portion may include physically dedicated elements (e.g., wired connections, wireless access points that operate over a dedicated set of frequencies, and the like). In embodiments, providing dedicated wireless access may include prioritization of security system access to existing wireless networks, such as by routing security system data packets, streams, and the like ahead of non-security system packets. As another example, a communication management system may allocate communication devices with greater battery energy (higher charge) and/or fixed power supply for security system use while allocating lower power, lower energy, and/or rechargeable devices for non-security system use. Security system communication resource management and control may be fleet-wide, job-specific, team-specific, deployment locale-based, geolocation-based, and the like.

[2250] A further cooperative operation of security system 13046 with the communication management system 13010 may include managing access by fleet resources to external resources (e.g., websites, and the like) as well as access by external resources to fleet resources. The security system 13046 may deploy security agents and the like to fleet resources based on allocation and/or configuration of those resources. As an example, a firewall-type security function of the security system 13046 may be deployed at, among other things, access points managed by the communication management system to connect distinct job-specific communication systems.

[2251] In embodiments, the communication management system 13010 may take advantage of intelligence capabilities of fleet resources, such as resources with artificial intelligence capabilities (optionally provided by AI-specific chips and chip sets and the like), to establish dynamic communication management functions that enrich and work with fleet security capabilities to further reduce the likelihood of a successful intrusion into a fleet communication system. As an example, AI-based functionality deployed throughout at least portions of fleet resources (e.g., individual smart container operating units and the like) may be relied upon to detect local environments with increased risk of intrusion or other threat (e.g., based on contextual and historical information representative of such environments and the like) so that the communication management system, optionally in cooperation with the security system 13046, may adapt fleet communication resources for reducing such risk.

[2252] The communication management system 13010 may make use of and/or facilitate control of use by others of the network system 13202. As an example of management of the

network system 13202, the communication management system 13010 may treat the network system 13202 as a resource to be managed for use by fleet resources for communicating, such as by determining and/or controlling which resources utilize the network, how resources using the network at the same time may be coordinated, network loading limits for such resources, and the like.

[2253] In embodiments, the smart container system includes a remote-control system 13012 that is configured to provide a framework for remotely controlling smart container operating units and other external resources to complete freight storage and/or transportation service orders. In embodiments, the remote-control system 13012 may manage definition and use of control signals for remote operation of smart container operating units, fleet support units, external resources and the like. Smart container remote-control as enabled by the remote-control system 13012 may include definition and management of local smart container operating unit to smart container operating unit control signaling, such as when a team supervisor smart container is directing one or more smart container team members to self-load onto a container ship. Other examples of remote-control signal management may include smart container-to-smart container fleet support signaling, intra-team smart container operating unit signaling, and the like.

[2254] In embodiments, the remote-control system 13012 is constructed to assist the order execution system 13022 and provide a framework for remotely controlling smart container operating units and other external resources to complete tasks and/or jobs. The remote-control system may manage definition and use of control signals for remote operation of smart container operating units, fleet support units, external resources and the like. Smart container remote-control as enabled by the remote-control system 13012 may include definition and management of local smart container operating unit to smart container operating unit control signaling, such as when a team supervisor smart container is directing one or more smart container team members to load and/or unload cargo. Other examples of remote-control signal management may include smart container-to-smart container fleet support signaling, intra-team smart container operating unit signaling, and the like. In embodiments, the remote-control system uses resources of the smart container system 13000, including, for example, the communication management system 13010, the security system 13046, and/or network system 13202 to access information, in some cases make decisions, and execute commands. The framework for remotely controlling smart container operating units may comprise a series of actions-based standard rules, adapted rules modified by situational awareness, emergency rules, exceptions, human decisions, ethical rules, the fleet intelligence system, etc. However, specialized, fall-over, or other communications necessary to handle a range of remote-control requirements may be part of the communication management system 13010 that may facilitate delivery of remote-control communication and/or signaling what the communications should be versus may be determined from use of the remote-control system 13012.

[2255] The remote-control system 13012 may recognize a plurality of initiators of remote-control signals, including local supervisor remote-control initiators, human (local or remote) remote-control initiators, automated fleet-based remote-control initiators (e.g., fleet artificial

intelligence system and the like), and third-party remote-control initiators (e.g., for law enforcement and the like). Remote control signaling may include managing remote control signals to fleet-external resources, such as fire and emergency response resources, infrastructure resources, third-party smart container service providers, and the like.

[2256] The fleet resources that may participate in remote-control operations may be diverse in both implementation and protocols, such as older generation smart container operating units, human fleet resources, quantum computing elements and the like. Therefore, the remote-control system 13012 (in cooperation with the communication management system 13010) may be constructed with knowledge of multiple remote operational protocol (multi-protocol) capabilities to ensure any two devices exchanging control signals can do so reliably. In embodiments, multi-protocol capabilities may include handling and/or providing as a service protocol-to-protocol translation, remote-control signal consolidation and interpretation, protocol normalization, and the like. In embodiments, the communication management system 13010 may utilize these protocol handling capabilities directly as noted above and by API and the like, or by being configured with such protocol handling capabilities (e.g., deployed with protocol handling capabilities of the remote-control system 13012. In embodiments, the remote-control system 13012 (or equivalent functions thereof integrated with the communication management system 13010) may rely on portions of the intelligence service 13004, such as digital twin and/or artificial intelligence service, to facilitate, for example, protocol translation and/or adaptation. Therefore, the remote-control system 13012 may provide real-time, on demand protocol translation, optionally assisted by the fleet intelligence system. The remote-control system 13012 may support fleet-external remote-control via a port that is configured for integration with external and/or third-party remote-control architectures. Remote-control may be communicated via dedicated infrastructure and/or communication features (e.g., short-distance broadcast capabilities).

[2257] Remote-control, such as control of smart container operating units, may be initiated, at least in part, by a human operator. In embodiments, a smart container 13026 may encounter unexpected and/or unknown conditions during order execution (e.g., as may exemplarily be reported by the order execution system 13022) and defer to a human operator to remotely control smart container operating unit(s). Optionally, one or more intelligence service 13004 components, such as an artificial intelligence system, may be referenced for at least candidate remote-control signals. In embodiments, an order execution plan may indicate, at a predetermined operational task, that smart container operation should be guided by a human operator. When such a task is anticipated to occur in a job workflow (e.g., by a shipping execution monitoring instance, such as a supervisor smart container and the like), the remote-control system 13012 may be called upon to oversee a remote-control connection between a suitable human operator and the smart container, smart container operating units, team, team supervisor, and the like, executing the workflow that calls for human operator control.

[2258] In embodiments, the remote-control system 13012 may have access to a set of remote-control signal sequences for performing certain tasks remotely. The remote-control system

13012 may, based on context of a workflow being performed, suggest to a human operator and/or an automated control system one or more remote-control signal sequences. In embodiments, the remote-control system may process input from a human operator (e.g., commands such as "stop", "unload" and the like), optionally with help of other fleet resources (e.g., an artificial intelligence system and the like) and generate a set of remote-control signals for remotely controlling fleet resource, such as a smart container operating unit and the like. Remote control signal sequences may be preconfigured for handling a range of real-time situations, such as security breaches, equipment failure, and the like. In addition to facilitating and/or managing remote-control of a smart container operating unit, remote-control signal sequences may be used for reconfiguration of fleet resources deployed and/or allocated for a job, task, workflow, and the like. A human operator (or an automated system monitor-type application) may provide remote control signals that are communicated to the viable members of the team to adjust task roles and actions accordingly, such as by communicating a remote-control signal to one or more of the viable members to communicate with a smart container operating unit configuration server to receive reconfiguration instructions and reconfiguration data.

[2259] Although generally described herein as remote-control signals, the remote-control system 13012 may facilitate remote-control by arranging remote control signals into remote control instructions (e.g., combinations of remote-control signals, abstractions thereof and the like) at the fleet level, team level, smart container level and the like. As an example of remote-control instruction functionality, the remote-control system 13012 may receive input, such as from a human operator desiring to instruct a smart container to drive up a ramp onto a container ship. In this example, the remote-control system may receive the human operator remote-control instruction, adapt that instruction into one or more different remote-control signals for the smart container 13026, generate corresponding remote-control signals, and ensure communication of those signals (e.g., via the communication management system 13010 resources) to the smart container 13026 to be remotely controlled by the human operator.

[2260] Smart container operating unit responsiveness to aggregated remote-control signals (e.g., instructions or set of instructions) may be based on a wide range of fleet intelligence capabilities, knowledge, priorities, goals, and the like. In general, use of system-based and/or smart container operating unit-based artificial intelligence capabilities supports wider independent decision-making capabilities for individual smart container operating units with greater contextual gravity.

[2261] In embodiments, the remote-control system 13012 may integrate security features to thwart takeover, compromise, misuse, or interference with control of remotely controlled smart container operating units. Resources used by the remote-control system 13012 (e.g., data storage resources, computing resources, remote-control system state data, and the like) may be configured with security features, such as encoding, decoding, packetizing, and the like. Further, the remote-control system 13012 may include and/or support control override capabilities that enable a human operator (for example) to securely gain remote-control of a smart container that

is otherwise not directly engaged with remote-control signaling or operating independently of remote-control signals, such as, autonomously, collaboratively with other smart container operating units and the like.

[2262] In embodiments, the smart container system 13000 may include a human interface system 13038 that provides a human interface that allows users to access the smart container system 13000 and/or individual smart container operating units (e.g., for remote control) from a remote device (e.g., a user device, a VR device, an AR device, and/or the like). In embodiments, the human interface system 13038 facilitates freight storage and/or transportation service order entry (including any job-related parameters), fleet operations management, fleet resource management, fleet computing system, software and data structure management (e.g., system upgrades and the like), human access to smart container operating units (e.g., for remote control of a smart container operating unit), augmented and/or virtual reality visualizations of fleet operation, and data extraction (e.g., for generation of and/or validation of smart contracts associated one or more freight storage and/or transportation service orders and the like). As an example of use of a human interface system 13038, a user may access status updates of a requested job via the human interface system 13038. The user may use a remote device to observe smart container operating units performing tasks for the requested job. In this example, the human interface system 13038 may interact with other fleet components, such as the order execution system 13022, to direct image capture resources (e.g., camera-based overhead drones) to provide images of smart container operating units assigned to and currently performing job tasks.

[2263] In embodiments, the fleet management system 13002 may include a job configuration system 13018, a fleet configuration system 13020, a resource provisioning system 13014, a logistics system 13016, and an order execution, monitoring, and reporting system 13022 (also referred to as a "order execution system" 13022).

[2264] In embodiments, the fleet management system 13002 includes a resource provisioning system 13014 that manages provisioning resources for smart container operating units in a fleet, such as provisioning resources for smart container teams, smart container fleets, smart containers, and/or supporting resources (e.g., edge devices, communication devices, container ships, cranes, additive manufacturing systems (e.g., 3D printers), and the like). In embodiments, resources may include physical resources, digital resources, and/or consumable resources. Examples of physical resources may include, but are not limited to, end effectors/manipulators, environmental shielding components, sensors and/or sensor systems, companion resources (e.g., drones, robots, container ships, trucks, railway systems, cranes, lifts, and the like), hardware resources (e.g., specialized processing modules, data storage, networking modules, tethering modules, and the like), spare parts, human resources (e.g., technicians, operators, and the like), power sources (e.g., generators, portable batteries), and the like. Non-limiting examples of digital resources may include software, operating parameters, job-specific data sets, and the like. Non-limiting examples of consumable resources may include fuel, packaging supplies, welding supplies, washdown/cleanup supplies, and many others.

[2265] In embodiments, the resource provisioning system 13014 may provision physical resources from an inventory of physical resources, such as fleet-specific inventories, regional public-use inventories, rental/per-use fee-based resource inventories, on-demand resource production systems (e.g., 3D printing of end effectors and the like), third party inventories, and the like.

[2266] In embodiments, the resource provisioning system 13014 may work cooperatively with other systems of the fleet operations system, such as fleet configuration systems, fleet resource scheduling and utilization systems, and the like to ensure fleet resource provisioning rules are followed. Physical resources to be provisioned may also include computing resources, such as on-smart container computing resources, smart container operating unit-local fleet-controlled computing resources, cloud / third-party based computing resources, computing and other modules and chips (e.g., for deployment with/within a smart container operating unit), and the like. In some embodiments, the fleet resource provisioning rules may be defined in governance standards libraries, such that the resource provisioning system 13014 interfaces with the intelligence service to ensure that provisioned resources comply with the provisioning rules.

[2267] In embodiments, digital resources to be provisioned by the resource provisioning system 13014 may be provisioned through fleet configuration capabilities, such as software/firmware update pushing (e.g., to update a smart container's on-board software), resource access credentialing (e.g., to access network resources, such as job-specific smart container configuration data and the like), on-smart container data storage configuration/allocation/utilization data, and the like. Use of a provisioning system 13014 may include provisioning equipment, material, software, data structures, and the like that are made and/or sourced specifically for a given freight storage and/or transportation service order.

[2268] In embodiments, the provisioning system 13014 may further operate cooperatively with contract systems, such as third-party smart contract systems, and the like. In some embodiments, a freight storage and/or transportation service order may reference or comprise a smart contract that may include and/or result in configuration of an instance of the provisioning system 13014 that is compliant with the request. As an example, a provisioning system 13014 may receive, such as from a job configuration system 13018, smart contract terms that call out provisioning constraints and/or guidance. The provisioning system 13014 may interpret these contract terms, thereby producing a set of fleet and consumable resource provisioning constraints.

[2269] While the examples described above for a resource provisioning system 13014 generally focus on order execution-related provisioning, the resource provisioning system 13014 may further handle provisioning of fleet resources, such as computing resources, access to and/or execution of fleet elements, such as a fleet configuration system, intelligence service, and the like. In embodiments, provisioning of certain resources may be enacted as part of a negotiation workflow for acceptance of a freight storage and/or transportation service order. As an example, provisioning certain intelligence services (e.g., a fleet level intelligence service) may result in a higher charge to a shipper than other intelligence services (e.g., only a smart container-level intelligence service being deployed smart container operating units). As noted

above and elsewhere herein, intelligence services can bring value to the fleet and job configuration functions of the system; therefore, provisioning such systems as part of a freight storage and/or transportation service order negotiation may justify the additional cost to the shipper. In some scenarios, prioritization of the system resources, such as a fleet configuration system, may impact provisioning system 13014 functions.

[2270] In embodiments, the fleet management system 13002 includes a logistics system 13016 that handles, among other things, logistics planning and execution for meeting shipment requirements, maintaining smart containers, maintaining availability of fleet resources (smart container operating units, physical resources, and the like), and pickup and delivery of parts (e.g., replacement parts, end effectors, supplies, and the like). In embodiments, the logistics system 13016 can leverage intelligence services, such as machine learning systems and/or artificial intelligence systems to recommend logistics plans.

[2271] Logistics plans may refer to a workflow that is generated to result in the delivery of a set of items to a particular location. In embodiments, the logistics system 13016 may generate logistics plans that utilize fleet resources (e.g., smart containers, container ships, robots, trucks, cranes, railways, or the like) for execution of a logistics plan. In embodiments, the fleet operation system 13002 may leverage the (system-level) intelligence service 13004 to assist in logistics planning and decision-making.

[2272] In embodiments, the fleet management system 13002 includes a maintenance management system 13028 that may be configured to schedule and effectuate maintenance for fleet resources, such as smart container operating units. A maintenance management system 13028 may handle field maintenance needs and requests, including scheduled maintenance of fleet recourses in the field to mitigate impact on smart container operating unit utilization due to travel from a deployed job site to a repair depot. The maintenance management system 13028 may also coordinate maintenance and repair operations at repair depots, and the like. In embodiments, a maintenance management system 13028 may include, provide access to, and/or be integrated with mobile maintenance vehicles, spare parts depots, third-party maintenance service providers and the like. In embodiments, maintenance needs for fleet resources housed in storage areas, such as warehouses, remote inventory depots and the like may be evaluated by the maintenance management system 13028 for pre-scheduled maintenance, such as when a preventive maintenance activity for a smart container is upcoming so that the smart container is less likely to require maintenance during a deployment.

[2273] In embodiments, the maintenance management system 13028 may monitor the state of the fleet resources, such as smart container operating units, via resource state reports that may be provided on a scheduled basis or in response to an inquiry for smart container operating unit state by the maintenance management system 13028 and the like. In embodiments, the maintenance management system 13028 may monitor smart container operating unit communication for an indication of a potential service condition, such as a smart container operating unit signaling that it is experiencing reduced power output, a smart container operating unit reporting exposure to certain ambient conditions (e.g., excessive heat), a smart container

operating unit reporting a leak involving liquid cargo that requires cleaning, a lack of heartbeat signal from a smart container operating unit to a smart container health monitor resource, and the like. Further, a maintenance management system 13028 may deploy probes within smart container operating and/or supervisory software that may perform maintenance management functions on a smart container operating unit, such as monitoring information in a smart container data store that stores smart container operating unit state information, activating self-test operating modes, collection of data that provides indications of smart container maintenance needs, and the like. Yet further, a maintenance management system 13028 may include maintenance robots that may be deployed with smart containers in a team of smart container operating units for performing a requested job.

[2274] A maintenance management system 13028 may be constructed to take advantage of a range of system services and capabilities to schedule and effectuate maintenance, including leveraging human/operator input (e.g., a human observer may indicate that a smart container operating unit appears to be operating erratically), smart container process automation of maintenance activities, artificial intelligence for predicting maintenance instances for scheduling, machine learning to help identify new opportunities for scheduling and performing maintenance (e.g., analyze performance of smart container operating units that have been maintained for certain conditions before operating under those conditions, such as upgrading the cooling system of a smart container before operating in a high temperature environment), and the like. In embodiments, a maintenance management system 13028 may receive maintenance-related input. In embodiments, candidate sources of maintenance related input may include human operators/observers, maintenance scheduling services, third-party service providers, smart container production vendors, and parts providers to schedule maintenance. The maintenance management system 13028 may also leverage business rules (e.g., rules established for a team, fleet, by a shipper, determined by a regulatory agency, and the like), association tables, data sets, databases, and/or maintenance management libraries to determine appropriate maintenance workflows, service actions, needed parts, and the like. In embodiments, a maintenance activity may be assigned by the maintenance management system to a fleet resource, such as a maintenance smart container, a human technician, a third-party service provider, and the like.

[2275] In embodiments, smart container operating units that are deployed may be configured with one or more maintenance protocols to perform, among other things, self-maintenance, such as self-cleaning, calibrating end effector operations, and the like. Self-maintenance may include, without limitation, reduction in capabilities responsive to detection of a compromised smart container operating unit feature, such as a faulty 3D printing system or faulty systems for securing cargo (e.g., steel strapping, polyester strapping, dunnage bags, or the like). A deployed smart container operating unit may determine that a capability is compromised and, optionally with support of the maintenance management system 13028, may switch assignments with another smart container so that the compromised capability can be resolved when time permits rather than causing a delay in completion of a shipment. Also, smart container operating unit

intelligence (e.g., on-smart container AI and the like) may predict a compromise in smart container capabilities based on, for example, time-to-failure data for the smart container capability.

[2276] In embodiments, the maintenance management system 13028 may leverage the intelligence service 13004 (e.g., the system level intelligence service 13004) to predict when maintenance may be performed for smart container operating units and/or components thereof. In some of these embodiments, the maintenance management system 13028 may request a digital twin of a smart container operating unit from the intelligence service 13004. In these embodiments, the digital twin may reflect a current condition of the smart container operating unit, such that the smart container operating unit digital twin may be analyzed to determine whether maintenance is required for the smart container operating unit. Additionally, or alternatively, the digital twin service of the intelligence service 13004 may run one or more simulations involving the smart container operating unit to predict when maintenance may be required. In some of these embodiments, outputs of the digital twin of the smart container operating unit may be analyzed (e.g., using a machine-learned prediction model or a neural network) to predict if/when maintenance may be required.

[2277] In embodiments, the fleet management system 13002 includes a job configuration system 13018. In embodiments, a shipment configuration system receives freight storage and/or transportation service orders, such as from customers that book a smart container shipping service. In embodiments, a freight storage and/or transportation service order may indicate a set of freight storage and/or transportation service order parameters. Non-limiting examples of freight storage and/or transportation service order parameters may include: timing requirements, origin and destination of shipment (e.g., region, address, coordinates, or the like), number of smart containers required, type of containers required (e.g., tank containers, bulk containers, 20-ft standard containers, 40-ft high-cube containers, or the like), container utilization requirements (e.g., full container (FCL) vs. shared container (LCL)), cargo descriptions (e.g., number of packages, total volume, or total weight), whether the cargo includes personal effects, other required tasks (e.g., inspection tasks, packaging tasks, unpackaging tasks, unloading tasks, loading tasks, 3D printing tasks, growing tasks, assembling tasks, monitoring tasks, or the like), pricing information, and any other suitable parameters. In embodiments, the freight storage and/or transportation service order parameters which may be indicative of what types of smart container operating units are needed and/or functionalities thereof. These and other freight storage and/or transportation service order details are described elsewhere herein.

[2278] In embodiments, quantum optimization may be enabled by a quantum computing service 13008 that may optimize assignments across fleet resources, such as smart container operating units and the like. A quantum computing service 13008 may further optimize routing (logical, physical, and electronic) associated with smart container fleets, shipments, team, communications, logistics and the like. Additionally, or alternatively, in some embodiments a quantum computing service 13008 may be employed to optimize combinations of smart container resources with other resources across a variety of fleet functions, including energy

consumption, computational capacity and utilization, infrastructure resource planning, engagement and utilization, risk management, computing storage capacity, and the like. The quantum computing service 13008 may also be used for optimizing smart container design, optimizing smart container services pricing, optimizing smart container charging (e.g., optimizing the route of a smart container having solar panels such that it receives sufficient levels of sunlight), or the like.

[2279] In embodiments, a job configuration system 13018 and other fleet resources (e.g., fleet configuration, system intelligence, smart container operation and the like) may benefit from use of deep learning techniques for task, workflow, and order execution plan optimization as well as for learning, among other things, from failures. In these embodiments, the job configuration system 13018 may request deep learning services from the system-level intelligence service 13004, which leverages neural networks and/or other machine-learned models to determine job configurations based on a set of features, including features extracted from a freight storage and/or transportation service order. In these embodiments, the artificial intelligence services may be configured to learn task workflows, job configurations, and the like.

[2280] In embodiments, job configuration, fleet configuration (which may include smart container configuration), and/or as order execution may further enhance fleet functions, performance, and outcomes through use of local context-adaptive task assignment, execution, resource routing and the like. This adaptive capability may be further enabled through peer-to-peer based communication (e.g., smart container operating units within a team) that reveals context of job activities rapidly and efficiently.

[2281] In embodiments, artificial intelligence for automation of smart container assignment and execution (e.g., smart container process automation through learning) may function cooperatively with elements of the smart container system 13000, such as a fleet management system 13002 and intelligence service 13004, to learn smart container assignment from, for example, human operator assignment activity. Other learning that an artificial intelligence system may yield in context of smart container fleet configuration and operation may be based on outcome measures of success, including task completion, time to completion, percentage of damage-free shipments delivered, cost of completion, quality of completion, ROI for resources, resource utilization, and others.

[2282] These and other job configuration details, including operational flows of the job configuration system 13018 are depicted and described in related figures herein.

[2283] In embodiments, the fleet management system 13002 includes a fleet and smart container configuration system 13020 (also referred to as fleet configuration system 13020) that may work cooperatively with a job configuration system 13018 to determine configurations of fleet resources (e.g., smart container operating units, teams, and the like) to satisfy freight storage and/or transportation service orders from a plurality of concurrent and/or overlapping freight storage and/or transportation service orders. The fleet configuration system 13020 may determine fleet and smart container configurations based on freight storage and/or transportation service orders, required tasks, budget, a timeline, availability of smart containers or smart

container types, availability of container ships or other modes of transport, traffic at container terminals or ports, and/or other suitable considerations. In some embodiments, the fleet configuration system 13020 may leverage the system-level intelligence service 13004 to determine fleet and/or smart container configurations. In some of these embodiments, the intelligence request may include a proposed fleet configuration and other relevant data (e.g., cost constraints, cargo type, origin location, destination location, route environments, etc.). In response, the intelligence service 13004 may output a proposed fleet configuration. Further details of a fleet configuration system 13020 are described and depicted in figures elsewhere herein.

[2284] In embodiments, a fleet management system 13002 may include an order execution, monitoring, and reporting system 13022 (also referred to as an order execution system 13022). An order execution system 13022 may receive an order execution plan from the job configuration system 13018 that it processes by coordinating activities of system functions, such as logistics for smart container and fleet resource delivery, data processing system 13024 allocation for facilitating data collection, cataloging, library management and data processing activities for order execution. In general, the order execution system 13022 may start a job with committing and managing resources, including resources beyond those configured by the job configuration system 13018, such as computing, storage, bandwidth, and the like as may be defined by and/or determined to be useful for executing the order execution plan.

[2285] In embodiments, the order execution system 13022 may further facilitate adherence to reporting requirements (e.g., shipment-specific, fleet-specific, compliance-related reporting, and the like) associated with order execution. In embodiments, reporting may include data collection (e.g., from smart container operating units, sensor systems, user devices, databases, and/or the like), data processing, and feedback preparation for use of order execution data by job and fleet configuration systems and the like. In embodiments, the order execution system 13022 may be assisted by other system capabilities that transmit, process, store, and manage data that impacts order execution, such as the maintenance management system 13028, the resource provisioning system 13014, and the communication management system 13010 that facilitates communications among smart container operating units, teams, and fleets, and others. These and other fleet and external resources may provide information to the order execution system 13022 for facilitating operational aspects of a requested job, such as which communication resources has the communication management system 13010 reserved and/or allocated for the requested job, service and/or maintenance requirements for smart container operating unit and other resources being used to execute a job, changes to resource provisioning that occur after operation of a job has commenced, and the like.

[2286] In embodiments, the order execution system 13022 may further facilitate evaluation and modification of an order execution plan while executing the job by, for example, identifying bottlenecks that are developing due to on-the-job conditions (e.g., heavy container port traffic, ground conditions not as expected due to excessive rain, and the like).

[2287] In embodiments, the order execution system 13022 may perform a variety of data pipeline functions during execution of a job. In embodiments, data pipeline functions may include, among other things, optimizing use of preconfigured sensor and detection packages that combine sensor selection, sensing, information collection, preprocessing, routing, consolidation, processing, and the like. In embodiments, sensor and detection packages may be activated by the order execution system 13022 when use thereof is indicated as serving a range of monitoring/reporting activities. Other data pipeline function examples include optimizing on-smart container storage, selective sensor data filtering for reduced impact on communication bandwidth (e.g., reducing the demand for wireless network utilization), exception condition detection and pipeline adaptation/data filtering, and others.

[2288] In embodiments, the order execution system 13022 may monitor, and if necessary, address smart container power demand during order execution. In these embodiments, the order execution system 13022 may ensure, for example, battery charge capacity (or other energy source levels, such as fuel levels) across multiple smart container operating units to meet job task and workflow requirements, such as a queue of tasks that should not be interrupted. In embodiments, smart container power demand management may include fleet, team, and individual smart container operating unit routing to complete tasks with reduced delays in overall productivity with integrated smart container charging activities. Further details of the functions and operation of the order execution system 13022 are described throughout the disclosure.

[2289] In embodiments, smart container functionality, including during order execution, may be combined with 3D printing services and systems to enable, for example, agile, remote, flexible manufacturing on an as-demanded basis through, for example, deployment and use of optionally automated smart container 3D printing and production capabilities for last-mile customization of products.

[2290] In embodiments, the order execution system 13022 may execute, deploy, and/or interface with a set of smart contracts that monitor and report on smart container operating units 13040. In embodiments, robust distributed data systems, such as distributed ledgers (e.g., public or private blockchains) may be utilized for tracking and enhancing smart container fleets and/or smart container activities, as well as allocation of smart container resource utilization cost to relevant parties. In some of these embodiments, the distributed ledger nodes store and execute smart contracts. In embodiments, the smart contracts may be configured to monitor freight storage and/or transportation service orders, order execution, resource use, and/or the like. For example, in some embodiments, smart container operating units may be configured to provide evidence of completion of a task (e.g., a delivery of cargo) to a smart contract, such that the smart contract may trigger actions (e.g., payments, recordation, or the like) in response to completed tasks. In another example, smart container operating units may be configured to report location data, sensor data, status data (e.g., charge levels, cargo condition and/or status, or the like), and/or other suitable data, whereby the smart contract may be configured to trigger certain actions based on the received data.

[2291] In embodiments, a smart container system 13000 may include a data processing system 13024 that may provide, among other things, access to scalable computation capabilities for any smart container freight service operations and/or intelligence resources, data management capabilities (e.g., data caching, storage allocation and management and the like), access to and control of fleet and/or job-related data stores, such as libraries, fleet resource inventory control and management data structures and the like.

[2292] In embodiments, the fleet management system 13002 may provide support for satisfying freight storage and/or transportation service orders. For example, the components of the fleet management system 13002 may facilitate resource provisioning and logistics to ensure that fleet resources (e.g., smart container operating units, physical modules, and/or support devices) are provided in an efficient manner to satisfy the freight storage and/or transportation service order, such as timing of order execution and the like. For example, in some embodiments, the fleet management system 13002 may employ "just-in-time" strategies to facilitate delivery of fleet resources and/or maintenance tasks to ensure fleet resources are allocated in an efficient manner without significantly impacting job completion times. In some of these embodiments, the fleet management system 13002 may leverage the intelligence services to anticipate the fleet resource needs corresponding to various freight storage and/or transportation service orders and/or order execution plans to anticipate the fleet resource needs and to arrange for delivery and/or maintenance of such fleet resources.

[2293] In embodiments, the order execution system 13022 may anticipate job-related resource needs in a job-specific manner to predict when specific resources will be required for a specific job. For example, the order execution system 13022 (working in combination with the intelligence service) may generate a schedule of in-progress and/or upcoming tasks for a specific freight storage and/or transportation service order, and in response, may determine when certain fleet resources are likely to be needed and/or to come available. Additionally, or alternatively, the order execution system 13022 may predict the job-related resources for a specific job in other suitable manners. For example, prediction of resource needs may be determined based on a pattern of fleet resource needs as derived from a freight storage and/or transportation service order history of the shipper; a resource usage history of the shipper from the previous N jobs performed for the shipper; timing of freight storage and/or transportation service orders (e.g., orders are typically received on a Thursday for jobs to start on Monday the following week), and/or the like. Business relationships among entities can form a basis for predicting fleet resource needs and timing of the shipper/buyer based on actions, including freight storage and/or transportation service orders, of the supplier/seller/consumer.

[2294] In embodiments, many other factors may impact fleet resource need predictions, such as weather forecasting and seasonal affects. Fleet resource need prediction may also be activated by events outside of the core freight storage and/or transportation service order process, such as natural disasters, accidents/emergencies, pandemics, and the like. In another example, other sources of information that may impact anticipation of fleet resource needs may include business goals and objectives, such as reducing or increasing spending near the end of a financial

reporting period (e.g., a fiscal quarter, year, etc.). An indication that a target shipper intends to cut back on expenses during the last few weeks or months of a fiscal reporting period may suggest that fleet resources that are typically allocated to freight storage and/or transportation service orders by the target shipper will be available for other actions, such as maintenance, upgrading, allocation to other shippers and the like. In embodiments, fleet goals or objectives may also impact fleet resource anticipation and therefore corresponding preparation activities and the like. One such example is a required upgrade of a class of smart container. In anticipation of needing to reserve the smart containers in this class, the fleet configuration functions may allocate alternate smart container types that can be reconfigured to satisfy the requirements of the reserved smart container class for the duration of the upgrade activity.

[2295] In embodiments, anticipation of fleet resource needs may be determined through use of smart container system 13000, such as the intelligence service 13004 and the fleet management system 13002. For example, in some embodiments the intelligence service 13004 may analyze sources of data that may impact fleet resource demands, such as weather forecasts, public activity calendars, freight storage and/or transportation service order data (e.g., timing, job parameters, relations to other freight storage and/or transportation service orders, and the like), social media activity, government activity and/or legislation, and the like. In this example, the intelligence service 13004, acting in cooperation with the fleet management system 13002, may predict fleet resource demand based on an analysis of the disparate data sources (e.g., using a neural network or the like). In these embodiments, the intelligence service 13004 may process the data from the disparate data sources and determine a likelihood of fleet resource needs across a range of factors.

[2296] In embodiments, a smart container system 13000 may interface with external data sources 13036 for performing various system functions including job configuration, fleet configuration, job negotiation (e.g., via a smart contract facility), order execution and the like. Examples of external data sources for use by the system include value chain entities (e.g., third parties paying for shipping services and the like), enterprise resource planning systems (ERPs) that may provide job context for performing team configuration and/or execution of a requested job, smart contracts, and the like. Other external data sources may include third-party sensor systems (e.g., GPS data, value chain logistics data, and the like) as well as third-party data streams (e.g., weather, traffic, electricity pricing, and the like).

[2297] In some embodiments, the smart container system 13000 may support the use of smart contracts in relation to freight storage and/or transportation service orders, job performance, resource allocation, and/or the like. In embodiments, freight storage and/or transportation service orders may be routed through a smart contract handler that captures job requirements, requestor goals and objectives, and fleet order execution constraints into a dynamic smart contract. In some embodiments, smart contracts may be utilized throughout a smart container fleet management system to address all manner of fleet operations, such as administering negotiated routing of a smart container from a first location (e.g., an origin location, container port or terminal, a temporary storage/service location) to a second location (e.g., a destination

location, a container port or terminal, or the like). As a further example, a smart contract may be put in place as a control for a bidding system for smart container time/task utilization. As another example, a smart contract may monitor certain activities (e.g., task-related activities and the like) relating to a freight storage and/or transportation service order. The smart contract may rely on and/or benefit from access to fleet system data, (e.g., route progress, sensor data, and the like) to trigger actions defined by the smart contract, such as payments upon completion of a delivery of smart container cargo. The smart container system 13000 may provide access to fleet resources, including fleet data through Application Programming Interfaces (APIs), infrastructure elements such as sensor networks, edge computing systems, and the like for updating states relevant to smart contract terms and conditions.

[2298] In embodiments, the job configuration system 13018 and the fleet configuration system 13020 collectively generate an order execution plan, according to some embodiments of the present disclosure. In embodiments, an order execution plan may define a smart container route and/or set of tasks that are to be performed in completion of a requested job and may further define a configuration of a fleet of smart container operating units that are to complete the job. In embodiments, an order execution plan may include task definitions (which may include route definitions), workflow definitions, fleet configurations (which may include smart container configurations of individual smart containers), team assignments, and references to (or incorporation of) contextual information, such as container port site details and the like. In embodiments, the job configuration system 13018 receives an order that defines the job to be done and the job configuration system 13018 may determine a set of task definitions that respectively define a shipping service and/or tasks that are performed by a smart container in completion of a job. In embodiments, the job configuration system 13018 further defines a set of workflow definitions. The workflow definitions define at least one order in which tasks are performed in completion of a project and/or job, including any loops, iterations, triggering conditions, or the like. In embodiments, the job configuration system 13018 may determine the workflows based on the task definitions that comprise a job. The job configuration system 13018 may leverage libraries of preconfigured workflows to complete certain jobs. Additionally, or alternatively, the job configuration system 13018 may leverage the intelligence service 13004 to obtain an initial workflow definition for a job and/or project that is part of a larger job. In some embodiments, a human may configure the initial workflow definition and/or may provide input that is used to determine the initial workflow definition. In embodiments, the job configuration system 13018 may interface with one or more components of the smart container system 13000 to exchange information for developing a smart container fleet order execution plan and/or to leverage one or more services thereof. For example, the job configuration system 13018 may interface with the data processing system 13024, a smart container configuration library of smart container, fleet, project, and task related information, the fleet-level intelligence service 13004, the fleet configuration system 13020, and the like.

[2299] In embodiments, the job configuration system 13018 may include a plurality of systems that perform order execution plan preparation functions by processing the information received

in the freight storage and/or transportation service order. In embodiments, the systems of the job configuration system 13018 may include a job parsing system, a task definition system, a workflow definition system, and a workflow simulation system. In the illustrated example, the job configuration system 13018 systems work in combination to generate an order execution plan that is used to define a set of smart container operating unit assignments. In embodiments, smart container operating unit assignments may be supplemental to or integrated with an order execution plan and may identify specific smart container teams and/or smart containers assigned to respective tasks. For example, smart container operating unit assignment may define specific tasks and, for each task, may identify a specific smart container assigned to a task via a smart container unique identifier and/or a specific smart container team with a team identifier assigned to the task. In embodiments, the smart container operating unit assignments may be generated by the job configuration system 13018 and/or the fleet configuration system 13020.

[2300] In embodiments, a job parsing system receives and parses a freight storage and/or transportation service order to determine a set of freight storage and/or transportation service order parameters that are ultimately used to determine a job definition, project definition(s), task definitions, workflow definitions, fleet configurations, and smart container configurations. In embodiments, a job parsing system may receive a freight storage and/or transportation service order from a user via a user interface, such as human interface system 13038 that receives input by an operator to configure, adapt, or otherwise facilitate parsing of the freight storage and/or transportation service order. Additionally, or alternatively, the job parsing system may receive the freight storage and/or transportation service order from a client device associated with a requesting organization.

[2301] In embodiments, the job parsing system may be configured with an ingestion facility for receiving electronic versions of job descriptions and related documents, such as GPS data, smart contract data and/or terms, links to the same, and the like. The ingestion facility may parse documents for keywords, references to activities and the like that can be useful for determining job requirements. Further, keywords in the ingested job content, such as weight terms, volume terms, route environment terms, and the like may be usefully applied by the job configuration system 13018 elements by providing insight as to the type(s) of smart containers needed and the configurations thereof. As an example, a keyword that suggests content to be moved weighs 25 tons, suggests a smart container transport device/team that has at least that amount of moving capacity.

[2302] In embodiments, the job parsing system may incorporate and/or utilize machine learning functionality (e.g., as may be provided by the intelligence service 13004) to improve techniques for parsing job content which may include description data. In addition to machine-based learning from human-generated feedback on job content parsing results, learning may be based on experience with other job content parsing actions (e.g., prior freight storage and/or transportation service orders), common and special knowledge bases (such as technical dictionaries), expert humans, and the like.

[2303] In embodiments, parsing of job content may include automated parsing of structured and unstructured text. In some embodiments, the job parsing system may be configured to identify (and optionally resolve) missing/unclear data and qualified job content data (collectively referred to as "insufficient information"). In response to identifying insufficient information, the job parsing system may generate and provide a request to a human operator via a user interface for clarification with respect to the insufficient information. Such a request may identify specific inputs from the user to provide, such that the request identifies the clarifying content that was missing or unclear initially. Additionally, or alternatively, the parsing system 13214 may determine the clarifying content from (e.g., through a query of) a library 13044 that maintains data from prior freight storage and/or transportation service orders, such that the clarifying content may be obtained using the prior freight storage and/or transportation service order information and context from the request. If the parsing job is unable to determine the clarifying content, the parsing system 13214 may generate a request for clarifying content, as discussed above.

[2304] In embodiments, a range of job description information may be provided to, determined, and/or extracted by the job configuration system 13018. Examples of freight storage and/or transportation service order parameters may include, but are not limited to: origin location and destination location information and/or other physical locations along a route; weight requirements; volume requirements; cargo descriptions; smart container type(s); the number of smart containers required; mode of transportation (container ship, truck, rail, self-driving smart container, hyperloop, and the like). 3D printing requirements (such as for last-mile customization); digital data for environment layouts of ships, shipping container ports, shipping container storage facilities, and the like, such as 3D CAD models or scans may be available or might be completed as part of initial job scoping and may be used to automatically provide task priority and workflow routing, smart container selection, supervisory needs, etc.; operating environment (such as along a route) including temperature, hazard description(s), terrain, weather, etc.; deliverables, such as data, reports, analysis, and the like; customer interfaces for data exchange, such as network interfaces, APIs, security; communication network availability, such as land line, 4G, 5G, Wi-Fi, private networks, satellite, connectivity constraints, and the like; budget constraints; timing requirements, including scheduling for port availability, scheduling for ship availability, earliest start time, latest finish time, rate of activity, such as the number of smart containers active at any given time, and the like. Examples of other job description information that may be handled by a job parsing system may include contract-related information, such as smart contract terms, certification level of smart container operational software for deployed smart containers, insurance provisions, regulatory requirements (e.g., customs requirements), site access requirements (e.g., a particular container port can be accessed only when humans are present or only through coordination with humans that are present on the site), conditions for assigning a proxy for a task, activity, workflow, or the entire job.

[2305] In embodiments, the job configuration system 13018 systems (e.g., job parsing system, task definition system, and workflow definition system) may reference a library 13044 to identify content and structural filters for distinguishing smart container automation job content from other job content (e.g., cost, payment, financing, etc.), preconfigured candidate tasks, workflows, and/or completed job configurations that substantially meet the requirements of the freight storage and/or transportation service order. In embodiments, the library 13044 or another job configuration library may facilitate mapping indicia of the job content with target terms that indicate smart container automation. As an example of a use of an automated task from the library 13044, a requested freight transportation service may include a requirement for measuring the temperature inside the smart container using a set of temperature sensors. The job parsing system may identify the temperature measurement requirement, and in response, the task definition system may identify an automated measurement task for measuring container temperature in the library 13044 that meets the requirements of that portion of the freight storage and/or transportation service order, which may be used in defining the order execution plan. If job configuration system 13018 determines that a suitable job configuration is available (e.g., from the library 13044), such as if the freight storage and/or transportation service ordered had previously been requested, the job configuration system 13018 may use a previous job configuration corresponding to the previously requested job as a proposed job configuration for further validation with current fleet standards and the like. For example, the intelligence service 13004 may analyze the proposed job configuration (e.g., with one or more intelligence services, including without limitation a machine learning service) with respect to a set of governance standards to ensure that the proposed job configuration comports with said standards. The intelligence service 13004 may perform other intelligence-based tasks with respect to the proposed job configuration.

[2306] In some scenarios, the job configuration system 13018 may determine that one or more tasks, workflows, routines, and the like do not have a suitable counterpart in the library 13044. In such a scenario, the job parsing system may generate a data set that includes smart container-fleet focused requirements (e.g., task definition parameters, smart container configuration parameters, suggested task order, and the like) for performing the task that is passed along to other shipment configuration system modules for processing. In embodiments, the job parsing system may rely on the intelligence service 13004 for suggestions of such requirements, including combinations of tasks that when optionally adapted may satisfy the job requirement.

[2307] In embodiments, the job parsing system may include and/or interface with the analysis modules/governance libraries of the intelligence service 13004 of the system 13000. The job parsing system may leverage the governance-based analyses by providing portions of the candidate smart container automation portions of the job content (e.g., terms and the like) for processing. The intelligence service 13004 may, in response to the provided portion of job content, provide and/or indicate one or more of safety standards and/or one or more of operational standards to be applied during preparation of the order execution plan by the job configuration system 13018.

[2308] In embodiments, the job parsing system may include a job requirements module that produces a set of freight storage and/or transportation service order instance-specific requirements for use when the job configuration system 13018 defines smart container tasks, configures fleet resources, defines workflows, simulates workflows, generates an order execution plan, and/or the like. In embodiments, the set of freight storage and/or transportation service order instance-specific requirements may be determined based on at least one or more of: the candidate portions of the job content that indicate smart container automation (e.g., terms that indicate a smart container task), one or more inputs from the user interface (e.g., clarification of terms), safety and operational standards (e.g., from the governance layer), and a recommended smart container task and associated contextual information (e.g., provided by a fleet intelligence service).

[2309] In embodiments, the job parsing system may apply content filters and/or structural filters to identify structural elements in the job content that may indicate one or more of tasks, sub-tasks, task ordering, task dependencies, task requirements, and the like. In embodiments, the detected structural elements may facilitate selection and configuration of smart container operating units by, for example, the fleet configuration system 13020. In an example, a structural element that distinguishes a set of tasks may be used by the fleet configuration system to avoid assigning the same smart container operating unit to tasks within the set of tasks delineated by the structural element and tasks outside of the set.

[2310] In embodiments, the job parsing system may incorporate and/or utilize a freight storage and/or transportation service order configuration agent/expert system that may be constructed to facilitate developing job description parsing capabilities.

[2311] In embodiments, the task definition system may organize job data into task definitions (e.g., discrete smart container tasks or tasks performed by smart container teams). The task definition system may further coordinate other systems of the job configuration system 13018, such as a workflow simulation system to optimize the task definitions.

[2312] In embodiments, the task definition system may refine job data compiled by the job parsing system to facilitate defining discrete operations of one or more smart container operating units in the fleet of smart containers in performance of a requested job. Defining tasks may be based on information regarding smart containers, shipping container ports, container ships, railways, trucks, hyperloops, smart container types, smart container features, and smart container configurations that can perform a defined task. In embodiments, the task definition system may further provide information in task definitions that facilitate a fleet configuration system 13020 in determining use of smart containers for each defined task. In embodiments, the task definition system may reference the library 13044, the intelligence service 13004, or other system-specific or accessible resources when making task suggestions.

[2313] As the task definition system defines the tasks of a job, the task definition may be cataloged and stored for future use, such as in the library 13044. In some embodiments, the task definition system may adapt a task definition from a previously cataloged task definition (e.g., adapting a task definition for a particular type of environment or certain conditions thereof from

a previously catalogued task definition). In these embodiments, the task definition system may catalogue the derivative task definition in the library 13044 with adaptation instructions. In some embodiments, a task definition that is catalogued in the library 13044 may be associated with an already cataloged task definition and/or may replace an already cataloged task definition, may be cataloged as a sub-task of an existing task, and the like. In general, task definition may include associated tasks, serialized tasks, nested tasks, and the like.

[2314] Information about a job may be stored in the library 13044 for future use; therefore, the task definition system may access the library 13044 to retrieve information about the job, smart containers, fleets, and the like. In an exemplary embodiment of self-stacking smart containers on a container ship, the information accessible through the library 13044 may include, for example, how to access information about the physical layout of the container ship. The task definition system may also access the library 13044 to update information, such as by adding one or more tasks to a list of tasks for the self-stacking task, results from optimizations of task definition performed by the order execution system, and the like.

[2315] Optimization features of the task definition system are described below in association with feedback from other elements of the job configuration system 13018, such as the workflow simulation system and the like.

[2316] Task definitions may be generated and provided to other elements of the job configuration system 13018, such as the workflow definition system and a fleet configuration system proxy. In embodiments, the fleet that may provide the task definitions (which may include route definitions and other suitable information) to the fleet configuration system 13020. In an example, a fleet configuration system proxy may narrow down sets of candidate smart containers for performing tasks (as indicated in task descriptions) to a specific smart container type (and optionally a specific smart container in the fleet) based on fleet configuration and fleet resource inventory and allocation data relevant to the requested job (e.g., based on geography, timing, and the like). The fleet configuration system proxy may process task definitions, which may include smart container identification information (e.g., smart container type and the like), for aligning resources of the fleet with the relevant task information. In an example, a fleet configuration system proxy may generate data suitable for use by fleet operational elements, such as a fleet resource provisioning system 13014, to perform fleet resource allocation, scheduling, and the like that supports at least a portion of the goals of a freight storage and/or transportation service order being processed through the job configuration system 13018. The fleet configuration system proxy may employ fleet configuration modeling to determine candidate fleet configurations that meet job requirements. The modeling may be useful in determining an impact on fleet resources that may then be taken into consideration during fleet configuration functions, resource allocation, and the like. In embodiments, fleet configuration modeling may include use of system intelligence service resources, such as machine learning, artificial intelligence, and the like when determining one or more preferred fleet configurations that also satisfy one or more job description requirements. The fleet configuration system 13020 is described in further detail elsewhere in this disclosure.

[2317] In embodiments, the job configuration system 13018 may include a workflow definition system that receives task definitions from the task definition system, fleet configuration information from the fleet configuration system 13020, other freight storage and/or transportation service order information that may facilitate task sequencing (e.g., timing of deliverables and/or tasks), and generates one or more task workflows based thereon. In embodiments, the workflow definition system incorporates information from the smart container fleet management system to identify workflow possibilities using output from the task definition, job parsing system, and real-time external data such as maintenance management systems, ERP systems, and so forth to determine the task workflows. In embodiments, a task workflow defines an order and manner in which tasks are performed for a project/job. In embodiments, the workflow definition system may apply job descriptive information to a set of task definitions and fleet configuration data to produce one or more workflows to perform one or more activities of the job. As an example, a workflow may cover an activity such as last-mile 3D printing of an athletic shoe within the container. The tasks defined for this activity may be collected into a workflow or portion thereof, ordered to ensure proper compliance with the job requirements, and published as a set of requirements to perform the activity/workflow. A job workflow definition may include information descriptive of quantities and types of smart containers, 3D printers, robots, tools and/or end effectors, and the like that may be provided by the fleet configuration system 13020 for one or more tasks being ordered by the workflow definition system. In embodiments, this portion of the workflow definition may be utilized by other modules of the job configuration system 13018 (e.g., order execution system 13022) to, for example, identify and determine required configurations of one or more smart containers, and the like to be readied ahead of performing a task in the workflow (e.g., ensuring that a smart container is (re)configured with a configuration that enables performing a task prior to performing the task that is defined in the workflow). Other information produced in an order execution plan may include sequence of tasks (e.g., as produced by a workflow system), which may further identify a sequence of smart containers required to perform the tasks.

[2318] A workflow definition system may utilize resources of the smart container configuration library when defining workflows. Workflow definition parameters, such as how to determine minimum time between tasks, inter-task coordination, task classification, workflow scope, and the like may be available in the library 13044, and/or in information retrieved from a freight storage and/or transportation service order. These and other parameters may include job-specific variables that can be set to default values, but adjusted by, for example, the workflow definition system to meet job-specific needs. An example of use of smart container configuration library information to develop job workflow definitions may include a cargo unloading task (e.g., by a set of robotic arms attached to the smart container or by robots embedded within the container), followed by a self-stacking storage task (e.g., by an on-container rail and/or lift system). Useful information that a workflow definition system may utilize from a smart container configuration library may include template, preconfigured or default workflows, such as workflows developed for a previous execution of the job. A

workflow definition system may determine which, if any, workflow in the library 13044 (base workflow) is suitable for use in the current job workflow definition instance; determine adjustments to the retrieved workflow; produce an instance-specific job workflow that may include additional tasks not found in the base workflow and/or exclude unnecessary tasks found in the base workflow, and the like.

[2319] Other examples of smart container configuration library information that may be useful for developing job workflow definitions include availability of sensor detection packages. These sensor detection packages may indicate a preferred sequence of sensing tasks and therefore may impact workflows of such tasks. These and related reconfigured sensor and detection packages may combine sensor selection, sensing, information collection, preprocessing, routing, consolidation, processing, and the like. These sensor and detection packages may be included in a fleet configuration process, such as being included in an order execution plan for use by the order execution, monitoring, and reporting system 13022. In embodiments, use thereof is indicated as serving a range of monitoring activities and the like.

[2320] A job workflow definition system may examine task to task dependency (e.g., performing a second task of unloading cargo is dependent on completing a first task of transporting the cargo to a destination container terminal) to identify potential workflow independence and dependence for, among other things, configuring an order execution plan that may include parallelized use of fleet resources, such as teams and the like.

[2321] Features of an intelligence service, such as digital twin capabilities and the like, may also be beneficially applied to simulate and validate workflows, such as with a workflow simulation system of the job configuration system 13018. The workflow simulation system may perform simulations of portions of a job configuration, such as those portions organized into job workflows by the workflow definition system. In an example of workflow simulation, a set of tasks defined by the task definition system and organized into a portion of a job workflow may be modeled using functional equivalents for smart containers, tasks, workflows and the like, such as smart container digital twins 13504, container ship digital twins, shipping container port digital twins, railway digital twins, truck digital twins, environment digital twins, task digital twins, workflow digital twins, team digital twins, fleet digital twins, and the like. These digital twins may be retrieved from the library 13044 and executed by a processor to simulate the set of tasks, such as to validate the defined tasks. In embodiments, the fleet intelligence system may be utilized for providing at least a portion of these workflow simulations, such as by applying workflow definitions and task definitions to one or more workflow models and/or digital twins operating in an artificial intelligence environment machine learning environment.

[2322] The workflow simulation system may also generate feedback from simulating workflows defined by the workflow definition system that may be useful in improving a workflow definition, a task definition, a smart container selection and the like.

[2323] The workflow simulation system may establish or otherwise access criteria for determining if a workflow meets the criteria, such as timely and successfully completing a task, job, and the like. By applying these criteria for measuring outcomes of workflow simulations,

the workflow simulation system may validate one or more workflow options, smart container options passed along to the workflow definition system, fleet configuration options, and the like before providing feedback to, for example, the task definition system, the job parsing system and the like. Options that do not meet the criteria (e.g., consumes an excess of resources, results in wear down of a smart container, fails to meet a schedule, results in a high percentage of damaged cargo, and the like) may be marked as such for improving job configuration functions, such as structuring tasks into workflows and the like.

[2324] Further, a workflow simulation system may leverage the system intelligence service. In embodiments, the system intelligence service may provide access to and operation of instances of fleet digital twin modules that may provide critical understanding of fleet-based impacts on workflow definition for performing a requested job. In embodiments, a logistics digital twin of the fleet intelligence system may provide useful workflow simulation information through operation of modeling of shipments and costs of smart containers, personnel, support equipment and the like for smart container fleet services. This modeling of fleet logistics may reveal that a first local fleet that will soon become available (perhaps after the preferred start date of a requested job) may complete the job at a lower cost than using a second currently available fleet. In embodiments, a fleet digital twin may facilitate identifying smart container operational assets that are available during the scheduled job by modeling fleet operations, such as smart container maintenance requirements for smart containers during the preferred order execution time. In embodiments, a task digital twin capability of the fleet intelligence system may facilitate modeling of smart container cargo configurations, such as when a smart container cargo is reconfigured during a job. A task digital twin capability of the fleet intelligence system may further benefit workflow definition clarity through workflow simulation by applying a virtual set of preconfigured smart container digital twins 13504 to perform a candidate workflow, or portion thereof, that is optionally being defined. In embodiments, a team digital twin capability of a fleet intelligence system may benefit a workflow simulation system of the job configuration system 13018 by using, for example, preconfigured smart container teams to operate and validate candidate workflows prepared by the workflow definition system.

[2325] In embodiments, a result of workflow simulation may include one or more data structures that are suitable for use in an order execution plan.

[2326] In addition to task definitions, smart container definitions, workflow definitions, fleet configuration parameters, and the like, an order execution plan may identify contracts for the job, such as smart contracts that may be constructed/configured by or in association with the job configuration system 13018, delivery times for job resources (e.g., fleets of smart containers), a schedule of deliverables, and the like.

[2327] In embodiments, the fleet configuration system 13020 configures resources of a fleet for a job based on the task definitions, workflow definitions, or the like. The fleet configuration system 13020 may determine the fleet configuration based on other considerations, such as cost, mode(s) of transportation (e.g., container ship, railway, truck, container hyperloop, and/or self-driving container), environmental conditions, time constraints, available inventory of smart

containers and/or parts, and/or the like. The fleet configuration system 13020 may operate cooperatively with a job configuration system 13018, such as when tasks are to be organized into workflows. Job workflows may be impacted by availability of each type of smart container, so a job configuration system 13018 may leverage the fleet configuration system 13020 when determining candidate job workflows.

[2328] In embodiments, fleet configuration for a requested job may include configuring fleet resources into a smart container team that is assigned to a specific task and/or project (noting that a smart container or a team of smart containers may be assigned multiple tasks and/or projects). Each smart container team may include one or more smart container operating units, which may comprise any one or more of smart containers, robots, humans, modes of transportation, machinery (e.g., 3D printers), tools, and the like. Further, a configured smart container team may be job-specific and team membership may be transient for any given smart container operating unit. As an example, a robot configured to perform cargo loading and/or unloading operations may be assigned to a first smart container team for only the duration of time during which cargo loading and/or unloading operations are being performed by the first smart container team. The same robot may also be assigned to a second smart container team for only the duration of time during which second smart container team cargo unloading and/or loading is being performed. Time-sharing of fleet resources, such as a robots, container ships, trucks, railways, reach stackers, forklifts, cranes, or the like can be communicated to a shipment configuration system from the fleet configuration system 13020, for example, so that workflows being defined by the shipment configuration system can consider availability of the cargo loading/unloading robot for each of the smart container teams. In embodiments, any given smart container or group of smart containers may be assigned to multiple teams spread across multiple jobs by the fleet configuration system 13020 using a smart container-specific time-sharing approach or other resource utilization optimization technique. In an example, a fleet configuration system 13020 may use a multi-dimensional smart container utilization planning system that allocates each smart container in a fleet to one job during a unit of time, such as a day, hour, or fraction thereof, allowing each instance of a shipment configuration system to request use of the smart container for a specific period of time. The fleet configuration system 13020 may respond to the request with smart container fleet configuration descriptions that inform job workflow definitions and the like.

[2329] In some embodiments, fleet configuration for a requested job may include allocating smart container support resources, such as edge devices, charging capabilities and/or charging stations, local data storage capabilities, container storage facilities, spare parts, human technicians, and the like.

[2330] In embodiments, the fleet configuration system 13020 may leverage libraries to determine the fleet configurations. In these embodiments, the fleet configuration system 13020 may determine team configurations for defined tasks or projects using a library 13044 that defines different configurations to perform certain tasks, whereby a lookup table or other association is used to determine the team configurations for given a set of tasks. In

embodiments, the library 13044 may include attributes of different smart container types. As an example, an attribute of a smart container may indicate size or volume of the smart container. In embodiments, the fleet configuration system 13020 may filter the types of smart containers that may perform a task based on the attributes and one or more freight storage and/or transportation service order parameters identified by the job parsing system (and optionally configured into a task definition). When a task or job operation requires (e.g., based on data generated by the job parsing system, an existing order execution plan, a freight storage and/or transportation service order, and the like) access through a tunnel that is smaller than the size smart container available, the fleet configuration system 13020 would not include the smart container; instead it would attempt to identify a different smart container and/or smart container type/configuration that could meet the tunnel size requirements. In embodiments, a fleet configuration system 13020 may reference combinations of smart container sizes and/or types and the like to fit requirements of a defined task. Further, the fleet configuration system 13020 may suggest two smart containers to perform a task when one may not meet other requirements of the task. In embodiments, the fleet configuration system 13020 may deliver to the job configuration system 13018 fleet definitions that include a plurality of smart containers, smart container types, smart container configurations, and the like. A general goal of a fleet configuration system 13020 may include generating fleet configuration(s) that require the fewest smart containers and/or smart container types for proper execution of a portion of the order. However, the fleet configuration system 13020 may work cooperatively with the task definition system to generate a task-specific fleet configuration that includes more than one smart container type/configuration combination, thereby allowing other elements of the smart container system 13000 to efficiently manage execution of a requested job. Such a fleet configuration may indicate a preferred smart container and/or smart container combination for meeting a goal, such as efficient use of smart containers and the like that other elements of the shipment configuration system (e.g., a job workflow generation system) may consider when configuring, for example, a plurality of defined smart container tasks into a job workflow. Therefore, a fleet configuration may include primary, secondary, and tertiary smart container indications for performing a task. Alternatively, a fleet configuration for a freight storage and/or transportation service order may identify a plurality of smart containers, each assigned utilization weights based on criteria, such as efficient job completion, profitability, fleet smart container use preferences and the like.

[2331] In embodiments, the fleet configuration system 13020 may reference an inventory data store to determine the available smart containers and/or modules (e.g., physical modules and/or software modules) to configure a smart container, locations of those smart containers and/or parts, statuses of the parts (e.g., whether maintenance is due or needed for available smart containers or parts), and the like. In this way, the fleet configuration for a job, task, team or the like may be determined by the available inventory of smart containers, modules, support equipment, and/or spare parts. Further, a fleet maintenance management system as described herein may track aspects of smart container status that may be added to and/or be supplemental to the inventory data store, such as which smart containers are being reserved from use for

critical maintenance, which smart containers can be deployed, but with diminished capability due to service and/or maintenance or other concerns, status of spare parts, or other service activities (e.g., due date, current location, anticipated installation, and the like). Therefore, the fleet configuration system 13020 may reference and/or be informed by the fleet maintenance management system about fleet resource maintenance knowledge that may be job-impacting. Additionally, or alternatively, the fleet configuration system 13020 may request a fleet configuration from the intelligence service 13004, where artificial intelligence modules 13404 may receive a set of parameters, including task definitions, workflow definitions, budget, environment definition, job timeline, or the like as input, evaluate a plurality of candidate fleet configurations and determine a target fleet configuration that can perform the job. In embodiments, a human can define or redefine any portion of a fleet configuration via a human interface of the fleet configuration system.

[2332] In embodiments, the job and fleet configurations may be fed to a digital twin system, whereby the digital twin system may perform a simulation of the job given the job and fleet configurations. The job configuration system 13018 and/or the fleet configuration system 13020 may iteratively redefine the job configuration and the fleet configuration to optimize (or substantially optimize) one or more parameters, such as a job timeline, overall cost, smart container downtime, maintenance-related downtime, shipping costs, or the like. Once the job configuration system 13018 and the fleet configuration system 13020 have determined the task and workflow definitions, as well as the fleet configurations, the smart container fleet management system may output the order execution plan corresponding to the freight storage and/or transportation service order.

[2333] In embodiments, the fleet configuration system 13020 may leverage digital twins when configuring fleet resources. Use of digital twins with fleet configuration may include identifying and/or defining one or more digital twins of one or more smart containers based on information in the task definition. Fleet configuration may include identifying configuration and/or operation of a smart container so that a smart container can perform the route and/or task or a portion thereof. Such smart container task configuration instructions may be generated through the use of a digital twin for one or more of a set of candidate smart containers for performing a task. In an illustrative example, a smart container may be associated with a plurality of configuration/operational data structures for configuring the smart container to perform routines, actions, routes, tasks and the like. The fleet configuration system 13020 may identify or otherwise be provided with one or more candidate smart container configuration data structures (e.g., from the library 13044) for use to perform a task. A portion of such a candidate configuration data structure may include a rate of movement for moving up a ramp onto a container ship. The requested job requirements may explicitly or implicitly indicate that a movement rate is different than the value in the candidate configuration data structure. In embodiments, the fleet configuration system may make any adjustments to the candidate configuration data structure (e.g., reducing movement rate), apply it to an instantiation of a digital twin of the candidate smart container, observe and/or evaluate the execution (e.g.,

simulation) of the digital twin with the adjusted configuration data structure, and store it in the library 13044 and the like. The newly stored configuration data structure may be cataloged based on the freight storage and/or transportation service order and/or other parameters of the requested job, task, and the like to make for efficient access in the future.

[2334] A smart container configuration library may include job information, smart container information, fleet information, task definition rules/metadata that may be useful to determine how to define smart container tasks, workflow configuration rules and/or techniques, prior freight storage and/or transportation service order results from application of the shipment configuration system (e.g., prior order execution plans), and the like. The library 13044 may be accessed and/or updated by functions of the job operations system. Illustrative examples of the library 13044 are described herein variously in conjunction with job operations system functions and features, such as job configuration and the like. As an example, the smart container configuration library may include specific reference to configurations of smart containers that may be utilized during fleet configuration, order execution and the like. In this example, the smart container configuration library may have references to smart container configuration data sets (e.g., data that when uploaded to a smart container may enable the smart container to perform a function, such as 3D printing, in-container packaging, and the like). Further, the library may provide a cross-reference of smart container configurations with other smart container-related information, such as base model, version, required features, and the like that may be required for successful deployment of a smart container configured with a given configuration. Yet further, the library may suggest alternatives to certain combinations of smart containers and configurations, such as indicating that a newer version of a smart container model may include built-in capabilities provided by a specific configuration. Therefore, the fleet configuration system may have greater flexibility in deciding which smart containers to deploy for different jobs. References are made herein to the library 13044, using contextual modifiers, such as smart container configuration library and the like. These contextual modifiers may suggest one or more portions and/or instance of the library 13044 for illustrative purposes only.

[2335] In embodiments, optimization features of the task definition system are described below in association with feedback from other elements of the job configuration system 13018, such as the workflow simulation system and the like.

[2336] In some embodiments, the fleet operations system and the fleet intelligence system perform a feedback for order execution-time iteration of configuration activities, such as for adapting and executing instances of an order execution plan. In these embodiments, feedback within a job configuration system 13018 facilitates iterating configuration activities when producing components of an order execution plan, such as task definitions and workflow definitions. As described for these embodiments, the intelligence service 13004 may be used for at least these iterations. However, it is envisioned that the resources of the intelligence service 13004 may also or, in addition, be used for enhancing execution of an order execution plan.

[2337] In embodiments, the order execution system 13022 of the fleet management system 13002 may receive order execution plans from the job configuration system 13018 responsive

to, for example, a freight storage and/or transportation service order. The order execution system 13022 may facilitate performance of an order execution plan by stepping through the plan, activating, and monitoring smart container units and other fleet resources, and providing feedback, optionally real-time feedback based on, for example, smart container unit monitoring data. This feedback may be processed by, for example, artificial intelligence capabilities of the intelligence service 13004 for determining adjustments to an order execution plan, such as task definitions and the like. When the feedback and adjustments are done in real-time or near real-time (e.g., before an upcoming order execution activity, such as a step in a workflow), functions of the job configuration system 13018 may be iterated to amend an existing order execution plan, such as an instance of a plan that is currently being executed by the order execution system 13022.

[2338] An artificial intelligence system of the intelligence service 13004 may perform simulations and use the results of the simulation as one or more as input to the job configuration system 13018 for updating corresponding task definitions. In embodiments, the fleet intelligence system may send an alert to the fleet management system 13002 regarding the need for adapting this task definition that may be used by the system to update, for example, preconfigured task definitions stored in the smart container task library 13044 and the like. Such an alert may be used by the fleet operations system to coordinate with the order execution system 13022 so that pending tasks are not executed before being refreshed in the order execution plan. In embodiments, the job configuration system 13018 may release only portions of the order execution plan to the order execution system 13022 so that unreleased portions can be adapted, thereby mitigating impacts on the order execution system, such as requiring work to be halted, delayed, or otherwise impaired while updates to the execution plan are made.

[2339] While the examples for job configuration and the like presented herein generally consider a single job being configured by the job configuration system 13018, there may be many jobs being configured concurrently. The methods and systems for real-time or near real-time feedback described herein may apply to any instance of job configuration activity being performed so that feedback on task definition of a first job may benefit task definition of a second job, while maintaining necessary job-isolation requirements (e.g., job identifying data may be obfuscated) to support concurrently processing freight storage and/or transportation service orders from different entities.

[2340] In embodiments, capturing data representative of completion of a requested job may include extracting such data from a job completion data set. This job completion data set may be constructed to facilitate identifying information that may be useful for learning and optimization. In an example, the job completion data set may designate, such as by use of metadata tags, logical and/or physical separation, or other indicia data that represents exceptions or large variants from expectation. In an example, at job completion, a percentage of damaged packages carried by a smart container may exceed an expected and/or acceptable number. This excessive count of damaged packages may be flagged as candidate information for learning and optimization feedback to be extracted and sent to the intelligence service 13004. In

embodiments, an order execution plan may be configured with indicators of types of data to be collected and used for learning and optimization feedback. The intelligence service 13004 may recommend to the job configuration system 13018 the types of data to be so indicated based on other factors known to the fleet intelligence system, such as inquiries made by smart container design engineering teams and the like. In embodiments, learning and optimization feedback may be used by the fleet intelligence service to perform, among other things, optimization of artificial intelligence service (e.g., recommending smart container teams, smart container types, workflows, and the like). Referring to descriptions herein, preconfigured tasks, smart container configurations, team configurations, and the like may be retrieved from the library 13044. When these preconfigured aspects of an order execution plan are executed, data representative of the performance thereof may be flagged for use as learning and optimization feedback to continuously improve these preconfigured aspects. An outcome of use of this data includes field condition-adapted preconfigured tasks that may perform better in the real world. Another outcome of use of this data includes improved digital twins and machine learning models.

[2341] In embodiments, a job description to be parsed may include relevant job descriptive details, goals, objectives, requirements, preferences, and the like and as may be described elsewhere herein. While not all pertinent job information may be included within the request, one or more links to ancillary job description data may be included. Ancillary job data may be stored remote from a freight storage and/or transportation service order data set (e.g., may be accessed through an Internet URL of the job description). Optionally, ancillary job data may be stored in data structures that are accessible to the smart container system 13000, such as in a fleet library 13044, requestor-specific storage, and the like. Ancillary job data may include formal standards (e.g., local disturbance regulations, safety (OSHA), electrical (NEC), quality, and the like), permitting requirements (e.g., forms, steps, timing, dependencies on other tasks, and the like), legal requirements (e.g., customs requirements, relevant laws, and the like) details of the job, shipper standards (e.g., an acceptable percentage of damaged cargo), industry norms (e.g., work hours, material selection, templates, and the like), approved vendors (e.g., from whom supplies and other consumables are to be acquired), references to preconfigured tasks, user interface templates/menus/screens for each aspect of a job (e.g., how a user can request status, observe activity, change a job requirement, respond to an inquiry, and the like) and the like. The freight storage and/or transportation service order data 13096 and, if indicated, the ancillary job data are processed by a task definition ingestion facility that works cooperatively with a job parsing system to generate job instance-specific content. This job instance-specific content may include, among other things, initial sequence timing as may be defined in the input data (e.g., "do task A before task B") and/or derived therefrom (e.g., securing cargo in the container with steel strapping necessarily must occur after the cargo is loaded into the container). The job parsing system may interact with the data processing system 13024 when converting job description data to utilize information derived from a smart container fleet management system accessible library, such as job and fleet library 13044. The ingestion facility

may store some job description content directly into the job instance storage, such as job identification information, links to internal ancillary data and the like.

[2342] In embodiments, one or more human interactive capabilities for facilitating job parsing and task definition may include knowledge-based systems (e.g., AI-based and the like) that may interact with a human (e.g., via text input, conversation-bot, haptic-input, and the like) to gather information for preformatting, organizing, and vetting job and task data. These interactions may be in lieu of or supplemental to receiving a job description.

[2343] The job parsing system may use job descriptive information produced by or passed through the ingestion facility to construct job instance content suitable for task definition. The job parsing system may use the information provided by the ingestion facility to query content in the library 13044 (e.g., via the data processing facility 13024 as optionally depicted). Content in the library that may be useful or informative of task definition may include job syntax (e.g., terms that are relevant to a given job, job type, set of tasks, smart container types, smart container capabilities (e.g., by type, size, cost, availability, etc.), keyword-to-task cross reference, workflow definition rules, order execution plan format/content/structure. Further, the library may include templates for various task definition-related activities, such as exemplary smart container configurations (e.g., based on task keyword and the like), exemplary team configurations (e.g., for performing certain types or classes of tasks), task definitions, workflows and workflow definitions, exemplary order execution plan(s) and the like.

[2344] A keyword-based task lookup module may retrieve information in the job instance storage, such as task-oriented keywords and the like and apply those to the library 13044 to potentially identify preconfigured or templated tasks or portions thereof. As an example, a job description may include keywords, such as "submerged" and the like that may suggest a need for smart containers that are configured to travel underwater. When such keywords are combined with an action "submerged 3D printing", the keyword-based task lookup module may identify smart container types that perform 3D printing and can travel underwater. If a descriptor of a task in the library aligns with one or more job description keywords, the task may be considered a candidate task for the job.

[2345] In embodiments, a task definer module may process candidate tasks provided by the task lookup module as well as information in the job instance storage to form definitions for tasks to be performed by one or more smart containers. Defining tasks may include tasks that are predefined by standards, laws (e.g., customs), and the like. Each task definition may include information useful for identifying a smart container type for performing the task.

[2346] In embodiments, the task definition system may process task data derived from a freight storage and/or transportation service order (e.g., as provided by the freight storage and/or transportation service order parser) in the context of smart container types by identifying characteristics of smart container types that align with the task data. In example embodiments, the task definition system may determine that task data indicates a characteristic of a smart container for shipping may include traveling in an arctic environment. In this example, the task definition system may generate a task definition for the shipping task that includes at least a

requirement for smart container selection based on this characteristic. In these example embodiments, the task definition may further include a required degree of tolerance to cold temperatures. The task definition system may further determine that characteristics of one or more smart containers (e.g., based on task information derived from the freight storage and/or transportation service order) that may not be suitable for incorporation in a single smart container/smart container type. This determination may be based on, for example, smart container characteristics and type data that is accessible in the library 13044. In such an example, the task definition system may define multiple tasks, each with smart container characteristics that are consistent with smart container characteristic information in the library 13044. In embodiments, the task definition system may define a task with multiple potentially incompatible smart container characteristics, optionally along with an indication of one or more portions of the task that require each type of the multiple incompatible smart container characteristics that a fleet configuration system 13020 may use when configuring fleet resources, such as smart containers and the like. In embodiments, a task definition may include one or more suggestions for types of smart containers for performing the task, such as based on alignment of task requirements (e.g., derived from task information of a freight storage and/or transportation service order), smart container characteristics, and smart container types that may be available in the library 13044. As will be explained below, a fleet configuration system 13020 may evaluate a task definition, including any suggested smart container types. Other exemplary data that may be communicated when defining a task may include task sequence dependencies that may be suitable for defining a workflow that includes the defined task. As an example, a container self-cleaning task may be required to be performed after an unloading task. Such a dependency may be documented and relied upon by a workflow definition system. The task definer module may save a defined task into the job instance storage where it may be cross referenced to job descriptive data (e.g., keywords and the like) so that future detections of the cross-referenced keywords can quickly result in a suitable task definition.

[2347] In embodiments, a fleet configuration system 13020 provides specific software, hardware, and smart container configuration requirements for completion of an order execution plan. In this example construction, a fleet configuration proxy module may be constructed to receive task definitions from a job configuration system 13018. The fleet configuration proxy module may be instantiated in association with processing of a freight storage and/or transportation service order by the job configuration system 13018 to facilitate access to and use of fleet configuration system 13020 resources and systems. This and other instantiations of the fleet configuration proxy module are further described in association with the job configuration system 13018 herein. The fleet configuration proxy module may process task definitions and forward them to fleet resource identification systems, such as a fleet smart container operating unit identification and a fleet non-smart container operating unit identification system. Each of these identification systems may process the task definition data provided through the fleet configuration proxy, separating operational data from fleet resource data. A task definition may describe a set of fleet resources required to perform the task, such as types of smart container

operating units, support resources (e.g., power systems, robots, cranes, communication systems, and the like). The smart container operating unit type identification system may provide job-specific smart container operating unit demand data to the fleet configuration scheduler. The job-specific smart container operating unit demand data may identify types and quantities of smart containers, specific smart container operating units (e.g., by unique identifier), smart container operating unit capabilities, and the like.

[2348] In some embodiments, a fleet configuration scheduler may respond to a freight storage and/or transportation service order by allocating fleet resources to meet the freight storage and/or transportation service order needs. These needs may be preprocessed, as described herein by a job configuration system 13018 and specifically by the task definition system to facilitate fleet configuration, allocation, and scheduling. The fleet configuration scheduler processes inputs that describe fleet inventories, such as smart container operating unit inventories and traditional container operating unit inventories to identify candidate inventory elements for satisfying a freight storage and/or transportation service order. These inventories may be adjusted based on existing allocations of smart container operating units and traditional container operating units. As an example, all smart containers of a type identified in the smart container operating unit job-specific demand data may be allocated throughout a duration of time within which a requested job is constrained to be performed. The fleet configuration scheduler (e.g., with support from other system resources such as intelligence service 13004, resource provisioning system 13014 and the like) may allocate, based on conditions in the freight storage and/or transportation service order and smart container type, equivalence data available to the fleet configuration scheduler, a smart container for the activities requested. To accomplish this allocation, an intelligence service 13004 may be provided with information descriptive of the functionality to be provided by the smart container indicated in the job-specific demand data and information descriptive of the tasks and/or activities required to be performed by the smart container. Other context, such as differences in specifications for performing tasks by a properly configured smart container, may also be available to the intelligence service 13004. Through use of artificial intelligence, which may include determining an impact on an overall freight storage and/or transportation service order based on use of the two different smart container types, the intelligence service 13004 may provide smart container substitution guidance to the fleet configuration scheduler. This guidance may result in allocation of a smart container and necessary configuration data/features for use when executing an order execution plan that corresponds to the freight storage and/or transportation service order that prompted this fleet configuration scheduling activity.

[2349] In embodiments, a task definition may include recommendations for one or more types of smart containers (e.g., based on alignment of, for example, task requirements, smart container characteristics, and smart container types), and a preferred type may be designated in the task definition.

[2350] The fleet configuration scheduler may rely on other fleet systems, such as a resource provisioning module 13014 that may contribute to and/or determine provisioning of fleet and third-party resources and supplies.

[2351] The intelligence service 13004, the resource provisioning module 13014 and other fleet systems, including the fleet configuration scheduler may interact with a fleet configuration modeling system that may facilitate generation of fleet configuration options that can be considered by the fleet configuration scheduler when configuring a fleet in response to job configuration activities and the like. The fleet configuration modeling system may provide simulation of fleet configurations, such as by using fleet digital twins, which may optionally be associated with a digital twin module 13420 of the intelligence service 13004.

[2352] In embodiments, the fleet configuration scheduler may rely on a fleet team organizer module that assists in determining and/or effecting team configurations. Job-specific data may identify (e.g., recommend) set(s) of smart container operating units to be configured as teams. Also, job-specific data may indicate information that may be indicative of configuring teams, such as co-location of smart containers at a container terminal and the like. The fleet team organizer module may confirm and/or designate team metadata for use when configuring a fleet. The team metadata may indicate team membership and time frame for the membership (e.g., from one date to another, from a start of a task until the task is complete, and the like).

[2353] The fleet configuration scheduler may update fleet allocation data sets (that may be used by fleet resource allocation and/or reservation capabilities described herein), such as the fleet smart container operating unit allocation data set and the fleet of non-container operating unit allocation data set with fleet configuration allocation information based on configuration(s) generated for the job-specific demand data provided. The various inputs, including fleet configuration impacting external data 13036 (e.g., weather, location data, traffic data, industry standards, job-specific contextual information, and the like) may be processed, optionally iteratively, by the fleet configuration scheduler to produce, among other things, fleet configurations that may be returned to an executing instance of a job configuration system 13018 via the fleet configuration proxy module.

[2354] In embodiments, a workflow definition system may be constructed to generate definitions of workflows for requested jobs utilizing resources of the smart container fleet management system. The construction of the workflow definition system may include an ingestion module that receives and processes task definitions that may be provided from the task definition system or sourced from the library 13044, and job specific fleet configuration information that may be provided from job configuration system 13018 interactions with the fleet configuration system 13020 (e.g., via the fleet configuration proxy module).

[2355] Ingestion of task definitions and/or fleet configuration information may include aligning the fleet configuration information with one or more task definitions. As an example of aligning tasks with fleet configuration information, fleet configuration information may be tagged as applying to one or more tasks in the set of task definitions ingested, such as with an identifier of the task or tasks. Other ways of aligning task definition(s) with fleet configuration

information may be based on timing of such ingestion so that, for example, when a fleet configuration reference/value is received contemporaneously with a task definition, the ingestion module may mark these two data items as aligned. Other ways of aligning task definition(s) with fleet configuration information may include one or more data values in the task definition, which may be a data set, linked list, flat file, structured data set and the like indicating fleet configuration information to which the task(s) should be aligned. Fleet configuration information may include one more task identifiers to which the fleet configuration information pertains and/or should be applied when generating workflow definitions.

[2356] Ingestion may further include processing references (e.g., URLs, hyperlinks, external names, and the like) to workflow content in the library 13044 that may be found in any of the ingested content. In an example, a task definition may include a name of a task that is stored in the library 13044. The ingestion module may identify the name by its syntax (e.g., a prefix may be added to a task identifier that indicates the task is to be retrieved from the library) and/or task definition structuring (e.g., a list of task names stored within a subset of the task definition that is structured to indicate the subset of tasks are to be retrieved from the library). While the examples of ingestion herein pertain to an instance of ingestion of one or more task definitions, ingestion may be performed on batches of tasks. Multiple instances of the ingestion module may be instantiated and operating concurrently to process a plurality of task definitions that may be performed. Optionally, a stream of tasks definitions may be received by ingestion and each task in the stream is ingested in sequence.

[2357] One or more outcomes of processing by the ingestion module may be presented to a set of workflow definition activities, including a task dependency determination module that may determine dependencies among tasks, such as which tasks need to be performed in a sequence and which tasks can be performed independently of other tasks. The task dependency determination module may also determine dependency of tasks on other factors, such as availability of fleet resources, calendar/date/time, readiness of supply materials, and the like. Dependency on other factors may be identified in the task definition, such as by marking a given job state as a start point for the task. Further, dependency on other factors may be attributed to a given task definition during ingestion (e.g., based on aligning a task with a fleet configuration that sets a dependency on availability of fleet resources, such as a special purpose smart container and the like).

[2358] A task grouping activity may process outcomes of the task dependency activity to generate groups of tasks based on a range of criteria, such as, tasks that depend on a given task being complete may be grouped for concurrent execution. Grouping tasks may be based on dependency on fleet resource availability, so that tasks that are dependent on a fleet resource may be grouped and performed once the resource is available. The order of performance of these grouped tasks may be based on inter-task dependency. Generally, tasks may be grouped for a range of purposes, such as cost savings, resource guarding, job prioritization, available order execution funds, anticipated fleet resource maintenance needs, earliest task start/finish time, latest task start/finish time and the like.

[2359] A task workflow step definition activity may determine which task(s) can be organized into each step of one or more workflows. Based on inter-task dependency (or lack thereof) multiple workflows may be defined, each workflow including one or more workflow steps that are defined in workflow step definition activity. Further, a workflow step, once defined, may be assigned to and/or referenced in a plurality of workflows. When dependencies exist, such as availability of a smart container for performing a task in a workflow step, a plurality of workflows may themselves be made dependent. Performance of other tasks in these workflows may be concurrent even if the initial task of opening the port must be done sequentially due to the fleet resource utilization dependency.

[2360] In embodiments, a defined workflow step may be an adapted variant of a candidate workflow step, such as a workflow step that is retrieved from the library 13044. The workflow step definition activity may request input from other fleet resource system services, such as the data processing system 13024 and/or artificial intelligence modules 13404 to adapt a candidate workflow step for use when defining one or more workflow steps for a given job.

[2361] Information such as workflow step dependency may be utilized by a workflow step linking activity that may receive step linking recommendation(s) from the intelligence service 13004 and the like. Workflow step linking activity may generate a data structure that indicates a sequence of performing defined workflow steps (e.g., a workflow definition. The workflow definition may include data that captures job-specific workflow information, such as workflow step ordering, workflow step performance sequence, workflow step independence, step-by-step links to workflow steps, workflow success criteria, cross-workflow dependencies, and/or the like.

[2362] In embodiments, workflow definition(s) may be stored in a job instance storage where they can be referenced as needed during job configuration and/or order execution. They may be stored in the fleet library 13044 where they can be referenced by other jobs, by third parties, such as shipper and the like. They may be stored elsewhere (e.g., a cloud storage facility) based on architectural considerations, such as being distributed to edge computing infrastructure resources proximal to job deployment sites and the like.

[2363] In embodiments, workflows may be simulated as indicated in the description of the job configuration system 13018. Outcomes of simulation may be directed to, for example, the ingestion module where ingestion operations, such as alignment of fleet configuration data with task description data may be improved. Outcomes may also be passed to as feedback to other components of the system to improve task definition, job configuration, fleet configuration, and/or the like.

[2364] FIG. 147 illustrates a digital twin module according to some embodiments of the present disclosure. In embodiments, the digital twin module 13420 generates a set of shipping digital twins 13302 (e.g., individual smart container digital twins 13504, smart container fleet digital twins, container ship digital twins, container port digital twins, smart container fleet manager or operator digital twins, shipper digital twins, and the like). In embodiments, the digital twin module 13420 maintains a set of states of the respective shipping digital twins

13302, such as using sensor data obtained from respective sensor systems 13304 that monitor the shipping digital twins 13302. In embodiments, the digital twin module 13420 may include a digital twin management system 13306, a digital twin I/O system 13308, a digital twin simulation system 13310, a digital twin dynamic model system 13312, and/or a digital twin control module 13314. In embodiments, the digital twin module 13420 may provide a real time sensor API that provides a set of capabilities for enabling a set of interfaces for the sensors of the respective sensor systems 13304. In embodiments, the digital twin module 13420 may include and/or employ other suitable APIs, brokers, connectors, bridges, gateways, hubs, ports, routers, switches, data integration systems, peer-to-peer systems, and the like to facilitate the transferring of data to and from the digital twin module 13420. In these embodiments, these connective components may allow an IIOT sensor or an intermediary device (e.g., a relay, an edge device, a switch, or the like) within a sensor system 13304 to communicate data to the digital twin module 13420 and/or to receive data (e.g., configuration data, control data, or the like) from the digital twin module 13420 or another external system. In embodiments, the digital twin module 13420 may further include a digital twin datastore 13316 that stores shipping digital twins 13302.

[2365] A digital twin may refer to a digital representation of one or more shipping entities, such as an individual smart container 13026, a fleet of smart containers 13026, a shipping environment (e.g., a physical location along a route, a shipping container port or terminal, a smart container charging station, a shipping yard, a container storage facility, a container ship, or the like), smart container machinery, a physical object, a device, a sensor, a human, or any combination thereof. Non-limiting examples of physical objects include smart container cargo, physical barriers along a route, raw materials, manufactured products, excavated materials, boxes, dumpsters, cooling towers, vats, pallets, barrels, palates, bins, and many more. Non-limiting examples of devices include robots, computers, vehicles (e.g., ships, cars, trucks, trains, etc.), machinery/equipment (e.g., forklifts, cranes, reach stackers, packaging systems, sorting systems, tractors, tillers, drills, presses, assembly lines, conveyer belts, etc.), and the like. The sensors may be any sensor devices and/or sensor aggregation devices that are found in a sensor system within an environment. Non-limiting examples of sensors that may be implemented in a sensor system may include temperature sensors, humidity sensors, vibration sensors, LIDAR sensors, SLAM sensors, SONAR sensors, motion sensors, chemical sensors, audio sensors, pressure sensors, weight sensors, radiation sensors, video sensors, wearable devices, relays, edge devices, crosspoint switches, and/or any other suitable sensors. Examples of different types of physical objects, devices, sensors, and environments are referenced throughout the disclosure.

[2366] In some embodiments, on-device sensor fusion and data storage for smart containers is supported, where data from multiple sensors is multiplexed at the device for storage of a fused data stream. For example, pressure and temperature data may be multiplexed into a data stream that combines pressure and temperature in a time series, such as in a byte-like structure (where time, pressure, and temperature are bytes in a data structure, so that pressure and temperature remain linked in time, without requiring separate processing of the streams by outside systems),

or by adding, dividing, multiplying, subtracting, or the like, such that the fused data can be stored on the smart container. Any of the sensor data types described throughout this disclosure, can be fused in this manner and stored in a local data pool, in storage, or on an IoT device, such as a data collector, a component of a machine, or the like.

[2367] In some embodiments, a set of digital twins may represent an entire organization, such as shipping lines, container terminal operators, shippers, manufacturers, energy production organizations, regulatory organizations, governments, and the like. In these examples, the digital twins may include digital twins of one or more facilities of the organization.

[2368] In embodiments, the digital twin management system 13306 generates digital twins. A digital twin may be comprised of (e.g., via reference) other digital twins. In this way, a discrete digital twin may be comprised of a set of other discrete digital twins. For example, a digital twin of a smart container may include digital twins of sensors on and within the smart container, digital twins of components that make up the smart container, digital twins of smart container cargo, digital twins of other devices that are incorporated in or integrated with the smart container (such as robots, 3D printers, packaging systems, or sorting systems), and the like. Taking this example one step further, a digital twin of a container terminal may include a digital twin representing the layout of the terminal, including the arrangement of physical assets and systems in or around the terminal, digital twins of the shipping entities within the terminal, as well as digital twins of storage areas in the terminal, and the like. In this second example, the digital twin of the container terminal may reference the embedded digital twins, which may then reference other digital twins embedded within those digital twins.

[2369] In some embodiments, a digital twin may represent abstract entities, such as workflows and/or processes, including inputs, outputs, sequences of steps, decision points, processing loops, and the like that make up such workflows and processes. For example, a digital twin may be a digital representation of a logistics workflow, a cargo loading process, a cargo unloading process, a customs process, a 3D printing process, a smart container energy charging process, or the like. In these embodiments, the digital twin may include references to the shipping entities that are included in the workflow or process. The digital twin of the shipping process may reflect the various stages of the process. In some of these embodiments, the digital twin module 13420 may receive real-time data from a smart container, shipping entity, and/or shipping environment (e.g., from a sensor system of the container port facility) in which the shipping process takes place and reflects a current (or substantially current) state of the process in real-time.

[2370] In embodiments, the digital representation may include a set of data structures (e.g., classes) that collectively define a set of properties of a represented smart container, smart container fleet, physical object (e.g., cargo), device, sensor, or shipping environment and/or possible behaviors thereof. For example, the set of properties of a smart container may include a type or class of smart container, the dimensions of the smart container, the mass or weight of the smart container, the material(s) of the smart container, the physical properties of the smart container materials(s), the surface of the smart container, the status of the smart container, a

location of the smart container, identifiers of other digital twins contained within the smart container, and/or other suitable properties.

[2371] Examples of the behaviors of a smart container may include a maximum acceleration of a smart container, a maximum speed of a smart container, ranges of motion of a smart container, a heating profile of a smart container interior, a cooling profile of a smart container interior, processes that are performed by the smart container, operations that are performed by the smart container, and the like.

[2372] The set of properties of a physical object may include a type of physical object, the dimensions of the physical object, the mass or weight of the physical object, the density of the physical object, the material(s) of the physical object, the physical properties of the materials(s), the surface of the physical object, the status of the physical object, a location of the physical object, identifiers of other digital twins contained within the physical object, and/or other suitable properties.

[2373] Examples of a behavior of a physical object may include a state of the physical object (e.g., a solid, liquid, or gas), a melting point of the physical object, a density of the physical object when in a liquid state, a viscosity of the physical object when in a liquid state, a freezing point of the physical object, a density of the physical object when in a solid state, a hardness of the physical object when in a solid state, the malleability of the physical object, the buoyancy of the physical object, the conductivity of the physical object, a burning point of the physical object, the manner by which humidity affects the physical object, the manner by which water or other liquids affect the physical object, a terminal velocity of the physical object, and the like.

[2374] The set of properties of a device may include a type of the device, the dimensions of the device, the mass or weight of the device, the density of the device, the material(s) of the device, the physical properties of the material(s), the surface of the device, the output of the device, the status of the device, a location of the device, a trajectory of the device, vibration characteristics of the device, identifiers of other digital twins that the device is connected to and/or contains, and the like.

[2375] Examples of the behaviors of a device may include a maximum acceleration of a device, a maximum speed of a device, ranges of motion of a device, a heating profile of a device, a cooling profile of a device, processes that are performed by the device, operations that are performed by the device, and the like.

[2376] Example properties of a shipping environment may include the dimensions of the environment, the boundaries of the environment, the temperature of the environment, the humidity of the environment, the airflow of the environment, the physical objects in the environment, currents of the environment (if a body of water), and the like. Examples of behaviors of an environment may include scientific laws that govern the environment, processes that are performed in the environment, rules or regulations that must be adhered to in the environment, and the like.

[2377] In embodiments, the properties of a digital twin may be adjusted. For example, the temperature of a digital twin, the humidity of a digital twin, the shape of a digital twin, the

material of a digital twin, the dimensions of a digital twin, or any other suitable parameters may be adjusted. As the properties of the digital twin are adjusted, other properties may be affected as well. For example, if the temperature within a smart container is increased, the pressure within the smart container may increase as well, such as a pressure of a gas in accordance with the ideal gas law. In another example, if a digital twin of a subzero shipping environment is increased to above freezing temperatures, the properties of an embedded twin of water in a solid state (i.e., ice) may change into a liquid state over time.

[2378] Digital twins may be represented in many different forms. In embodiments, a digital twin may be a visual digital twin that is rendered by a computing device, such that a human user can view digital representations of a smart container fleet, individual smart containers, physical objects (e.g., cargo or the like), devices, sensors, and/or shipping environments. In embodiments, the digital twin may be rendered and output to a display device. In some of these embodiments, the digital twin may be rendered in a graphical user interface (e.g., a scalable vector graphics (SVG) enabled user interface), such that a user may interact with the digital twin. For example, a user may "drill down" on a particular element (e.g., a smart container) to view additional information regarding the element (e.g., the state of a smart container, properties of the smart container, or the like). In some embodiments, the digital twin may be rendered and output in a virtual reality display. For example, a user may view a 3D rendering of a shipping environment (e.g., using monitor, augmented reality headset, or virtual reality headset). While doing so, the user may view/inspect digital twins of smart containers, physical assets, devices, or the like in the environment.

[2379] In some embodiments, a data structure of the visual digital twins (i.e., digital twins that are configured to be displayed in a 2D or 3D manner) may include surfaces (e.g., splines, meshes, polygons meshes, or the like). In some embodiments, the surfaces may include texture data, shading information, and/or reflection data. In this way, a surface may be displayed in a more realistic manner. In some embodiments, such surfaces may be rendered by a visualization engine (not shown) when the digital twin is within a field of view and/or when existing in a larger digital twin (e.g., a digital twin of a shipping environment). In these embodiments, the digital twin module 13420 may render the surfaces of digital objects, whereby a rendered digital twin may be depicted as a set of adjoined surfaces.

[2380] In embodiments, a user may provide input that controls one or more properties of a digital twin via a graphical user interface. For example, a user may provide input that changes a property of a digital twin. In response, the digital twin module 13420 can calculate the effects of the changed property and may update the digital twin and any other digital twins affected by the change of the property.

[2381] In embodiments, a user may view processes being performed with respect to one or more digital twins (e.g., last-mile customization of a product via a 3D printer in the smart container, cargo inspection, cargo sorting, and the like). In these embodiments, a user may view the entire process or specific steps within a process.

[2382] In some embodiments, a shipping digital twin (and any digital twins embedded therein) may be represented in a non-visual representation (or "data representation"). In these embodiments, a digital twin and any embedded digital twins exist in a binary representation, but the relationships between the digital twins are maintained. For example, in embodiments, each digital twin and/or the components thereof may be represented by a set of physical dimensions that define a shape of the digital twin (or component thereof). Furthermore, the data structure embodying the digital twin may include a location of the digital twin. In some embodiments, the location of the digital twin may be provided in a set of coordinates. For example, a digital twin of a shipping environment may be defined with respect to a coordinate space (e.g., a Cartesian coordinate space, a polar coordinate space, or the like). In embodiments, embedded digital twins may be represented as a set of one or more ordered triples (e.g., [x coordinate, y coordinate, z coordinates] or other vector-based representations). In some of these embodiments, each ordered triple may represent a location of a specific point (e.g., center point, top point, bottom point, or the like) on the shipping entity (e.g., smart container, object, device, sensor, or the like) in relation to the environment in which the shipping entity resides. In some embodiments, a data structure of a digital twin may include a vector that indicates a motion of the digital twin with respect to the environment. For example, fluids (e.g., liquids or gasses) or solids may be represented by a vector that indicates a velocity (e.g., direction and magnitude of speed) of the entity represented by the digital twin. In embodiments, a vector within a digital twin may represent a microscopic subcomponent, such as a particle within a fluid, and a digital twin may represent physical properties, such as displacement, velocity, acceleration, momentum, kinetic energy, vibrational characteristics, thermal properties, electromagnetic properties, and the like.

[2383] In some embodiments, a set of two or more digital twins may be represented by a graph database that includes nodes and edges that connect the nodes. In some implementations, an edge may represent a spatial relationship (e.g., "abuts", "rests upon", "contains", and the like). In these embodiments, each node in the graph database represents a digital twin of an entity (e.g., a shipping entity) and may include the data structure defining the digital twin. In these embodiments, each edge in the graph database may represent a relationship between two entities represented by connected nodes. In some implementations, an edge may represent a spatial relationship (e.g., "abuts", "rests upon", "interlocks with", "bears", "contains", and the like). In embodiments, various types of data may be stored in a node or an edge. In embodiments, a node may store property data, state data, and/or metadata relating to a facility, system, subsystem, and/or component. Types of property data and state data will differ based on the entity represented by a node. For example, a node representing a shipping robot may include property data that indicates a material of the robot, the dimensions of the robot (or components thereof), a mass of the robot, and the like. In this example, the state data of the robot may include a current pose of the robot, a location of the robot (e.g., within a smart container or on a container ship), or the like. In embodiments, an edge may store relationship data and metadata data relating to a relationship between two nodes. Examples of relationship data may include the nature of the relationship, whether the relationship is permanent (e.g., a fixed component would have a

permanent relationship with the structure to which it is attached or resting on), and the like. In embodiments, an edge may include metadata concerning the relationship between two entities. For example, a sensor may take measurements relating to a state of a smart container, whereby one relationship between the sensor and the smart container may include "measured" and may define a measurement type that is measured by the sensor. In this example, the metadata stored in an edge may include a list of N measurements taken and a timestamp of each respective measurement. In this way, temporal data relating to the nature of the relationship between two entities may be maintained, thereby allowing for an analytics engine, machine-learning engine, and/or visualization engine to leverage such temporal relationship data, such as by aligning disparate data sets with a series of points in time, such as to facilitate cause-and-effect analysis used for prediction systems.

[2384] In some embodiments, a graph database may be implemented in a hierarchical manner, such that the graph database relates a set of facilities, systems, and components. For example, a digital twin of a shipping environment may include a node representing the shipping environment. The graph database may further include nodes representing various systems within the shipping environment, such as nodes representing a smart container fleet, a smart container charging area, a storage area, and the like, all of which may connect to the node representing the shipping environment. In this example, each of the systems may further connect to various subsystems and/or components of the system. For example, the smart container system may connect to a subsystem node representing a cooling system of the smart container, a second subsystem node representing a heating system of the smart container, a third subsystem node representing the fan system of the smart container, and one or more nodes representing a thermostat of the smart container (or multiple thermostats). Carrying this example further, the subsystem nodes and/or component nodes may connect to lower-level nodes, which may include subsystem nodes and/or component nodes. For example, the subsystem node representing the cooling subsystem may be connected to a component node representing an air conditioner unit. Similarly, a component node representing a thermostat device may connect to one or more component nodes representing various sensors (e.g., temperature sensors, humidity sensors, and the like).

[2385] In embodiments, where a graph database is implemented, a graph database may relate to a single environment or may represent a larger enterprise. In the latter scenario, a company may have various shipping distribution facilities. In these embodiments, an enterprise node representing the enterprise may connect to environment nodes of each respective facility. In this way, the digital twin module 13420 may maintain digital twins for multiple shipping facilities of an enterprise.

[2386] In embodiments, the digital twin module 13420 may use a graph database to generate a digital twin that may be rendered and displayed and/or may be represented in a data representation. In embodiments, the digital twin module 13420 may receive a request to render a digital twin, whereby the request includes one or more parameters that are indicative of a view that will be depicted. For example, the one or more parameters may indicate a shipping

environment to be depicted and the type of rendering (e.g., "real-world view" that depicts the environment as a human would see it, an "infrared view" that depicts objects as a function of their respective temperature, an "airflow view" that depicts the airflow in a digital twin, or the like). In response, the digital twin module 13420 may traverse a graph database and may determine a configuration of the environment to be depicted based on the nodes in the graph database that are related (either directly or through a lower-level node) to the environment node of the environment and the edges that define the relationships between the related nodes. Upon determining a configuration, the digital twin module 13420 may identify the surfaces that are to be depicted and may render those surfaces. The digital twin module 13420 may then render the requested digital twin by connecting the surfaces in accordance with the configuration. The rendered digital twin may then be output to a viewing device (e.g., VR headset, AR headset, monitor, or the like). In some scenarios, the digital twin module 13420 may receive real-time sensor data from a sensor system of an environment and may update the visual digital twin based on the sensor data. For example, the digital twin module 13420 may receive sensor data (e.g., vibration data from a vibration sensor) relating to smart container cargo. Based on the sensor data, the digital twin module 13420 may update the visual digital twin to indicate the approximate vibrational characteristics of the cargo within a digital twin of the smart container.

[2387] In scenarios where the digital twin module 13420 is providing data representations of digital twins (e.g., for dynamic modeling, simulations, machine learning), the digital twin module 13420 may traverse a graph database and may determine a configuration of the environment to be depicted based on the nodes in the graph database that are related (either directly or through a lower level node) to the environment node of the environment and the edges that define the relationships between the related nodes. In some scenarios, the digital twin module 13420 may receive real-time sensor data from a sensor system of a shipping entity and/or environment and may apply one or more dynamic models to the digital twin based on the sensor data. In other scenarios, a data representation of a digital twin may be used to perform simulations, as is discussed in greater detail throughout the specification.

[2388] In some embodiments, the digital twin module 13420 may execute a digital ghost that is executed with respect to a digital twin of a shipping entity (e.g., a smart container fleet or individual smart container) and/or a shipping environment. In these embodiments, the digital ghost may monitor one or more sensors of a sensor system of a shipping entity and/or environment to detect anomalies that may indicate a malicious virus, compromised sensors, or other security issues.

[2389] As discussed, the digital twin module 13420 may include a digital twin management system 13306, a digital twin I/O system 13308, a digital twin simulation system 13310, a digital twin dynamic model system 13312, and/or a digital twin control module 13314.

[2390] In embodiments, the digital twin management system 13306 generates new digital twins, maintains/updates existing digital twins, and/or renders digital twins. The digital twin management system 13306 may receive user input, uploaded data, and/or sensor data to create and maintain existing digital twins. Upon creating a new digital twin, the digital twin

management system 13306 may store the digital twin in the digital twin datastore 13316. Creating, updating, and rendering digital twins are discussed in greater detail throughout the disclosure.

[2391] In embodiments, the digital twin I/O system 13308 receives input from various sources and outputs data to various recipients. In embodiments, the digital twin I/O system receives sensor data from one or more sensor systems. In these embodiments, each sensor system may include one or more sensors that output respective sensor data. Each sensor may be assigned an IP address or may have another suitable identifier. Each sensor may output sensor packets that include an identifier of the sensor and the sensor data. In some embodiments, the sensor packets may further include a timestamp indicating a time at which the sensor data was collected. In some embodiments, the digital twin I/O system 13308 may interface with a sensor system via the real-time sensor API. In these embodiments, one or more devices (e.g., sensors, aggregators, edge devices) in the sensor system may transmit the sensor packets containing sensor data to the digital twin I/O system 13308 via the API. The digital twin I/O system may determine the sensor system that transmitted the sensor packets and the cargo thereof and may provide the sensor data and any other relevant data (e.g., time stamp, environment identifier/sensor system identifier, and the like) to the digital twin management system 13306.

[2392] In embodiments, the digital twin I/O system 13308 may receive imported data from one or more sources. For example, the digital twin module 13420 may provide a portal for users to create and manage their digital twins. In these embodiments, a user may upload one or more files (e.g., image files, LIDAR scans, blueprints, and the like) in connection with a new digital twin that is being created. In response, the digital twin I/O system 13308 may provide the imported data to the digital twin management system 13306. The digital twin I/O system 13308 may receive other suitable types of data without departing from the scope of the disclosure.

[2393] In some embodiments, the digital twin simulation system 13310 is configured to execute simulations using the digital twin. For example, the digital twin simulation system 13310 may iteratively adjust one or more parameters of a digital twin and/or one or more embedded digital twins. In embodiments, the digital twin simulation system 13310, for each set of parameters, executes a simulation based on the set of parameters and may collect the simulation outcome data resulting from the simulation. Put another way, the digital twin simulation system 13310 may collect data relating to the properties of the digital twin and the digital twins within or containing the digital twin used during the simulation as well as any outcomes stemming from the simulation. For example, in running a simulation on a digital twin of a potential new smart container design, the digital twin simulation system 13310 can vary the dimensions, materials, capabilities, and/or other relevant parameters and can execute simulations that output outcomes resulting from different combinations of the parameters. In another example, the digital twin simulation system 13310 may simulate the vibration of cargo within a smart container. In this example, the digital twin of the smart container may include a set of operating parameters of the smart container. In some embodiments, the operating parameters

may be varied to evaluate the effect of the operating parameters on cargo damage. The digital twin simulation system 13310 is discussed in further detail throughout the disclosure.

[2394] In embodiments, the digital twin dynamic model system 13312 is configured to model one or more behaviors with respect to a digital twin of an environment. In embodiments, the digital twin dynamic model system 13312 may receive a request to model a certain type of behavior regarding a shipping entity, environment, or process and may model that behavior using a dynamic model, the digital twin of the environment or process, and sensor data collected from one or more sensors that are monitoring the environment or process. For example, an operator of a smart container fleet may wish to model the performance of the fleet to determine whether the fleet can withstand an increase in freight transportation service demand. In this example, the digital twin dynamic model system 13312 may execute a dynamic model that is configured to determine whether an increase in demand would result in adverse consequences (e.g., failures, downtime, or the like). The digital twin dynamic model system 13312 is discussed in further detail throughout the disclosure.

[2395] In embodiments, the intelligence service 13004 performs machine learning and artificial intelligence-related tasks on behalf of the digital twin system. In embodiments, the intelligence service 13004 train machine learned models using the output of simulations executed by the digital twin simulation system 13310. In some of these embodiments, the outcomes of the simulations may be used to supplement training data collected from real-world environments and/or processes. In embodiments, the intelligence service 13004 leverages machine learned models to make predictions and classifications and provide decision support relating to the real-world environments and/or processes represented by respective digital twins.

[2396] For example, a machine-learned prediction model may be used to predict the cause of irregular vibrational patterns for a bearing of an engine of a smart container. In this example, the intelligence service 13004 may receive vibration sensor data from one or more vibration sensors disposed on or near the engine and may receive maintenance data from the smart container and may generate a feature vector based on the vibration sensor data and the maintenance data. The intelligence service 13004 may input the feature vector into a machine-learned model trained specifically for the engine (e.g., using a combination simulation data and real-world data of causes of irregular vibration patterns) to predict the cause of the irregular vibration patterns. In this example, the causes of the irregular vibrational patterns could be a loose bearing, a lack of bearing lubrication, a bearing that is out of alignment, a worn bearing, the phase of the bearing may be aligned with the phase of the engine, loose housing, loose bolt, and the like.

[2397] In embodiments, the digital twin control module 13314 controls one or more aspects of smart containers, smart container fleets, and/or other shipping entities and environments. In embodiments, the digital twin control module 13314 may leverage the digital twin simulation system 13310, the digital twin dynamic model system 13312, and/or the intelligence service 13004 to determine one or more control instructions. In embodiments, the digital twin control module 13314 may implement a rules-based and/or a machine-learning approach to determine the control instructions. In response to determining a control instruction, the digital twin control

module 13314 may output the control instruction to the smart container, smart container fleet, and/or other shipping entities and environments via the digital twin I/O system 13308.

[2398] In embodiments, the digital twin management system 13306 may include, but is not limited to, a digital twin configuration module 13318, a digital twin update module 13320, and a digital twin visualization module 13322.

[2399] In embodiments, the digital twin configuration module 13318 may configure a set of new digital twins of a set of environments using input from users, imported data (e.g., blueprints, specifications, and the like), image scans of the environment, 3D data from a LIDAR device and/or SLAM sensors, and other suitable data sources. For example, a user (e.g., a user affiliated with an organization/customer account) may, via a client application 13324 (such as via the smart container system 13000), provide input to create a new shipping digital twin. In doing so, the user may upload 2D or 3D image scans and/or blueprints of the shipping entity and/or environment. The user may also upload 3D data, such as taken by a camera, a LIDAR device, an IR scanner, a set of SLAM sensors, a radar device, an EMF scanner, or the like. In response to the provided data, the digital twin configuration module 13318 may create a 3D representation of the shipping entity or environment, which may include any objects that were captured in the image data/detected in the 3D data. In embodiments, the intelligence service 13004 may analyze input data (e.g., blueprints, image scans, 3D data) to classify rooms, pathways, equipment, and the like to assist in the generation of the 3D representation. In some embodiments, the digital twin configuration module 13318 may map the digital twin to a 3D coordinate space (e.g., a Cartesian space having x, y, and z axes).

[2400] In some embodiments, the digital twin configuration module 13318 may output the 3D representation of the shipping entity and/or environment to a graphical user interface (GUI). In some of these embodiments, a user may identify certain areas and/or objects and may provide input relating to the identified areas and/or objects. For example, a user may label specific rooms, equipment, machines, devices, sensors, and the like. Additionally, or alternatively, the user may provide data relating to the identified objects and/or areas. For example, in identifying a smart container, the user may provide a make/model number of the smart container. In some embodiments, the digital twin configuration module 13318 may obtain information from a manufacturer of a device, a piece of equipment, or machinery. This information may include one or more properties and/or behaviors of the device, equipment, or machinery. In some embodiments, the user may, via the GUI, identify locations of sensors throughout the shipping entity and/or environment. For each sensor, the user may provide a type of sensor and related data (e.g., make, model, IP address, and the like). The digital twin configuration module 13318 may record the locations (e.g., the x, y, z coordinates of the sensors) in the shipping digital twin. In embodiments, the digital twin module 13420 may employ one or more systems that automate the population of digital twins. For example, the digital twin module 13420 may employ a machine vision-based classifier that classifies makes and models of devices, equipment, or sensors. Additionally, or alternatively, the digital twin module 13420 may iteratively ping different types of known sensors to identify the presence of specific types of sensors that are in

an environment. Each time a sensor responds to a ping, the digital twin module 13420 may extrapolate the make and model of the sensor.

[2401] In some embodiments, the manufacturer may provide or make available digital twins of their products (e.g., sensors, devices, machinery, equipment, raw materials, and the like). In these embodiments, the digital twin configuration module 13318 may import the digital twins of one or more products that are identified in the environment and may embed those digital twins in the digital twin of the environment. In embodiments, embedding a digital twin within another digital twin may include creating a relationship between the embedded digital twin with the other digital twin. In these embodiments, the manufacturer of the digital twin may define the behaviors and/or properties of the respective products. For example, a digital twin of a 3D printer in a smart container may define the manner by which the 3D printer operates, the inputs/outputs of the 3D printer, and the like. In this way, the digital twin of the 3D printer may reflect the operation of the 3D printer given a set of inputs.

[2402] In embodiments, a user may define one or more shipping processes. In these embodiments, the user may define the steps in the process, the machines/devices that perform each step in the process, the inputs to the process, and the outputs of the process.

[2403] In embodiments, the digital twin configuration module 13318 may create a graph database that defines the relationships between a set of digital twins. In these embodiments, the digital twin configuration module 13318 may create nodes for the shipping entity and/or environment, systems, and subsystems of the shipping entity and/or environment, devices in the shipping entity and/or environment, sensors in the shipping entity and/or environment, workers that work in a shipping environment, shipping processes that are performed involving the shipping entity and/or environment, and the like. In embodiments, the digital twin configuration module 13318 may write the graph database representing a set of digital twins to the digital twin datastore 13316.

[2404] In embodiments, the digital twin configuration module 13318 may, for each node, include any data relating to the entity in the node representing the entity. For example, in defining a node representing a container ship, the digital twin configuration module 13318 may include the dimensions, boundaries, layout, pathways, and other relevant spatial data in the node. Furthermore, the digital twin configuration module 13318 may define a coordinate space with respect to the container ship. In the case that the digital twin may be rendered, the digital twin configuration module 13318 may include a reference in the node to any shapes, meshes, splines, surfaces, and the like that may be used to render the environment. In representing a system, subsystem, device, or sensor, the digital twin configuration module 13318 may create a node for the respective entity and may include any relevant data. For example, the digital twin configuration module 13318 may create a node representing a shipping robot. In this example, the digital twin configuration module 13318 may include the dimensions, behaviors, properties, location, and/or any other suitable data relating to the robot in the node representing the robot. The digital twin configuration module 13318 may connect nodes of related entities with an edge, thereby creating a relationship between the entities. In doing so, the created relationship between

the entities may define the type of relationship characterized by the edge. In representing a process, the digital twin configuration module 13318 may create a node for the entire process or may create a node for each step in the process. In some of these embodiments, the digital twin configuration module 13318 may relate the process nodes to the nodes that represent the machinery/devices that perform the steps in the process. In embodiments, where an edge connects the process step nodes to the machinery/device that performs the process step, the edge or one of the nodes may contain information that indicates the input to the step, the output of the step, the amount of time the step takes, the nature of processing of inputs to produce outputs, a set of states or modes the process can undergo, and the like.

[2405] In embodiments, the digital twin update module 13320 updates sets of digital twins based on a current status of one or more shipping entities and/or environments. In some embodiments, the digital twin update module 13320 receives sensor data from a sensor system of a shipping entity and/or environment and updates the status of the digital twin of the shipping entity or environment and/or digital twins of any affected systems, subsystems, devices, workers, processes, or the like. As discussed, the digital twin I/O system 13308 may receive the sensor data in one or more sensor packets. The digital twin I/O system 13308 may provide the sensor data to the digital twin update module 13320 and may identify the entity or environment from which the sensor packets were received and the sensor that provided the sensor packet. In response to the sensor data, the digital twin update module 13320 may update a state of one or more digital twins based on the sensor data. In some of these embodiments, the digital twin update module 13320 may update a record (e.g., a node in a graph database) corresponding to the sensor that provided the sensor data to reflect the current sensor data. In some scenarios, the digital twin update module 13320 may identify certain areas within the entity or environment that are monitored by the sensor and may update a record (e.g., a node in a graph database) to reflect the current sensor data. For example, the digital twin update module 13320 may receive sensor data reflecting different vibrational characteristics of a smart container and/or components. In this example, the digital twin update module 13320 may update the records representing the vibration sensors that provided the vibration sensor data and/or the records representing the smart container and/or the smart container components to reflect the vibration sensor data. In another example, in some scenarios, workers in a shipping environment (e.g., container port, container storage facility, or the like) may be required to wear wearable devices (e.g., smart watches, smart helmets, smart shoes, or the like). In these embodiments, the wearable devices may collect sensor data relating to the worker (e.g., location, movement, heartrate, respiration rate, body temperature, or the like) and/or the environment surrounding the worker and may communicate the collected sensor data to the digital twin module 13420 (e.g., via the real-time sensor API 13326) either directly or via an aggregation device of the sensor system. In response to receiving the sensor data from the wearable device of a worker, the digital twin update module 13320 may update a digital twin of a worker to reflect, for example, a location of the worker, a trajectory of the worker, a health status of the worker, or the like. In some of these embodiments, the digital twin update module 13320 may update a node

representing a worker and/or an edge that connects the node representing the environment with the collected sensor data to reflect the current status of the worker.

[2406] In some embodiments, the digital twin update module 13320 may provide the sensor data from one or more sensors to the digital twin dynamic model system 13312, which may model a behavior of a shipping environment and/or one or more shipping entities to extrapolate additional state data.

[2407] In embodiments, the digital twin visualization module 13322 receives requests to view a visual digital twin or a portion thereof. In embodiments, the request may indicate the digital twin to be viewed (e.g., smart container identifier). In response, the digital twin visualization module 13322 may determine the requested digital twin and any other digital twins implicated by the request. For example, in requesting to view a digital twin of smart container, the digital twin visualization module 13322 may further identify the digital twins of any shipping entities within the smart container. In embodiments, the digital twin visualization module 13322 may identify the spatial relationships between the shipping entities and the smart container based on, for example, the relationships defined in a graph database. In these embodiments, the digital twin visualization module 13322 can determine the relative location of embedded digital twins within the containing digital twin, relative locations of adjoining digital twins, and/or the transience of the relationship (e.g., is an object fixed to a point or does the object move). The digital twin visualization module 13322 may render the requested digital twins and any other implicated digital twin based on the identified relationships. In some embodiments, the digital twin visualization module 13322 may, for each digital twin, determine the surfaces of the digital twin. In some embodiments, the surfaces of a digital may be defined or referenced in a record corresponding to the digital twin, which may be provided by a user, determined from imported images, or defined by a manufacturer of a shipping entity. In the scenario that an object can take different poses or shapes (e.g., a shipping robot), the digital twin visualization module 13322 may determine a pose or shape of the object for the digital twin. The digital twin visualization module 13322 may embed the digital twins into the requested digital twin and may output the requested digital twin to the client application.

[2408] In some of these embodiments, the request to view a digital twin may further indicate the type of view. As discussed, in some embodiments, digital twins may be depicted in a number of different view types. For example, a shipping entity or environment may be viewed in a "real-world" view that depicts the environment or device as they typically appear, in a "heat" view that depicts the environment or entity in a manner that is indicative of a temperature of the environment or entity, in a "vibration" view that depicts shipping entities in a manner that is indicative of vibrational characteristics of the entities, in a "velocity" view that depicts shipping entities in a manner that is indicative of the velocity of the entities, in a "filtered" view that only displays certain types of objects or components (such as objects that require attention resulting from, for example, recognition of a fault condition, an alert, an updated report, or other factor), an augmented view that overlays data on the digital twin, and/or any other suitable view types.

[2409] In embodiments, digital twins may be depicted in a number of different role-based view types. For example, a smart container fleet may be viewed in a "manager" view that depicts the smart container in a manner suitable for a smart container fleet manager, a container terminal environment may be viewed in an "operator" view that depicts the container terminal in a manner that is suitable for a container terminal operator, a "regulatory" view that depicts the facility in a manner that is suitable for regulatory managers, a shipper may view a smart container digital twin 13504 in a "shipper" view that depicts the smart container in a manner suitable for a shipper, and the like. In response to a request that indicates a view type, the digital twin visualization module 13322 may retrieve the data for each digital twin that corresponds to the view type. For example, if a user has requested a heat view of a smart container fleet, the digital twin visualization module 13322 may retrieve temperature data for that set of smart containers (which may include temperature measurements taken from smart containers, shipping environments, different smart container components, and/or temperature measurements that were extrapolated by the digital twin dynamic model system 13312 and/or simulated temperature data from digital twin simulation system 13310) as well as available temperature data for any other shipping entities. In this example, the digital twin visualization module 13322 may determine colors corresponding to each smart container that represents a temperature fault level state (e.g., red for alarm, orange for critical, yellow for suboptimal, and green for normal operation). The digital twin visualization module 13322 may then render the digital twins of the smart containers based on the determined colors. It is noted that in some embodiments, the digital twin module 13420 may include an analytics system (not shown) that determines the manner by which the digital twin visualization module 13322 presents information to a human user. For example, the analytics system may track outcomes relating to human interactions with real-world environments or objects in response to information presented in a visual digital twin. In some embodiments, the analytics system may apply cognitive models to determine the most effective manner to display visualized information (e.g., what colors to use to denote an alarm condition, what kind of movements or animations bring attention to an alarm condition, or the like) or audio information (what sounds to use to denote an alarm condition) based on the outcome data. In some embodiments, the analytics system may apply cognitive models to determine the most suitable manner to display visualized information based on the role of the user. In embodiments, the visualization may include display of information related to the visualized digital twins, including graphical information, graphical information depicting physical characteristics, graphical information depicting financial characteristics, graphical information depicting performance characteristics, recommendations from intelligence service 13004, predictions from intelligence service 13004, probability of failure data, maintenance history data, time to failure data, cost of downtime data, probability of downtime data, cost of repair data, cost of replacement data (e.g., replacing a smart container or smart container component), and the like.

[2410] In embodiments, a smart container fleet manager digital twin 13328 is a digital twin configured for a manager and/or operator of a fleet of smart containers. In embodiments, the

smart container fleet manager digital twin 13328 may work in connection with the system 13000 to provide simulations, optimizations, classifications, configuration and/or control, predictions, statistical summaries, and decision-support based on analytics, machine learning, and/or other AI and learning-type processing of inputs (e.g., maritime data, traffic data, weather data, sensor data, regulatory data, and the like). In embodiments, a smart container fleet manager digital twin 13328 may provide functionality including, but not limited to, confirming freight storage and/or transportation service orders, selecting smart container modes of transportation/routes, engaging in maintenance service transactions with third-party service providers, inspecting individual smart containers, monitoring smart container fleets, generating smart contracts, monitoring regulatory compliance, performing risk management, and other fleet manager-related activities.

[2411] In embodiments, the types of data that may populate a smart container fleet manager digital twin 13328 may include, but are not limited to: financial data, weather data, macroeconomic data, microeconomic data, forecast data, demand planning data, analytic results of AI and/or machine learning modeling (e.g., financial forecasting), prediction data, asset data, recommendation data, strategic competitive data (e.g., news and events regarding industry trends and competitors), shipping data, maritime data, trucking fleet data, freight data, aviation data, railway data, traffic data, social media data, survey data, and many others. In embodiments, the digital twin module 13420 may obtain financial data from, for example, publicly disclosed financial statements, third-party reports, tax filings, public news sources, and the like. In embodiments, macroeconomic data may be derived analytically from various financial and operational data collected by the system 13000. In embodiments, the business performance metrics may be derived analytically, based at least in part on real-time operations data, by the intelligence service 13004 and/or provided from other users and/or their respective trader digital twins.

[2412] In embodiments, a smart container fleet manager digital twin 13328 may include high-level views of different states of a fleet, real-time representations of the fleet, historical representations of the fleet, projected representations of the fleet (e.g., future states), real-time representations of individual smart containers, historical representations of individual smart containers, projected representations of individual smart containers (e.g., future states), real-time representations of shippers, historical representations of shippers, projected representations of shippers, real-time representations of shipping lines, historical representations of shipping lines, projected representations of shipping lines, news and/or television data, economic sentiment data, social media data, charts, countdown to close information, lease terms, smart contract terms, contract terms, and many others. In embodiments, a smart container fleet manager digital twin 13328 may allow a user to access and/or interact with other shipping digital twins. In embodiments, a smart container fleet manager digital twin 13328 may allow a user to access and/or interact with a fleet of smart container digital twins 13504 and/or individual smart container digital twins 13504. In embodiments, a smart container fleet manager digital twin 13328 may allow a user to interact with another smart container fleet manager digital twin 13328 and/or a shipper digital twin 13502. The smart container fleet manager digital twin 13328

may initially depict the various states at a lower granularity level. In embodiments, a user that is viewing the smart container fleet manager digital twin 13328 may select to drill down into a selected state and view the selected state at a higher level of granularity. For example, the smart container fleet manager digital twin 13328 may initially depict a subset of the various states of a smart container fleet at a lower granularity level, including a pricing state (e.g., a visual indicator indicating pricing for smart containers). In response to a selection, the smart container fleet manager digital twin 13328 may provide data, analytics, summary, and/or reporting including, but not limited to, real-time, historical, aggregated, comparison, and/or forecasted pricing data (e.g., real-time, historical, simulated, and/or forecasted revenues, liabilities, and the like). In embodiments, the smart container fleet manager digital twin 13328 may initially present the user (e.g., the fleet manager) with a view of various different aspects of the fleet (e.g., different indicators to indicate different "health" levels of a fleet) but may allow the user to select which aspects require more of his or her attention. In response to such a selection, the smart container fleet manager digital twin 13328 may request a more granular view of the selected state(s) from the system 13000, which may return the requested states at the more granular level.

[2413] In embodiments, the digital twin simulation system 13310 may receive a request to perform a simulation requested by the smart container fleet manager digital twin 13328, where the request indicates one or more parameters that are to be varied in one or more digital twins. In response, the digital twin simulation system 13310 may return the simulation results to the smart container fleet manager digital twin 13328, which in turn outputs the results to the user via the client device display. In this way, the user may be provided with various outcomes corresponding to different parameter configurations. For example, a user may request a set of simulations to be run to test different fleet configurations to see how the different configurations affect the overall impact on profits and losses. The digital twin simulation system 13310 may perform the simulations by varying the different configurations and may output the financial forecasts for each respective configuration. In some embodiments, the user may select a parameter set based on the various outcomes, and iterate simulations based at least on the varied prior outcomes. In some embodiments, an intelligent agent may be trained to recommend and/or select a parameter set based on the respective outcomes associated with each respective parameter set.

[2414] In embodiments, a smart container fleet manager digital twin 13328 may be configured to store, aggregate, merge, analyze, prepare, report, and distribute material relating to pricing, scheduling, financial reporting, performance, maintenance, regulatory data, or other data related to a smart container shipping services. A smart container fleet manager digital twin 13328 may link to, interact with, and be associated with external data sources, and able to upload, download, aggregate external data sources, including with the system's 13000 internal data, and analyze such data, as described herein. Data analysis, machine learning, AI processing, and other analysis may be coordinated between the smart container fleet manager digital twin 13328 and the intelligence service 13004. This cooperation and interaction may include assisting with seeding shipping-related data elements and domains in the digital twin data store 13316 for use

in modeling, machine learning, and AI processing to identify an optimal fleet configuration, optimal scheduling execution of freight storage and/or transportation service orders, or some other shipping-related metric or aspect, as well as identification of the optimal data measurement parameters on which to base judgement of a fleet configuration or scheduling execution success. In embodiments, the digital twin module 13420 abstracts the different views (or states) within the digital twin to the appropriate granularity. For instance, the digital twin module 13420 may have access to all the sensor data collected on behalf of the 13000 as well as access to real-time sensor data streams. In this example, if the sensor readings from a particular smart container are indicative of a potentially critical situation (e.g., failure state, dangerous condition, damaged cargo, potentially illegal cargo, or the like), then the analytics that indicate the potentially critical situation may become very important to the fleet manager. Thus, the digital twin module 13420, when building the appropriate perspective for the fleet manager, may include a state indicator of the smart container in the fleet manager digital twin 13328. In this way, the fleet manager can drill down into the state indicator of the smart container to view the potentially critical situation at a greater granularity (e.g., smart container machinery and an analysis of the sensor data used to identify the situation).

[2415] In embodiments, a smart container fleet manager digital twin 13328 may be configured to report on the performance of smart containers in the fleet. As described herein, reporting may include timing performance metrics, financial performance metrics, physical performance metrics, cargo damage metrics, data regarding resource usage, or some other type of reporting data. In embodiments, an intelligent agent trained by the user may be trained to surface the most important reports to the user. For example, if the user (e.g., the fleet manager) consistently views and follows up on timing performance but routinely skips over reports relating to financial performance, the executive agent may automatically surface reports related to timing metrics to the user while suppressing financial performance data.

[2416] In embodiments, a smart container fleet manager digital twin 13328 may be configured to monitor, store, aggregate, merge, analyze, prepare, report, and distribute material relating to other shipping entities (e.g., shippers, shipping lines, container terminals, or named entities of interest). In embodiments, such data may be collected by the system 13000 via data aggregation, webscraping, or other techniques to search and collect shipping entity information from sources including, but not limited to, regulatory information, information on shipping, press releases, SEC or other financial reports, or some other publicly available data. For example, a user wishing to monitor a certain shipping entity may request that the smart container fleet manager digital twin 13328 provide materials relating to the certain shipping entity. In response, the system 13000 may identify a set of data sources that are either publicly available or to which the fleet manager has access (e.g., internal data sources, licensed 3rd party data, or the like).

[2417] In embodiments, the client application 13324, such as 13000, that executes the smart container fleet manager digital twin 13328 may be configured with an intelligent agent that is trained on the fleet manager's actions (which may be indicative of behaviors, and/or preferences). In embodiments, the intelligent agent may record the features relating to the

actions (e.g., the circumstances relating to the user's action) to the intelligent agent system. For example, the intelligent agent may record each time the user approves a freight storage and/or transportation service order (which is the action) as well as the features surrounding the approval (e.g., the type of action, the type of order, the price of the order, the shipper, the quantity of smart containers, route information, and the like). The intelligent agent may report the actions and features to the intelligent agent system that may train the intelligent agent on the manner by which the intelligent agent can undertake or recommend approval tasks and other tasks in the future. Once trained, the intelligent agent may automatically perform actions and/or recommend actions to the user. Furthermore, in embodiments, the intelligent agent may record outcomes related to the performed/recommended actions, thereby creating a feedback loop with the intelligent agent system.

[2418] In embodiments, a smart container fleet manager digital twin 13328 may provide an interface for a fleet manager to perform one or more fleet manager-related workflows. For example, the smart container fleet manager digital twin 13328 may provide an interface for a manager to perform, supervise, or monitor freight transportation order approval workflows, smart container maintenance workflows, logistics workflows, smart contract workflows, shipping and/or delivery workflows, regulatory workflows, and the like.

[2419] In another example, a user may request a filtered view of a digital twin of a process, whereby the digital twin of the process only shows shipping entities that are involved in the process. In this example, the digital twin visualization module 13322 may retrieve a digital twin of the process, as well as any related digital twins (e.g., a digital twin of the environment and digital twins of any shipping entities that impact the process). The digital twin visualization module 13322 may then render each of the digital twins (e.g., the environment and the relevant shipping entities) and then may perform the process on the rendered digital twins. It is noted that, as a process may be performed over a period of time and may include moving items and/or parts, the digital twin visualization module 13322 may generate a series of sequential frames that demonstrate the process. In this scenario, the movements of the shipping entities implicated by the process may be determined according to the behaviors defined in the respective digital twins of the machines and/or devices.

[2420] As discussed, the digital twin visualization module 13322 may output the requested digital twin to a client application 13324. In some embodiments, the client application 13324 is a virtual reality application, whereby the requested digital twin is displayed on a virtual reality headset. In some embodiments, the client application 13324 is an augmented reality application, whereby the requested digital twin is depicted in an AR-enabled device. In these embodiments, the requested digital twin may be filtered such that visual elements and/or text are overlaid on the display of the AR-enabled device.

[2421] It is noted that, while a graph database is discussed, the digital twin module 13420 may employ other suitable data structures to store information relating to a set of digital twins. In these embodiments, the data structures, and any related storage system, may be implemented

such that the data structures provide for some degree of feedback loops and/or recursion when representing iteration of flows.

[2422] In embodiments, a digital twin I/O system 13308 interfaces with the shipping entity and/or environment, the digital twin module 13420, and/or components thereof to provide bi-directional transfer of data between coupled components according to some embodiments of the present disclosure.

[2423] In embodiments, the transferred data includes signals (e.g., request signals, command signals, response signals, etc.) between connected components, which may include software components, hardware components, physical devices, virtualized devices, simulated devices, combinations thereof, and the like. The signals may define material properties (e.g., physical quantities of temperature, pressure, humidity, density, viscosity, etc.), measured values (e.g., contemporaneous or stored values acquired by the device or system), device properties (e.g., device ID or properties of the device's design specifications, materials, measurement capabilities, dimensions, absolute position, relative position, combinations thereof, and the like), set points (e.g., targets for material properties, device properties, system properties, combinations thereof, and the like), and/or critical points (e.g., threshold values such as minimum or maximum values for material properties, device properties, system properties, etc.). The signals may be received from systems or devices that acquire (e.g., directly measure or generate) or otherwise obtain (e.g., receive, calculate, look-up, filter, etc.) the data, and may be communicated to or from the digital twin I/O system 13308 at predetermined times or in response to a request (e.g., polling) from the digital twin I/O system 13308. The communications may occur through direct or indirect connections (e.g., via intermediate modules within a circuit and/or intermediate devices between the connected components). The values may correspond to real-world elements or virtual elements (e.g., an input or output for a digital twin and/or a simulated element that provides data).

[2424] In embodiments, the real-world elements may be elements within a shipping entity or environment. The real-world elements may include, for example, non-networked elements, the devices (smart or non-smart), sensors, and humans. The real-world elements may be process or non-process equipment within the shipping entities or environments. For example, process equipment may include motors, cranes, reach stackers, forklifts, pumps, fans, and the like, and non-process equipment may include personal protective equipment, safety equipment, emergency stations or devices (e.g., safety showers, eye wash stations, fire extinguishers, sprinkler systems, etc.), container terminal or other facility features (e.g., walls, floor layout, etc.), obstacles (e.g., persons or other items within an entity or environment), and the like.

[2425] In embodiments, the virtual elements may be digital representations of or that correspond to contemporaneously existing real-world elements. Additionally, or alternatively, the virtual elements may be digital representations of or that correspond to real-world elements that may be available for later addition and implementation into the entity or environment. The virtual elements may include, for example, simulated elements and/or digital twins. In embodiments, the simulated elements may be digital representations of real-world elements that

are not present within the shipping entity or environment. The simulated elements may mimic desired physical properties which may be later integrated within the entity or environment as real-world elements (e.g., a "black box" that mimics the dimensions of a real-world elements). The simulated elements may include digital twins of existing objects (e.g., a single simulated element may include one or more digital twins for existing sensors). Information related to the simulated elements may be obtained, for example, by evaluating behavior of corresponding real-world elements using mathematical models or algorithms, from libraries that define information and behavior of the simulated elements (e.g., physics libraries, chemistry libraries, or the like).

[2426] In embodiments, the digital twin may be a digital representation of one or more real-world elements. The digital twins are configured to mimic, copy, and/or model behaviors and responses of the real-world elements in response to inputs, outputs, and/or conditions of the surrounding environment. Data related to physical properties and responses of the real-world elements may be obtained, for example, via user input, sensor input, and/or physical modeling (e.g., thermodynamic models, electrodynamic models, mechanodynamic models, etc.). Information for the digital twin may correspond to and be obtained from the one or more real-world elements corresponding to the digital twin. For example, in some embodiments, the digital twin may correspond to one real-world element that is a fixed digital vibration sensor on a piece of smart container cargo, and vibration data for the digital twin may be obtained by polling or fetching vibration data measured by the fixed digital vibration sensor on the cargo. In a further example, the digital twin may correspond to a plurality of real-world elements that are each a fixed digital vibration sensor on a smart container component, and vibration data for the digital twin may be obtained by polling or fetching vibration data measured by each of the fixed digital vibration sensors on the plurality of real-world elements. Additionally, or alternatively, vibration data of a first digital twin may be obtained by fetching vibration data of a second digital twin that is embedded within the first digital twin, and vibration data for the first digital twin may include or be derived from vibration data for the second digital twin. For example, the first digital twin may be a digital twin of a smart container and the second digital twin may be a digital twin corresponding to a cargo within the smart container such that the vibration data for the first digital twin is obtained from or calculated based on data including the vibration data for the second digital twin.

[2427] In embodiments, the digital twin module 13420 monitors properties of the real-world elements using sensors that may be represented by a digital twin and/or outputs of models for one or more simulated elements. In embodiments, the digital twin module 13420 may minimize network congestion while maintaining effective monitoring of processes by extending polling intervals and/or minimizing data transfer for sensors that correspond to affected real-world elements and performing simulations (e.g., via the digital twin simulation system 13310) during the extended interval using data that was obtained from other sources (e.g., sensors that are physically proximate to or have an effect on the affected real-world elements). Additionally, or alternatively, error checking may be performed by comparing the collected sensor data with data obtained from the digital twin simulation system 13310. For example, consistent deviations or

fluctuations between sensor data obtained from the real-world element and the simulated element may indicate malfunction of the respective sensor or another fault condition.

[2428] In embodiments, the digital twin module 13420 may optimize features of smart container fleets, smart containers, and other shipping entities and/or environments through use of one or more simulated elements. For example, the digital twin module 13420 may evaluate effects of the simulated elements within a digital twin of a smart container to quickly and efficiently determine costs and/or benefits flowing from inclusion, exclusion, or substitution of real-world elements within the smart container. The costs and benefits may include, for example, manufacturing costs, maintenance costs, efficiency (e.g., process optimization to reduce waste or increase throughput), climate considerations (e.g., carbon footprint), lifespans, minimization of component faults, component downtime, or the like.

[2429] In embodiments, the digital twin I/O system 13308 may include one or more software modules that are executed by one or more controllers of one or more devices (e.g., server devices, user devices, and/or distributed devices) to affect the described functions. The digital twin I/O system 13308 may include, for example, an input module, an output module, and an adapter module.

[2430] In embodiments, the input module may obtain or import data from data sources in communication with the digital twin I/O system 13308, such as the sensor system and the digital twin simulation system 13310. The data may be immediately used by or stored within the digital twin module 13420. The imported data may be ingested from data streams, data batches, in response to a triggering event, combinations thereof, and the like. The input module may receive data in a format suitable to transfer, read, and/or write information within the digital twin module 13420.

[2431] In embodiments, the output module may output or export data to other system components (e.g., the digital twin datastore 13316, the digital twin simulation system 13310, the intelligence service 13004, etc.), devices, and/or the client application 13324. The data may be output in data streams, data batches, in response to a triggering event (e.g., a request), combinations thereof, and the like. The output module may output data in a format that is suitable to be used or stored by the target element (e.g., one protocol for output to the client application and another protocol for the digital twin datastore 13316).

[2432] In embodiments, the adapter module may process and/or convert data between the input module and the output module. In embodiments, the adapter module may convert and/or route data automatically (e.g., based on data type) or in response to a received request (e.g., in response to information within the data).

[2433] In embodiments, the digital twin module 13420 may represent a set of shipping workpiece elements in a digital twin, and the digital twin simulation system 13310 simulates a set of physical interactions of a worker or shipping robot with the workpiece elements.

[2434] In embodiments, the digital twin simulation system 13310 may determine process outcomes for the simulated physical interactions accounting for simulated human factors. For example, variations in workpiece throughput may be modeled by the digital twin module 13420

including, for example, worker response times to events, worker fatigue, discontinuity within worker actions (e.g., natural variations in human-movement speed, differing positioning times, etc.), effects of discontinuities on downstream processes, and the like. In embodiments, individualized worker interactions may be modeled using historical data that is collected, acquired, and/or stored by the digital twin module 13420. The simulation may begin based on estimated amounts (e.g., worker age, industry averages, workplace expectations, etc.). The simulation may also individualize data for each worker (e.g., comparing estimated amounts to collected worker-specific outcomes).

[2435] In embodiments, information relating to workers (e.g., fatigue rates, efficiency rates, and the like) may be determined by analyzing performance of specific workers over time and modeling said performance.

[2436] In embodiments, the digital twin module 13420 includes plurality of proximity sensors within the sensor array. The proximity sensors are or may be configured to detect elements of a shipping entity or environment that are within a predetermined area. For example, proximity sensors may include electromagnetic sensors, light sensors, and/or acoustic sensors.

[2437] The electromagnetic sensors are or may be configured to sense objects or interactions via one or more electromagnetic fields (e.g., emitted electromagnetic radiation or received electromagnetic radiation). In embodiments, the electromagnetic sensors include inductive sensors (e.g., radio-frequency identification sensors), capacitive sensors (e.g., contact and contactless capacitive sensors), combinations thereof, and the like.

[2438] The light sensors are or may be configured to sense objects or interactions via electromagnetic radiation in, for example, the far-infrared, near-infrared, optical, and/or ultraviolet spectra. In embodiments, the light sensors may include image sensors (e.g., charge-coupled devices and CMOS active-pixel sensors), photoelectric sensors (e.g., through-beam sensors, retroreflective sensors, and diffuse sensors), combinations thereof, and the like. In embodiments, the light sensors may include liquid lens vision systems. Further, the light sensors may be implemented as part of a system or subsystem, such as a light detection and ranging ("LIDAR") sensor.

[2439] The acoustic sensors are or may be configured to sense objects or interactions via sound waves that are emitted and/or received by the acoustic sensors. In embodiments, the acoustic sensors may include infrasonic, sonic, and/or ultrasonic sensors. Further, the acoustic sensors may be grouped as part of a system or subsystem, such as a sound navigation and ranging ("SONAR") sensor.

[2440] In embodiments, the digital twin module 13420 stores and collects data from a set of proximity sensors. The collected data may be stored, for example, in the digital twin datastore 13316 for use by components the digital twin module 13420 and/or visualization by a user. Such use and/or visualization may occur contemporaneously with or after collection of the data (e.g., during later analysis and/or optimization of processes).

[2441] In embodiments, data collection may occur in response to a triggering condition. These triggering conditions may include, for example, expiration of a static or a dynamic

predetermined interval, obtaining a value short of or in excess of a static or dynamic value, receiving an automatically generated request or instruction from the digital twin module 13420 or components thereof, interaction of an element with the respective sensor or sensors (e.g., in response to an object coming within a predetermined distance from the proximity sensor), interaction of a user with a digital twin (e.g., selection of a smart container digital twin, a sensor array digital twin, or a sensor digital twin), combinations thereof, and the like.

[2442] In some embodiments, the digital twin module 13420 collects and/or stores RFID data in response to interaction of a worker or robot with a real-world element. For example, in response to a robot interaction with a smart container cargo, the digital twin will collect and/or store RFID data from RFID sensors associated with the corresponding cargo. Additionally, or alternatively, robot interaction with a sensor-array digital twin will collect and/or store RFID data from RFID sensors within or associated with the corresponding sensor array. Similarly, robot interaction with a sensor digital twin will collect and/or store RFID data from the corresponding sensor. The RFID data may include suitable data attainable by RFID sensors such as proximate RFID tags, RFID tag position, authorized RFID tags, unauthorized RFID tags, unrecognized RFID tags, RFID type (e.g., active or passive), error codes, combinations thereof, and the like.

[2443] In embodiments, the digital twin module 13420 may further embed outputs from one or more devices within a corresponding digital twin. In embodiments, the digital twin module 13420 embeds output from a set of individual-associated devices into a shipping digital twin. For example, the digital twin I/O system 13308 may receive information output from one or more wearable devices or mobile devices (not shown) associated with an individual. The wearable devices may include image capture devices (e.g., body cameras or augmented-reality headwear), navigation devices (e.g., GPS devices, inertial guidance systems), motion trackers, acoustic capture devices (e.g., microphones), radiation detectors, combinations thereof, and the like.

[2444] In embodiments, upon receiving the output information, the digital twin I/O system 13308 routes the information to the digital twin configuration module 13318 to check and/or update the shipping digital twin and/or associated digital twins. Further, the digital twin module 13420 may use the embedded output to determine characteristics of the shipping entity or environment.

[2445] In embodiments, the digital twin module 13420 embeds output from a LIDAR point cloud system into a shipping digital twin. For example, the digital twin I/O system 13308 may receive information output from one or more LIDAR devices. The LIDAR devices are configured to provide a plurality of points having associated position data (e.g., coordinates in absolute or relative x, y, and z values). Each of the plurality of points may include further LIDAR attributes, such as intensity, return number, total returns, laser color data, return color data, scan angle, scan direction, etc. The LIDAR devices may provide a point cloud that includes the plurality of points to the digital twin module 13420 via, for example, the digital twin I/O system 13308. Additionally, or alternatively, the digital twin module 13420 may receive a

stream of points and assemble the stream into a point cloud or may receive a point cloud and assemble the received point cloud with existing point cloud data, map data, or three dimensional (3D)-model data.

[2446] In embodiments, upon receiving the output information, the digital twin I/O system 13308 routes the point cloud information to the digital twin configuration module 13318 to check and/or update the shipping digital twin and/or associated digital twins. In some embodiments, the digital twin module 13420 is further configured to determine closed-shape objects within the received LIDAR data. For example, the digital twin module 13420 may group a plurality of points within the point cloud as an object and, if necessary, estimate obstructed faces of objects (e.g., a face of the object contacting or adjacent a floor or a face of the object contacting or adjacent another object such as another piece of equipment). The system may use such closed-shape objects to narrow search space for digital twins and thereby increase efficiency of matching algorithms (e.g., a shape-matching algorithm).

[2447] In embodiments, the digital twin module 13420 embeds output from a simultaneous location and mapping ("SLAM") system in an environment digital twin. For example, the digital twin I/O system 13308 may receive information output from the SLAM system, such as SLAM sensor, and embed the received information within an environment digital twin corresponding to the location determined by the SLAM system. In embodiments, upon receiving the output information from the SLAM system, the digital twin I/O system 13308 routes the information to the digital twin configuration module 13318 to check and/or update the shipping digital twin and/or associated digital twins. Such updating provides digital twins of non-connected elements automatically and without need of user interaction with the digital twin module 13420.

[2448] In embodiments, the digital twin module 13420 can leverage known digital twins to reduce computational requirements for the SLAM sensor by using suboptimal map-building algorithms. For example, the suboptimal map-building algorithms may allow for a higher uncertainty tolerance using simple bounded-region representations and identifying possible digital twins. Additionally, or alternatively, the digital twin module 13420 may use a bounded-region representation to limit the number of digital twins, analyze the group of potential twins for distinguishing features, then perform higher precision analysis for the distinguishing features to identify and/or eliminate categories of, groups of, or individual digital twins and, in the event that no matching digital twin is found, perform a precision scan of only the remaining areas to be scanned.

[2449] In embodiments, the digital twin module 13420 may further reduce compute required to build a location map by leveraging data captured from other sensors within the environment (e.g., captured images or video, radio images, etc.) to perform an initial map-building process (e.g., a simple bounded-region map or other suitable photogrammetry method), associate digital twins of known environmental objects with features of the simple bounded-region map to refine the simple bounded-region map, and perform more precise scans of the remaining simple bounded regions to further refine the map. In some embodiments, the digital twin module 13420 may detect objects within received mapping information and, for each detected object,

determine whether the detected object corresponds to an existing digital twin of a real-world-element. In response to determining that the detected object does not correspond to an existing real-world-element digital twin, the digital twin module 13420 may use, for example, the digital twin configuration module 13318 to generate a new digital twin corresponding to the detected object (e.g., a detected-object digital twin) and add the detected-object digital twin to the real-world-element digital twins within the digital twin datastore. Additionally, or alternatively, in response to determining that the detected object corresponds to an existing real-world-element digital twin, the digital twin module 13420 may update the real-world-element digital twin to include new information detected by the simultaneous location and mapping sensor, if any.

[2450] In embodiments, the digital twin module 13420 represents locations of autonomously or remotely moveable elements and attributes thereof within a shipping digital twin. Such movable elements may include, for example, cargo, vehicles, autonomous vehicles, robots, etc. The locations of the moveable elements may be updated in response to a triggering condition. Such triggering conditions may include, for example, expiration of a static or a dynamic predetermined interval, receiving an automatically generated request or instruction from the digital twin module 13420 or components thereof, interaction of an element with a respective sensor or sensors (e.g., in response to a worker or machine breaking a beam or coming within a predetermined distance from a proximity sensor), interaction of a user with a digital twin (e.g., selection of a shipping digital twin, a sensor array digital twin, or a sensor digital twin), combinations thereof, and the like.

[2451] In embodiments, the time intervals may be based on probability of the respective movable element having moved within a time period. For example, the time interval for updating a robot location may be relatively shorter for robots expected to move frequently (e.g., a robot tasked with lifting and carrying cargo within and through a container terminal) and relatively longer for robots expected to move infrequently (e.g., a robot tasked with monitoring a process). Additionally or alternatively, the time interval may be dynamically adjusted based on applicable conditions, such as increasing the time interval when no movable elements are detected, decreasing the time interval as or when the number of moveable elements within an environment increases (e.g., increasing number of robots and robot interactions), increasing the time interval during periods of reduced activity, decreasing the time interval during periods of abnormal activity (e.g., inspections or maintenance), decreasing the time interval when unexpected or uncharacteristic movement is detected (e.g., frequent movement by a typically sedentary element or coordinated movement, for example, of robots approaching an exit or moving cooperatively to carry a large object), combinations thereof, and the like. Further, the time interval may also include additional, semi-random acquisitions. For example, occasional mid-interval locations may be acquired by the digital twin module 13420 to reinforce or evaluate the efficacy of the particular time interval.

[2452] In embodiments, the digital twin module 13420 may analyze data received from the digital twin I/O system 13308 to refine, remove, or add conditions. For example, the digital twin module 13420 may optimize data collection times for movable elements that are updated more

frequently than needed (e.g., multiple consecutive received positions being identical or within a predetermined margin of error).

[2453] In embodiments, the digital twin module 13420 may receive, identify, and/or store a set of states related to shipping entities or environments. The set of states may be, for example, data structures that include a plurality of attributes and a set of identifying criteria to uniquely identify each respective state. In embodiments, the set of states may correspond to states where it is desirable for the digital twin module 13420 to set or alter conditions of real-world elements and/or the environment (e.g., increase/decrease monitoring intervals, alter operating conditions, etc.).

[2454] In embodiments, the set of states may further include, for example, minimum monitored attributes for each state, the set of identifying criteria for each state, and/or actions available to be taken or recommended to be taken in response to each state. Such information may be stored by, for example, the digital twin datastore 13316 or another datastore. The set of states or portions thereof may be provided to, determined by, or altered by the digital twin module 13420. Further, the set of states may include data from disparate sources. For example, details to identify and/or respond to occurrence of a first state may be provided to the digital twin module 13420 via user input, details to identify and/or respond to occurrence of a second state may be provided to the digital twin module 13420 via an external system, details to identify and/or respond to occurrence of a third state may be determined by the digital twin module 13420 (e.g., via simulations or analysis of process data), and details to identify and/or respond to occurrence of a fourth state may be stored by the digital twin module 13420 and altered as desired (e.g., in response to simulated occurrence of the state or analysis of data collected during an occurrence of and response to the state).

[2455] In embodiments, the plurality of attributes includes at least the attributes needed to identify the respective state. The plurality of attributes may further include additional attributes that are or may be monitored in determining the respective state, but are not needed to identify the respective state. For example, the plurality of attributes for a first state may include relevant information such as rotational speed, battery level, energy input, linear speed, acceleration, temperature, strain, torque, volume, weight, etc.

[2456] The set of identifying criteria may include information for each of the set of attributes to uniquely identify the respective state. The identifying criteria may include, for example, rules, thresholds, limits, ranges, logical values, conditions, comparisons, combinations thereof, and the like.

[2457] The change in operating conditions or monitoring may be any suitable change. For example, after identifying occurrence of a respective state, the digital twin module 13420 may increase or decrease monitoring intervals for a smart container (e.g., decreasing monitoring intervals in response to a measured parameter differing from nominal operation) without altering operation of the smart container. Additionally, or alternatively, the digital twin module 13420 may alter operation of the smart container (e.g., reduce speed or power input) without altering monitoring of the smart container. In further embodiments, the digital twin module 13420 may

alter operation of the smart container (e.g., reduce speed or power input) and alter monitoring intervals for the device (e.g., decreasing monitoring intervals).

[2458] In embodiments, a set of identified set of states related to shipping entities and environments that the digital twin module 13420 may identify and/or store for access by intelligent systems (e.g., the intelligence service 13004) or users of the digital twin module 13420, according to some embodiments of the present disclosure. The set of states may include operational states (e.g., suboptimal, normal, optimal, critical, or alarm operation of one or more components), excess or shortage states (e.g., supply-side or output-side quantities), combinations thereof, and the like.

[2459] In embodiments, the digital twin module 13420 may monitor attributes of real-world elements and/or digital twins to determine the respective state. The attributes may be, for example, operating conditions, set points, critical points, status indicators, other sensed information, combinations thereof, and the like. For example, the attributes may include power input, operational speed, critical speed, and operational temperature of the monitored elements. While the illustrated example illustrates uniform monitored attributes, the monitored attributes may differ by target device (e.g., the digital twin module 13420 would not monitor rotational speed for an object with no rotatable components).

[2460] Each of the set of states includes a set of identifying criteria meeting particular criteria that are unique among the group of monitored set of states. The digital twin module 13420 may identify the overspeed state, for example, in response to the monitored attributes meeting a first set of identifying criteria (e.g., operational speed being higher than the critical speed).

[2461] In response to determining that one or more set of states exists or has occurred, the digital twin module 13420 may update triggering conditions for one or more monitoring protocols, issue an alert or notification, or trigger actions of subcomponents of the digital twin module 13420. For example, subcomponents of the digital twin module 13420 may take actions to mitigate and/or evaluate impacts of the detected set of states. When attempting to take actions to mitigate impacts of the detected set of states on real-world elements, the digital twin module 13420 may determine whether instructions exist (e.g., are stored in the digital twin datastore 13316) or should be developed (e.g., developed via simulation and intelligence services or via user or worker input). Further, the digital twin module 13420 may evaluate impacts of the detected set of states, for example, concurrently with the mitigation actions or in response to determining that the digital twin module 13420 has no stored mitigation instructions for the detected set of states.

[2462] In embodiments, the digital twin module 13420 employs the digital twin simulation system 13310 to simulate one or more impacts, such as immediate, upstream, downstream, and/or continuing effects, of recognized states. The digital twin simulation system 13310 may collect and/or be provided with values relevant to the evaluated set of states. In simulating the impact of the one or more set of states, the digital twin simulation system 13310 may recursively evaluate performance characteristics of affected digital twins until convergence is achieved. The digital twin simulation system 13310 may work, for example, in tandem with the intelligence

service 13004 to determine response actions to alleviate, mitigate, inhibit, and/or prevent occurrence of the one or more set of states. For example, the digital twin simulation system 13310 may recursively simulate impacts of the one or more set of states until achieving a desired fit (e.g., convergence is achieved), provide the simulated values to the intelligence service 13004 for evaluation and determination of potential actions, receive the potential actions, and/or evaluate impacts of each of the potential actions for a respective desired fit (e.g., cost functions for minimizing production disturbance, preserving critical components, minimizing maintenance and/or downtime, optimizing system, worker, user, or personal safety, etc.).

[2463] In embodiments, the digital twin simulation system 13310 and the intelligence service 13004 may repeatedly share and update the simulated values and response actions for each desired outcome until desired conditions are met (e.g., convergence for each evaluated cost function for each evaluated action). The digital twin module 13420 may store the results in the digital twin datastore 13316 for use in response to determining that one or more set of states has occurred. Additionally, simulations and evaluations by the digital twin simulation system 13310 and/or the intelligence service 13004 may occur in response to occurrence or detection of the event.

[2464] In embodiments, simulations and evaluations are triggered only when associated actions are not present within the digital twin module 13420. In further embodiments, simulations and evaluations are performed concurrently with use of stored actions to evaluate the efficacy or effectiveness of the actions in real time and/or evaluate whether further actions should be employed or whether unrecognized states may have occurred. In embodiments, the intelligence service 13004 may also be provided with notifications of instances of undesired actions with or without data on the undesired aspects or results of such actions to optimize later evaluations.

[2465] In embodiments, the digital twin module 13420 evaluates and/or represents the impact of downtime of smart containers within a digital twin of a smart container fleet. For example, the digital twin module 13420 may employ the digital twin simulation system 13310 to simulate the immediate, upstream, downstream, and/or continuing effects of a smart container downtime state. The digital twin simulation system 13310 may collect or be provided with performance-related values such as optimal, suboptimal, and minimum performance requirements for elements (e.g., real-world elements and/or nested digital twins) within the affected digital twins, and/or characteristics thereof that are available to the affected digital twins, effect on nested digital twins, redundant systems within the affected digital twins, combinations thereof, and the like.

[2466] In embodiments, the digital twin module 13420 is configured to: simulate one or more operating parameters for the real-world elements in response to the shipping entity or environment being supplied with given characteristics using the real-world-element digital twins; calculate a mitigating action to be taken by one or more of the real-world elements in response to being supplied with the contemporaneous characteristics; and actuate, in response to detecting the contemporaneous characteristics, the mitigating action. The calculation may be

performed in response to detecting contemporaneous characteristics or operating parameters falling outside of respective design parameters or may be determined via a simulation prior to detection of such characteristics.

[2467] Additionally, or alternatively, the digital twin module 13420 may provide alerts to one or more users or system elements in response to detecting states.

[2468] In embodiments, the digital twin I/O system 13308 includes a pathing module. The pathing module may ingest navigational data from the elements, provide and/or request navigational data to components of the digital twin module 13420 (e.g., the digital twin simulation system 13310, the digital twin dynamic model system 13312, and/or the intelligence service 13004), and/or output navigational data to elements (e.g., to the wearable devices). The navigational data may be collected or estimated using, for example, historical data, guidance data provided to the elements, combinations thereof, and the like.

[2469] For example, the navigational data may be collected or estimated using historical data stored by the digital twin module 13420. The historical data may include or be processed to provide information such as acquisition time, associated elements, polling intervals, task performed, laden or unladen conditions, whether prior guidance data was provided and/or followed, conditions of a shipping entity or environment, other elements within the shipping entity or environment, combinations thereof, and the like. The estimated data may be determined using one or more suitable pathing algorithms. For example, the estimated data may be calculated using suitable order-picking algorithms, suitable path-search algorithms, combinations thereof, and the like. The order-picking algorithm may be, for example, a largest gap algorithm, an s-shape algorithm, an aisle-by-aisle algorithm, a combined algorithm, combinations thereof, and the like. The path-search algorithms may be, for example, Dijkstra's algorithm, the A* algorithm, hierarchical path-finding algorithms, incremental path-finding algorithms, any angle path-finding algorithms, flow field algorithms, combinations thereof, and the like.

[2470] In embodiments, the digital twin module 13420 ingests navigational data for a set of smart containers for representation in a digital twin. Additionally, or alternatively, the digital twin module 13420 ingests navigational data for a set of mobile equipment assets of a shipping environment into a digital twin.

[2471] In embodiments, the digital twin module 13420 ingests a system for modeling traffic of mobile elements (e.g., smart containers, container ships, robots, trucks, trains, cargo, or the like) in a shipping digital twin. For example, the digital twin module 13420 may model traffic patterns for a set of smart containers, mobile equipment assets, cargo combinations thereof, and the like. The traffic patterns may be estimated based on modeling traffic patterns from historical data and contemporaneous ingested data. Further, the traffic patterns may be continuously or intermittently updated depending on conditions.

[2472] The digital twin module 13420 may alter traffic patterns (e.g., by providing updated navigational data to one or more of the mobile elements) to achieve one or more predetermined criteria. The predetermined criteria may include, for example, increasing process efficiency,

decreasing interactions between smart containers and mobile equipment assets, minimizing smart container path length, routing smart containers around paths or potential paths of persons, combinations thereof, and the like.

[2473] In embodiments, the digital twin module 13420 may provide traffic data and/or navigational information to mobile elements in a shipping digital twin. The navigational information may be provided as instructions or rule sets, displayed path data, or selective actuation of devices. For example, the digital twin module 13420 may provide a set of instructions to a smart container to direct smart container to and/or along a desired route from an origin location to one or more specified locations along the route. The smart container may communicate updates to the system including obstructions, reroutes, unexpected interactions with other assets along the route.

[2474] In some embodiments, an ant-based system enables shipping entities, including smart containers, to lay a trail with one or more messages for other shipping containers and/or shipping entities, including themselves, to follow in later journeys. In embodiments, the messages include information related to measurement collection.

[2475] In embodiments, the digital twin module 13420 includes design specification information for representing a real-world element using a digital twin. The digital twin may correspond to an existing real-world element or a potential real-world element. The design specification information may be received from one or more sources. For example, the design specification information may include design parameters set by user input, determined by the digital twin module 13420 (e.g., the via digital twin simulation system 13310), optimized by users or the digital twin simulation system 13310, combinations thereof, and the like. The digital twin simulation system 13310 may represent the design specification information for the component to users, for example, via a monitor or a virtual reality headset. The design specification information may be displayed schematically (e.g., as part of a process diagram or table of information) or as part of an augmented reality or virtual reality display. The design specification information may be displayed, for example, in response to a user interaction with the digital twin module 13420 (e.g., via user selection of the element or user selection to generally include design specification information within displays). Additionally, or alternatively, the design specification information may be displayed automatically, for example, upon the element coming within view of an augmented reality or virtual reality device. In embodiments, the displayed design specification information may further include indicia of information source (e.g., different displayed colors indicate user input versus digital twin module 13420 determination), indicia of mismatches (e.g., between design specification information and operational information), combinations thereof, and the like. In some embodiments, the digital twin module 13420 may provide an augmented reality view that displays mismatches between design parameters or expected parameters of real-world elements to the wearer. The displayed information may correspond to real-world elements that are not within the view of the wearer (e.g., elements within another room or obscured by machinery). This allows the worker to quickly and accurately troubleshoot mismatches to determine one or

more sources for the mismatch. The cause of the mismatch may then be determined, for example, by the digital twin module 13420 and corrective actions ordered. In example embodiments, a wearer may be able to view malfunctioning subcomponents of machines without removing occluding elements (e.g., housings or shields). Additionally, or alternatively, the wearer may be provided with instructions to repair the device, for example, including display of the removal process (e.g., location of fasteners to be removed), assemblies or subassemblies that should be transported to other areas for repair (e.g., dust-sensitive components), assemblies or subassemblies that need lubrication, and locations of objects for reassembly (e.g., storing location that the wearer has placed removed objects and directing the wearer or another wearer to the stored locations to expedite reassembly and minimize further disassembly or missing parts in the reassembled element). This can expedite repair work, minimize process impact, allow workers to disassemble and reassemble equipment (e.g., by coordinating disassembly without direct communication between the workers), increase equipment longevity and reliability (e.g., by assuring that all components are properly replaced prior to placing back in service), combinations thereof, and the like.

[2476] In embodiments, the digital twin module 13420 may include, integrate, integrate with, manage, handle, link to, take input from, provide output to, control, coordinate with, or otherwise interact with a digital twin dynamic model system 13312. The digital twin dynamic model system 13312 can update the properties of a set of digital twins of a set of shipping entities and/or environments, including properties of physical shipping assets, workers, processes, shipping facilities, warehouses, and the like (or any of the other types of entities or environments described in this disclosure or in the documents incorporated by reference herein) in such a manner that the digital twins may represent those shipping entities and environments, and properties or attributes thereof, in real-time or very near real-time. In some embodiments, the digital twin dynamic model system 13312 may obtain sensor data received from a sensor system and may determine one or more properties of a shipping environment or a shipping entity based on the sensor data and based on one or more dynamic models.

[2477] In embodiments, the digital twin dynamic model system 13312 may update/assign values of various properties in a digital twin and/or one or more embedded digital twins, including, but not limited to, vibration values, probability of failure values, probability of downtime values, cost of downtime values, pricing values, energy values, performance values, financial values, temperature values, humidity values, heat flow values, cargo load values, fluid flow values, radiation values, substance concentration values, velocity values, acceleration values, location values, pressure values, stress values, strain values, light intensity values, sound level values, volume values, shape characteristics, material characteristics, and dimensions.

[2478] In embodiments, a digital twin may be comprised of (e.g., via reference) other embedded digital twins. For example, a digital twin of a container terminal may include an embedded digital twin of a container ship and one or more embedded digital twins of one or more respective smart containers enclosed within the container ship. A digital twin may be embedded, for example, in the memory of a smart container that has an onboard IT system (e.g.,

the memory of an Onboard Diagnostic System, control system (e.g., SCADA system) or the like). Other non-limiting examples of where a digital twin may be embedded include the following: on a wearable device of a worker; in memory on a local network asset, such as a switch, router, access point, or the like; in a cloud computing resource that is provisioned for an environment or entity; and on an asset tag or other memory structure that is dedicated to an entity.

[2479] In embodiments, the digital twin dynamic model system 13312 can update the properties of a digital twin and/or one or more embedded digital twins on behalf of a client application 13324 (such as the smart container system 13000). In embodiments, a client application 13324 may be the smart container system 13000, an application relating to a shipping component or environment (e.g., monitoring a shipping facility or a component within, simulating a shipping environment, or the like). In embodiments, the client application 13324 may be used in connection with both fixed and mobile data collection systems. In embodiments, the client application 13324 may be used in connection with Industrial Internet of Things sensor system.

[2480] In embodiments, the digital twin dynamic model system 13312 leverages digital twin dynamic models 13374 to model the behavior of a shipping entity and/or environment. Dynamic models 13374 may enable digital twins to represent physical reality, including the interactions of shipping entities, by using a limited number of measurements to enrich the digital representation of a shipping entity and/or environment, such as based on scientific principles. In embodiments, the dynamic models 13374 are formulaic or mathematical models. In embodiments, the dynamic models 13374 adhere to scientific laws, laws of nature, and formulas (e.g., Newton's laws of motion, second law of thermodynamics, Bernoulli's principle, ideal gas law, Dalton's law of partial pressures, Hooke's law of elasticity, Fourier's law of heat conduction, Archimedes' principle of buoyancy, and the like). In embodiments, the dynamic models are machine-learned models.

[2481] In embodiments, the digital twin module 13420 may have a digital twin dynamic model datastore 13376 for storing dynamic models 13374 that may be represented in digital twins. In embodiments, digital twin dynamic model datastore 13376 can be searchable and/or discoverable. In embodiments, digital twin dynamic model datastore 13376 can contain metadata that allows a user to understand what characteristics a given dynamic model can handle, what inputs are required, what outputs are provided, and the like. In some embodiments, digital twin dynamic model datastore 13376 can be hierarchical, such as where a model can be deepened or made simpler based on the extent of available data and/or inputs, the granularity of the inputs, and/or situational factors (such as where something becomes of high interest and a higher fidelity model is accessed for a period of time).

[2482] In embodiments, a digital twin or digital representation of a shipping entity or environment may include a set of data structures that collectively define a set of properties of a represented physical shipping asset, device, worker, process, facility, and/or environment, and/or possible behaviors thereof. In embodiments, the digital twin dynamic model system 13312 may

leverage the dynamic models 13374 to inform the set of data structures that collectively define a digital twin with real-time data values. The digital twin dynamic models 13374 may receive one or more sensor measurements, Industrial Internet of Things device data, and/or other suitable data as inputs and calculate one or more outputs based on the received data and one or more dynamic models 13374. The digital twin dynamic model system 13312 then uses the one or more outputs to update the digital twin data structures.

[2483] In one example, the set of properties of a digital twin of an shipping entity that may be updated by the digital twin dynamic model system 13312 using dynamic models 13374 may include the vibration characteristics of the shipping entity, temperature(s) of the shipping entity, the state of the shipping entity (e.g., a solid, liquid, or gas), the location of the shipping entity, the displacement of the shipping entity, the velocity of the shipping entity, the acceleration of the shipping entity, probability of downtime values associated with the shipping entity, cost of downtime values associated with the shipping entity, financial information associated with the shipping entity, heat flow characteristics associated with the shipping entity, fluid flow rates associated with the shipping entity (e.g., fluid flow rates of a fluid flowing through a pipe), identifiers of other digital twins embedded within the digital twin of the shipping entity and/or identifiers of digital twins embedding the digital twin of the shipping entity, and/or other suitable properties. Dynamic models 13374 associated with a digital twin of an asset can be configured to calculate, interpolate, extrapolate, and/or output values for such asset digital twin properties based on input data collected from sensors and/or devices disposed in the industrial setting and/or other suitable data and subsequently populate the asset digital twin with the calculated values.

[2484] In some embodiments, the set of properties of a digital twin of an shipping device that may be updated by the digital twin dynamic model system 13312 using dynamic models 13374 may include the status of the device, a location of the device, the temperature(s) of a device, a trajectory of the device, identifiers of other digital twins that the digital twin of the device is embedded within, embeds, is linked to, includes, integrates with, takes input from, provides output to, and/or interacts with, and the like. Dynamic models 13374 associated with a digital twin of a device can be configured to calculate or output values for these device digital twin properties based on input data and subsequently update the device digital twin with the calculated values.

[2485] Example properties of a digital twin of a shipping environment that may be updated by the digital twin dynamic model system 13312 using dynamic models 13374 may include the dimensions of the shipping environment, the temperature(s) of the shipping environment, the humidity value(s) of the shipping environment, the fluid flow characteristics in the shipping environment, the heat flow characteristics of the shipping environment, the lighting characteristics of the shipping environment, the acoustic characteristics of the shipping environment the physical objects in the environment, processes occurring in the shipping environment, currents of the shipping environment (if a body of water), and the like. Dynamic models associated with a digital twin of a shipping environment can be configured to calculate

or output these properties based on input data collected from sensors and/or devices disposed in the shipping environment and/or other suitable data and subsequently populate the shipping environment digital twin with the calculated values.

[2486] In embodiments, dynamic models 13374 may adhere to physical limitations that define boundary conditions, constants or variables for digital twin modeling. For example, the physical characterization of a digital twin of a shipping entity or shipping environment may include a gravity constant (e.g., 9.8 m/s^2), friction coefficients of surfaces, thermal coefficients of materials, maximum temperatures of assets, maximum flow capacities, and the like. Additionally, or alternatively, the dynamic models may adhere to laws of nature. For example, dynamic models may adhere to the laws of thermodynamics, laws of motion, laws of fluid dynamics, laws of buoyancy, laws of heat transfer, laws of radiation, laws of quantum dynamics, and the like. In some embodiments, dynamic models may adhere to biological aging theories or mechanical aging principles. Thus, when the digital twin dynamic model system 13312 facilitates a real-time digital representation, the digital representation may conform to dynamic models, such that the digital representations mimic real world conditions. In some embodiments, the output(s) from a dynamic model can be presented to a human user and/or compared against real-world data to ensure convergence of the dynamic models with the real world. Furthermore, as dynamic models are based partly on assumptions, the properties of a digital twin may be improved and/or corrected when a real-world behavior differs from that of the digital twin. In embodiments, additional data collection and/or instrumentation can be recommended based on the recognition that an input is missing from a desired dynamic model, that a model in operation isn't working as expected (perhaps due to missing and/or faulty sensor information), that a different result is needed (such as due to situational factors that make something of high interest), and the like.

[2487] Dynamic models may be obtained from a number of different sources. In some embodiments, a user can upload a model created by the user or a third party. Additionally, or alternatively, the models may be created on the digital twin system using a graphical user interface. The dynamic models may include bespoke models that are configured for a particular environment and/or set of shipping entities and/or agnostic models that are applicable to similar types of digital twins. The dynamic models may be machine-learned models. In embodiments, the dynamic models may be machine-learned models provided by the intelligence service 13004.

[2488] In embodiments, digital twin dynamic model system 13312 leverages one or more dynamic models 13374 to update a set of properties of a digital twin and/or one or more embedded digital twins on behalf of client application 13324 based on the impact of collected sensor data from sensor system, data collected from Internet of Things connected devices 13338, and/or other suitable data in the set of dynamic models 13374 that are used to enable the shipping digital twins. In embodiments, the digital twin dynamic model system 13312 may be instructed to run specific dynamic models using one or more digital twins that represent physical shipping entities, devices, workers, processes, and/or shipping environments that are managed, maintained, and/or monitored by the client applications 13324.

[2489] In embodiments, the digital twin dynamic model system 13312 may obtain data from other types of external data sources that are not necessarily shipping data sources, but may provide data that can be used as input data for the dynamic models. For example, traffic data, trucking fleet data, aviation data, road data, freight data, maritime data, weather data, news events, social media data, and the like may be collected, crawled, subscribed to, and the like to supplement sensor data, Industrial Internet of Things device data, and/or other data that is used by the dynamic models. In embodiments, the digital twin dynamic model system 13312 may obtain data from a machine vision module 13422. Machine vision module 13422 may use video and/or still images to provide measurements (e.g., locations, statuses, and the like) that may be used as inputs by the dynamic models.

[2490] In embodiments, the digital twin dynamic model system 13312 may feed this data into one or more of the dynamic models discussed above to obtain one or more outputs. These outputs may include calculated vibration characteristics, probability of failure values, probability of downtime values, cost of downtime values, time to failure values, temperature values, pressure values, humidity values, precipitation values, visibility values, air quality values, strain values, stress values, displacement values, velocity values, acceleration values, location values, performance values, financial values, pricing values, electrodynamic values, thermodynamic values, fluid flow rate values, and the like. The client application 13324 may then initiate a digital twin visualization event using the results obtained by the digital twin dynamic model system 13312. In embodiments, the visualization may be a heat map visualization.

[2491] As illustrated by FIG. 148, the digital twin dynamic model system 13312 may receive requests to update one or more properties of digital twins of shipping entities and/or environments such that the digital twins represent the shipping entities and/or environments in real-time. At step A100, the digital twin dynamic model system 13312 receives a request to update one or more properties of one or more of the digital twins of shipping entities and/or environments. For example, the digital twin dynamic model system 13312 may receive the request from a client application 13324 or from another process executed by the digital twin module 13420 (e.g., a predictive maintenance process). The request may indicate the one or more properties and the digital twin or digital twins implicated by the request. In step A102, the digital twin dynamic model system 13312 determines the one or more digital twins required to fulfill the request and retrieves the one or more required digital twins, including any embedded digital twins, from digital twin datastore 13316. At step A104, digital twin dynamic model system 13312 determines one or more dynamic models required to fulfill the request and retrieves the one or more required dynamic models from digital twin dynamic model datastore 13376. At step A106, the digital twin dynamic model system 13312 selects one or more sensors from sensor system, data collected from Internet of Things connected devices 13338, and/or other data sources from digital twin I/O system 13308 based on available data sources and the one or more required inputs of the dynamic model(s). In embodiments, the data sources may be defined in the inputs required by the one or more dynamic models or may be selected using a lookup table. At step A108, the digital twin dynamic model system 13312 retrieves the selected

data from digital twin I/O system 13308. At step A110, digital twin dynamic model system 13312 runs the dynamic model(s) using the retrieved input data (e.g., velocity sensor data, image data, and the like) as inputs and determines one or more output values based on the dynamic model(s) and the input data. At step A112, the digital twin dynamic model system 13312 updates the values of one or more properties of the one or more digital twins based on the one or more outputs of the dynamic model(s).

[2492] In example embodiments, client application 13324 may be configured to provide a digital representation and/or visualization of the digital twin of a shipping entity. In embodiments, the client application 13324 may include one or more software modules that are executed by one or more server devices. These software modules may be configured to quantify properties of the digital twin, model properties of a digital twin, and/or to visualize digital twin behaviors. In embodiments, these software modules may enable a user to select a particular digital twin behavior visualization for viewing. In embodiments, these software modules may enable a user to select to view a digital twin behavior visualization playback. In some embodiments, the client application 13324 may provide a selected behavior visualization to digital twin dynamic model system 13312.

[2493] In embodiments, the digital twin dynamic model system 13312 may receive requests from client application 13324 to update properties of a digital twin in order to enable a digital representation of a shipping entity and/or environment wherein the real-time digital representation is a visualization of the digital twin. In embodiments, a digital twin may be rendered by a computing device, such that a human user can view the digital representations of real-world shipping entities, devices, workers, processes and/or environments. For example, the digital twin may be rendered an outcome to a display device. In embodiments, dynamic model outputs and/or related data may be overlaid on the rendering of the digital twin. In embodiments, dynamic model outputs and/or related information may appear with the rendering of the digital twin in a display interface. In embodiments, the related information may include real-time video footage associated with the real-world entity represented by the digital twin. In embodiments, the related information may be graphical information. In embodiments, graphical information may depict motion, wherein a user is enabled to select a view of the graphical information in the x, y, and z dimensions. In embodiments, the related information may be cost data, including cost of downtime per day data, cost of repair data, cost of new part data, cost of new machine data, and the like. In embodiments, related information may be probability of downtime data, probability of failure data, and the like. In embodiments, related information may be time to failure data.

[2494] In embodiments, the related information may be recommendations and/or insights. For example, recommendations or insights received from the intelligence service related to a smart container may appear with the rendering of the digital twin of a smart container in a display interface.

[2495] In embodiments, clicking, touching, or otherwise interacting with the digital twin rendered in the display interface can allow a user to "drill down" and see underlying subsystems

or processes and/or embedded digital twins. In embodiments, clicking, touching, or otherwise interacting with information related to the digital twin rendered in the display interface can allow a user to "drill down" and see underlying information

[2496] In some embodiments, the digital twin dynamic model system 13312 may receive requests from client application 13324 to update properties of a digital twin in order to enable a digital representation of shipping entities and/or environments wherein the digital representation is a heat map visualization of the digital twin. In embodiments, a platform is provided having heat maps displaying collected data from the sensor system, Internet of Things connected devices 13338, and data outputs from dynamic models 13374 for providing input to a display interface. In embodiments, the heat map interface is provided as an output for digital twin data, such as for handling and providing information for visualization of various sensor data, dynamic model output data, and other data (such as map data, analog sensor data, and other data), such as to another system, such as a mobile device, tablet, dashboard, computer, AR/VR device, or the like. A digital twin representation may be provided in a form factor (e.g., user device, VR-enabled device, AR-enabled device, or the like) suitable for delivering visual input to a user, such as the presentation of a map that includes indicators of levels of analog sensor data, digital sensor data, and output values from the dynamic models. In embodiments, signals from various sensors or input sources (or selective combinations, permutations, mixes, and the like) as well as data determined by the digital twin dynamic model system 13312 may provide input data to a heat map. Coordinates may include real world location coordinates (such as geo-location or location on a map), as well as other coordinates, such as time-based coordinates, frequency-based coordinates, or other coordinates that allow for representation of analog sensor signals, digital signals, dynamic model outputs, input source information, and various combinations, and/or in a map-based visualization, such that colors may represent varying levels of input along the relevant dimensions. For example, among many other possibilities, if a container terminal is operating at a critical level state (e.g., due to heavy traffic or delays), the heat map interface may alert a user by showing the container port in orange. In the example of a heat map, clicking, touching, or otherwise interacting with the heat map can allow a user to drill down and see underlying container ships, dynamic model outputs, or other input data that is used as an input to the heat map display. In other examples, such as ones where a digital twin is displayed in a VR or AR environment, if a smart container machine component is vibrating outside of normal operation, a haptic interface may induce vibration when a user touches a representation of the machine component, or if a machine component is operating in an unsafe manner, a directional sound signal may direct a user's attention toward the machine in digital twin, such as by playing in a particular speaker of a headset or other sound system.

[2497] In embodiments, the digital twin dynamic model system 13312 may take a set of ambient environmental data and/or other data and automatically update a set of properties of a digital twin of a shipping entity or environment based on the impact of the environmental data and/or other data in the set of dynamic models 13374 that are used to enable the digital twin. Ambient environmental data may include temperature data, pressure data, humidity data, wind

data, rainfall data, tide data, storm surge data, cloud cover data, current data, snowfall data, visibility data, water level data, and the like. Additionally, or alternatively, the digital twin dynamic model system 13312 may use a set of environmental data measurements collected by a set of Internet of Things connected devices 13338 disposed in an industrial setting as inputs for the set of dynamic models 13374 that are used to enable the digital twin. For example, digital twin dynamic model system 13312 may feed the dynamic models 13374 data collected, handled or exchanged by Internet of Things connected devices, such as cameras, monitors, embedded sensors, mobile devices, diagnostic devices and systems, instrumentation systems, telematics systems, and the like, such as for monitoring various parameters and features of machines, devices, components, parts, operations, functions, conditions, states, events, workflows and other elements (collectively encompassed by the term "states") of shipping environments. Other examples of Internet of Things connected devices include smart fire alarms, smart security systems, smart air quality monitors, smart/learning thermostats, and smart lighting systems.

[2498] FIG. 149 illustrates an example embodiment of a method for updating a set of cost of downtime values in the digital twin of a smart container. In the present example, the digital twin dynamic model system 13312 may receive requests from a client application 13324 to populate real-time cost of downtime values associated with a smart container in a smart container fleet digital twin. At step B200, digital twin dynamic model system 13312 receives a request from the client application 13324 to update one or more cost of downtime values of the smart container digital twin 13504 and any embedded digital twins (e.g., robots, cargo, and the like) from the client application 13324. Next, in step B202, the digital twin dynamic model system 13312 determines the one or more digital twins required to fulfill the request and retrieves the one or more required digital twins. In this example, the digital twin dynamic model system 13312 may retrieve the digital twins of the fleet, the smart containers, and any other embedded digital twins from digital twin datastore 13316. At step B204, digital twin dynamic model system 13312 determines one or more dynamic models required to fulfill the request and retrieves the one or more required dynamic models from dynamic model datastore 13316. At step B206, the digital twin dynamic model system 13312 selects dynamic model input data sources (e.g., one or more sensors from sensor system and/or any other suitable data) based on available data sources (e.g., available sensors from a set of sensors in sensor system) and the one or more required inputs of the dynamic model(s) via digital twin I/O system 13308. In the present example, the retrieved dynamic model(s) may be configured to take historical downtime data and operational data as input and output data representing cost of downtime per day for smart containers in the smart container fleet. At step B208, digital twin dynamic model system 13312 retrieves historical downtime data and operational data from digital twin I/O system 13308. At step B210, digital twin dynamic model system 13312 runs the dynamic model(s) using the retrieved data as input and calculates one or more outputs that represent cost of downtime per day for smart containers in the smart container fleet. Next, at step B212, the digital twin dynamic model system 13312 updates one or more cost of downtime values of the smart container digital twin 13504and embedded digital twins based on the one or more outputs of the dynamic model(s).

[2499] In embodiments, the smart container system 13000 includes a robotic process automation (RPA) module 13416 configured to automate internal shipping workflows based on robotic process automation. The RPA module 13416 may develop a programmatic interface to a user interface of an external system such as devices, programs, networks, databases, and the like. The RPA module 13416 is configured to allow the smart container system 13000 to interface with an external system without using an application programming interface (API), or in addition to an API. The RPA module 13416 may develop an action list by watching a user perform a task in a graphical user interface (GUI) and recording the tasks in the action list. The RPA module 13416 may automate a workflow by repeating tasks of the action list in the GUI.

[2500] In some embodiments, the RPA module 13416 may include and/or communicate with an intelligence service 13004 configured to perform robotic process automation processes. The intelligence service 13004 may employ one or more machine learning techniques to develop one or more machine-learned models. The machine-learned models may be capable of developing, defining, and/or implementing RPA-based programmatic interfaces to facilitate interfacing of the system 13000 with one or more external devices.

[2501] The RPA module 13416 may be necessary for the smart container system 13000 to communicate with an external system that does not have an API or that has an outdated API. For example, the RPA module 13416 may allow the smart container system 13000 to interface with an older external device that does not include an API or that has an outdated API. The RPA module 13416 may allow the smart container system 13000 to interface with an external system similarly to how a user would interface with the external system, such as via a user interface of the external system. In some embodiments, the RPA module 13416 allows the smart container system 13000 to emulate an action and/or a series of actions performable by a user to interface with an external system. Examples of programmatic interfacing by the RPA module 13416 to interface with an external system include manipulation of markup language, emulating computer mouse movements and/or "clicking on" one or more elements of a user interface, entering information into fillable fields and submitting the information via a client program and/or portal, and transmitting digital signals to an external system that appear to be from sent from a user device.

[2502] In some embodiments, the RPA module 13416 may be configured to facilitate communicating with new and/or updated external systems. When a new external system is developed or an external system is updated, the RPA module 13416 may develop a new and/or updated programmatic interface to facilitate interfacing with the new and/or updated external system by the smart container system 13000 in a manner that is consistent with interfacing with an outdated external device, i.e., the external device prior to release of the new and/or updated external system. For example, the RPA module 13416 may be configured to provide inputs to the outdated external device, provide inputs to the new and/or updated external device, compare related outputs, and adjust inputs to the new and/or updated external device such that the smart container system 13000 may interface with the new and/or updated external device in a manner

consistent with how the smart container system 13000 interfaced with the outdated external device.

[2503] In some embodiments, the RPA module 13416 may act as an API to outdated and/or external systems. The RPA module 13416 may be configured such that the smart container system 13000 is externally represented as having an API capable of interfacing with one or more external devices or otherwise being capable of programmatically handling signals transmitted by external devices, wherein the RPA module 13416 has developed a programmatic interface for handling such requests other than an API. For example, an outdated external system may be configured to communicate via a series of signals understood by an outdated API. The RPA module 13416 may configure the smart container system 13000 to act as if the smart container system 13000 includes the outdated API.

[2504] In some embodiments, the RPA module 13416 may be configured to provide a user interface for use by one or more users of the smart container system 13000. The intelligence service 13004 may, by one or more machine learning methods, create a user interface that allows a user to interface with one or more components and/or functions of the smart container system 13000. The RPA module 13416 may use robotic process automation techniques to operate the user interface created by the intelligence service 13004. The intelligence service 13004 may dynamically create and/or adjust the user interface according to variables such as changing demand conditions, new and/or modified functions of the smart container system 13000, new and/or modified conditions of systems external to the smart container system 13000, and the like. Examples of new and/or modified conditions of systems external to the smart container system 13000 may include changes to third-party service offerings, regulatory changes, and the like.

[2505] In some embodiments, the RPA module 13416 may be configured to avoid detection of robotic process automation by systems external to the smart container system 13000. Some of the external systems may be designed to attempt to detect, when the external system is communicating with a system using robotic process automation, such as the smart container system 13000. Upon detecting that the smart container system 13000 is using robotic process automation, the external system may restrict, eliminate, or modify communication capabilities of the smart container system 13000 with the external system. The RPA module 13416 may emulate human interfacing with the external system to "trick" the external system into believing that the RPA module 13416 is a human user to avoid detection of the robotic process automation and avoid restriction or elimination of communication by the external system. The RPA module 13416 may avoid detection by, for example, dynamically changing paths of interaction with the external system, interacting with user interface elements with inconsistent timing, making human-like errors such as "misclicks" or "typos," and the like.

[2506] In some embodiments, the intelligence service 13004 may be configured to create a machine-learned model for avoiding detection of robotic process automation. The machine-learned model may be created by using data from interaction with one or more graphical interfaces by real human beings and developing robotic process automation techniques that

emulate ways in which real humans interface with the one or more graphical user interfaces. For example, training data may include mouse and/or touch timings and accuracy, typing speed and accuracy, elements of the graphical user interface used, and the like.

[2507] In some embodiments, the RPA module 13416 may be configured to validate data transmitted to and/or received from external systems. The RPA module 13416 may validate one or more of data transmitted to the smart container system 13000 by users of the external system, data transmitted to the smart container system 13000 by users of the smart container system 13000, and/or data transmitted to the external system by users of the smart container system 13000. The RPA module 13416 may validate data by one or more of performing optical character recognition, performing image recognition and/or processing, identifying data stored on webpages, receiving data from a backend database of the external system, receiving data from a backend database of the smart container system 13000, and the like.

[2508] In some embodiments, the intelligence service 13004 may be configured to develop one or more machine-learned models for data validation. For example, the intelligence service 13004 may use data transmitted by users and/or data received from one or more databases and/or sources external to the smart container system 13000 as training data to "learn" to identify valid data. The intelligence service 13004 may transmit the one or more machine-learned models for data validation to the RPA module 13416. The RPA module 13416 may implement the one or more machine-learned models for data validation.

[2509] In some embodiments, the RPA module 13416 may be configured to facilitate validation of processes performed by the RPA module 13416. The RPA module 13416 may create a plurality of process validation logs as the RPA module 13416 performs one or more processes related to the smart container system 13000 and/or external systems on behalf of one or more users. The process validation logs may include one or more of timestamps, transaction receipts, user interface screenshots, or any other suitable data entry, file, and the like for providing validation of processes performed by the RPA module 13416. The RPA module 13416 may store the process validation logs in one or more databases and may transmit the process validation logs to the smart container system 13000 and/or users of the smart container system 13000. The RPA module 13416 may transmit the process validation logs automatically according to a schedule, upon demand by a user of the smart container system 13000, upon one or more conditions being true, and the like.

[2510] In some embodiments, the RPA module 13416 may be configured to adjust behavior of the robotic process automation in response to feedback acquired via one or both of data validation and process validation. A user of the smart container system 13000 may view validations of data provided by the RPA module 13416 and, in response to the validations of data, instruct the RPA module 13416 to adjust behavior of the RPA module 13416. A user of the smart container system 13000 may view one or more of the process validation logs and, in response to the one or more process validation logs, instruct the RPA module 13416 to adjust behavior of the RPA module 13416. Adjustment of behavior of the RPA module 13416 may include using different robotic process automation techniques to perform features of the RPA

module 13416, such as, for example, changing RPA-based user interface elements presented to users of the smart container system 13000, adjusting how the RPA module 13416 interfaces with one or more external systems, and any other suitable adjustment by the RPA module 13416.

[2511] In some embodiments, the intelligence service 13004 may use data validation information and/or feedback, process validation logs, or a combination thereof as training data. The intelligence service 13004 may train one or more machine-learned models to influence, adjust, and/or otherwise control behavior of the RPA module 13416 based upon the data validation information and/or feedback, process validation logs, or a combination thereof.

[2512] In some embodiments, the RPA module 13416 may be configured to perform image processing to recognize images in graphical user interfaces with which the RPA module 13416 interfaces. Graphical user interfaces of external systems with which the RPA module 13416 interfaces may be changed and/or updated, thereby potentially disrupting robotic process automation-based interfacing with the GUI. The RPA module 13416 may automatically detect changes to the GUI via image recognition and/or image processing. The RPA module 13416 may automatically update robotic process automation-based interfacing with the updated GUI to facilitate continued interfacing with the updated GUI and avoid errors or interruptions in communication with the external system.

[2513] In some embodiments, the intelligence service 13004 may use image process optimization to use one or more machine-learned models to automatically correct robotic process automation-based interfacing with the external system of the RPA module 13416. For example, the intelligence service 13004 may use a plurality of GUIs having images as training data to create a machine-learned model capable of automatically detecting changes in GUIs of external systems and determining how to adjust robotic process automation of the RPA module 13416 such that the RPA module 13416 may automatically continue interfacing with the GUI in light of a change to the GUI.

[2514] In some embodiments, the RPA module 13416 may be configured to develop a human training system for instructing humans to interface with one or more user interfaces of the smart container system 13000 and/or one or more external systems. The human training system may teach one or more human users a plurality of actions and/or techniques employed by the RPA module 13416 to interface with the one or more user interfaces such that the human users may perform tasks similarly to the RPA module 13416. The human training system may include one or more documents, videos, tutorials, and the like for facilitating human learning of actions and/or techniques for interfacing with the user interfaces.

[2515] In some embodiments, the RPA module 13416 may be configured to process and document success criteria of robotic process automation implemented by the RPA module 13416. The processed and documented success criteria is descriptive such that a human user of the smart container system 13000 and/or the RPA module 13416 may use the processed and documented success criteria to understand one or more process steps and/or algorithms used by the RPA module 13416 to facilitate interfacing with external systems and/or to automate internal marketplace workflows of the smart container system 13000.

[2516] In some embodiments, the RPA module 13416 may implement gamification of robotic process automation capabilities of the smart container system 13000. The gamification of robotic process automation capabilities may include awarding points to users for performing tasks desirable to operation of the smart container system 13000 and/or desirable for improvement of robotic process automation operations of the smart container system 13000. For example, points may be awarded for augmentation of a robotic process automation algorithm. Users who have been awarded points may compete with one another, and digital and/or physical prizes may be awarded to users who have achieved one or more point thresholds and/or have ranked above one or more other users on a points leaderboard.

[2517] In embodiments, the smart container system 13000 includes an edge device configured to perform edge computation and intelligence. In some embodiments, edge computation and intelligence may include performing one or both of data processing and data storage in an area that is physically close to where the processed and/or stored data is needed. In some embodiments, the smart container system 13000 may include a plurality of edge devices. By way of example, the edge device may be a router, a routing switch, an integrated access device, a multiplexer, a local area network (LAN) and/or wide area network (WAN) access device, an Internet of Things device, a smart container, and/or any other suitable device. In some embodiments, edge computation and intelligence may include performing data processing and/or data filtering. The processed and/or filtered data may be transmitted directly to devices that will use the processed and/or filtered data. The processed and/or filtered data may be transmitted along transmission paths with less congestion than general-purpose or high-traffic data transmission paths. Transmission of the processed and/or filtered data may use lower bandwidth than would transmission of unprocessed and/or unfiltered data.

[2518] In some embodiments, the edge device may implement local edge intelligence to anticipate relevant shipping factors using data received by and/or stored by the edge device. The edge device may be directed to collecting and processing data related to one or more of a particular smart container, class of smart containers, shippers, class of shippers, shipping lines, class of shipping lines, container ports, class of container ports, and the like. In some embodiments, the edge device may be situated physically near a remote container port or shipping hub area. For example, the edge device may be positioned and configured to collect data regarding performance related to a particular type of smart container in a geographical region. The edge device may perform data processing, analytics, filtering, trend finding, prediction making, and the like related to the data and may send processing results, analytics, filtered data, trends, predictions, etc. or portions thereof to a more centralized server, processor and/or data center within the smart container system 13000.

[2519] In some embodiments, the edge device may be configured to perform decision making while being physically and/or electronically isolated from some or all other components of the smart container system 13000. Herein, electronic isolation may mean or include being temporarily unable to communicate with one or more other systems, devices, components, etc. The edge device may make decisions based upon outputs and/or conclusions drawn from the

data processing, analytics, filtering, trend finding, prediction making, etc. related to data received by the edge device. Examples of decisions made by the edge device include whether to validate one or more pieces of data, whether to validate a user of the smart container system 13000 or a portion thereof, whether a freight storage and/or transportation service order has been executed, and the like. The edge device may transmit data related to decisions made by the edge device to other components of the smart container system 13000.

[2520] In some embodiments, in cases where the edge device is temporarily electronically isolated from other components of the smart container system 13000, the edge device may make decisions on behalf of other components of the smart container system 13000, and may have the decisions audited, evaluated, and/or recorded by other components of the smart container system 13000 upon being reconnected with the other components of the smart container system 13000. The edge device may be restricted from making some decisions in absence of connection to and/or oversight by other components of the smart container system 13000. Examples of restricted decisions may include decisions related to shipping transactions where confidentiality and/or security are of concern, where sensitive cargo is to be shipped, and the like.

[2521] In some embodiments, the edge device may store a copy of a distributed ledger, the distributed ledger containing information related to one or more smart containers, smart container fleets, and/or shipping transactions managed by the smart container system 13000. The distributed ledger may be a cryptographic ledger, such as a blockchain. The edge device may write blocks to the distributed ledger containing smart container information and may have the blocks verified by comparison with copies of the distributed ledger stored on other components of the smart container system 13000.

[2522] In some embodiments, the smart container system 13000 may include a ledger management system configured to manage a network of devices, such as edge devices, that store copies of the distributed ledger. The devices that store copies of the distributed ledger may be configured to transmit copies stored thereon to the ledger management system for aggregation, comparison, and/or validation. The ledger management system may establish a whitelist of trusted parties and/or devices, a blacklist of untrusted parties and/or devices, or a combination thereof. The ledger management system may assign permissions to particular users, devices, and the like. Versions of the distributed ledger may be compared to prevent duplicate transactions such as the sale of multiple copies of a unique good. In embodiments, where the smart container system 13000 includes a plurality of edge devices that may each store a copy of the distributed ledger and may compare copies against one another with respect to validation of blocks and addition of new blocks by and/or all of the edge devices.

[2523] In some embodiments, the smart container system 13000 may implement one or more distributed update management algorithms for updating distributed devices such as the edge device. The distributed update management algorithm may include one or more procedures for how and when to roll out updates to the distributed devices. The smart container system 13000 may manage versions of edge computation software via the distributed update management

algorithms. The distributed devices may receive updates directly from the smart container system 13000, may transmit updates to one another, or a combination thereof.

[2524] In some embodiments, wherein the smart container system 13000 includes a plurality of edge devices, the edge devices may communicate with one another to record and/or validate shipping data. The edge devices may also communicate data with one another related to one or more smart containers, smart container fleets, container ships, container terminals, shipping yards, charging stations, regions, users, shippers, shipping lines, third parties, and the like. An edge device of the plurality of edge devices may communicate such information when able in cases where an edge device is electronically isolated from other edge devices and/or other components of the smart container system 13000.

[2525] In some embodiments, a first edge device that is electrically isolated and is assigned to facilitate a smart container repair may be supported by a second edge device. The second edge device may be assigned to facilitate the same repair in case the first edge device fails to facilitate the repair and/or is out of communication with other components of the smart container system 13000 for an extended period of time such that facilitation of repair by the first edge device is unverifiable. Upon reentering communication range, the first edge device may update the second edge device and/or other components of the smart container system 13000 with maintenance operations that took place while the first edge device was electronically isolated.

[2526] In some embodiments, the smart container system 13000 may implement a hardware failure algorithm configured to make decisions when one or more components of the smart container system 13000, such as the edge device, ceases operation and/or is otherwise unable to completely operate properly. The hardware failure algorithm may include, for example, assigning an edge device to overtake operations that had been previously assigned to a now malfunctioning or nonfunctioning edge device.

[2527] In some embodiments, the smart container system 13000 may implement a data routing algorithm configured to optimize flow of data transmitted to and/or from the edge device, other components of the fleet system, external systems, or a combination thereof. The edge device may include one or more signal amplifiers, signal repeaters, digital filters, analog filters, digital-to-analog converters, analog-to-digital converters and/or antennae configured to optimize the flow of data. In some embodiments, the network enhancement system may include a wireless repeater system such as is disclosed by US Patent No. 7,623,826 to Pergal, the entirety of which is hereby incorporated by reference. The edge device may optimize the flow of data by, for example, filtering data, repeating data transmission, amplifying data transmission, adjusting one or more sampling rates and/or transmission rates, and implementing one or more data communication protocols. In embodiments, the edge device may transmit a first portion of data over a first path of the plurality of data paths and a second portion of data over a second path of the plurality of data paths. The edge device may determine that one or more data paths, such as the first data path, the second data path, and/or other data paths, are advantageous for transmission of one or more portions of data. The edge device may make determinations of advantageous data paths based upon one or more networking variables, such as one or more

types of data being transmitted, one or more protocols being suitable for transmission, present and/or anticipated network congestion, timing of data transmission, present and/or anticipated volumes of data being or to be transmitted, and the like. Protocols suitable for transmission may include transmission control protocol (TCP), user datagram protocol (UDP), and the like. In some embodiments, the edge device may be configured to implement a method for data communication such as is disclosed by US Patent No. 9,979,664 to Ho et al., the entirety of which is hereby incorporated by reference.

[2528] In embodiments, the smart container system 13000 includes a digital twin module 13420 configured to receive data from the edge device and create a digital twin from the received data. The digital twin created by the digital twin module 13420 may be a digital twin of one or more of a smart container fleet, a smart container, a fleet manager, a container terminal, a shipping yard, a container ship, a shipper, cargo, and the like, and may be created using any or all of the data received from the edge device. The edge device may transmit shipping-related data, such as data related to a smart container, smart container cargo, a shipper, a container port, and the like, or a combination thereof. In embodiments, where the smart container system 13000 includes a plurality of edge devices, the digital twin module 13420 may create the digital twin based on data received from multiple of the plurality of edge devices.

[2529] In some embodiments, the edge device may be configured to facilitate pre-calculation and aggregation of data for a set of user-configured reports. The user-configured reports may be integrated into the digital twin created by the digital twin module 13420. A user of the smart container system 13000 may define one or more parameters of the user-configured report to be included in the digital twin. The edge device may implement one or more data processing and/or filtering according to the parameters of the user-configured report. The edge device may transmit processed and/or filtered data relevant to the user-configured report parameters to the digital twin module 13420. Upon receiving the processed and/or filtered data, the digital twin module 13420 may create the digital twin including the user-configured report using the received data and present the digital twin to the user.

[2530] In some embodiments, the edge device may be configured to collect and process data for use by one or more artificial intelligence (AI) systems. The AI systems may include the intelligence service 13004, one or more artificial intelligence systems configured to facilitate creation of the digital twin by the digital twin module 13420, and/or any other artificial intelligence systems connected to and/or included in the smart container system 13000. The edge device may be configured to collect and process and/or filter data such that the data is suitable for use by the one or more AI systems. An example of processed and/or filtered data collected by the edge device for use by the one or more AI systems is training data for use in training one or more machine-learned models.

[2531] In some embodiments, the edge device may be configured to locally store data related to creation of the digital twin by the digital twin module 13420. In cases where the digital twin is related to a particular region, shipper, smart container, fleet, container port, ship, or the like, the edge device may be particularly positioned to collect and store data for use in populating the

digital twin, for example, by being positioned nearby to the particular region, shipper, smart container, fleet, container port, ship, etc. The edge device may receive, process, filter, organize, and/or store data prior to transmission of the data to the digital twin module 13420 such that the data is relevant to and/or suitable for population of the digital twin. In some embodiments, the edge device may be configured to organize timing of transmission of data used to populate the digital twin. The edge device may implement one or more algorithms configured to measure and/or predict congestion of one or more network paths and/or routes and may perform organization of timing of transmission data based on the measurements and/or predictions of the congestion. The edge device may in some cases prioritize transmission of some types of data over others, such as according to priorities set by a user or by the digital twin module 13420. For example, the edge device may schedule regular transmissions of low-priority information during evening hours, when congestion is low, and may transmit high-priority information substantially immediately upon receiving the high-priority information and/or receiving a request for the high-priority information. In some embodiments, the edge device may be configured to select a data protocol for transmission of data used to populate the digital twin. The edge device may implement one or more algorithms configured to select one or more optimal network paths and/or routes and may select the data transmission protocol based on the measurements and/or predictions of the congestion.

[2532] In some embodiments, the edge device may be in communication with and receive data from a plurality of sensors. The edge device may be configured to intelligently multiplex alternative sensors among available sensors in a shipping environment for the digital twin.

DIGITAL PRODUCT NETWORKS

[2533] FIG. 150 illustrates communications between entities in an example digital product network 14000 according to some embodiments of the present disclosure. In some embodiments, digital product networks are communicatively coupled entities of a value chain network that may provide data related to product level behavior, product level usage, environmental data, data that is processed at the product level, and the like. For example, the product data may relate to at least one of sensors, vibration, humidity, temperature, pressure, proximity, level, accelerometers, gyroscope, infrared sensors, MEMs, liquid lenses, shock, security, machine, product, pneumatic, conductive, state dependent frequency monitor, ultrasonic, capacitance, or microwave.

[2534] An intelligence layer of the digital product network may then use the product level data to enable companies to solve challenges associated with customer demands for quality, efficiency, response, agility, and transparency. For example, the product level behavior and usage data may be combined with third-party sources to be analyzed and manipulated by artificial intelligence (AI) systems, machine learning (ML) systems, digital twin systems, robotic process automation (RPA) systems, etc. Data processing techniques may be related to at least one of obfuscation, forecasting, simulation, transformation, automation, reporting, matching,

stream processing, event processing and policy, dispatch and orchestration, analytics and algorithms, or machine learning.

[2535] In some embodiments, the analytics may be related to at least one of descriptive analytics, diagnostic analytics, predictive analytics, or prescriptive analytics. The descriptive analytics describe what is happening using compressive, accurate, and live data for effective visualization. The diagnostic analytics provide ability to drill down to a root cause and an ability to isolate confounding information. The predictive analytics describe business strategy, active adaption, and simulation. The prescriptive analytics may be evidence-based recommendations to recommend actions and strategies based on challenger testing and may use advanced AI and analytical techniques to make specific recommendations.

[2536] In some embodiments, the digital product network is a network of products that have a familial relationship to each other. For example, the products may all have the same brand, be part of the same metaverse, generate data according to the same standardized format, be specifically designed to interact or communicate with each other, or the like. The digital product network collects information from different pieces of a product family to generate information and outcomes that are not available from a single product. The family may include physical goods or physical goods mixed with content. For example, the content may be technical data, user profile information, or other content.

[2537] In some embodiments, the analysis and manipulation may lead to valuable insights throughout the development, manufacturing, supply chain, and customer relationship stages of a product lifecycle. For example, emerging connectivity and technologies in connected products enable intelligent provisioning, data aggregation, and analytics that can be used to create product connection, transaction, and enablement platforms. The data generated by the connected products may be analyzed to bridge the gap between supply and demand chains.

[2538] Two of the types of interactions that may take place in the digital product network are loosely coupled interactions and platform interactions. For loosely coupled interactions, the products are not directly tied to each other. The products operate separately and do not inherently trust interactions with each other. For example, while cars are on the road, their systems do not rely on the data from other cars for vehicle steering, acceleration, or braking control. Products in these types of interactions may use shared intention information, such as when a nearby car indicates that the nearby car will soon change lanes. Products receiving and interpreting the intention may consider the intention when evaluating response patterns. Data from products that have loosely coupled interactions may be fused or integrated for use in artificial intelligence systems, machine learning systems, robotic process automation systems, digital twins, and the like.

[2539] Platform based interactions involve different products that share the same operating platform or ecosystem. This shared ecosystem is able to coordinate different kinds of response patterns and encourage or demand a specific response pattern. For example, smoke detectors in a building may be designed to operate independently, but by sharing a common framework they may trigger alarms or even critical event responses (e.g., set off sprinklers). A smoke detector

may also increase its level of monitoring (e.g., frequency of sensor polling, frequency of data transmission, data fidelity) during periods of heightened alert to enable capabilities that may be otherwise dormant for reduced battery consumption. In the smoke detector example, the smoke detector may be communicatively coupled to a self-driving car system such that the car is redirected away from fire events. In some embodiments, a self-driving fire truck may drive to the fire event in response to the smoke detector alert. Such a self-responding fire truck may be beneficial where, for example, a community does not have a full-time professional fire department, such as in some rural locations where firefighters may respond to the fire location without first retrieving the fire truck.

[2540] In FIG. 150, an example of a digital product network service 14002 communicates with and executes algorithms related to a plurality of digital entities, such as connected products or intelligent products. For example, the digital product network service 14002 may be a version of the intelligence services described herein that is adapted for the specific functions of the digital product network 14000 described below.

[2541] In some example embodiments, the connected product may be enabled with a set of capabilities such as data processing, networking, sensing, autonomous operation, intelligent agent, natural language processing, speech recognition, voice recognition, touch interfaces, remote control, self-organization, self-healing, process automation, computation, artificial intelligence, analog or digital sensors, cameras, sound processing systems, data storage, data integration, and/or various Internet of Things (IoT) capabilities, among others. The connected product may include a form of information technology. The connected product may have a processor, computer random access memory, and a communication module. The product may be considered a value chain network entity that fits in a value chain network to provide product usage data.

[2542] In the example provided, a connected product 14010, an ad-hoc network 14012, an ad-hoc network 14014, a local network 14016, and a local network 14018 communicate with the digital product network service 14002 directly or through a network 14019.

[2543] The connected products may be consumer products, industrial products, or other products that have digital components that may communicate with or at least partially include the digital product network service 14002. The connected products may be various entities within various industries. For example, each of the connected products may relate to apparel, electronics (general), computers and computer peripherals, chemicals (specialty), machinery, food processing, auto parts, steel, retail (online), retail (distributors), retail (special lines), retail (general), retail (grocery and food), electronics (consumer and office), farming/agriculture, food wholesalers, or healthcare products.

[2544] The connected product 14010 communicates directly with the digital product network service. For example, the connected product 14010 may include an antenna to send electromagnetic band communications directly to an entity that hosts the digital product network service 14002. In some embodiments, the digital product network service 14002 is at least partially hosted within the connected product 14010. For example, the connected product 14010

may include sensors that send sensor data directly to various intelligence layer modules of the digital product network service 14002 that are programmed into processors of the connected product 14010.

[2545] The ad-hoc network 14012 includes a connected product 14020 and a connected product 14022. The connected product 14020 and the connected product 14022 communicate directly with each other and collectively communicate with the digital product network service 14002.

[2546] The ad-hoc network 14014 includes a connected product 14024 and a connected product 14026. The connected product 14024 and the connected product 14026 communicate directly with each other and communicate with the digital product network service 14002 through the network 14019.

[2547] The local network 14016 includes a gateway 14030, at least one sensor system 14032, at least one connected product 14034, and additional data sources 14036. In the example provided, the gateway 14030 communicates with each of the sensor systems 14032, connected products 14034, and additional data sources 14036. The gateway 14030 then communicates directly with the digital product network service 14002. In some embodiments, the gateway 14030 hosts the digital product network service 14002.

[2548] The local network 14018 includes a gateway 14040, at least one sensor system 14042, at least one connected product 14044, and at least one additional data source 14046. The gateway 14040 communicates with each of the sensor systems 14042, connected products 14044, and additional data sources 14046. The gateway 14040 then communicates with the digital product network service 14002 through the network 14019. For example, the gateway 14040 may be a router or home automation system hub.

[2549] Network 14019 may be any network for communicating data across large distances. In the example provided, the network 14019 is the Internet accessed through an internet service provider (ISP).

[2550] FIG. 151 illustrates an example of a connected product 14110. In the example provided, the connected product 14110 includes a network interface 14112, at least one processor 14114, and at least one memory 14116. In some embodiments, the connected products 14010, 14020, 14022, 14024, 14026, 14034, and 14044 have configurations that are similar to that of the connected product 14110.

[2551] The connected product 14110 includes at least one network interface 14112, at least one processor 14114, and at least one memory 14116. The network interface 14112 includes one or more communication units that communicate with a network (e.g., the Internet, a private network, and the like).

[2552] The processor 14114 may be any kind of computational or processing device capable of executing program instructions, codes, binary instructions and the like, including a central processing unit (CPU), a general processing unit (GPU), a logic board, a chip (e.g., a graphics chip, a video processing chip, a data compression chip, or the like), a chipset, a controller, a system-on-chip (e.g., an RF system on chip, an AI system on chip, a video processing system on

chip, or others), an integrated circuit, an application specific integrated circuit (ASIC), a field programmable gate array (FPGA), an approximate computing processor, a quantum computing processor, a parallel computing processor, a neural network processor, or other type of processor.

[2553] In the example provided, the processor 14114 includes a data collection module 14120, a data reporting module 14122, a data analysis module 14124, and intelligence services 14126. For example, the modules may be dedicated electronic circuits or non-transitory computer code committed to a computer for instructing the processor to perform the algorithm coded therein and described herein.

[2554] The data collection module 14120 instructs the connected product 14110 to receive data from sensors and/or the network interface 14112 and commit the received data to the memory 14116. The data reporting module 14122 retrieves data stored in the memory 14116 or redirects data from the sensors or the network interface 14112 and transmits the data out from the network interface 14112 to a recipient entity. The data analysis module 14124 and the intelligence services 14126 perform analysis and execute artificial intelligence and/or machine learning algorithms on the data.

[2555] The memory 14116 may be any type of non-transitory storage medium, such as one or more of a CD-ROM, DVD, memory, hard disk, flash drive, RAM, ROM, cache, network-attached storage, server-based storage, and the like. The memory 14116 stores methods, programs, codes, program instructions or other type of instructions capable of being executed by the processor 14114.

[2556] The memory 14116 stores data in various data structures. In the example provided, the data structures include a usage data structure 14130, a sensor data structure 14132, and a derived data structure 14134. The usage data structure 14130 stores data related to the use of the connected product 14110. For example, the usage data structure may store the time, location, settings, and other details regarding when and how the connected product has been used by a user. The sensor data structure 14132 stores data collected from sensors related to the connected product 14110. For example, the sensor data may be stored as quantized digital data corresponding to analog sensor signals generated from sensors within the connected product 14110 or received at the network interface 14112. The derived data structure 14134 stores data derived from the usage data and the sensor data. For example, the data analysis module 14124 may compare usage frequency from the usage data with environmental temperature from the sensor data to determine a frequency of use categorized by environmental temperature range to be stored in the derived data structure 14134.

[2557] FIG. 152 illustrates a digital product network 14200. In the example provided, a collection of digital products 14210 share product data 14212 and enhanced product data 14214 with an intelligence layer 14220. For example, products (including goods and services) may create and transmit data, such as product level data, to a communication layer within the value chain network technology stack and/or to an edge data processing facility. This data may produce enhanced product level data and may be combined with third party data for further

processing, modeling or other adaptive or coordinated intelligence activity at the intelligence layer. This may include, but is not limited to, producing and/or simulating product and value chain use cases, the data for which may be utilized by products, product development processes, product design, and the like.

[2558] The digital products 14210 may include industrial products 14216, consumer products 14218, and other types of connected products that may communicate with the intelligence layer 14220. In some embodiments, the digital products 14210 include at least one connected product 14110 of FIG. 151.

[2559] A third-party data system 14221 shares third party data 14222 with the intelligence layer 14220. For example, the third-party data systems 14221 may share third party data 14222 related to any supporting data used by the intelligence layer 14220 that is not already available in product data 14212.

[2560] The intelligence layer 14220 includes various modules that perform analysis on the product data 14212, the enhanced product data 14214, and the third party data 14220. The analysis outputs configured data 14226 to send to at least one user system 14228.

[2561] In the example provided, the intelligence layer 14220 includes a demand aggregation module 14230, a supply chain management module 14232, a new product development module 14234, a customer relationship management module 14236, a product lifecycle management (PLM) module 14238, a digital twin module 14240, a synchronized planning module 14242, an intelligent procurement module 14244, and a dynamic fulfillment module 14246. It should be appreciated that other embodiments may include other combinations and types of modules without departing from the scope of the present disclosure.

[2562] The user systems 14228 may be third party systems that purchase the configured data 14226, may purchase analytics produced by the user system 14228, or may be systems owned by the same enterprise that operates the intelligence layer 14220.

[2563] In the example provided, the user systems 14228 include a demand aggregation system 14250, a supply chain management system 14252, a new product development system 14254, a customer relationship management system 14256, a product lifecycle management (PLM) system 14258, a digital twin system 14260, a synchronized planning system 14262, an intelligent procurement system 14264, and a dynamic fulfillment system 14266. Each of the user systems corresponds to a different use for the configured data and is generated by a corresponding module in the intelligence layer.

[2564] PLM system 14238 may provide accurate and up-to-date product information accessible throughout the value chain and product lifecycle. The PLM system may enable enhanced cross-function and cross-organizational involvement in the design, collaborative innovation, design for manufacture/procurement, platform-based design philosophies, quicker time-to-market, and improved portfolio management.

[2565] New product development system 14234 is associated with developing and managing product and service value chains that are responsive to customer experience and are transformed by smart real-time data, advanced technologies, and agile innovation. The new product

development systems may contribute to improved design quality, increased productivity, and enhanced communication and visibility. For example, improvements may be realized in: simulations that benefit from virtual model processing in detail without spending resources to physically test design in a real-world environment; monitoring with up to date/real time monitoring of user habits for future designs; ease of assembly design; design for ease of manufacturing/collection of parts that will form the product after assembly; design and conformance to specifications providing the fundamental basis for managing operations to produce quality products; and end-to-end transparency, real-time root cause analytics, and proactive resolution driven by customer connectivity for faster problem resolution, problem prevention, customer satisfaction, performance, compliance verification, and avoided warranties. Additional benefits may include supply chain management with the application of the Internet of Things, the use of advanced robotics, and the application of advanced analytics of big data in supply chain management performance and customer satisfaction. In addition to driving other user systems, many of the additional benefits may influence design decisions. Demand forecasting may be improved with predictive analytics to understand and predict customer demand to optimize supply decisions by corporate supply chain and business management. Predictive procurement may forecast the future price trends, price fluctuations, future risks to manage and the potentials required with the aid of a proper analysis based on previous procurement data. Real time/up to date product management may improve customer engagement and extend product lifecycles. Firms (manufacturing firms or 3rd Party contractors) may develop the capabilities to provide services and solutions that supplement their traditional product offerings (e.g., equipment maintenance, data migration, data storage).

[2566] In customer relationship management system 14236, an integrated solution can combine customer profiles, interactions, and transaction information from multiple applications to provide a view of customers with a solution that is equipped with industry-specific functionalities as well as business intelligence capabilities. For example, the digital product network may enable: remote diagnosis such that the subjects can be separated by physical distance instead of the subject being co-located with the person or system performing diagnostics; inter-machine connectivity (M2) by enabling a sensor or meter to communicate the information it records to application software that can use it; and warranty/repair with proactive and pre-emptive warranty management that becomes easier with an IoT based digital warranty management system. The digital product network may further improve: brand/product agility with real time product monitoring and ability to quickly survey the marketplace leading to greater brand agility; digital product quality with end-to-end transparency, real-time root cause analytics, and proactive resolution driven by customer connectivity; simulation by giving customer tools to virtual model process/use VR and AR in detail without spending resources to physically test design in a real-world environment; fractional ownership usage and tracking and physical good real-world compliance to meet parameters of agreements; common platform and product architecture for a set of stable components that support variety and ability to evolve in a

system by constraining the linkages among the other components; and design for consumption insights and methods to improve how customers use/consume products.

[2567] FIG. 153 illustrates an example digital product network 14300 and FIG. 154 illustrates a method 14400 of using the product level data according to some embodiments of the present disclosure. The digital product network 14300 is similar to the digital product network 14000, where like numbers refer to like components.

[2568] Digital products 14310 are similar to digital products 14210. In the example provided, the digital products include a set of digital products each having a product processor, a product memory, and a product network interface. In some embodiments, one of the digital products 14310 is a product network control tower that has a control tower processor, a control tower memory, and a control tower network interface. In some embodiments, the product network control tower is a server or a product that is not one of the digital products 14310. The product processor and the control tower processor collectively include non-transitory instructions that program the digital product network system as described herein. For example, the intelligence layer 14320 may be distributed amongst the digital products 14310 and remote servers.

[2569] In some embodiments, the digital products 14310 include a display 14311. In some embodiments, the display 14311 is associated with the product network control tower. The display 14311 presents images to a user of the display 14311. For example, the display 14311 may be a screen on a mobile phone, a television, a projector, or the like.

[2570] In the example provided, the set of digital products and the product network control tower have a set of microservices and a microservices architecture. The digital products 14210 or the digital products 14310 generate product level data at the product processor in task 14410 of method 14400. The digital products 14210 or digital products 14310 transmit the product level data from the product network interface in task 14412.

[2571] The product network control tower receives the product level data at the control tower network interface in task 14414. In the example provided, the product processor and the control tower processor are further programmed to communicate based on a shared communication system configured for facilitating communication of the product level data from the set of digital products amongst themselves and with the product control tower. In some embodiments, the shared communication system includes an electromagnetic licensed to an enterprise who operates or owns the digital product network 14300. In some embodiments, the communication system includes a shared security protocol for communicating over shared electromagnetic bands, local area networks, Internet, 5G, and the like.

[2572] The digital product network 14300 encodes the product level data as a product level data structure configured to convey parameters indicated by the product level data across the set of digital products in task 14416. The digital product network 14300 writes the product level data structure to at least one of the product memory and the control memory in task 14418. The digital product network 14300 processes the product level data structure in task 14420. The digital product network 14300 transmits the processed data to the user system in task 14422.

[2573] In some embodiments, the intelligence layer 14320 includes a graphical user interface (GUI) module 14340 and a proximity module 14342. The GUI module may generate at least one user interface display for presentation on the display 14311. The GUI module 14340 may generate the parameters of at least one digitally enabled product of the set of digital products in the at least one user interface display and may generate a proximity display of proximal digital products of the set of digital products in the at least one user interface display. In some embodiments, generating the proximity display includes generating the proximity display of proximal products that are geographically proximate, where the digital product network is further programmed to filter the proximal products by at least one of product type, product capability, or product brand. In some embodiments, generating the proximity display includes generating the proximity display of proximal products that are proximate to one of the set of digital products by product type proximity, product capability proximity, or product brand proximity.

[2574] In some embodiments, the intelligence layer 14320 includes a data integration module 14344. In some embodiments, the intelligence layer 14320 includes an edge computation and edge intelligence module or edge module 14346 for edge distributed decision making among the set of digital products. In some embodiments, the edge module 14346 is configured for edge network bandwidth management between or out of the set of digital products.

[2575] In some embodiments, the intelligence layer 14320 includes a distributed ledger system module 14348. In some embodiments, the distributed ledger system may be distributed exclusively within the digital products 14310. In some embodiments, the distributed ledger is a block chain ledger.

[2576] In some embodiments, the intelligence layer 14320 includes a quality management system having a product complaint module 14350 for capturing product complaints at the set of digital products. In some embodiments, the digital products 14310 detect complaints about other digital products 14310. For example, a digital product may use machine vision or sound processing to identify dissatisfaction of a user while the user is using a different digital product.

[2577] In some embodiments, the intelligence layer 14320 includes a product condition module 14352. Product condition module 14352 may identify a condition of the set of digital products. Product condition module 14352 may further encode the condition as one of the parameters of the product level data structure. Product condition module 14352 may further yet track and/or monitor the condition across the set of digital products. For example, a bicycle manufacturer may monitor the condition of sold smart bicycles to determine potential demand for repair parts or new bicycles. In another example, a rentable scooter company may monitor the condition of the active scooters in the scooter fleet to budget for repairs and replacement scooters.

[2578] In some embodiments, the intelligence layer 14320 includes a smart contract module 14354 for enabling the creation of smart contracts based on the product level data structure. In some embodiments, the intelligence layer 14320 configures the smart contracts based on a co-

location-sensitive configuration of terms such that smart contract terms and conditions depend on proximity of a plurality of digital products of the set of digital products.

[2579] In some embodiments, the intelligence layer 14320 includes a robotic program automation (RPA) module 14356. In some embodiments, the RPA module 14356 is configured to gamify an interaction based on what digital products are in the set of digital products. In some embodiments, the RPA module 14356 generates RPA processes based on use of a plurality of digital products of the set of digital products.

[2580] FIG. 155 illustrates an example of a digital product network system 14508 where a data enhancement system 14510 receives data from digital products 14512 for use by data user systems 14514. In some embodiments, the data enhancement includes at least one of data fusion and data integration to leverage cross-product data. The data enhancement system 14510 may be part of the intelligence service or layer, part of a digital twin, part of a control tower, in distributed processors in the products, or in other suitable systems.

[2581] The digital products 14512 are similar to the connected products 14110 described above. Each of the digital products 14512 provides data to the data enhancement system 14510. In the example provided, three different digital products 14512 are sharing data with the data enhancement system 14510. The data may be usage data for the product, sensor data collected by the product, data retrieved from other products, data incorporated from external sources, or other data obtained through other methods. For example, usage data may include a timestamp indicating when a product was used, length of time data indicating how long the product is in use, data indicating what other products the product interacted with during use, and any other suitable usage data. Sensor data may include environmental data, condition data, image data, sound data, and the like.

[2582] The data user system 14514 may be any systems that use or generate enhanced data. In some embodiments, the data user systems incorporate the data enhancement system 14510. For example, a machine learning system may train on various data streams from the products 14512 to generate enhanced data. In the example provided, the data user systems 14514 include AI/ML systems, Robotic Process Automation (RPA) systems, and digital twin systems.

[2583] In some embodiments, the digital product network system 14508 is a construction, home improvement, quality control, or similar system. For example, the products 14512 may be part of a family of tools. A laser level may provide leveling data input to a hand held self-levelling drill for ensuring accurate drill positioning. The digital product network may retrieve relevant specifications (e.g., for proper load bearing) provided from a job control facility. A tool belt may indicate the appropriate tool to use or access for the next task based on the specification. A tool box with digital capabilities may then indicate the appropriate drill bit and fastener type based on the material of the substrate to be drilled. The self-leveling drill may then retrieve the specification to set rotation speed, turn on or off a hammer drill function, etc. Data generated by the digital product tools may then be combined for validation of proper execution according to a workmanship specification.

[2584] In some embodiments, the digital product network system 14508 may be an air quality system, an energy auditing system, or a similar system. For example, the digital products 14512 may be cleaning products, air heating and cooling products, air filter products, window state detection products, or the like. A digital vacuum cleaner may detect the amount of dust and debris picked up during vacuum operations. The data enhancement system 14510 may then then fuse the dust data with data from a digital heating/cooling and air filter product system and weather data from a third party. Data user system 14514 may then train an AI system, an ML system, an RPA system, or the like with the fused data to predict indoor air quality metrics and potential causes of poor indoor air quality.

[2585] In some embodiments, the digital product network system 14508 is a sleep quality system. For example, the digital products 14512 may include a digital bed product, a light switch product, a refrigerator door state detector, or the like. The digital bed product may detect sleep duration, restlessness, and other sleep data. The light switch product may indicate the status of lights to indicate the amount of ambient light near the bed. The refrigerator door state detector may indicate what time the door was last opened before the user started sleeping in the bed. The data enhancement system 14510 may then fuse the sleep data with refrigerator use data and ambient light data. The data user system 14514 may then train an AI system, an ML system, an RPA system, or the like with the fused data to identify potential foods or eating behavior that may be contributing to poor sleep.

[2586] In some embodiments, the digital product network system 14508 is an electrical circuit analysis system. For example, the digital products 14512 may include a circuit breaker digital product, sensitive electronic products, or the like. The circuit breaker digital product may generate circuit use data. The sensitive electronic products may generate performance data or input voltage data. The data enhancement system 14510 may then fuse the circuit use data with performance data and voltage input data from various home digital products. The data user system 14514 may then train an AI system, an ML system, an RPA system, or the like with the fused data to map circuits in a building, recommend different receptacles to use for sensitive electronics to avoid performance issues from voltage drops on heavily loaded circuits, or the like.

[2587] In some embodiments, the digital product network system 14508 is a child entertainment management system. For example, the digital products 14512 may include digital children toys, televisions with viewing category data, or the like. The digital children toys may generate use data. The televisions may generate data indicating the time and duration of children show viewership. The data enhancement system 14510 may then fuse the children toy use data with the children show viewership. The data user system 14514 may then train an AI system, an ML system, an RPA system, or the like with the fused data to identify the types and features of toys that draw children away from the television, market new toys, develop new toys, calibrate toy focus groups, or the like.

[2588] In some embodiments, the digital product network system 14508 is a curation system for relating digital entertainment content to augmented reality. For example, the digital products

14512 may include televisions, augmented reality headwear, GPS locators, or the like. The data enhancement system 14510 may then fuse the television data with location information and landmark information. The data user system 14514 may then train an AI system, an ML system, an RPA system, or the like with the fused data to contextualize augmented reality depictions based on the substance of entertainment choices made on a playback device. For example, a television show set in town X may be linked to phone and headset digital products to present—in augmented reality—depictions, labels, markers, and other things that are thematically related to the substance of the television show while the user is in town X. The labels and markers may identify buildings where scenes occurred in the television show, such as indicating that "this building is where the Mafia Boss Z ran his operation." In some embodiments, the system may present material related to botany. For example, augmented reality may curate indicators of flora-related environment features, etc. This could be used to curate a "tour" of a location new to a user. In some embodiments, the system may suggest five routes through a city when the user enters the city. The routes may be supplemented by augmented reality pertaining to user interests inferred from user media/entertainment consumption. The system may then offer related content on a user media player, television, book reader, phone etc.

[2589] In some embodiments, the digital product network system 14508 is an exercise system. For example, the digital products 14512 may include treadmills, exercise bicycles, stair mills, medicine balls with sensors, machine vision products, or the like. The exercise products may generate recordings, summaries, and analysis of workouts across a range of devices. The data enhancement system 14510 may then fuse the data generated across the exercise equipment products. The data user system 14514 may train an AI system, an ML system, an RPA system, or the like with the fused data to guide a user to use equipment in a manner that complements what the user has done on other equipment. The system may coordinate with devices that understand which muscle groups, calories, etc. are implicated or used. For example, when a user rides ten miles on a bike but has not used a treadmill, weights, step counter, etc., the system may indicate that the user should perform some exercise on specific equipment for a given duration based on the usage information. In some embodiments, the system may be used to monitor patients in cardio rehab. In some embodiments, the system may monitor athletes for sports-specific enhancements, including based on training sets of data by elite athletes across their platforms.

[2590] In some embodiments, the digital product network system 14508 is a carbon footprint calculation system. For example, the digital products 14512 may include personal devices or devices that detect actions that contribute to carbon release, such as cars, thermostats, appliances, food purchases (POS data), clothing, etc. The data enhancement system 14510 may then fuse the data generated across the carbon footprint calculation products. The data user system 14514 may then train an AI system, an ML system, an RPA system, or the like with the fused data to create a plan in line with a personal goal, family goal, business goal, regulatory requirement, or the like. In some embodiments, the plan implements device control to limit use of high-carbon release appliances when the footprint exceeds a threshold.

[2591] In some embodiments, the digital product network system 14508 is a cross-platform or cross-product reputation system. For example, the digital products 14512 may include various digital products that are capable of interacting with online communities. The data enhancement system 14510 may then fuse the data generated across the digital products. The data user system 14514 may then train an AI system, an ML system, an RPA system, or the like with the fused data to authenticate upstanding digital citizens and identify digital bad actors. The system may identify cheating, poor behavior, poor sportsmanship, adult language, or other indicators of potential activities that may conflict with terms of use or rules in various online communities, forums, applications, and games. The system may use metaverse IDs, government IDs, credit reports, criminal reports, or the like. The information may be shared across devices (e.g., personal computers, gaming devices, game consoles, gaming handhelds, mobile devices, wearables, virtual reality headsets, etc.) and databases. Metaverse IDs may be tied in with government IDs (e.g., state IDs, federal IDs, driver's licenses, passports, etc.) which may then also be tied to an individual's ID across one or more product categories (e.g., an ID for a website, an ID for an entity, a general metaverse ID), such that poor behavior, cheating, hacking, or the like is able to be flagged and/or punished across platforms. In some embodiments, the following types of behaviors are tracked: posting hateful content/discussion on social media, using cheating third-party programs in competitive environments and/or secure applications (e.g., cheat programs in video games, DDoSing websites/apps/game servers, terms of service violations of websites/apps/secure databases, money/transaction fraud through taking advantage of system vulnerabilities or third party programs, etc.). The IDs may be used to log into PCs, laptops, mobile devices, smart watches, smart devices, or the like. The IDs may be tied to a network gateway, cellular IDs, or other information further up the data stream from the device to prevent data from any device, IP address, user, or the like related to the flagged ID from participating in certain activities. Also, such traffic and interactions may be throttled, may be modified, subject to auditing, subject to real-time AI/ML monitoring, and the like. Furthermore, AI/ML processes may be trained to identify cheats, ToS violations, poor behavior, poor sportsmanship, etc. AI chipsets may be developed and implemented in devices for identifying such behaviors, programs, and the like. In some embodiments, the system includes incentive programs that provide rewards (e.g., NFTs) for good behavior across products. The rewards and financial details may be embodied in a digital wallet.

[2592] In some embodiments, the digital product network system 14508 is a personal health management system. The digital products 14512 may be a family that includes an implantable/permanent medical device, a wearable device, a smart phone, an external treatment device, or other health products. Implantable devices may generate data for tracking of blood chemistry, blood pressure, immune response, other "lab" data, as well as internal load bearing (such as to measure relative pressures on a joint). Wearable devices may measure and generate data for generalized health conditions, movement, activity, etc. Smart phone devices may measure and generate data for location and various user behavior characteristics, including social engagement, affect, happiness, and social metrics. External treatment devices may

generate data indicating compliance with medication, physical therapy, and other treatment regimens. The data enhancement system 14510 may then fuse the data generated across the digital products and the data user system 14514 may then train an AI system, an ML system, an RPA system, or the like with the fused data to form a digital twin of the patient and the regimen for simulation, diagnosis, adjustment of treatment, communications and coaching, advance problem detection, etc. For example, the personal health management system may automate diagnosis, prescription, insurance (underwriting, making claims, auditing, payout, adjustment), treatment (medication, PT, surgery), long-term health care planning and recommendations, recommendations for wellness improvement (exercise modifications, social engagement), gamification of health-related behaviors, and other health related tasks and fields. In some embodiments, the system may monitor sleep patterns, heart rate, blood pressure, and other health parameters combined with data from a smart refrigerator to recommend the food a person should be eating to improve overall health.

[2593] In some embodiments, the digital product network system 14508 is an automobile digital reality system. The digital products 14512 may include automobiles, hearing devices, augmented reality (AR) devices, virtual reality (VR) devices, mixed reality (MR) devices, and the like. Such a family of products may revolve around a customer's car and look to leverage data streams across various products that could link to the vehicle. For example, fusing driving data and in-vehicle passenger observation with hearable data including noise, entertainment tracks, and spoken word content may give a holistic sense of the driver or passenger. An in-ear device may be specifically designed to work in a family of products with the car. AR/VR headsets may be equipped to help a driver learn to drive a specific car based on the current status and configuration of the car as determined by the products, rather than just for a type or model of car detached from the current configuration. An AR/VR headset may be configured to allow users to play social video games, such as games where a car owner may race their own car against friends in their own cars based on data indicating current tire condition, fuel levels, locations, etc.

[2594] In some embodiments, the digital product network system 14508 is a product family that has elements configured to reside and operate in a digital wallet, in the metaverse, in AR/VR devices, in a vehicle, in individual rooms of the home, at work, in a smart city, in nature, etc.

[2595] In some embodiments, the digital product network system 14508 is an industrial system. The digital products 14512 may include machine sensors indicating the need for adjustments to the machine (e.g., a need for increasing fan usage for a machine that is too hot, a need for lubrication, a need for materials in terms of manufacturing or packaging systems, a need for fixing broken or missing rollers indicated by a conveyor belt sensor, or the like). The data enhancement system 14510 may fuse sensor data within a warehouse for specific purposes such as environment (e.g., temperature, airflow, humidity, lighting, UV light, etc.). This fusing may relate to each of these types of data, or a combination of this data may be fused on a separate device such that the results of this data from an analysis engine may be only outputted

to a mobile device based on thresholds (e.g., too cold - suggest heat, too much humidity - initiate dehumidifier or initiate humidifier when too dry, pull down shades if too much UV light, open windows or turn on fans for increased airflow etc.). This environment data may be fused with sensor data relating to manufacturing systems or systems for packaging devices. This data may be fused separately to an analysis engine providing results of machine statuses. The data user system 14514 may then train an AI system, an ML system, an RPA system, or the like with the fused data to create an analysis engine, recommendation engine, and/or automation engine that outputs to a software application on the mobile device with results of a combination of machine sensing and environment sensing to provide recommendations and/or automate systems to resolve environment issues or machine status issues. The system may also monitor a combination of environment conditions with machine status conditions for determining optimal conditions for greatest output to automatically adjust the machine and environment conditions to provide the optimal conditions while keeping costs minimal.

[2596] In some embodiments, the digital product network system 14508 is a sports equipment system. The digital products 14512 may include golf clubs and golf balls, baseball bats and baseballs, hockey sticks and hockey pucks, tennis racquets and tennis balls, bowling balls, and the like. The various striking implements and balls may generate data indicating how far, how straight, how on target the ball travels. A machine vision system or sensors in the striking implement may generate data about acceleration, angle, rotation, and other data about the swing of the striking implement. The data enhancement system 14510 may then fuse the data generated across the sports equipment, and the data user system 14514 may train an AI system, an ML system, an RPA system, or the like with the fused data to identify corrections to coach the user and improve the swing. In some embodiments, the system fuses data from smart exercise machines and smart watches/wearables.

[2597] In some embodiments, the digital product network system 14508 is a physical retail system. The digital products 14512 may include items to be purchased, packaging of the items, a shopping cart, a smartphone, or the like. The products may indicate the type of items added to the cart, the quantity of items added to the cart, the items on a shopping list in a smartphone, etc. The data enhancement system 14510 may fuse the data, and the data user system 14514 may train an AI system, an ML system, an RPA system, or the like with the fused data to make suggestions for complementary products, indicate the locations of the complementary products in the store, offer incentives, or the like. For example, the incentives may include discounts, reward points, digital badges, or the like.

[2598] In some embodiments, the digital product network system 14508 is a commercial lending risk management system. The digital products 14512 may include products in a warehouse, packaging, environment sensors, or similar products. The products may generate data indicating a proximity of different products in the same warehouse or the presence of the same or different products in different warehouses. The data enhancement system 14510 may fuse the data, and the data user system 14514 may train an AI system, an ML system, an RPA system, or the like with the fused data to alert the lender of movements in inventories that may

indicate risks or non-compliance with loan (credit line) terms or put pricing in a different bracket or trigger extra fees. The system may also indicate extreme risks that government authorities could take interest in, such as hazardous or explosive materials stored or moved in dangerous conditions.

[2599] In some embodiments, the digital product network system 14508 is a media consumption recommendation system. The digital products 14512 may include microphones, televisions, and the like. The products may generate data indicating the music a person listens to, the person's taste in the books, the person's interest in television and movie content. The data enhancement system 14510 may fuse the data, and the data user system 14514 may train an AI system, an ML system, an RPA system, or the like with the fused data to recommend video games that may appeal to the person.

[2600] In some embodiments, the digital product network system 14508 is a health improvement system. The digital products 14512 may include networked exercise equipment, rowing machines, stationary bicycles, a smart appliance (e.g., refrigerator), wearables (e.g., smart ring or smart watch), smart beds, and other products. The products generate data that may be used to gain a better understanding of a user's overall health. The data enhancement system 14510 may fuse the data, and the data user system 14514 may train an AI system, an ML system, an RPA system, or the like with the fused data to learn about the user's eating habits, exercise habits, and sleeping/sitting habits. The system may determine if the user is burning too many calories or eating the wrong foods given their workout routines. The system may also track the user's sleep patterns and determine whether the user is exercising and/or eating at the right time. The networked exercise equipment may be owned by a user or may be owned by a gym. When the equipment is located at a gym, the exercise devices may pair with the user's phone or wearable device to know who is on the equipment, how long they used it, and the like. The smart refrigerator may include sensors and imaging devices that determine what the user is buying, what they are actually eating, and when they are eating it. In some embodiments, the smart refrigerator includes a profile of the user (e.g., family with kids, single, cohabitating but no kids, etc.) and/or a voice-controlled interface that verifies who is eating, what they are cooking and the like. The data may train the AI system to determine the user's overall health profile. The system may be configured to make recommendations to the user, such as better foods to eat, better times to eat, how much to exercise, what times to exercise, and the like.

[2601] In some embodiments, the digital product network system 14508 is a product maintenance system. The digital products 14512 may include any product or machinery that has some level of connectivity and some components of warranties/repair. The resulting data sets and cumulative data layer can be analyzed and used for remote diagnosis, warranty pricing, repair pricing, offers for replacements, offers for upgrades, or the like. For remote diagnosis, the subject can be separated by physical distance instead of the subject being co-located with the person or system performing the diagnostics. For warranty and repair pricing, proactive and pre-emptive warranty management becomes easier with an IoT based digital warranty management system.

[2602] In some embodiments, the digital product network system 14508 is a power consumption management system. The digital products 14512 may include thermostats, light switches, light bulbs, refrigerators, coffee makers, HVAC products, and the like. A power consumption monitor split out by breaker at an electrical service panel box can be linked to various household appliances/circuits. In some embodiments, the products provide sufficient data that the circuit panel box monitor may be omitted in favor of watching the usage patterns by product. A single circuit may be monitored for understanding different appliance consumption patterns (fridge on/off, vacuum on/off, HVAC on/off/heat/cool/fan) and may be a parent-umbrella over other smart devices (thermostats, light switches/bulbs, etc.). The system may combine the data and perform analysis of usage patterns (fridge temperature setting, coffee maker on-time, thermostat/HVAC usage, etc.) for maintenance, behavioral usage guidance, etc. For example, an HVAC may monitor airflow by power consumption (accounting for temperature, humidity, etc.) for recommending filter changes or behavioral suggestions to save energy.

[2603] In some embodiments, the digital product network system 14508 is a task management system. The digital products 14512 may include location sensors, status sensors, task completion sensors, and the like. The data enhancement system 14510 may fuse the data, and the data user system 14514 may train an AI system, an ML system, an RPA system, or the like with the fused data to coordinate tasks and/or services in a metaverse, in real life, or in both. For example, the system may use geolocation, couponing, logistics, etc. to determine which employees, family members, or other participants are in the best position to perform a task. The best position may be pre-programed or AI optimized for priorities such as savings, timing, importance, or the like. The system may provide task ordering, task instruction, and coordination of the other participants accordingly. The system may operate based on tasks to be performed in real life and in the metaverse work environments and may link the metaverse and real life activities. In some embodiments, the system may put services out to bid. In some embodiments, the system provides a metaverse work environment and a market for services in the metaverse for metaverse workers and real-life workers to work collaboratively to get to a result.

[2604] In some embodiments, the digital product network system 14508 is a personal health system. The digital products 14512 may include wearable devices, eyeglasses, eyeglasses with liquid lenses, active clothing (heating, cooling, stress/strain, forces, etc.), recreational devices (GPS monitor devices, etc.), building and other environmental systems (temperature, humidity, lighting, etc.), automotive systems, and the like. The products generate sensor or other data defined (micro or macro) that impacts personal health. The data enhancement system 14510 may fuse multiple data streams, including those outside of ecosystems that could be integrated to monitor and manage personal health. The data user system 14514 may train an AI system, an ML system, an RPA system, or the like with the fused data to augment and validate certain analytical models (GPS navigation algorithms, etc.). The system may provide active alerts, automated reporting that builds a personal profile over time, suggested active measures, instructions to enact the active measures (e.g., by activated clothing or other devices, etc.). The

system may perform psychological evaluation, recommendations, referrals, identification of hazards such as temperature, UV exposure, pathogen presence, etc., accumulated exposure to carcinogens or other things that could lead to long-term illness, life-long medical analysis, activating clothing for temperature changes, massage, etc.

FUTURES SMART CONTRACT

[2605] FIG. 156 illustrates a smart futures contract system 15000. The smart futures contract system 15000 may relate to, for example, a set of smart contracts associated with various value chain network entities (e.g., goods with a intelligence features, packaging or containers with intelligence features, infrastructure or fixtures with intelligence features, transport systems with intelligence features, planning systems, etc.), such as ones that are configured to manage or mitigate risk (such as by hedging for or providing improved outcomes in case of various potentially adverse contingencies, such as shortages in supply, supply chain disruptions, changes in demand, changes in prices of inputs, changes in market prices, and the like), to provide operational efficiencies (such as by insuring availability of items based on plans or predictions), to improve returns (such as by obtaining inputs at more favorable prices than would otherwise be available, and the like) and/or to provide other benefits, such as by engaging with futures markets (including various markets for options, futures, and the like involving commodities, equities, currencies, energy, and other items) that are relevant to a set of items that are provided by or within the value chain network. The items involved in the smart contracts may include goods, services, and any blended product that includes components of goods and services of the various types described herein and in the documents incorporated herein by reference.

[2606] In some embodiments, robotic process automation may operate in demand-side planning to orchestrate futures contracts. For example, a robotic agent may perform a set of de-risking algorithms to configure terms and conditions for a set of smart futures contracts that set prices, delivery times, and delivery locations for a set of inputs (e.g., parts, components, fuel, materials, or many others) that will be required in order to provide a planned set of inventory of an item, such that the set of smart futures contracts automatically execute to obtain commitments for supply upon discovery of market conditions that satisfy a set of parameters or conditions (such as pricing conditions) set in the de-risking algorithms. The robotic agent may be trained on a training set of data, such as a training set of interactions of a set of expert procurement professionals with a set of inputs, such as demand planning inputs (e.g., demand forecasts, inventory forecasts, and the like, demand elasticity curves, predictions of competitive behavior, supply chain predictions and many others), including contracts recommended or engaged by such professionals under such conditions. This may include interactions of such professionals within enterprise demand planning software suites. The agent may include or be trained to interact with a set of demand planning models, such as models that forecast demand factors, supply factors, pricing factors, and other factors, including anticipated equilibria between supply and demand, and ones that generate estimates of appropriate inventory, recommendations for pricing, location and timing recommendations for supply and/or distribution, and the like. In

embodiments, the de-risking algorithms may include ones for reducing a variety of risks and contingencies, including the ones noted above, such as shortages in supply, supply chain disruptions, changes in demand, changes in prices of inputs, and changes in market prices, as well as ones involving macro-economic factors, geopolitical disruptions, disruptions due to weather and climate, impacts of epidemics or pandemics, counterparty risks (including anti-money laundering risks, credit risks, risk of default, and many others), and the like. In embodiments, de-risking algorithms may include algorithms that seek to mitigate risks created by use of other algorithms, such as ones that help identify various biases, which may include input bias (such as biases in training inputs, biases in models, biases due to incomplete or inaccurate data, and the like), biases in weighting, and others, as well as ones that identify where algorithmic performance is inferior to human performance (such as where intelligence systems cannot effectively replicate some important element of a human decision maker). In embodiments, such de-risking algorithms can provide a set of recommendations for adjustments to smart futures contracts and/or to the de-risking algorithms that are used to configure smart futures contracts. In some embodiments, the smart futures contract system 15000 operates from, embodies, or integrates with a digital twin (e.g., supply chain digital twin or a general digital twin interface).

[2607] In some embodiments, the smart contract system 15000 configures and/or enters a set of smart future contracts with the futures system 15006 based on conditions in a value chain network. In some embodiments, the smart futures contract system 15000 acts on the value chain network based on conditions and prices in a set of futures markets.

[2608] In some embodiments, the smart futures contract system 15000 may be at least partially incorporated in a product or product packaging to manage or mitigate risk. For example, if a product or product packaging is exposed to adverse environmental conditions, a smart futures contract may be automatically configured as an option to acquire a set of replacement products, covering the contingency that the product has incurred damage that will require replacement. This may occur, for example, while the product/package is still in transport, such as determined by sensors on the product, the package, a transport vehicle, or proximal infrastructure, such as before it is possible or convenient to test a set of products well enough to determine whether replacement will in fact be required. Configuration of such an option-type futures contract may be based on a model or predictive artificial intelligence system (such as one generated by an algorithm that may be trained on historical data sets and other inputs) that provides a prediction as to the probability that a product (or some subset thereof) will need to be replaced based on known exposure data, as well as upon a prediction of the impact of the need for replacement (including the impact of delays and/or reduced supply on pricing and other factors). In embodiments, the smart futures contract may be configured with an appropriate duration of option to allow for determination of the actual extent of need for replacement, an appropriate option price, and the like, such that the risk of a catastrophic loss is mitigated, while the likelihood of a profitable outcome is maintained to the extent possible under the circumstances. In embodiments, an option-type futures contract to acquire replacement goods may be paired

with an automatically configured set of futures contracts that mitigate the risk by setting terms and conditions for alternatives to replacement, such as a set of smart contracts that offer refunds to customers, that offer alternatives goods or services, that offer incentives to accept delayed goods, or the like. Such contracts may be configured using similar inputs, models and algorithms to the ones used for other smart futures contracts described herein.

[2609] In some embodiments, the smart futures contract system 15000 renegotiates a set of future prices based on a current market state. Renegotiation may be performed by a set of robotic process automation agents or other artificial intelligence system, such as trained on historical data, on feedback from outcomes, and/or upon human interactions involved in contract negotiations. As one of many examples, upon recognition of a likely widespread supply chain disruption for an input component for a set of goods, the system may offer to renegotiate future pricing of inputs (such as to ensure continuity of supply), future pricing of outputs (such as to reflect likely increases in market prices), and other factors, which may be offered in a set of futures smart contracts that embody offered terms and conditions of renegotiation.

[2610] In some embodiments, the smart futures contract system 15000 relates to or undertakes predictive procurement to forecast future price trends, price fluctuations, future risks to manage, and other elements potentially required, optionally with the aid of an analysis, model, or the like based on previous procurement data. This may include models that account for weather, climate, geopolitical situations, epidemics/pandemics, counterparty behaviors, government behavior (including import and export regulations and their enforcement), traffic, congestion at ports, inventory levels of key components, availability and pricing of materials, and many other factors.

[2611] In the example provided, the smart futures contract system 15000 includes at least one contracting entity 15001, at least one data source 15002, at least one intelligence service 15004, at least one futures system 15006, and at least one distribution system 15008. The contracting entity 15001 is the entity of the value chain network that owns, rents, leases, purchases, or otherwise controls the intelligence service 15004. For example, the contracting entity 15001 may be a manufacturer of goods who is interested in managing the risk of raw material scarcity in future product cycles. In another example, the contracting entity 15001 may be an apparel manufacturer who is interested in early identification and price negotiation for fabrics, dies, designs, or the like that may become popular for the next fashion season. In yet another example, the contracting entity 15001 may be an industrial entity who monitors the status of components within various machines and places orders for future delivery of components that are predicted to fail in the near future. In the industrial entity example, the contracting entity 15001 may configure the intelligence service 15004 to compare future prices for purchasing new machines with futures prices for selling non-failing components of the machine to enter contracts for "parting out" a machine rather than repairing when futures prices indicate that parting out and purchasing a new machine is less costly than continued repair.

[2612] The data source 15002 generates data for use by the intelligence service 15004. The data may be locally measured (such as by sensors or IoT devices), retrieved from third parties,

determined or enhanced by other intelligence services, or gathered in any other way without departing from the scope of the present disclosure. For example, the data source 15002 may generate product level data, customer level data, or data at other value chain levels. In the example provided, the data source 15002 includes directly connected customers 15010, intelligent products 15012, and environment sensors 15014. The intelligent products 15012 and environmental sensors 15014 may provide sensor data associated with any measurable parameter, such as at least one of vibration, humidity, temperature, pressure, proximity, level, accelerometers, gyroscope, infrared sensors, optical sensors, MEMS, liquid lenses, shock, security, machine, product, pneumatic, conductive, state dependent frequency monitor, ultrasonic, capacitance, or microwave. The data source 15002 may generate data associated with any suitable topic or industry, such as at least one of Internet of Things (IoT), social networks, social media, automated agent behavior, business entity behavior, human behavior, data source outcomes, data source parameters, wearables, personal, financial, economic, credit score, environment, weather, labor, employment, census, crime, health, living, journalism/media, entertainment, location/motion, loyalty, reputation, real estate, reviews, marketing, food and drug, education, retail, transportation, biometric, travel, event, or customer activity.

[2613] The intelligence service 15004 may be a configured version of the intelligence service 13004. For example, the intelligence service 15004 may be adapted to execute the specific functions of the smart futures contract system 15000 described below. In the example provided, the intelligence service 15004 includes at least one data storage 15019, a smart contract service 15020, a demand aggregation service 15022, a digital wallet 15024, a risk determination service 15026, and a robotic process automation (RPA) service 15028.

[2614] The data storage 15019 may be any type of non-transitory storage medium, such as one or more of a CD-ROM, DVD, memory, hard disk, flash drive, RAM, ROM, cache, network-attached storage, server-based storage, and the like. The data storage 15019 stores methods, programs, codes, program instructions, or other type of instructions capable of being executed by processors of the intelligence service 15004.

[2615] The data storage 15019 stores the data in various data structures. In the example provided, the data storage 15019 includes a risk data structure 15021 and a robotic process automation (RPA) data structure 15022. The risk data structure 15021 stores risk tolerance information, risk identification, risk assessment, and other risk information associated with the contracting entity 15001. For example, the risk data structure 15021 may store a price fluctuation tolerance and a maximum price the contracting entity 15001 may be interested in paying for products in the future.

[2616] The RPA data structure 15022 stores the robotic process automation algorithms executed by the RPA service 15028. The algorithms may use various artificial intelligence embodiments described throughout this disclosure and the documents incorporated by reference herein, such as neural networks of various types, various algorithms and expert systems, and others.

[2617] The smart contract service 15020 creates, modifies, and monitors performance of smart contracts based on data from the data sources 15002, information received from the futures systems 15006, and analysis from other features of the intelligence service 15004. For example, the smart contract service 15020 may detail the type of commodity, a number of units (e.g., barrels of oil, bushels of wheat, ounces of gold, or the like), a contract price to be paid for the commodity, the execution date of the futures contract, and other suitable parameter values in a smart contract governing a futures contract with respect to a commodity. In some embodiments, the smart contract service 15020 may indicate parameter values corresponding to triggering actions, such as initiating a certification process associated with the transaction, initiating a reporting process associated with the transaction, configuring logistics information associated with the transaction, reconfiguring of terms (e.g., premium rates, interest rates, contract price, delivery date, payment due date, and/or the like). It should be appreciated that the types of data that may be used to parameterize a smart contract may differ without departing from the scope of the present disclosure.

[2618] In some embodiments, the smart contract service 15020 may operate autonomously. For example, the smart contract service 15020 may operate without human intervention based on instructions from the RPA service 15028 or based on other criteria provided by the contracting entity 15001.

[2619] In some embodiments, the demand aggregation service 15022 may predict that demand for a specific raw material used in the manufacture of a product may increase in the near future based on data from environment sensors 15014. Based on the predicted demand increase, the smart contract service 15020 may create a smart contract with the futures system 15006 for future delivery of the raw materials in anticipation of a price increase due to the predicted demand increase and other data from data sources 15002 suggesting that production of the raw materials may not outpace the anticipated rise in demand.

[2620] The smart contract service 15020 receives evidence of completion of a task to trigger actions (e.g., payments, recordation, or the like) in response to completed tasks. In another example, the smart contract service 15020 may monitor futures pricing and purchase or sell goods and services based on risk tolerances indicated by the contracting entity.

[2621] The demand aggregation service 15022 aggregates demand across groups, locales, etc. The aggregation may include aggregating demand for at least one of hypothetical products, hypothetical events, hypothetical services, or services related to the hypothetical products or events. The demand aggregation service 15022 monitors demand response across multiple systems, such as how demand responds to changes in supply (e.g., scarcity effects), price changes, customization, pricing, advertising, etc.

[2622] In some embodiments, the demand aggregation service 15022 aggregates information, orders, and/or commitments (optionally embodied in one or more contracts, which may be smart contracts) for one or more products, categories, raw materials, components, logistics reservations, consumables, equipment, or the like. The demand aggregation may include current demand for existing products and future demand for products that are not yet available.

[2623] The digital wallet 15024 stores banking and finance information for payments into and out of the futures system 15006. For example, the digital wallet 15024 may store cryptocurrency information, bank balance and routing information, and other information that may be used to complete transactions in the futures systems and distribution systems 15008.

[2624] The risk determination service 15026 determines the risk associated with events and conditions received by data sources 15002, demand aggregation service 15022, and futures system 15006. For example, the risk determination service 15026 may supply data to the smart contracts service 15020 indicating that the financial risk of waiting to purchase raw materials as they are needed is greater than the risk of purchasing the raw materials in the futures system 15006 at some time before the raw materials are needed for delivery when the raw materials are needed. In some embodiments, the risk determination service 15026 retrieves risk information—such as price fluctuation tolerance—from the risk data 15021. With a low price fluctuation tolerance, the smart contract service 15020 may execute a smart contract for future delivery of the raw materials as the futures price approaches the maximum price the contracting entity 15001 is interested in paying. With a high price fluctuation tolerance, the smart contract service 15020 may allow the future price to exceed the maximum price in the hope that the price may later decrease.

[2625] The robotic process automation (RPA) service 15028 may facilitate, among other things, computer automation of producing and validating smart contracts between the contracting entity 15001 and the futures system 15006. In some embodiments, the RPA service 15028 monitors human interaction with various systems to learn patterns and processes performed by humans in performance of respective tasks. This may include observation of human actions that involve interactions with hardware elements, with software interfaces, and with other elements. Observations may include field observations as humans perform real tasks, as well as observations of simulations or other activities in which a human performs an action with the explicit intent to provide a training data set or input for the RPA system, such as where a human tags or labels a training data set with features that assist the RPA system in learning to recognize or classify features or objects, among many other examples.

[2626] In some embodiments, the RPA service 15028 may learn to perform certain tasks based on the learned patterns and processes, such that the tasks may be performed by the RPA service 15028 in lieu or in support of a human decision maker. For example, the RPA service 15028 may identify that a farmer typically reserves trucking services to transport a crop to a place of sale approximately two weeks before harvesting a crop. The RPA service 15028 may further identify that the farmer performs an annual service on a harvesting machine and that the crop has grown to a consistent height approximately three weeks before harvesting the crop. Based on detecting the annual service of the harvesting machine (e.g., by data from the machine itself, by identifying fuel filters in a credit card receipt, by machine vision identifying the service, etc.) or based on identifying that the height of the crop has reached the consistent height (e.g., by machine vision data from data source 15002), the RPA service 15028 may query the logistics reservations system 15038. Based on the response from the logistics reservations system 15038,

the smart contract 15020 may present reservation options to the farmer or negotiate reservations on the farmer's behalf for trucking services three weeks from the service or crop height determination.

[2627] The futures system 15006 may be any system in which goods and services to be delivered or performed in the future are bought and sold. For example, the futures system 15006 may involve forward contracts, stock exchange futures, options, various derivatives, and the like. The goods and services to be delivered or performed may include real property, commodities, raw materials, finished goods, computation services, or any other physical material or performable service that may be subject to an obligation to deliver or perform in the future. In the example provided, the futures system 15006 includes components futures 15030, materials futures 15032, consumables futures 15034, equipment futures 15036, and logistics reservations 15038.

[2628] The components futures 15034 may relate to machinery parts, repair parts of goods, wearable parts of goods, upgrade parts for goods, parts to be assembled by a manufacturer into a new good, and other component types. In some embodiments, the components futures 15030 are associated with circular economy systems. For example, the smart contract service 15020 may perform circular economy optimization based on futures pricing of goods, such as components.

[2629] The raw materials futures 15032 may relate to material used to create other goods. For example, the raw materials 15032 may be copper, steel, iron, lithium, and the like. The consumables futures 15034 may relate to items that are consumed when creating goods or performing services. For example, the consumables may include razor blades, coffee pods, single use batteries, pork bellies, and the like.

[2630] The equipment futures 15036 may relate to machinery, vehicles, and other equipment. The logistics reservations futures 15038 may relate to future services for warehousing, transportation, and the like. For example, the logistics reservations futures 15038 may include port docking reservations, trucking reservations, warehouse space rental, canal passage reservations, and the like.

[2631] The distribution system 15008 relates to at least one of picking, packing, moving, storing, warehousing, transporting or delivering of a set of items in a supply chain. In the example provided, the smart contract service 15020 enters contracts for delivery, storage, and other handling of the items with the logistics reservations system 15038 in concert with delivery dates and locations detailed in smart contracts for future delivery, storage, and handling of physical items through the distribution system 15008.

[2632] In some embodiments, a value chain may include an that intelligent agent system receives feedback from users regarding respective intelligent agents. For example, in some embodiments, a client application that leverages an intelligent agent may provide an interface by which a user can provide feedback regarding an action output by an intelligent agent. In embodiments, the user provides the feedback that identifies and characterizes any errors by the intelligent agent. In some of these embodiments, a report may be generated (e.g., by the client application or the platform) that indicates the set of errors encountered by the user. The report

may be used to reconfigure/retrain the intelligent agent. In embodiments, the reconfiguring/retraining an intelligent agent may include removing an input that is the source of the error, reconfiguring a set of nodes of the artificial intelligence system, reconfiguring a set of weights of the artificial intelligence system, reconfiguring a set of outputs of the artificial intelligence system, reconfiguring a processing flow within the artificial intelligence system (such as placing gates on a recurrent neural network to render it a gated RNN that balances learning with the need to diminish certain inputs in order to avoid exploding error problems), reengineering the type of the artificial intelligence system (such as by modifying the neural network type among a convolutional neural network, a recurrent neural network, a feed forward neural network, a long-term/short-term memory (LSTM) neural network, a self-organizing neural network, or many other types and combinations), and/or augmenting the set of inputs to the artificial intelligence system.

[2633] In embodiments, a library of neural network resources representing combinations of neural network types that mimic or simulate neocortex activities may be configured to allow selection and implementation of modules that replicate the combinations used by human experts to undertake various activities that are subjects of development of intelligent agents, such as involving robotic process automation. In embodiments, various neural network types from the library may be configured in series and/or in parallel configurations to represent processing flows, which may be arranged to mimic or replicate flows of processing in the brain, such as based on spatiotemporal imaging of the brain when involved in the activity that is the subject of automation. In embodiments, an intelligent software agent for agent development may be trained, such as using any of the training techniques described herein, to select a set of neural network resource types, to arrange the neural network resource types according to a processing flow, to configure input data sources for the set of neural network resources, and/or to automatically deploy the set of neural network types on available computational resources to initiate training of the configured set of neural network resources to perform a desired intelligent agent/automation workflows. In embodiments, the intelligent software agent used for agent development operates on an input data set of spatiotemporal imaging data of a human brain, such as an expert who is performing the workflows that is the subject of development of a further and uses the spatiotemporal imaging data to automatically select and configure the selection and arrangement of the set of neural network types to initiate learning. Thus, a system for developing an intelligent agent may be configured for (optionally automatic) selection of neural network types and/or arrangements based on spatiotemporal neocortical activity patterns of human users involved in workflows for which the agent is trained. Once developed, the resulting intelligent agent/process automation system may be trained as described throughout this disclosure.

[2634] In embodiments, a system for developing an intelligent agent (including the aforementioned agent for development of intelligent agents) may use information from brain imaging of human users to infer (optionally automatically) what data sources should be selected as inputs for an intelligent agent. For example, for processes where neocortex region O1 is

highly active (involving visual processing), visual inputs (such as available information from cameras, or visual representations of information like price patterns, among many others) may be selected as favorable data sources. Similarly, for processes involving region C3 (involving storage and retrieval of facts), data sources providing reliable factual information (such as blockchain-based distributed ledgers) may be selected. Thus, a system for developing an intelligent agent may be configured for (optionally automatic) selection of input data types and sources based on spatiotemporal neocortical activity patterns of human users involved in workflows for which the agent is trained.

[2635] FIG. 157 illustrates an example environment of an edge networking (EDNW) system 16100 according to some embodiments of the present disclosure. In embodiments, the edge networking system 16100 provides a framework for providing edge networking services to one or more edge environments 16102-108. In some embodiments, the edge networking service 16100 may be at least partially replicated in respective edge environments 16102-108. Examples of edge environments 16102-108 in which the edge networking system 16100 may be at least partially replicated include devices 16102, premises 16104, telecom installations 16106, and computing clouds 16108. In these embodiments, an individual instance of the edge networking system 16100 may include some or all of the capabilities and/or modules of the edge networking system 16100 discussed herein, whereby the edge networking system 16100 is adapted for the specific functions performed by the respective edge environment 16102-108 on which the edge networking system 16100 is replicated. Examples of edge devices 16102 include client devices, smart devices, and connected devices, wearable devices, and any other suitable device. Examples of the premises 16104 include home/residential buildings, factory buildings, office buildings, campuses, government buildings, medical buildings, and any other suitable building, campus, or premises. Examples of edge telecom installations 16106 include base stations, satellites, regional data centers, relay stations, signal arrays, and any other suitable telecom installation. Examples of computing clouds 16108 include in-cloud computation networks, private clouds, public clouds, hybrid clouds, multiclouds, infrastructure-as-a-service clouds, platforms-as-a-service clouds, software-as-a-service clouds, and any other suitable type of computing clouds.

[2636] Additionally or alternatively, in some embodiments, the edge networking system 16100 may be implemented as a set of microservices, such that different edge environments 16102-108 may leverage the edge networking system via one or more APIs exposed to the edge environments 16102-108. In these embodiments, the edge networking system 16100 may be configured to perform various types of edge networking services that may be adapted for different edge environments 16102-108. In either of these configurations, an edge environment 16102-108 may provide a networking request to the edge networking system 16100, whereby the request is to perform a specific networking task (e.g., a connection initiation, a series of connection initiations, an encryption of data, a transmission of encrypted data over a connection, usage of a protocol for connection and/or data transmission, a routing determination or calculation, usage of an application-specific protocol for data transmission, an AI chipset

interfacing instance, 5G software definition, AI-assisted or enabled networking, tunable signal filtering, AI-assisted or enabled network enhancement, or digital twin network formulation, simulation, prediction, testing, and/or the like). In response, the edge networking system 16100 executes the requested networking task for the respective edge environment 16102-108.

[2637] Additionally or alternatively, in some embodiments, the edge networking system 16100 may be implemented using one or more specialized chips that are configured to microservices and/or networking tasks. In embodiments, the edge networking system 16100 may communicate via the VCN bus 16110. One or more of the edge environments 16102-108 may be connected to the VCN bus, thereby allowing instances of the edge networking system 16100 to communicate with one another via the bus. The VCN control tower 16112 may also be connected to the bus. As such, one or more instances of the edge networking system 16100 may transmit data to and receive signals from the VCN control tower 16112.

[2638] FIG. 158 illustrates an exemplary embodiment of an environment of the edge networking system 16100 wherein a plurality of VCN system services 16202-206 are connected to the VCN bus 16110. In embodiments, the edge networking system 16100 may transmit data to and/or receive data from one or more of the VCN control tower and/or other VCN system services 16202-206 (e.g., the DPNW system, the ROBO system, an energy system and process such as NRGY system, etc.). The energy system and process may be referred to as the energy system (e.g., NRGY system) which may be or may include an energy system, process, module, service, platform, and/or the like as described in the disclosure. Data received by the edge networking system 16100 from the VCN control tower 16112 may include, for example, data related to VCN tasks to be directed by the VCN control tower and completed by sharing of data between multiple of the VCN entities. The edge networking system 16100 may perform one or more networking tasks according to the one or more VCN tasks, such as encryption codes, routing data, protocol information, data, AI predictions, AI routing information, AI conclusions, or any other suitable data. The edge networking system 16100 may additionally or alternatively transmit data to other of the VCN entities via the VCN bus.

[2639] In some embodiments, the edge networking system 16100 is configured to facilitate optimization of communication and processes between other VCN modules. The edge networking system 16100 may perform one or more networking tasks with relation to one or more of the other VCN modules, for example by optimizing data packet communication and/or encryption protocols for a data stream between two of the other VCN modules, and/or between one or more data sources and other of the VCN modules. For example, a VCN task requiring fast transmission of data from IoT sensors to one or modules of the ROBO system as well as fast reporting of energy systems by the NRGY system to the ROBO system may involve the VCN control tower 16112 instructing the edge networking system 16100 to optimize data routes and protocols between the ROBO system and one or more of the IoT data sources and the NRGY system.

[2640] FIG. 159 illustrates an exemplary embodiment of an edge device 16102 containing an instance of the edge networking system 16100. While FIG. 159 illustrates the edge networking

system 16100 installed on a device 16102, it is to be appreciated that the edge networking system and/or configured instances thereof may be uploaded to/installed/operated on or within any suitable type of edge environment 16102-108 disclosed herein. The instance of the edge networking system 16100 may include one or more modules configured to facilitate performing of networking tasks by the edge networking system 16100. The modules that an instance of the edge networking system 16100 may be specifically changed, added, removed, and/or otherwise tailored to suit the desired performance of the instance of the edge networking system 16100 for the particular edge environment on which the configured instance of the edge networking system 16100 is stored. For example, different configurations of the edge networking system 16100 may be configured for and uploaded to/installed on each of the different types of edge environments 16102-108, as well as to/on individual edge environments within the types of edge environments 16102-108 on a case-by-case basis. The configurations of the individual instances of the edge networking system may be determined by the VCN control tower 16112 according to one or more of the VCN tasks.

[2641] In embodiments, the edge networking system 16100 may include one or more of the following modules: edge device-as-a-service module 16302, application-specific protocol module 16304, edge robotics module 16306, SDWAN module 16308, network customization module 16310, AI chipset interfacing module 16312, 5G software definition module 16314, edge networking AI module 16316, tunable signal filtering module 16318, network routing module 16320, AI network enhancement module 16322, and edge network digital twin module 16324.

[2642] In embodiments, the edge device-as-a-service module 16302 is configured to facilitate provision of one or more functions of the edge environment 16102-108 on which the edge networking system 16100 is installed and/or of one or more functions of the configured edge networking device 16100 to other devices and/or platforms with which the edge networking system 16100 is in communication, such as via the VCN bus 16110. For example, a configured instance of the edge networking system 16100 installed on a smart container may make functions of the smart container available to other connected items (e.g., a fulfillment system) via the edge device-as-a-service module 16302.

[2643] In embodiments, the application-specific protocol module 16304 is configured to determine and/or facilitate provision of one or more application-specific networking protocols to the edge environment 16102-108 on which the edge networking system 16100 is installed and/or to one or more other devices and/or platforms with which the edge networking system 16100 is in communication, such as via the VCN bus 16110. For example, the application-specific protocol module 16304 may facilitate communication to and/or from an application that requires transmitting and/or receiving data via a proprietary encrypted communication protocol.

[2644] In embodiments, the edge robotics module 16306 is configured to facilitate networking related to robotics at the edge environment 16102-16108. The edge robotics module 16306 may, for example, provide one or more of robotics-related data routing, robotics-related communication protocol selection and enabling, local control interfacing, remote control

interfacing, sensor data transmission and reception, and other suitable features to robots local to and/or remote from the edge environment 16102-108 on which the edge networking system 16100 is installed.

[2645] In embodiments, the SDWAN module 16308 is configured to facilitate creation, management, and/or handling of communications via a software-defined wide area network (SDWAN). The edge networking system 16100 may, for example, define a SDWAN via the SDWAN module 16308, and/or some or all of the devices connected to the SDWAN may have instances of the edge networking system 16100 installed thereon to facilitate communications within the SDWAN defined by one or more SDWAN modules 16308.

[2646] In embodiments, the network customization module 16310 is configured to facilitate creation, management, customization, and/or handling of one or more networks. The edge networking system 16100 may customize a network for a specific VCN task via the network customization module 16310. For example, the network customization module may facilitate customization of a network related to a VCN task involving demand prediction for a particular product and/or industry. The network may be customized to facilitate fast, efficient, secure communication between devices connected thereto.

[2647] In embodiments, the AI chipset interfacing module 16312 is configured to enable performing of one or more networking tasks by the edge networking system 16100 via one or more AI chipsets. For example, the edge networking system 16100 may make one or more network routing determinations via an AI system embedded on an AI chipset. Additionally or alternatively, the AI chipset interfacing module 16312 may be configured to facilitate receiving data from and/or transmitting data to an AI chipset in communication with the edge environment 16102-108 on which the edge networking system 16100 is installed, such as via the VCN bus 16110.

[2648] In embodiments, the 5G software definition module 16314 is configured to facilitate management, customization, handling, and/or other tasks related to 5G networks. For example, telecom installation 16106 on which the edge networking system 16100 is installed may be or include a 5G base station, and the software definition module 16314 of the edge networking system 16100 of the 5G base station may perform one or more networking tasks related to managing traffic passing through the 5G base station. Additionally or alternatively, in some examples, 5G-enabled mobile devices connected to a 5G network may have communication via the network facilitated by instances of the 5G software definition module 16314 installed thereon.

[2649] In embodiments, the edge networking AI module 16316 is configured to perform artificial intelligence and/or machine-learning-related functions related to one or more of the networking tasks. For example, routing determinations, protocol selections, protocol management, encryption processes, filtering determinations, and/or any other suitable type of networking task may be performed and/or assisted by AI/ML via the edge networking AI module 16316.

[2650] In embodiments, the tunable signal filtering module 16318 is configured to perform tuning of digital signals transmitted and/or received by and/or within the edge environment 16102-108. The tunable signal filtering module 16318 may include one or more tunable digital filters. The tunable digital filters may tune signals to, for example, reduce network traffic by culling unnecessary communications, remove or reduce third-party signals "piggybacking" on the edge environment 16102-108, filter IoT sensor data, and/or the like.

[2651] In embodiments, the network routing module 16320 is configured to perform network routing operations with respect to signals sent and/or received by the edge environment 16102-108. The network routing operations may include networking tasks such as, for example, determining an optimal data path for sensor data within a premises, determining optimal traffic flow for a 5G network, determining a routing device by which mobile data should be transmitted, and the like.

[2652] In embodiments, the AI network enhancement module 16322 is configured to optimize network performance via one or more AI and/or machine-learning processes. For example, the AI network enhancement module 16322 may use one or more AI and/or machine learning processes to determine optimal protocols for data throughput, and/or to make predictions and/or simulations of network conditions and congestion/throughput thereof.

[2653] In embodiments, the edge network digital twin module 16324 is configured to create and/or manage one or more digital twins related to networking by, at, and/or on one or more of the edge environments 16102-108. For example, the digital twin module 16324 may model a network within a production factory and run simulations via the digital twin to predict network congestion.

[2654] In some embodiments, the edge network system 16100 has a system for decoupling congestion control from link loss.

[2655] In some embodiments, the edge network system 16100 has an intelligent layer on top of UDP.

[2656] In some embodiments, the edge network system 16100 has an automated policy and governance engine for edge workload deployment.

[2657] In some embodiments, the edge network system 16100 has edge data integration with service-oriented architecture.

[2658] In some embodiments, the edge network system 16100 has edge-specific protocols.

[2659] In some embodiments, the edge network system 16100 has an edge storage protocol.

[2660] In some embodiments, the edge network system 16100 has an edge storage protocol integrated with AI-managed storage.

[2661] In some embodiments, the edge network system 16100 has a distributed edge database.

[2662] In some embodiments, the edge network system 16100 has edge-distributed query language.

[2663] In some embodiments, the edge network system 16100 has an edge policy engine.

[2664] In some embodiments, the edge network system 16100 has an automated edge data marketplace.

[2665] In some embodiments, the edge network system 16100 has an RF filtering system for wireless nodes.

[2666] In some embodiments, the edge network system 16100 has network coding.

[2667] In some embodiments, the edge network system 16100 has a machine learning and/or artificial intelligence system at each node of a network.

[2668] In some embodiments, the edge network system 16100 has a machine learning and/or artificial intelligence system at each node of a network configured for filtering and multi-level signal compression based on signal characteristics.

[2669] In some embodiments, the edge network system 16100 has a machine learning and/or artificial intelligence system at each node of a network configured for filtering based on context and/or content.

[2670] In some embodiments, the edge network system 16100 has a machine learning and/or artificial intelligence system at each node of a network configured for filtering based on feedback on outcomes.

[2671] In some embodiments, the edge network system 16100 has a machine learning and/or artificial intelligence system configured for archiving at an optimal level of granularity.

[2672] In some embodiments, the edge network system 16100 has an AI-enhanced edge-aware network fabric.

[2673] In some embodiments, the edge network system 16100 has a machine learning and/or artificial intelligence system configured for optimization of storage capacity.

[2674] In some embodiments, the edge network system 16100 has a machine learning and/or artificial intelligence system configured for optimization of compute.

[2675] In some embodiments, the edge network system 16100 has a machine learning and/or artificial intelligence system configured for optimization of energy.

[2676] In some embodiments, the edge network system 16100 has a mail protocol for mail.

[2677] In some embodiments, the edge network system 16100 has a video streaming protocol for video streaming.

[2678] In some embodiments, the edge network system 16100 has a gaming protocol for gaming.

[2679] In some embodiments, the edge network system 16100 has a system for monitoring packet activity.

[2680] In some embodiments, the edge network system 16100 has a system for storing and replicating data streams for later use by a machine learning and/or artificial intelligence system.

[2681] In some embodiments, the edge network system 16100 has robotics as edge devices.

[2682] In some embodiments, the edge network system 16100 has a system for enabling local control.

[2683] In some embodiments, the edge network system 16100 has a system for customizing security of the network and/or devices on the network.

[2684] In some embodiments, the edge network system 16100 has a system for configuring channels for various types of communications.

[2685] In some embodiments, the edge network system 16100 has a system for configuring an environment after discovery of devices.

[2686] In some embodiments, the edge network system 16100 has a system for customizing a network by data scheduling and resource availability.

[2687] In some embodiments, the edge network system 16100 has a system for customization of data routing, processing, and/or computing based on data type and/or security.

[2688] In some embodiments, the edge network system 16100 has custom virtualization deployments.

[2689] In some embodiments, the edge network system 16100 has a system for customization of neural network layering to form new AI structures.

[2690] In some embodiments, the edge network system 16100 has a system for customization of antenna layouts and power supply to meet specified needs.

[2691] In some embodiments, the edge network system 16100 has a system for enabling wireless charging that includes AI-based battery optimization and AI management of heat production.

[2692] In some embodiments, the edge network system 16100 has a system for customizing the human interface.

[2693] In some embodiments, the edge network system 16100 has a system for customization of the optimal routing algorithm in service customized 5G networks.

[2694] In some embodiments, the edge network system 16100 has a network device.

[2695] In some embodiments, the edge network system 16100 has an AI chipset.

[2696] In some embodiments, the edge network system 16100 has channelization beyond the front end.

[2697] In some embodiments, the edge network system 16100 has channelization beyond the interface.

[2698] In some embodiments, the edge network system 16100 has a system for creating and managing a digital twin of a network and/or AI edge system.

[2699] In some embodiments, the edge network system 16100 has an edge-device-as-a-service system.

[2700] In some embodiments, the edge network system 16100 has a reader-as-a-service system.

[2701] In some embodiments, the edge network system 16100 has a gateway-as-a-service system.

[2702] In some embodiments, the edge network system 16100 has a repeater-as-a-service system.

[2703] In some embodiments, the edge network system 16100 has an asset tag-as-a-service system.

[2704] In some embodiments, the edge network system 16100 has a robotic data collector-as-a-service system.

DUAL PROCESS ARTIFICIAL NEURAL NETWORKS

[2705] Referring to FIG. 104 in combination with FIG. 160, in embodiments, the intelligence services include a dual process artificial neural network (DPANN) system 20000. The DPANN system 20000 includes an artificial neural network (ANN) having behaviors and operational processes (such as decision-making) that are products of a training system and a retraining system. The training system is configured to perform automatic, trained execution of ANN operations. The retraining system performs effortful, analytical, intentional retraining of the ANN, such as based on one or more relevant aspects of the ANN, such as memory, one or more input data sets (including time information with respect to elements in such data sets), one or more goals or objectives (including ones that may vary dynamically, such as periodically and/or based on contextual changes, such as ones relating to the usage context of the ANN), and/or others. In cases involving memory-based retraining, the memory may include original/historical training data and refined training data. The DPANN system 20000 includes a dual process learning function (DPLF) configured to manage and perform an ongoing data retention process. The DPLF (including, where applicable, memory management process) facilitate retraining and refining of behavior of the ANN. The DPLF provides a framework by which the ANN creates outputs such as predictions, classifications, recommendations, conclusions and/or other outputs based on a historic inputs, new inputs, and new outputs (including outputs configured for specific use cases, including ones determined by parameters of the context of utilization (which may include performance parameters such as latency parameters, accuracy parameters, consistency parameters, bandwidth utilization parameters, processing capacity utilization parameters, prioritization parameters, energy utilization parameters, and many others).

[2706] In embodiments, the DPANN system 20000 stores training data, thereby allowing for constant retraining based on results of decisions, predictions, and/or other operations of the ANN, as well as allowing for analysis of training data upon the outputs of the ANN. The management of entities stored in the memory allows the construction and execution of new models, such as ones that may be processed, executed or otherwise performed by or under management of the training system. The DPANN system 20000 uses instances of the memory to validate actions (e.g., in a manner similar to the thinking of a biological neural network (including retrospective or self-reflective thinking about whether actions that were undertaken under a given situation where optimal) and perform training of the ANN, including training that intentionally feeds the ANN with appropriate sets of memories (i.e., ones that produce favorable outcomes given the performance requirements for the ANN).

[2707] In embodiments, the DPLF may be or include the continued process retention of one or more training datasets and/or memories stored in the memory over time. The DPLF thereby allows the ANN to apply existing neural functions and draw upon sets of past events (including ones that are intentionally varied and/or curated for distinct purposes), such as to frame understanding of and behavior within present, recent, and/or new scenarios, including in simulations, during training processes, and in fully operational deployments of the ANN. The DPLF may provide the ANN with a framework by which the ANN may analyze, evaluate,

and/or manage data, such as data related to the past, present and future. As such, the DPLF plays a crucial role in training and retraining the ANN via the training system and the retraining system.

[2708] In embodiments, the DPLF is configured to perform a dual-process operation to manage existing training processes and is also configured to manage and/or perform new training processes, i.e., retraining processes. In embodiments, each instance of the ANN is trained via the training system and configured to be retrained via the retraining system. The ANN encodes training and/or retraining datasets, stores the datasets, and retrieves the datasets during both training via the training system and retraining via the retraining system. The DPANN system 20000 may recognize whether a dataset (the term dataset in this context optionally including various subsets, supersets, combinations, permutations, elements, metadata, augmentations, or the like, relative to a base dataset used for training or retraining), storage activity, processing operation and/or output, has characteristics that natively favor the training system versus the retraining system based on its respective inputs, processing (e.g., based on its structure, type, models, operations, execution environment, resource utilization, or the like) and/or outcomes (including outcome types, performance requirements (including contextual or dynamic requirements), and the like. For example, the DPANN system 20000 may determine that poor performance of the training system on a classification task may indicate a novel problem for which the training of the ANN was not adequate (e.g., in type of data set, nature of input models and/or feedback, quantity of training data, quality of tagging or labeling, quality of supervision, or the like), for which the processing operations of the ANN are not well-suited (e.g., where they are prone to known vulnerabilities due to the type of neural network used, the type of models used, etc.), and that may be solved by engaging the retraining system to retrain the model to teach the model to learn to solve the new classification problem (e.g., by feeding it many more labeled instances of correctly classified items). With periodic or continuous evaluation of the performance of the ANN, the DPANN system may subsequently determine that highly stable performance of the ANN (such as where only small improvements of the ANN occur over many iterations of retraining by the retraining system) indicates readiness for the training system to replace the retraining system (or be weighted more favorably where both are involved). Over longer periods of time, cycles of varying performance may emerge, such as where a series of novel problems emerge, such that the retraining system of the DPANN is serially engaged, as needed, to retrain the ANN and/or to augment the ANN by providing a second source of outputs (which may be fused or combined with ANN outputs to provide a single result (with various weightings across them), or may be provided in parallel, such as enabling comparison, selection, averaging, or context- or situation-specific application of the respective outputs).

[2709] In embodiments, the ANN is configured to learn new functions in conjunction with the collection of data according to the dual-process training of the ANN via the training system and the retraining system. The DPANN system 20000 performs analysis of the ANN via the training system and performs initial training of the ANN such that the ANN gains new internal functions

(or internal functions are subtracted or modified, such as where existing functions are not contributing to favorable outcomes). After the initial training, the DPANN system 20000 performs retraining of the ANN via the retraining system. To perform the retraining, the retraining system evaluates the memory and historic processing of the ANN to construct targeted DPLF processes for retraining. The DPLF processes may be specific to identified scenarios. The ANN processes can run in parallel with the DPLF processes. By way of example, the ANN may function to operate a particular make and model of a self-driving car after the initial training by the training system. The DPANN system 20000 may perform retraining of the functions of the ANN via the retraining system, such as to allow the ANN to operate a different make and model of car (such as one with different cameras, accelerometers and other sensors, different physical characteristics, different performance requirements, and the like), or even a different kind of vehicle, such as a bicycle or a spaceship.

[2710] In embodiments, as quality of outputs and/or operations of the ANN improves, and as long as the performance requirements and the context of utilization for the ANN remain fairly stable, performing the dual-process training process can become a decreasingly demanding process. As such, the DPANN system 20000 may determine that fewer neurons of the ANN are required to perform operations and/or processes of the ANN, that performance monitoring can be less intensive (such as with longer intervals between performance checks), and/or that the retraining is no longer necessary (at least for a period of time, such as until a long-term maintenance period arrives and/or until there are significant shifts in context of utilization). As the ANN continues to improve upon existing functions and/or add new functions via the dual-process training process, the ANN may perform other, at times more "intellectually-demanding" (e.g., retraining intensive) tasks simultaneously. For example, utilizing dual process-learned knowledge of a function or process being trained, the ANN can solve an unrelated complex problem or make a retraining decision simultaneously. The retraining may include supervision, such as where an agent (e.g., human supervisor or intelligent agent) directs the ANN to a retraining objective (e.g., "master this new function") and provides a set of training tasks and feedback functions (such as supervisory grading) for the retraining. In-embodiments, the ANN can be used to organize the supervision, training and retraining of other dual process-trained ANNs, to seed such training or retraining, or the like.

[2711] In embodiments, one or more behaviors and operational processes (such as decision-making) of the ANN may be products of training and retraining processes facilitated by the training system and the retraining system, respectively. The training system may be configured to perform automatic training of ANN, such as by continuously adding additional instances of training data as it is collected by or from various data sources. The retraining system may be configured to perform effortful, analytical, intentional retraining of the ANN, such as based on memory (e.g., stored training data or refined training data) and/or optionally based on reasoning or other factors. For example, in a deployment management context, the training system may be associated with a standard response by the ANN, while the retraining system may implement DPLF retraining and/or network adaptation of the ANN. In some cases, retraining of the ANN

beyond the factory, or "out-of-the-box," training level may involve more than retraining by the retraining system. Successful adjustment of the ANN by one or more network adaptations may be dependent on the operation of one or more network adjustments of the training system.

[2712] In embodiments, the training system may facilitate fast operating by and training of the ANN by applying existing neural functions of the ANN based on training of the ANN with previous datasets. Standard operational activities of the ANN that may draw heavily on the training system may include one or more of the methods, processes, workflows, systems, or the like described throughout this disclosure and the documents incorporated herein, such as, without limitation: defined functions within networking (such as discovering available networks and connections, establishing connections in networks, provisioning network bandwidth among devices and systems, routing data within networks, steering traffic to available network paths, load balancing across networking resources, and many others); recognition and classification (such as of images, text, symbols, objects, video content, music and other audio content, speech content, and many others); spoken words; prediction of states and events (such as prediction of failure modes of machines or systems, prediction of events within workflows, predictions of behavior in shopping and other activities, and many others); control (such as controlling autonomous or semi-autonomous systems, automated agents (such as automated call-center operations, chat bots, and the like) and others); and/or optimization and recommendation (such as for products, content, decisions, and many others). ANNs may also be suitable for training datasets for scenarios that only require output. The standard operational activities may not require the ANN to actively analyze what is being asked of the ANN beyond operating on well-defined data inputs, to calculate well-defined outputs for well-defined use cases. The operations of the training system and/or the retraining system may be based on one or more historic data training datasets and may use the parameters of the historic data training datasets to calculate results based on new input values and may be performed with small or no alterations to the ANN or its input types. In embodiments, an instance of the training system can be trained to classify whether the ANN is capable of performing well in a given situation, such as by recognizing whether an image or sound being classified by the ANN is of a type that has historically been classified with a high accuracy (e.g., above a threshold).

[2713] In embodiments, network adaptation of the ANN by one or both of the training system and the retraining system may include a number of defined network functions, knowledge, and intuition-like behavior of the ANN when subjected to new input values. In such embodiments, the retraining system may apply the new input values to the DPLF system to adjust the functional response of the ANN, thereby performing retraining of the ANN. The DPANN system 20000 may determine that retraining the ANN via network adjustment is necessary when, for example, without limitation, functional neural networks are assigned activities and assignments that require the ANN to provide a solution to a novel problem, engage in network adaptation or other higher-order cognitive activity, apply a concept outside of the domain in which the DPANN was originally designed, support a different context of deployment (such as where the use case, performance requirements, available resources, or other factors have

changed), or the like. The ANN can be trained to recognize where the retraining system is needed, such as by training the ANN to recognize poor performance of the training system, high variability of input data sets relative to the historical data sets used to train the training system, novel functional or performance requirements, dynamic changes in the use case or context, or other factors. The ANN may apply reasoning to assess performance and provide feedback to the retraining system. The ANN may be trained and/or retrained to perform intuitive functions, optionally including by a combinatorial or re-combinatorial process (e.g., including genetic programming wherein inputs (e.g., data sources), processes/functions (e.g., neural network types and structures), feedback, and outputs, or elements thereof, are arranged in various permutations and combinations and the ANN is tested in association with each (whether in simulations or live deployments), such as in a series of rounds, or evolutionary steps, to promote favorable variants until a preferred ANN, or preferred set of ANNs is identified for a given scenario, use case, or set of requirements). This may include generating a set of input "ideas" (e.g., combinations of different conclusions about cause-and-effect in a diagnostic process) for processing by the retraining system and subsequent training and/or by an explicit reasoning process, such as a Bayesian reasoning process, a casuistic or conditional reasoning process, a deductive reasoning process, an inductive reasoning process, or others (including combinations of the above) as described in this disclosure or the documents incorporated herein by reference.

[2714] Referring to Figure 160, in embodiments, the DPLF may perform an encoding process of the DPLF to process datasets into a stored form for future use, such as retraining of the ANN by the retraining system. The encoding process enables datasets to be taken in, understood, and altered by the DPLF to better support storage in and usage from the memory. The DPLF may apply current functional knowledge and/or reasoning to consolidate new input values. The memory can include short-term memory (STM), long-term memory (LTM), or a combination thereof. The datasets may be stored in one or both of the STM and the LTM. The STM may be implemented by the application of specialized behaviors inside the ANN (such as recurrent neural network, which may be gated or un-gated, or long-term short-term neural networks). The LTM may be implemented by storing scenarios, associated data, and/or unprocessed data that can be applied to the discovery of new scenarios. The encoding process may include processing and/or storing, for example, visual encoding data (e.g., processed through a Convolution Neural Network), acoustic sensor encoding data (e.g., how something sounds, speech encoding data (e.g., processed through a deep neural network (DNN), optionally including for phoneme recognition), semantic encoding data of words, such to determine semantic meaning, e.g., by using a Hidden Markov Model (HMM); and/or movement and/or tactile encoding data (such as operation on vibration/accelerometer sensor data, touch sensor data, positional or geolocation data, and the like). While datasets may enter the DPLF system through one of these modes, the form in which the datasets are stored may differ from an original form of the datasets and may pass-through neural processing engines to be encoded into compressed and/or context-relevant format. For example, an unsupervised instance of the ANN can be used to learn the historic data into a compressed format.

[2715] In embodiments, the encoded datasets are retained within the DPLF system. Encoded datasets are first stored in short-term DPLF, i.e., STM. For example, sensor datasets may be primarily stored in STM, and may be kept in STM through constant repetition. The datasets stored in the STM are active and function as a kind of immediate response to new input values. The DPANN system 20000 may remove datasets from STM in response to changes in data streams due to, for example, running out of space in STM as new data is imported, processed and/or stored. For example, it is viable for short-term DPLF to only last between 15 and 30 seconds. STM may only store small amounts of data typically embedded inside the ANN.

[2716] In embodiments, the DPANN system 20000 may measure attention based on utilization of the training system, of the DPANN system 20000 as a whole, and/or the like, such as by consuming various indicators of attention to and/or utilization of outputs from the ANN and transmitting such indicators to the ANN in response (similar to a "moment of recognition" in the brain where attention passes over something and the cognitive system says "aha!"). In embodiments, attention can be measured by the sheer amount of the activity of one or both of the systems on the data stream. In embodiments, a system using output from the ANN can explicitly indicate attention, such as by an operator directing the ANN to pay attention to a particular activity (e.g., to respond to a diagnosed problem, among many other possibilities). The DPANN system 20000 may manage data inputs to facilitate measures of attention, such as by prompting and/or calculating greater attention to data that has high inherent variability from historical patterns (e.g., in rates of change, departure from norm, etc.), data indicative of high variability in historical performance (such as data having similar characteristics to data sets involved in situations where the ANN performed poorly in training), or the like.

[2717] In embodiments, the DPANN system 20000 may retain encoded datasets within the DPLF system according to and/or as part of one or more storage processes. The DPLF system may store the encoded datasets in LTM as necessary after the encoded datasets have been stored in STM and determined to be no longer necessary and/or low priority for a current operation of the ANN, training process, retraining process, etc. The LTM may be implemented by storing scenarios, and the DPANN system 20000 may apply associated data and/or unprocessed data to the discovery of new scenarios. For example, data from certain processed data streams, such as semantically encoded datasets, may be primarily stored in LTM. The LTM may also store image (and sensor) datasets in encoded form, among many other examples.

[2718] In embodiments, the LTM may have relatively high storage capacity, and datasets stored within LTM may, in some scenarios, be effectively stored indefinitely. The DPANN system 20000 may be configured to remove datasets from the LTM, such as by passing LTM data through a series of memory structures that have increasingly long retrieval periods or increasingly high threshold requirements to trigger utilization (similar to where a biological brain "thinks very hard" to find precedent to deal with a challenging problem), thereby providing increased salience of more recent or more frequently used memories while retaining the ability to retrieve (with more time/effort) older memories when the situation justifies more comprehensive memory utilization. As such, the DPANN system 20000 may arrange datasets

stored in the LTM on a timeline, such as by storing the older memories (measured by time of origination and/or latest time of utilization) on a separate and/or slower system, by penalizing older memories by imposing artificial delays in retrieval thereof, and/or by imposing threshold requirements before utilization (such as indicators of high demand for improved results). Additionally or alternatively, LTM may be clustered according to other categorization protocols, such as by topic. For example, all memories proximal in time to a periodically recognized person may be clustered for retrieval together, and/or all memories that were related to a scenario may be clustered for retrieval together.

[2719] In embodiments, the DPANN system 20000 may modularize and link LTM datasets, such as in a catalog, a hierarchy, a cluster, a knowledge graph (directed/acyclic or having conditional logic), or the like, such as to facilitate search for relevant memories. For example, all memory modules that have instances involving a person, a topic, an item, a process, a linkage of n-tuples of such things (e.g., all memory modules that involve a selected pair of entities), etc. The DPANN system 20000 may select sub-graphs of the knowledge graph for the DPLF to implement in one or more domain-specific and/or task-specific uses, such as training a model to predict robotic or human agent behavior by using memories that relate to a particular set of robotic or human agents, and/or similar robotic or human agents. The DPLF system may cache frequently used modules for different speed and/or probability of utilization. High value modules (e.g., ones with high-quality outcomes, performance characteristics, or the like) can be used for other functions, such as selection/training of STM keep/forget processes.

[2720] In embodiments, the DPANN system 20000 may modularize and link LTM datasets, such as in various ways noted above, to facilitate search for relevant memories. For example, memory modules that have instances involving a person, a topic, an item, a process, a linkage of n-tuples of such things (such as all memory modules that involve a selected pair of entities), or all memories associated with a scenario, etc., may be linked and searched. The DPANN system 20000 may select subsets of the scenario (e.g., sub-graphs of a knowledge graph) for the DPLF for a domain-specific and/or task-specific use, such as training a model to predict robotic or human agent behavior by using memories that relate to a particular set of robotic or human agents and/or similar robotic or human agents. Frequently used modules or scenarios can be cached for different speed/probability of utilization, or other performance characteristics. High value modules or scenarios (ones where high-quality outcomes results) can be used for other functions, such as selection/training of STM keep/forget processes, among others.

[2721] In embodiments, the DPANN system 20000 may perform LTM planning, such as to find a procedural course of action for a declaratively described system to reach its goals while optimizing overall performance measures. The DPANN system 20000 may perform LTM planning when, for example, a problem can be described in a declarative way, the DPANN system 20000 has domain knowledge that should not be ignored, there is a structure to a problem that makes the problem difficult for pure learning techniques, and/or the ANN needs to be trained and/or retrained to be able to explain a particular course of action taken by the DPANN system 20000. In embodiments, the DPANN system 20000 may be applied to a plan

recognition problem, i.e., the inverse of a planning problem: instead of a goal state, one is given a set of possible goals, and the objective in plan recognition is to find out which goal was being achieved and how.

[2722] In embodiments, the DPANN system 20000 may facilitate LTM scenario planning by users to develop long-term plans. For example, LTM scenario planning for risk management use cases may place added emphasis on identifying extreme or unusual, yet possible, risks and opportunities that are not usually considered in daily operations, such as ones that are outside a bell curve or normal distribution, but that in fact occur with greater-than-anticipated frequency in "long tail" or "fat tail" situations, such as involving information or market pricing processes, among many others. LTM scenario planning may involve analyzing relationships between forces (such as social, technical, economic, environmental, and/or political trends) in order to explain the current situation, and/or may include providing scenarios for potential future states.

[2723] In embodiments, the DPANN system 20000 may facilitate LTM scenario planning for predicting and anticipating possible alternative futures along with the ability to respond to the predicted states. The LTM planning may be induced from expert domain knowledge or projected from current scenarios, because many scenarios (such as ones involving results of combinatorial processes that result in new entities or behaviors) have never yet occurred and thus cannot be projected by probabilistic means that rely entirely on historical distributions. The DPANN system 20000 may prepare the application to LTM to generate many different scenarios, exploring a variety of possible futures to the DPLM for both expected and surprising futures. This may be facilitated or augmented by genetic programming and reasoning techniques as noted above, among others.

[2724] In embodiments, the DPANN system 20000 may implement LTM scenario planning to facilitate transforming risk management into a plan recognition problem and apply the DPLF to generate potential solutions. LTM scenario induction addresses several challenges inherent to forecast planning. LTM scenario induction may be applicable when, for example, models that are used for forecasting have inconsistent, missing, unreliable observations; when it is possible to generate not just one but many future plans; and/or when LTM domain knowledge can be captured and encoded to improve forecasting (e.g., where domain experts tend to outperform available computational models). LTM scenarios can be focused on applying LTM scenario planning for risk management. LTM scenarios planning may provide situational awareness of relevant risk drivers by detecting emerging storylines. In addition, LTM scenario planning can generate future scenarios that allow DPLM, or operators, to reason about, and plan for, contingencies and opportunities in the future.

[2725] In embodiments, the DPANN system 20000 may be configured to perform a retrieval process via the DPLF to access stored datasets of the ANN. The retrieval process may determine how well the ANN performs with regard to assignments designed to test recall. For example, the ANN may be trained to perform a controlled vehicle parking operation, whereby the autonomous vehicle returns to a designated spot, or the exit, by associating a prior visit via retrieval of data stored in the LTM. The datasets stored in the STM and the LTM may be

retrieved by differing processes. The datasets stored in the STM may be retrieved in response to specific input and/or by order in which the datasets are stored, e.g., by a sequential list of numbers. The datasets stored in the LTM may be retrieved through association and/or matching of events to historic activities, e.g., through complex associations and indexing of large datasets.

[2726] In embodiments, the DPANN system 20000 may implement scenario monitoring as at least a part of the retrieval process. A scenario may provide context for contextual decision-making processes. In embodiments, scenarios may involve explicit reasoning (such as cause-and-effect reasoning, Bayesian, casuistic, conditional logic, or the like, or combinations thereof) the output of which declares what LTM-stored data is retrieved (e.g., a timeline of events being evaluated and other timelines involving events that potentially follow a similar cause-and-effect pattern). For example, diagnosis of a failure of a machine or workflow may retrieve historical sensor data as well as LTM data on various failure modes of that type of machine or workflow (and/or a similar process involving a diagnosis of a problem state or condition, recognition of an event or behavior, a failure mode (e.g., a financial failure, contract breach, or the like), or many others).

VCN SYSTEM OF SYSTEMS

[2727] As discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may configure 17400 a set of secondary computing devices of a set of value chain network entities for communication with a primary computing device of an enterprise operator, wherein the primary computing device may manage the set of secondary computing devices. In some implementations, VCN process 10 may receive 17402 (e.g., via at least one member of the set of secondary computing devices) a set of primary commands from the primary computing device, wherein each of the set of commands may be at least one of a task or a request. In some implementations, VCN process 10 may assign 17404 at least a portion of one or more computing devices capable of fulfilling the primary command as a set of one or more computing devices to be managed by the set of secondary computing devices. In some implementations, VCN process 10 (e.g., via the set of secondary computing devices) configure 17406 the set of one or more computing devices to fulfill one or more secondary commands based upon, at least in part, the primary command. In some implementations, VCN process 10 may (e.g., via the set of secondary computing devices) fulfill 17408 the primary command based upon, at least in part, the set of one or more computing devices fulfilling the one or more secondary commands. In some implementations, VCN process 10 may send 17410 a generated system output to the primary computing device responding to the primary command based upon, at least in part, the set of one or more computing devices fulfilling the one or more secondary commands.

[2728] In some implementations, configuring the set of one or more computing devices to fulfill the one or more secondary commands may include generating 17412 a set of at least one configured system service (CSS). In some implementations, generating the set of at least one CSS may include utilizing 17414 an output of the primary computing device as an input to

generate one or more control parameters. In some implementations, configuring the set of one or more computing devices to fulfill the one or more secondary commands may include providing 17416 intelligence received from the at least one CSS to the set of one or more computing devices. In some implementations, assigning at least the portion of one or more computing devices capable of fulfilling the primary command as the set of one or more computing devices to be managed by the secondary computing device may include executing 17418 an enrollment process between the set of one or more computing devices and the secondary computing device. In some implementations, executing the enrollment process may include conducting 17420 an inventory of communication protocols and data formats used by the set of one or more computing devices. In some implementations, the secondary computing device (e.g., via VCN process 10) may obtain 17422 one or more application programming interfaces (APIs) to enable communication and data format translation between each computing device of the set of one or more computing devices and the secondary computing device. In some implementations, the primary computing device (e.g., via VCN process 10) may be bypassed 17424 to receive external data at the secondary computing device when the external data is unused by the primary computing device. In some implementations, generating the set of at least one CSS may include generating 17426 at least one CSS for each interface layer in a management stack. In some implementations, intelligent decision-making regarding strategy for the primary command may be performed 17428 based upon, at least in part, a configured intelligence service (CIS). In some implementations, the set of the value chain network entities may include at least one of products, suppliers, producers, manufacturers, retailers, businesses, owners, operators, operating facilities, customers, consumers, workers, mobile devices, wearable devices, distributors, resellers, supply chain infrastructure facilities, supply chain processes, logistics processes, reverse logistics processes, demand prediction processes, demand management processes, demand aggregation processes, machines, ships, barges, warehouses, maritime ports, airports, airways, waterways, roadways, railways, bridges, tunnels, online retailers, ecommerce sites, demand factors, supply factors, delivery systems, floating assets, points of origin, points of destination, points of storage, points of use, networks, information technology systems, software platforms, distribution centers, fulfillment centers, containers, container handling facilities, customs, export control, border control, drones, robots, robotic handling systems, 3D printers, vehicles, autonomous vehicles, hauling facilities, waterways, or port infrastructure facilities.

[2729] As also discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may configure 17800 a set of sub-level computing devices for communication with a primary computing device, wherein the primary computing device may manage the set of sub-level computing devices to orchestrate performance of a set of value chain network entities. In some implementations, VCN process 10 may receive 17802 (e.g., via the set of sub-level computing devices) a primary command from the primary computing device, wherein the command may be one of a task or a request associated with the value chain network. In some implementations, VCN process 10 may assign 17804 at least a portion of one or more computing devices capable of fulfilling the primary

command as a set of one or more computing devices to be managed by the sub-level computing device, wherein the sub-level computing device may be a computing device that manages or executes performance of a particular entity or relationship of the value chain network. In some implementations, VCN process 10 may (e.g., via the sub-level computing device) configure 17806 the set of one or more computing devices to fulfill one or more secondary commands based upon, at least in part, the primary command. In some implementations, VCN process 10 may (e.g., via the sub-level computing device) fulfill 17808 the primary command based upon, at least in part, the set of one or more computing devices fulfilling the one or more secondary commands.

[2730] Configuring the set of one or more computing devices to fulfill the one or more secondary commands may include generating 17812 a set of at least one configured system service (CSS). Generating the set of at least one CSS may include utilizing 17814 an output of a plurality of sources as an input to generate one or more control parameters. Configuring the set of one or more computing devices to fulfill the one or more secondary commands may include providing 17816 intelligence received from the at least one CSS to the set of one or more computing devices. Assigning at least the portion of one or more computing devices capable of fulfilling the primary command as the set of one or more computing devices to be managed by the sub-level computing device may include executing 17818 an enrollment process between the set of one or more computing devices and the sub-level computing device. Executing the enrollment process may include conducting 17820 an inventory of communication protocols and data formats used by the set of one or more computing devices. The sub-level computing device may obtain 17822 one or more application programming interfaces (APIs) to enable communication and data format translation between each computing device of the set of one or more computing devices and the sub-level computing device. The primary computing device may be bypassed 17824 to receive external data at the sub-level computing device when the external data is unused by the primary computing device. Generating the set of at least one CSS may include generating 17826 at least one CSS for each interface layer in a management stack. Intelligent decision-making may be performed 17828 regarding strategy for the primary command based upon, at least in part, a configured intelligence service (CIS). The set of the value chain network entities may include at least one of products, suppliers, producers, manufacturers, retailers, businesses, owners, operators, operating facilities, customers, consumers, workers, mobile devices, wearable devices, distributors, resellers, supply chain infrastructure facilities, supply chain processes, logistics processes, reverse logistics processes, demand prediction processes, demand management processes, demand aggregation processes, machines, ships, barges, warehouses, maritime ports, airports, airways, waterways, roadways, railways, bridges, tunnels, online retailers, ecommerce sites, demand factors, supply factors, delivery systems, floating assets, points of origin, points of destination, points of storage, points of use, networks, information technology systems, software platforms, distribution centers, fulfillment centers, containers, container handling facilities, customs, export control, border control, drones, robots, robotic handling systems, 3D printers, vehicles, autonomous vehicles,

hauling facilities, waterways, or port infrastructure facilities. A generated system output may be sent 17810 to the primary computing device responding to the primary command based upon, at least in part, the set of one or more computing devices fulfilling the one or more secondary commands.

[2731] As also discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may receive 17900, by a computing device, information associated with a set of value chain network entities of a value chain network, the information generated by at least one of a set of sensors of the set of value chain network entities, a set of IoT devices configured to collect data relating to the set of value chain network entities, or a set of APIs configured to publish data relating to the set of value chain network entities. In some implementations, VCN process 10 may provide 17902 the information to a set of Artificial Intelligence (AI)-based learning models, wherein at least one member of the set of AI-based learning models may be trained on a training data set of a set of value chain network entities operating data to classify at least one of: an operating state, a fault condition, an operating flow, or a behavior of at least one value chain entity of the set of value chain network entities. In some implementations, VCN process 10 may determine 17904 a potential risk in the value chain based upon, at least in part, an output of the AI-based learning classification. In some implementations, VCN process 10 may execute 17906 an action to mitigate the potential risk in the value chain network.

[2732] Executing the action to mitigate the potential risk in the value chain network may include flagging 17908 the potential risk in the value chain network. Executing the action to mitigate the potential risk in the value chain network may include responding 17910 to the potential risk in the value chain network. Executing the action to mitigate the potential risk in the value chain network may include resolving 17912 an out-of-stock situation. Executing the action to mitigate the potential risk in the value chain network may include predicting 17914 when to place an order based upon, at least in part, upstream data. Executing the action to mitigate the potential risk in the value chain network may include supply planning 17916. Executing the action to mitigate the potential risk in the value chain network may include optimizing 17918 an inventory mix. External data may be received 17920, and a strategy to reduce transportation costs may be determined 17922 based upon, at least in part, the external data. Data associated with warehouse management, inventory management, order management, analytics may be unified 17924 to optimize an omnichannel fulfillment. A platform may be provided 17926 with a plurality of AI-based learning models for download. The set of the value chain network entities may include at least one of products, suppliers, producers, manufacturers, retailers, businesses, owners, operators, operating facilities, customers, consumers, workers, mobile devices, wearable devices, distributors, resellers, supply chain infrastructure facilities, supply chain processes, logistics processes, reverse logistics processes, demand prediction processes, demand management processes, demand aggregation processes, machines, ships, barges, warehouses, maritime ports, airports, airways, waterways, roadways, railways, bridges, tunnels, online retailers, ecommerce sites, demand factors, supply factors, delivery systems,

floating assets, points of origin, points of destination, points of storage, points of use, networks, information technology systems, software platforms, distribution centers, fulfillment centers, containers, container handling facilities, customs, export control, border control, drones, robots, robotic handling systems, 3D printers, vehicles, autonomous vehicles, hauling facilities, waterways, or port infrastructure facilities. The set of AI-based learning models may include at least one of a transformer model, a convolutional neural network, a deep learning model trained on a set of outcomes of the value chain network entity, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model. The training data set for the set of AI-based learning models may include one of a set of objects or events that are labeled to classify the set of objects or events according to a classification taxonomy that may include at least one of the operating state, the fault condition, the operating flow, or the behavior.

[2733] As also discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may 18001 receive, by a computing device, information associated with a set of value chain network entities of a value chain network, the information generated by at least one of a set of sensors of the set of value chain network entities, a set of IoT devices configured to collect data relating to the set of value chain network entities, or a set of APIs configured to publish data relating to the set of value chain network entities. In some implementations, VCN process 10 may provide 18003 the information to a set of Artificial Intelligence (AI)-based learning models, wherein at least one member of the set of AI-based learning models may be trained on a training data set of a set of value chain network entities operating data to classify at least one of: an operating state, a fault condition, an operating flow, or a behavior of at least one value chain entity of the set of value chain network entities. In some implementations, VCN process 10 may determine 18005 a procurement action to be taken in the value chain network based upon, at least in part, an output of the set of AI-based learning models. In some implementations, VCN process 10 may execute 18007 the procurement action to facilitate an improvement of at least one of an operating state, a condition, a flow or a behavior of at least one entity of the set of value chain network entities.

[2734] In some implementations, executing the procurement action may include resolving 18009 an out-of-stock situation. In some implementations, executing the procurement action may include predicting 18011 when to place an order based upon, at least in part, upstream data. In some implementations, VCN process 10 may provide 18013 an alert describing the procurement action that was executed. In some implementations, the information may include past behavior over time, historical data, and current data. In some implementations, VCN process 10 may provide 18015 real-time information on supplier performance. In some implementations, VCN process 10 may monitor 18017 compliance of suppliers and procurement teams. In some implementations, VCN process 10 may automatically generate 18019 purchase orders associated with the procurement action. In some implementations, VCN process 10 may automatically process 18021 invoice processing associated with the procurement action. In some implementations, VCN process 10 may unify 18023 data associated with warehouse management, inventory management, order management, analytics to optimize an omnichannel

fulfillment. In some implementations, the set of the value chain network entities may include at least one of products, suppliers, producers, manufacturers, retailers, businesses, owners, operators, operating facilities, customers, consumers, workers, mobile devices, wearable devices, distributors, resellers, supply chain infrastructure facilities, supply chain processes, logistics processes, reverse logistics processes, demand prediction processes, demand management processes, demand aggregation processes, machines, ships, barges, warehouses, maritime ports, airports, airways, waterways, roadways, railways, bridges, tunnels, online retailers, ecommerce sites, demand factors, supply factors, delivery systems, floating assets, points of origin, points of destination, points of storage, points of use, networks, information technology systems, software platforms, distribution centers, fulfillment centers, containers, container handling facilities, customs, export control, border control, drones, robots, robotic handling systems, 3D printers, vehicles, autonomous vehicles, hauling facilities, waterways, or port infrastructure facilities. In some implementations, the set of AI-based learning models may include at least one of a transformer model, a convolutional neural network, a deep learning model trained on a set of outcomes of the value chain network entity, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model. In some implementations, the training data set for the set of AI-based learning models may include one of a set of objects or events that are labeled to classify the set of objects or events according to a classification taxonomy that may include at least one of the operating state, the fault condition, the operating flow, or the behavior. In some implementations, VCN process 10 may execute the procurement action by a value chain network digital twin.

[2735] As also discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may receive 18101, by a computing device, information associated with a set of value chain network entities of a value chain network, the information generated by at least one of a set of sensors of the set of value chain network entities, a set of IoT devices configured to collect data relating to the set of value chain network entities, or a set of APIs configured to publish data relating to the set of value chain network entities. In some implementations, VCN process 10 may provide 18103 the information to a first set of Artificial Intelligence (AI)-based learning models, wherein at least one member of the first set of AI-based learning models may be trained on a training data set of value chain network data to generate a prediction of future demand for an item in the value chain network. In some implementations, VCN process 10 may provide 18105 the information to a second set of AI-based learning models, wherein at least one member of the second set of AI-based learning models may be trained on a training data set of a set of value chain network entities operating data to classify at least one of: an operating state, a fault condition, an operating flow, or a behavior of at least one value chain entity of the set of value chain network entities. In some implementations, VCN process 10 may determine 18107 a potential risk in the value chain network associated with the at least one value chain network entity based upon, at least in part, an output of the AI-based learning models. In some implementations, VCN process 10 may

output 18109 a recommendation to mitigate the potential risk in the value chain network or may automatically execute 18111 an action to mitigate the potential risk in the value chain network.

[2736] In some implementations, executing the action to mitigate the potential risk in the value chain network associated with the item may include flagging 18113 the potential risk in the value chain network associated with the item. In some implementations, executing the action to mitigate the potential risk in the value chain network associated with the item may include responding 18115 to the potential risk in the value chain network associated with the item. In some implementations, executing the action to mitigate the potential risk in the value chain network associated with the item may include resolving 18117 an out-of-stock situation. In some implementations, executing the action to mitigate the potential risk in the value chain network associated with the item may include predicting 18119 when to place an order based upon, at least in part, upstream data. In some implementations, VCN process 10 may unify 18121 data associated with warehouse management, inventory management, order management, analytics to optimize an omnichannel fulfillment. In some implementations, VCN process 10 may provide 18123 an alert describing the action to mitigate the potential risk in the value chain network associated with the item that was executed. The information may include past behavior over time, historical data, and current data. In some implementations, the potential risk may be a potential disruption in the value chain network associated with the item. In some implementations, VCN process 10 may render 18125 a visualization associated with at least one of inbound or outbound shipments associated with the item. In some implementations, the set of the value chain network entities may include at least one of products, suppliers, producers, manufacturers, retailers, businesses, owners, operators, operating facilities, customers, consumers, workers, mobile devices, wearable devices, distributors, resellers, supply chain infrastructure facilities, supply chain processes, logistics processes, reverse logistics processes, demand prediction processes, demand management processes, demand aggregation processes, machines, ships, barges, warehouses, maritime ports, airports, airways, waterways, roadways, railways, bridges, tunnels, online retailers, ecommerce sites, demand factors, supply factors, delivery systems, floating assets, points of origin, points of destination, points of storage, points of use, networks, information technology systems, software platforms, distribution centers, fulfillment centers, containers, container handling facilities, customs, export control, border control, drones, robots, robotic handling systems, 3D printers, vehicles, autonomous vehicles, hauling facilities, waterways, or port infrastructure facilities. In some implementations, the set of AI-based learning models may include at least one of a transformer model, a convolutional neural network, a deep learning model trained on a set of outcomes of the value chain network entity, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model. In some implementations, the training data set for the set of AI-based learning models may include one of a set of objects or events that are labeled to classify the set of objects or events according to a classification taxonomy that may include at least one of the operating state, the fault condition, the operating flow, or the behavior.

[2737] As also discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may receive 18200, by a computing device, information associated with a value chain network, the information generated by at least one of a set of sensors of a set of value chain network entities, a set of IoT devices configured to collect data relating to the set of value chain network entities, or a set of APIs configured to publish data relating to the set of value chain network entities. In some implementations, VCN process 10 may provide 18202 the information to a set of Artificial Intelligence (AI)-based learning models, wherein at least one member of the set of AI-based learning models may be trained on a training data set of a set of value chain network entities operating data to classify at least one of: an operating state, a fault condition, an operating flow, or a behavior of at least one value chain entity of the set of value chain network entities. In some implementations, VCN process 10 may determine 18204 a task to be completed for the value chain network based upon, at least in part, on an output of the set of AI-based learning models. In some implementations, VCN process 10 may execute 18206 the task to facilitate an improvement in the value chain network.

[2738] In some implementations, executing the task may include predicting 18208 future demand for an item in the value chain network. In some implementations, executing the task may include detecting 18210 defects and quality issues in an item in the value chain network. In some implementations, executing the task may include predicting 18212 when an item in the value chain network will fail. In some implementations, executing the task may include identifying 18214 a value chain process capable of optimization based upon, at least in part, analyzing the information associated with the value chain network, and optimizing 18216 the value chain process. In some implementations, executing the task may include analyzing 18218 user data of a user from at least one source, and identifying 18220 one or more attributes of the user based upon, at least in part, the user data. The information may include one or more of historical sales data and market trends associated with the item. The information may include one or more of a video and a photo associated with the item. The information may include data from one or more sensors associated with the item. The value chain process may include one or more of transportation routing, inventory management, or supplier selection. The set of the value chain network entities may include at least one of products, suppliers, producers, manufacturers, retailers, businesses, owners, operators, operating facilities, customers, consumers, workers, mobile devices, wearable devices, distributors, resellers, supply chain infrastructure facilities, supply chain processes, logistics processes, reverse logistics processes, demand prediction processes, demand management processes, demand aggregation processes, machines, ships, barges, warehouses, maritime ports, airports, airways, waterways, roadways, railways, bridges, tunnels, online retailers, ecommerce sites, demand factors, supply factors, delivery systems, floating assets, points of origin, points of destination, points of storage, points of use, networks, information technology systems, software platforms, distribution centers, fulfillment centers, containers, container handling facilities, customs, export control, border control, drones, robots, robotic handling systems, 3D printers, vehicles, autonomous vehicles, hauling facilities,

waterways, or port infrastructure facilities. The set of AI-based learning models may include at least one of a transformer model, a convolutional neural network, a deep learning model trained on a set of outcomes of the value chain network entity, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model. The training data set for the set of AI-based learning models may include one of a set of objects or events that are labeled to classify the set of objects or events according to a classification taxonomy that may include at least one of the operating state, the fault condition, the operating flow, or the behavior.

[2739] As also discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may receive 18300, by a computing device, information associated with a value chain network, the information generated by at least one of a set of sensors of a set of value chain network entities, a set of IoT devices configured to collect data relating to the set of value chain network entities, or a set of APIs configured to publish data relating to the set of value chain network entities. In some implementations, VCN process 10 may provide 18302 the information to a set of Artificial Intelligence (AI)-based learning models, wherein at least one member of the set of AI-based learning models may be trained on a training data set of a set of value chain network entities operating data to classify at least one of: an operating state, a fault condition, an operating flow, or a behavior of the value chain network and at least one member of the set of AI-based learning models is trained on the training data set to determine, upon receiving the classification, a task to be completed for the value chain network. In some implementations, VCN process 10 may provide 18304 a computer code instruction set to a machine to execute the task to facilitate an improvement in the operation of the value chain network.

[2740] In some implementations, providing the computer code instruction set to the smart machine to execute the task may include instructing 18306 the machine to move an item throughout the value chain network. In some implementations, providing the computer code instruction set to the machine to execute the task may include instructing 18308 the machine to detect defects and quality issues in an item in the value chain network. In some implementations, providing the computer code instruction set to the machine to execute the task may include instructing 18310 the machine to predict when an item in the value chain network will fail. In some implementations, providing the computer code instruction set to the machine to execute the task may include instructing 18312 the machine to identify a value chain process capable of optimization based upon, at least in part, analyzing the information associated with the value chain network, and optimize the value chain process. In some implementations, providing the computer code instruction set to the machine to execute the task may include instructing 18314 the machine to transport the item between locations. The machine may include one or more of a robot, an automated guided vehicle (AGV), or a drone. The information associated with the value chain network may include one or more of a video and a photo associated with the item to detect the defects and quality issues in the item in the value chain network. The information associated with the value chain network may include data from one or more sensors associated with the item to predict when the item in the value chain network will fail. The value chain

process may include one or more of transportation routing, inventory management, supplier selection, or warehouse management. The set of the value chain network entities may include at least one of products, suppliers, producers, manufacturers, retailers, businesses, owners, operators, operating facilities, customers, consumers, workers, mobile devices, wearable devices, distributors, resellers, supply chain infrastructure facilities, supply chain processes, logistics processes, reverse logistics processes, demand prediction processes, demand management processes, demand aggregation processes, machines, ships, barges, warehouses, maritime ports, airports, airways, waterways, roadways, railways, bridges, tunnels, online retailers, ecommerce sites, demand factors, supply factors, delivery systems, floating assets, points of origin, points of destination, points of storage, points of use, networks, information technology systems, software platforms, distribution centers, fulfillment centers, containers, container handling facilities, customs, export control, border control, drones, robots, robotic handling systems, 3D printers, vehicles, autonomous vehicles, hauling facilities, waterways, or port infrastructure facilities. The set of AI-based learning models may include at least one of a transformer model, a convolutional neural network, a deep learning model trained on a set of outcomes of the value chain network entity, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model. The training data set for the set of AI-based learning models may include one of a set of objects or events that are labeled to classify the set of objects or events according to a classification taxonomy that may include at least one of the operating state, the fault condition, the operating flow, or the behavior.

[2741] As also discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may receive 18400, by a computing device, information associated with a value chain network, the information generated by at least one of a set of sensors of a set of value chain network entities, a set of IoT devices configured to collect data relating to the set of value chain network entities, or a set of APIs configured to publish data relating to the set of value chain network entities. In some implementations, VCN process 10 may provide 18402 the information to a set of Artificial Intelligence (AI)-based learning models, wherein at least one member of the set of AI-based learning models may be trained on a training data set of a set of value chain network entities operating data to classify at least one of: an operating state, a fault condition, an operating flow, or a behavior of the value chain network and at least one member of the set of AI-based learning models is trained on the training data set to determine, upon receiving the classification, a task to be completed for the value chain network. In some implementations, VCN process 10 may (e.g., via a robotic process automation system) configure 18404 the robotic process automation system to execute the task to facilitate an improvement in the value chain network.

[2742] In some implementations, the task may include automatically processing 18406 one or more orders for an item in the value chain network based upon, at least in part, the information, wherein automatically processing the one or more orders for the item in the value chain network may include extracting 18408 order data of the one or more orders from one or more sources and automatically inputting 18410 the order data extracted from the one or more sources into an

order management system. In some implementations, the task may include monitoring 18412 an inventory level for an item in the value chain network and automatically generating 18414 one or more purchase orders for the item when the inventory level for the item in the value chain network falls below a threshold. In some implementations, VCN process 10 may track 18416 a shipment of the item in real-time and the inventory level for the item in the value chain network may be automatically updated 18418 based upon, at least in part, tracking the shipment of the item in real-time. In some implementations, the task may include VCN process 10 extracting 18420 invoice data of the one or more invoices from one or more sources and automatically inputting 18422 the invoice data extracted from the one or more sources into an accounting system. In some implementations, VCN process 10 may render 18424 a user interface enabling a user to visually design automation workflows. In some implementations, VCN process 10 may render 18426 a user interface enabling a user to manage automation processes. In some implementations, VCN process 10 may render 18428 a user interface enabling a user to create a plurality of AI-based learning models and select a plurality of application programming interfaces to integrate the plurality of AI models into one or more automation workflows. In some implementations, VCN process 10 may render 18430 a user interface enabling a user to track automation performance and generate custom dashboards based upon, at least in part, the automation performance. The set of the value chain network entities may include at least one of products, suppliers, producers, manufacturers, retailers, businesses, owners, operators, operating facilities, customers, consumers, workers, mobile devices, wearable devices, distributors, resellers, supply chain infrastructure facilities, supply chain processes, logistics processes, reverse logistics processes, demand prediction processes, demand management processes, demand aggregation processes, machines, ships, barges, warehouses, maritime ports, airports, airways, waterways, roadways, railways, bridges, tunnels, online retailers, ecommerce sites, demand factors, supply factors, delivery systems, floating assets, points of origin, points of destination, points of storage, points of use, networks, information technology systems, software platforms, distribution centers, fulfillment centers, containers, container handling facilities, customs, export control, border control, drones, robots, robotic handling systems, 3D printers, vehicles, autonomous vehicles, hauling facilities, waterways, or port infrastructure facilities. The set of AI-based learning models may include at least one of a transformer model, a convolutional neural network, a deep learning model trained on a set of outcomes of the value chain network entity, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model. The training data set for the set of AI-based learning models may include one of a set of objects or events that are labeled to classify the set of objects or events according to a classification taxonomy that may include at least one of the operating state, the fault condition, the operating flow, or the behavior.

[2743] As also discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may receive 18500, by a value chain network digital twin, information associated with a value chain network, wherein the information may include a virtual representation of a plurality of associations between physical

data items of the value chain network, and wherein the information may be dynamic, real-time and time-phased. In some implementations, VCN process 10 may provide 18502 the information to a set of Artificial Intelligence (AI)-based learning models, wherein at least one member of the set of AI-based learning models may be trained on a training data set of a set of value chain network entities operating data to classify at least one of: an operating state, a fault condition, an operating flow, or a behavior of the value chain network and at least one member of the set of AI-based learning models may be trained on the training data set to determine, upon receiving the classification, a task to be completed for the value chain network. In some implementations, VCN process 10 may provide 18504 at least one of an instruction for executing the task in the value chain network digital twin or provide 18506 a recommendation for executing the task in the value chain network digital twin may be provided.

[2744] In some implementations, receiving the information associated with the value chain network may include receiving 18508 sensor data indicative of inbound and outbound shipment conditions. In some implementations, VCN process 10 may render 18510 one of a virtual reality (VR) environment, an augmented reality (AR) environment, a mixed reality (MR) environment, or a diminished reality (DR) environment for a user to interact with the sensor-based virtual representation of the plurality of associations between the physical data items of the value chain network. In some implementations, the information may include real-time data about one of inbound prepaid shipments from suppliers linked to orders or inventory coming into a network associated with the value chain network. In some implementations, VCN process 10 may generate 18512 simulations for the value chain network digital twin, wherein the simulations for the value chain network digital twin may be generated with a graphical neural network (GNN). In some implementations, VCN process 10 may generate 18514 optimizations for the value chain network digital twin, wherein the simulations for the value chain network digital twin may be generated with a graphical neural network (GNN). In some implementations, a robotic operating system may enable the value chain network digital twin. In some implementations, the value chain network digital twin may operate within a digital twin system having one or more sets of one or more digital twins, wherein each digital twin of the one or more sets may include an embedded marketplace for digital twin simulations. In some implementations, the value chain network digital twin may operate within a digital twin system having one or more sets of one or more digital twins, wherein each digital twin of the one or more sets may include an embedded marketplace for one of artificial intelligence-based learning models or artificial intelligence-based algorithms. In some implementations, the value chain network digital twin may operate within a digital twin system having one or more sets of one or more digital twins, wherein each digital twin of the one or more sets may include an embedded marketplace for data. In some implementations, the set of the value chain network entities may include at least one of products, suppliers, producers, manufacturers, retailers, businesses, owners, operators, operating facilities, customers, consumers, workers, mobile devices, wearable devices, distributors, resellers, supply chain infrastructure facilities, supply chain processes, logistics processes, reverse logistics processes, demand prediction processes, demand management processes, demand aggregation

processes, machines, ships, barges, warehouses, maritime ports, airports, airways, waterways, roadways, railways, bridges, tunnels, online retailers, ecommerce sites, demand factors, supply factors, delivery systems, floating assets, points of origin, points of destination, points of storage, points of use, networks, information technology systems, software platforms, distribution centers, fulfillment centers, containers, container handling facilities, customs, export control, border control, drones, robots, robotic handling systems, 3D printers, vehicles, autonomous vehicles, hauling facilities, waterways, or port infrastructure facilities. In some implementations, the set of AI-based learning models may include at least one of a transformer model, a convolutional neural network, a deep learning model trained on a set of outcomes of the value chain network entity, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model. In some implementations, the training data set for the set of AI-based learning models may include one of a set of objects or events that are labeled to classify the set of objects or events according to a classification taxonomy that may include at least one of the operating state, the fault condition, the operating flow, or the behavior.

[2745] As autonomous and semi-autonomous systems (generally referred to as autonomous-oriented systems) become more prevalent, the interaction among and between such systems will require varying degrees of management. This management may range from high-level coordination to direct facilitation and/or direct control. For example, an autonomous-oriented system may rely on or interact with one or more other autonomous-oriented systems. To illustrate, one autonomous-oriented system may be assigned or otherwise assume a principal task. This autonomous-oriented system may be referred to as a primary autonomous-oriented (PAO) system.

[2746] In various implementations, the principal task can be divided into subtasks. These subtasks may be controlled by or utilize one or more secondary autonomous-oriented (SAO) systems. In a simple configuration, this could mean that one SAO system is responsible for each subtask. In other configurations, one SAO system could be responsible for multiple subtasks. In various implementations, a single subtask may be handled by a set of SAO systems.

[2747] In a situation where the principal task has many subtasks, the PAO system therefore has the responsibility to manage some aspect of the SAO systems. For instance, the PAO system may communicate information to an SAO system to initiate functionality of the SAO system to complete the subtask (for example, by providing an initial input to the SAO system). In other situations, the PAO system leverages SAO systems that are generating data or information at some ongoing frequency to manage a particular subtask. In this situation, the PAO system may be configured to access or to request some portion of the information generated by the ongoing SAO system. As an example, the primary task, such as a logistics task, may have a subtask to determine the current weather or a prediction of the weather at a future date. Here, there may be an SAO system (e.g., operated by a third party) that determines weather information on an ongoing basis. Since such an SAO system already exists in operation, part of the PAO system's responsibility to perform the primary task would be to interface with the SAO system to obtain the necessary weather information.

[2748] Depending on the extent of the primary task, a subtask may be further nested — that is, much like a primary task, a subtask could be divided into more tasks that can each be controlled by one or more SAO systems. Dividing a primary task into multiple levels of subtasks (e.g., a first level of subtasks, a second level of sub-subtasks, a third level of sub-sub-subtasks, etc.) may be advantageous for autonomous/semi-autonomous systems. One example and non-limiting advantage in various implementations is parallel processing. With a primary task divided into tasks and levels of tasks, the execution of the primary task may be distributed across a greater number of computing resources (e.g., computer resources underlying SAO systems). Leveraging individual systems allows each system to execute their task(s) autonomously such that a certain set of tasks may be executed simultaneously. This parallel approach may therefore reduce the processing time for the entirety of the primary task because, to the extent logistically and technologically feasible, subtasks are completed at overlapping times rather than sequentially.

[2749] While distributing executable tasks across a vast number of resources (e.g., SAO systems) may result in efficient time for processing, this efficiency has a cost in terms of coordination effort and complexity. The coordination between autonomous-oriented systems may be difficult. For example, knowing what resources to make accessible to autonomous-oriented systems or knowing how to configure a set of autonomous-oriented systems for a primary task can dissuade even those who could ultimately derive value from coordinating such implementation. To further complicate the matter, one or more autonomous-oriented systems may already be deployed performing functions that are independent of the primary task. Here, it may be beneficial to utilize these deployed autonomous-oriented systems, but configuring the PAO system to integrate deployed systems to assist with the primary task can present compatibility issues.

[2750] One environment that is ripe for autonomous-oriented systems management is an organization or enterprise. A business organization that functions as an enterprise can have a lot of moving pieces with a particular overarching purpose, goal, or objective. For instance, a business purpose may be to produce a particular product line. To achieve its purpose, the enterprise may have a structure that includes various business units, such as divisions, departments, job roles, facilities, etc. An enterprise may span multiple business sectors and may therefore have business units, such as divisions, that can be dedicated to a particular business sector.

[2751] Although the structure of an enterprise in terms of its business units may differ, there are organizational roles that may be common across many enterprises. A corporate entity typically has tax obligations, human resources to manage, and financial and contractual obligations. From this perspective, enterprise-style businesses tend to have, among others, an accounting department for financial and tax matters, a sales department to initiate contractual obligations, a human resources department to manage the human resources, a legal department to oversee contracts and other legal matters, etc. The business units of an enterprise can also differ depending on the type of company or activity that a particular portion of the company (i.e., division) performs. As an example, when divisions of an enterprise make products, these

divisions may have additional departments to support production, such as an engineering department, a quality department, a procurement team, a manufacturing department, a logistics department, a general operations team, etc.

[2752] The nature of an enterprise's autonomous-oriented systems likely depends to some degree on the structure of the enterprise. To illustrate, some organizations may be structured such that a business unit is shared by multiple divisions. As an example, an organization shares various administrative functions. That is, although an organization may have several divisions, all of the divisions use the same legal department or human resources department. In other situations, it may make sense that a particular role or activity is included in each business unit. For instance, a manufacturing company may have several divisions where each division manufactures different products. Here, each division may have its own accounting department or sales department because overseeing those departments may be contextually dependent on the product manufactured. In other words, a sales department for a first product (e.g., a software product) may demand different job skills or educational background than a sales department for a second product (e.g., a semiconductor).

[2753] With many permutations as to the structure of an enterprise, certain aspects of the enterprise may be or become disjointed from others aspect of the enterprise. For example, a quality department in one division may have little to no idea what a quality department in another division is doing. Unfortunately, this can mean that autonomous-oriented systems — or non-autonomous system(s) relied on by autonomous-oriented systems — that are deployed by the first quality department can be unknown to the second quality department even though the systems may be of value to the second quality department. As an enterprise becomes larger, this type of problem can amplify such that managing or tracking resources such as autonomous-oriented systems can become seemingly untenable. If this type of situation arises, it is nearly inevitable that compatibility and cooperation among autonomous-oriented systems can be difficult and/or non-existent. This disappointing reality can result in underutilization of resources and/or a lack of cooperative synergy. Moreover, without addressing some of these issues, the increasing prevalence of autonomous-oriented systems can translate to an ever-increasing collective mismanagement of available autonomous-oriented resources. For example, an enterprise may struggle to operate autonomously or semi-autonomously even though it has the capability or may deploy future resources that hinder its current autonomous capabilities.

[2754] One approach to address some of the issues with resource management at the enterprise level is to design a control architecture based on an enterprise's value chain. A value chain can refer to a set of connections between organizations, business units, or individuals associated with these entities. In a value chain, the connections are based on interactions that promote a measure of value. For example, an enterprise value chain is a set of connections that promote value for the overarching purpose, goal, or objective of the enterprise. For a commercial enterprise, the value chain may generally be constructed according to a set of relationships that produce and/or increase owner/shareholder value as the measure of value.

[2755] In some configurations, value chains may be further classified into value chain networks. Similar to a value chain that includes a set of connections, the set of connections for a value chain network includes a group of entities with one or more similar attributes (e.g., similar asset management responsibilities/controls). This group may be considered a "network" of a value chain because, for example, the interactions of the group demand shared information, data, and/or resources. In some implementations, such as an enterprise value chain, a value chain network may refer to a grouping that occurs at a particular level within the enterprise. For instance, each "network" of the value chain network may be formed at the business unit level of the enterprise. Each network may be responsible for the execution of some range of tasks or activities in furtherance of the goal or purpose of the enterprise. For example, a particular business unit can be referred to as a unit structure because the members of business units share similar role obligations (e.g., share, collaborate, and/or manage similar resources, information, and/or data). In some implementations, a set or group of the value chain network entities may include, but is not limited to one or more of products, suppliers, producers, manufacturers, retailers, businesses, owners, operators, operating facilities, customers, consumers, workers, mobile devices, wearable devices, distributors, resellers, supply chain infrastructure facilities, supply chain processes, logistics processes, reverse logistics processes, demand prediction processes, demand management processes, demand aggregation processes, machines, ships, barges, warehouses, maritime ports, airports, airways, waterways, roadways, railways, bridges, tunnels, online retailers, ecommerce sites, demand factors, supply factors, delivery systems, floating assets, points of origin, points of destination, points of storage, points of use, networks, information technology systems, software platforms, distribution centers, fulfillment centers, containers, container handling facilities, customs, export control, border control, drones, robots, robotic handling systems, 3D printers, vehicles, autonomous vehicles, hauling facilities, waterways, or port infrastructure facilities.

[2756] In various implementations, an enterprise may have multiple value chain networks. This could mean that one value chain network may refer to an operations business unit of the enterprise (i.e., an operations value chain network). Another value chain network may be a marketing and sales business unit of the enterprise (i.e., a marketing and sales value chain network). Yet another value chain network may be for a logistics business unit of the enterprise (i.e., a logistics value chain network). In this sense, a value chain network for a commercial business may be an economic ecosystem where each member of the network relies on other members of the network to promote value. The members of these networks may be internal members of the enterprise (e.g., teams or individual employees) or external members (e.g., customers).

[2757] As systems, such as autonomous-oriented systems, continue to improve, custom or selectively enhanced value chains according to the architecture disclosed herein may further expand (e.g., contribute to) the value capacity of these value chains. For example, the control architecture seeks to coordinate connectivity, high-level strategy, and/or control capabilities across one or more enterprise value chains to increase a target value metric. Moreover, the

architecture may promote incremental value benefits for downstream elements (e.g., SAO systems) by providing a structure that enables cooperative configurations of task/subtask processing. In other words, SAO systems that provide services can have their configurations tuned on a higher management plane (e.g., a control plane) rather than at the particular individual SAO system level (e.g., a data plane). In this respect, SAO systems can be configured to cooperate together with configurations that optimize their collective autonomy.

[2758] Referring to the example implementation of FIG. 163A, in some implementations, a control architecture 21000 generally includes a primary system 21100 (e.g., a PAO system) and one or more secondary systems 21200 (SAO system(s)). Each of the primary system 21100 and the second secondary system(s) 21200 functions in the control architecture 21000 as a system of systems (SOS). Here, a "system of systems" refers to a structure that provides cooperative coordination among a set of systems (e.g., already deployed/available systems such as autonomous-oriented systems) that are configurable for the execution of one or more services/tasks. The terminology of "system" of systems therefore indicates that a particular system (e.g., primary or secondary system) is the liaison system for a set of underlying systems. For instance, an SOS is deployed for a particular management or facilitation goal (e.g., to achieve a particular target metric or quantifiable measure of value). This type of SOS structure allows a first SOS to communicate with a second SOS without the need to interface with the set of systems for which an SOS is responsible for.

[2759] By having a first SOS communicate with a second SOS without the need to interface with the set of systems for which the second SOS is responsible, the control architecture 21000 may be able to minimize compatibility issues between all of the systems demanded for execution a primary task (e.g., autonomous execution). For example, if the underling systems are combinations of different hardware and/or programmable software, being able to have a uniform communication language or protocol to have the systems communicate with each can be incredibly difficult. With the control architecture 21000, systems may be set up in a set or a grouping that is configured by a particular SOS that is capable of communicating with members of the set. In this respect, the SOS of the group/set only needs communication tools for its set of systems and for outside communication with one or more SOSs. For instance, the secondary system 21200 includes communication tools to configure its underlying set of systems and communication tools to interface with the primary system 21100. The control architecture 21000 therefore can be quite elastic and permit scalability for communication between multiple SOSs without any individual SOS being responsible for all or a substantial portion of communication tools for all systems utilized within a particular implementation (i.e., instance) of the control architecture 21000.

[2760] As will be discussed in greater detail below, VCN process 10 may assign at least a portion of one or more computing devices capable of fulfilling the primary command as a set of one or more computing devices to be managed by the set of secondary computing devices. In some implementations, assigning at least the portion of one or more computing devices capable of fulfilling the primary command as the set of one or more computing devices to be managed

by the secondary computing device may include executing 17418 an enrollment process between the set of one or more computing devices and the secondary computing device, and in some implementations, executing the enrollment process may include conducting 17420 an inventory of communication protocols and data formats used by the set of one or more computing devices. In some configurations, to promote communication compatibility, the systems of a set of systems for an SOS undergo an enrollment process. In this respect, the enrollment process may function as a configuration stage where an SOS ensures that it can communicate with the set of systems that it is intended to manage. For instance, each system may include its own data format(s) and/or communication protocol(s). In order for the SOS to manage and/or to configure its corresponding systems, it may therefore need to inventory and/or learn one or more ways to communicate using the communication protocols of its underlying system(s) and one or more ways to translate data formats amongst its enrolled members.

[2761] In some implementations, this configuration state may include enrolling a member system by determining at least one communication protocol for the enrollee and/or at least one data format for the enrollee. Once determined, the SOS may log or map this information (e.g., the communication protocol and/or data format) to inform the SOS the means of communication or data formatting to use when communicating with a particular system. In some configurations, the enrollment process can serve as a form of maintenance to ensure that the SOS is capable of communicating with and among its systems. For instance, when a system enrolls with the SOS, the SOS can check that it supports the enrolling systems' communication protocol(s) and/or data format(s). As an example of this check, the SOS may determine whether it has the latest version of a communication protocol or data format.

[2762] In some implementations, the secondary computing device (e.g., via VCN process 10) may obtain 17422 one or more application programming interfaces (APIs) to enable communication and data format translation between each computing device of the set of one or more computing devices and the secondary computing device. For instance, the enrollment process may configure aspects of an interface layer (e.g., discussed in detail below with respect to the interface layer 21350). For example, the enrollment process may determine and/or assign the appropriate application programming interfaces (APIs) or software development kits (SDKs) (or portions thereof) to be accessible or available to an SOS. For instance, the enrollment process generates a library of communication tools that permit communication with the systems associated with the SOS such that the SOS can reference or implement tools from the library to configure systems, integrate system outputs, and/or communicate data to/from a particular system.

[2763] In some examples, the set of systems corresponding to an SOS is a grouping of similar or interoperable systems. For instance, a clustering algorithm may identify systems that can be grouped together and managed by an SOS to perform a particular task/service. To form such a grouping, the clustering algorithm may consider various communication protocols and/or data formats. Additionally and/or alternatively, the clustering algorithm considers the task or service that the SOS is configuring and generates a set of candidate systems that are capable of

performing some portion of the task (e.g., individually or collectively). For instance, some aspect of robotics is involved in the task and the clustering algorithm identifies candidate robots from a robotic fleet.

[2764] Generally, there are at least two primary avenues for companies to achieve control towers. As an example, large companies may create their own solutions in their respective ecosystems through the integration of disparate tools (e.g., Enterprise resource planning (ERP), TCM, product lifecycle management (PLM), etc.), where the ultimate control tower may be driven/enabled by ERP systems. As another example, small and medium companies may opt to contract and outsource control tower capabilities and operations with third/fourth party logistics providers (e.g., FedEx, DHL, BlueYonder, etc.) that integrate with ERP systems and are possibly connected by the cloud providers (both private and public). However, as noted above, while distributing executable tasks across a vast number of resources (e.g., SAO systems) may result in efficient time for processing, this efficiency has a cost in terms of coordination effort and complexity, not to mention communication protocol and data formatting compatibility issues. As will be discussed throughout, VCN process 10 may achieve the efficiency with less complexity and coordination effort, thereby simplifying and improving the processing time. Instead of sharing data linearly (i.e., from party to party), value chain network participants may use VCN process 10 to send all relevant data to a unified data repository, where the information is accessed by relevant partners (e.g., suppliers, manufacturers, warehouses/distribution centers, businesses, customers, etc.). Control towers allow companies to analyze operational data in real-time, allowing for proactive risk management, and more granular control over operations overall. Moreover, as discussed herein, a control tower dashboard may be a real-time dashboard(s), with advanced analytics, alert-driven event management, AI-based flagging and responses to potential disruptions in the value chain, intelligent procurement, predictive sourcing, automation (e.g., smart machine and robotic process automation), and digital twin information, all in one place. An example control tower dashboard (e.g., control tower dashboard 17300) is shown in the example implementation of FIG. 161.

CONTROL TOWER FOR COMPUTATIONAL TASKS OF VALUE CHAIN NETWORK ENTITIES

[2765] In some implementations, a VCN process, such as VCN process 10, may configure 17400 a set of secondary computing devices (e.g., secondary systems 21200) of a set of value chain network entities for communication with a primary computing device (e.g., primary system 21100) of an enterprise operator, wherein the primary computing device may manage the set of secondary computing devices. For instance, in the example implementation depicted in FIG. 163A, the primary system 21100 is deployed as a control tower SOS. When a system is arranged as a control tower SOS, the system is typically deployed as a manager or primary facilitator among a set of secondary systems 21200 (e.g., as shown in FIG. 163B). As a manager (or other similar user), the overarching goal of the control tower may be to propagate a strategy (e.g., optimize a set of secondary systems 21200 for a particular primary task or primary

service), to provide oversight to a system arrangement (e.g., system monitoring), and/or to control a set of systems (e.g., tune input parameters to secondary systems 21200 to produce a target result).

[2766] In some implementations, VCN process 10 may receive 17402 (e.g., via at least one member of the set of secondary computing devices) a set of primary commands from the primary computing device, wherein each of the set of commands may be at least one of a task or a request. For instance, and referring at least to the example implementation of FIG. 165A, the primary system 21100 receives a set of inputs 21102. Here, some examples of these inputs 21102 include external data (e.g., similar to external data 21050), external controls imposed on the system, and/or operational feedback. As a control tower or primary system 21100, upon receipt of the inputs 21102 at 21402, the primary system 21100 (e.g., using a CSS1) identifies that the inputs 21102 correspond to a particular request to perform a primary task. As part of the performance of the primary task, the primary system 21100 may be configured to perform managerial functions. These managerial functions may include: determining a strategy to perform the requested task; providing oversight for execution of the requested task; and/or controlling actions that execute the requested task.

[2767] As shown in FIG. 163A, the secondary system 21200 is also capable of generating a system output 21204 that may be communicated to the primary system 21100. The primary system 21100 may receive or otherwise obtain the system output 21204 at various times during an instance of the secondary system 21200. In other words, the generation of a system output 21204 may occur during initialization of the secondary system 21200, during simulation of the secondary system 21200, during operation/implementation of the secondary system 21200, or during some wind-down or final phase of the secondary system 21200 (e.g., in response to the secondary system 21200 completing a task/service).

[2768] In some examples, the system output 21204 functions as a feedback loop. For instance, as a feedback loop, the system output 21204 may inform the intelligence of the CSS. Here, by informing the intelligence of the CSS, the primary system 21100 via its CSS may further tune or fine tune the parameters that are generated and provided to the secondary system 21200 as system inputs 21202. In other words, in some circumstances, systems inputs 21202 may be provided to the secondary system 21200 on an ongoing basis (e.g., for ongoing product production). In these circumstances, the system outputs 21204 of the secondary system 21200 may impact the next round or iteration of system inputs 21202 provided to the secondary system 21200. In other words, the system outputs 21204 are capable of updating and/or modifying the system inputs 21202 due to the intelligent functionality of the CSS of the primary system 21100.

[2769] Referring further to FIG. 163A, the secondary system 21200 is a value chain SOS. In other words, the configuration promoted by the secondary system 21200 is generally optimized for a particular value metric or target metric. The focus and/or dependence on this value metric is therefore generally carried through or applied to the CSS of the secondary system 21200. For instance, the target metric is profit and therefore the secondary system 21200 performs its

functionality with profit as a primary optimization variable when configuring its associated systems.

[2770] As shown in FIG. 163A, in some examples, the CSS configures the set of systems associated with the secondary system 21200. Here, the set of systems that is configurable by the CSS2 is illustrated by n number of additional CSSs(1–n). In other words, a secondary system 21200 may be responsible for performing some group of subtask(s) or service(s) to execute a primary task/service. Each subtask/service within that group may be associated with one or more systems (e.g., SOA systems). Stated differently, the one or more systems are capable of enabling and/or performing a subtask/service when configured. Meaning that, systems, such as SAO systems, are capable of performing functions that result in the execution of a range of tasks or services. These functions may be parameterized (e.g., according to a configuration) to tune the system to perform a particular task/service within the range or a specialized version of a task/service. In this respect, the CSSs of the secondary system 21200 therefore may enable or configure the set of systems that perform the corresponding subtask(s)/service(s).

[2771] As a simple example, the CSSs2 of the secondary system 21200 includes three systems and a CSS (e.g., CSS3–CSS5) that corresponds to each system (though a one-to-one relationship is described, other relationships are possible). In this example, the CSS2 of the secondary system 21200 would have to configure three CSSs to provide the services/tasks associated with the secondary system 21200. To illustrate, if the primary task was production of a product, the secondary system 21200 may be responsible for a subtask/service of the production – e.g., logistics. Here, although the secondary system 21200 is responsible for logistics, part of that responsibility may be the management or facilitation of systems associated with three different logistic channels – e.g., trucking logistics, flight logistics, and water vessel logistics. Accordingly, each of those three logistic channels may be configured to have its own CSS such that the secondary system 21200 provides configuration data for the operations of the three CSSs associated with each of those logistic channels. In this respect, the secondary system 21200 is able to generate configuration data that ensures that each CSS associated with each of the logistic channels collectively is optimized for the primary task. For instance, instead of each of the CSSs of the logistic channels only seeking their own self-optimization, the optimization is driven from a higher level. Meaning, that, for example, the water vessel logistics on its own may not seem to be optimized specifically for water vessel logistics of the product, but in the scheme of the entire logistics for the product, it is optimized in conjunction with the flight logistics and the trucking logistics so that the target metric is maximized (or minimized) across all of the logistic systems.

[2772] In some implementations, the primary system 21100 is the system that dictates or determines the set of services/tasks performed by each secondary system 21200. For example, the intelligence associated with the primary system 21100 determines the number of secondary systems 21200 that may be required for a particular primary task and/or the available systems that would enable the primary task. For instance, the primary system determines a combination of available systems that would enable the primary task. In this situation, the intelligence of the

primary system 21100 recognizes that individually configured systems working together in some combination can perform some aspect of the primary task.

[2773] In some implementations, as noted above, VCN process 10 may assign 17404 at least a portion of one or more computing devices capable of fulfilling the primary command as a set of one or more computing devices to be managed by the set of secondary computing devices. For example, primary system 21100 as a control tower SOS receives a primary task or service request, as discussed above. In response to the receipt of the primary task or service request, the primary system 21100 determines a set of systems that can fulfill the request from a pool of available system resources (e.g., a pool of autonomous-oriented systems). In some implementations, the determined set of systems are parsed or classified into groups where each group is assigned to a secondary system 21200. As will be discussed below, each secondary system 21200 may generate a set of CSSs for the set of systems that are assigned to it.

[2774] In some implementations, VCN process 10 (e.g., via the set of secondary computing devices) may configure 17406 the set of one or more computing devices to fulfill one or more secondary commands based upon, at least in part, the primary command. For instance, with the CSSs scaled to the assigned set of systems, the secondary system 21200 configures each system of the set using the CSSs so that the set associated with the secondary system 21200 can collectively perform/enable the primary task with execution of its one or more tasks/services.

[2775] In some implementations, as noted above, configuring the set of one or more computing devices to fulfill the one or more secondary commands may include generating 17412 a set of at least one configured system service (CSS). For instance, FIG. 163A depicts a single primary system 21100 as the control tower SOS and a secondary system 21200 as a value chain SOS. Each SOS (e.g., the primary system 21100 or the secondary system 21200) generally includes at least one configured system service (CSS) and a general system service (GSS). For example, the primary system 21100 is shown with a first CSS (CSS1) and a first GSS (GSS1) while the secondary system 21200 is shown with a second CSS (CSS2) and a second GSS (GSS2). In this respect, each CSS and GSS may be tailored or dependent upon the SOS with which it is associated. For example, in some implementations, when the primary system 21100 as the control tower SOS is set up for oversight, the CSS1 and the GSS1 are configured to provide service(s) for oversight.

[2776] It will be appreciated after reading the present disclosure that any individual parts of the present disclosure that use a processor may include some or all of VCN process 10 (and *vice versa*). For example, VCN process 10 may include some or all of a CSS, a GSS, a primary system, a secondary system, a service, an application, etc. That is, any individual parts of the present disclosure that use a processor may be configured to effectuate some or all of the functionality of VCN process 10 (and *vice versa*). Accordingly, in some implementations, VCN process 10 may be a purely server-side process, a purely client-side process, or a hybrid server-side / client-side process that is cooperatively executed. Furthermore, it will be appreciated after reading the present disclosure that VCN process 10 may apply equally to the demand side as the supply side. That is, VCN process 10 is described with examples of obtaining information and

insights for things affecting the supply of an item; however, VCN process 10 may also be used with examples of obtaining information and insights for things affecting the demand of an item. As such, the description of VCN process 10 being used for the supply side should be taken as example only and not to otherwise limit the scope of the present disclosure.

[2777] Factors that may affect the demand of an item may include, e.g.,: Customer attributes, such as geographic location, historical purchasing habits and preferences, financial capacity, interactions with similar or proximal products, lifetime value; Market trends, such as popularity of particular products or categories of products, activism or social movements (e.g., palm oil is linked to the destruction of biodiversity, deforestation, etc. and demand for products with this ingredient may be suppressed as a result of increasing social awareness of negative impacts), seasonal demand; Competition, such as availability/price/appearance/brand value of competing or substitute products; Economic, such as correlation of item purchases with economic factors such as consumer spending, interest rates, exchange rates, etc.; Governmental/Regulatory, such as trade restrictions, tariffs, regulations related to import/export control or materials/ingredients; Marketing, such as advertising campaign metrics (e.g., website traffic, total page views, bounce rate, engagement rate, cost per click, cost per lead, cost per acquisition, conversion rate, longevity).

[2778] The GSS functions to provide general system integration and operations such as data storage, data processing, networking, and other shared functionality (e.g., the GSS may have similar functionality to aspects of data processing systems 1612, 10206, 12030, 12130, 12142, 13024 and/or data storage systems 624). In FIGS. 163A and 163B, the GSS is shown with a dashed-lined perimeter to represent that the GSS may be included locally within a deployed instance of an SOS (e.g., a primary system or a secondary system) or operate remotely yet in communication with an SOS. When deployed locally, the GSS may be configured in dedication to its associated SOS. In that respect, aspects of the GSS may be optimized, programmed, or configured to the instance of the SOS. When functioning remotely, the GSS may operate as a global GSS that one or more systems (e.g., a primary system 21100 and/or a secondary system(s) 21200) can access/utilize. Here, this type of global configuration may be advantageous, depending on the deployment of the control architecture 21000, because data storage and data processing functionality is shared among systems. Meaning that, data format compatibility or other data compliance related aspects are potentially addressed on the front-end (e.g., designed for compatibility).

[2779] In some implementations, generating the set of at least one CSS may include utilizing 17414 an output of the primary computing device as an input to generate one or more control parameters. The CSS for an SOS functions to configure the set of systems corresponding to the SOS to perform a set of tasks or services based on intelligence determined by the CSS. The intelligence performed for the CSSs is generally determined by a configured intelligence system CIS that is a part of (e.g., as shown in FIG. 165A) or associated with the CSSs. More particularly, the configured intelligence service CIS used by the CSS has the intelligence capabilities of or that are similar to the intelligence services system 8800 except that the

configured intelligence system CIS is an intelligence services system that is configured, for example, by the CSS to provide intelligence for a particular set of system services. In this respect, the CSSs may act akin to the intelligence service client 8836 in its relationship with the configured intelligence system CIS. For instance, if the primary task of primary system 21100 is to control the production of a product, the intelligence of the CSS identifies system resources that (e.g., a set of systems) are available (e.g., within the enterprise ecosystem) to control production of the product and configures these control-based resources to generate control parameters that downstream production resources demand to produce the product. To extend this example to FIG. 163A, the primary system 21100 generates an output that is provided to the secondary system 22000 as a system input 21202. If the CSS1 generates control parameters, these control parameters may be fed as output of the primary system 21100 to the secondary system 21200 as system inputs 21202. The secondary system 21200 may then utilize the system inputs 21202 to configure its own CSS (e.g., the CSS2).

[2780] In some implementations, VCN process 10 may (e.g., via the set of secondary computing devices) fulfill 17408 the primary command based upon, at least in part, the set of one or more computing devices fulfilling the one or more secondary commands. For instance, FIG. 163B is similar to FIG. 163A except that FIG. 163B illustrates multiple secondary systems 21200a–n being managed by the primary system 21100. That is, multiple SOS instances may be coordinated via a single control tower SOS instance. The number of secondary systems 21200 associated with a control tower SOS or primary system 21100 may depend on several variables. Some of these variables may include, e.g., the selected set of systems to fulfill a service/task request, the type of systems selected, the configurable parameters of the selected systems, the communication capabilities of the selected systems, the manner in which the systems may be combined or cooperate, and the structure or characteristics of the enterprise deploying the control architecture 21000.

[2781] In some configurations, the set of systems selected to fulfill a service/task request (e.g., a request for a primary task) includes one or more third-party systems that the enterprise can access or utilize. For instance, for autonomous generation of a product, the primary system 21100 may inquire about demand for the product using a customer relations management (CRM) system managed by a third party. Here, the primary system 21100 or a secondary system 21200 may provide the CRM system with data that characterizes the product to be generated in order to query the CRM system to determine an estimated demand forecast from customers who have an interest in the type of product that has been characterized. In some implementations, the CRM system returns an output (e.g., a forecasted demand) based on the input data that is then configured to inform or be communication to one or more other systems. Therefore, when third-party systems are integrated in the configured systems workflow of the control architecture 21000, the SOS can determine acceptable inputs to these third-party systems and expected/anticipated outputs so that outputs can be pipeline data to the appropriate CSS.

[2782] In some implementations, VCN process 10 may send 17410 a generated system output to the primary computing device responding to the primary command based upon, at least in

part, the set of one or more computing devices fulfilling the one or more secondary commands. For instance, and to expand on the previous example using FIG. 163B for example purposes only, when the set of systems that fulfill the request are parsed or classified into n groups, the primary system 21100 assigns the first group to the first secondary system 21200a, the second group to the second secondary system 21200b, and the nth group to the nth secondary system 21200n. Here, outputs from the primary system 21100 may be provided to any or all of the secondary systems 21200a–n to form the system inputs 21200a–n for the secondary systems 21200. Much like the single secondary system example of FIG. 163A, each secondary system 21200 is capable of generating system outputs 21204a–n that are communicated to or obtained by the primary system 21100. Although not shown, each of these secondary systems 21200, as SOS instances, may include CSSs and/or GSSs. Therefore, each secondary system 21200 generates a set of CSSs for the set of systems that are assigned to it.

[2783] In some implementations, an SOS has the capabilities to interface with entities or resources that are external to the SOS. For instance, FIGS. 163A and 163B illustrate the primary system 21100 as the control tower receiving external data inputs/outputs (I/O) 21050. Some examples of external data I/Os 21050 include asset indicators (e.g., asset statuses, asset locations, asset time of life, etc.), market data (e.g., for markets impacted/associated with an enterprise asset), weather data, sensor data (e.g., from robotic fleet management, IoT, digital twin, environmental container conditions such as temperature, humidity or light intensity, etc.), enterprise resource planning (ERP) data, network data (e.g., connectivity data), event data (e.g., holidays, event logs, cycle time, running time, etc.), local media, social media, geospatial data, economic data (e.g., inflation rates, unemployment rates, exchange rates, stock prices, investor sentiment data), web analytics (e.g., website traffic, search engine trends, website interaction behaviors), supplier performance data (e.g., supplier reputation and performance data and trends, supplier lead times, supplier quality), logistics and shipping data (e.g., freight rates, carrier performance, shipping route data), national/global news media (e.g., worker strikes, labor shortages, natural disasters, geopolitical instability). In some examples, the external data I/O 21050 is provided by another control tower SOS. Additionally and/or alternatively, the external data I/O 21050 may be generated by a third-party system that is or is not included in the control architecture 21000 such as a software as a service (SaaS) provider to the enterprise.

[2784] In some implementations, the primary computing device (e.g., via VCN process 10) may be bypassed 17424 to receive external data at the secondary computing device when the external data is unused by the primary computing device. For example, the control architecture 21000 is not limited to only the primary system 21100 receiving the external data 21050. In some configurations, it may be more efficient from a data management or data flow approach to feed external data 21050 directly to a secondary system 21200 or to a component of a secondary system 21200 (e.g., a CSS). For instance, a system of the secondary system 21200 rather than a system of the primary system 21100 is the system that consumes the external data 21050. In some instances, if the external data 21050 is not utilized by the primary system 21100 (e.g., the CSS), then having the primary system 21100 ingest, store, and/or relay the external data 21050

to a secondary system 21200 that consumes the external data 21050 may become burdensome or computationally expensive.

[2785] Referring to the example implementations of FIGS. 164A and 164B, the control architecture 21000 may be adapted to cater to a specific organization of an enterprise. In other words, the SOS structure that includes the CSS may be deployed to provide system management at any business unit level. To illustrate, FIG. 164A depicts a management stack 21300 (also referred to as stack 21300) that includes a control layer 21310, an operational layer 21320, an activity layer 21330, and a service layer 21340. Although the management stack 21300 is depicted as a 4-layer management stack 21300, the principles of a primary SOS system and a secondary SOS system may be applied to more or less layers (e.g., a 3-layer stack, a 5-layer stack, or a 10-layer stack). As shown in FIG. 164B, one reason for the 4-layer management stack 21300 is that it may track an enterprise's value chain workflow. For instance, in FIG. 164B, an enterprise may have a plurality of enterprise value chain networks that correspond to the operational groups/teams of the enterprise. FIG. 164A has four different operational groups – marketing and sales, logistics, service, and operations. Each operational group may be capable or expected to perform one or more activities for the enterprise. And moreover, each activity may use a set of services to perform the respective activity. In this sense, the service layer 21340 of the management stack 21300 corresponds to the set of services 21342a-n (e.g., data sourcing services, data processing services, intelligence services, analytics services, smart contracts services, distributed ledger services, governance services, security services, risk management services, etc.) that perform an activity 21332. The activity layer 21330 corresponds to the activity 21332 performed by an operational group of the enterprise and the operational layer 21320 corresponds to the particular operational team performing the activity 21332 with the set of services 21342.

[2786] In some implementations, a distributed ledger service may increase traceability of material supply chain to ensure corporate standards are met, as well as lower losses from counterfeit/gray market trading. A distributed ledger service may also improve visibility and compliance over outsourced contract manufacturing, as well as reduce paperwork and administrative costs, strengthen corporate reputation through providing transparency of materials used in products, improve credibility and public trust of data shared, reduce potential public relations risk from supply chain malpractice, and engage stakeholders.

[2787] In some implementations, a governance service may be used for access of a system in a VCN setting, including a set of policies, procedures, and controls that are implemented to ensure secure access to the system. The governance service may be responsible for managing and controlling access to the system by employees, suppliers, and other stakeholders in the supply chain network. The governance service may define the rules and requirements for accessing the system, including the authentication and authorization processes. This may involve establishing user roles and permissions, defining access levels, and implementing controls to ensure that only authorized individuals can access the system. The governance service may also be responsible for monitoring and auditing system access to detect and prevent unauthorized access or misuse

of the system. This may involve regular review of user access logs and other system activity to identify potential security breaches or policy violations. Additionally, the governance service may be responsible for enforcing compliance with regulatory requirements and industry standards for data privacy and security. This may involve establishing and maintaining security protocols and procedures to protect sensitive data and information from unauthorized access or disclosure. In some implementations, innovations such as haptics, biometrics, and AI may be applied to enhance the security and functionality of the governance service. For instance, haptics may be used to provide a multi-factor authentication process that includes physical verification such as fingerprints or facial recognition, in addition to traditional login credentials such as username and password. Biometrics may also be used to enable continuous authentication, which may involve monitoring user behavior and biometric data to detect and prevent unauthorized access or suspicious activity. AI may be used to analyze access logs and other system activity data to identify potential security threats or policy violations in real-time. This may include identifying patterns of access that are outside of normal behavior or detecting unusual activity that could indicate a security breach. A scoring system may be used to assess the performance or behavior of individuals or organizations within the governance system. This may be used to identify areas for improvement or to provide incentives for good behavior. A Know Your Business (KYB) system may be used to verify the identity and legitimacy of businesses that are operating within the governance system. This may help prevent fraud, money laundering, or other illegal activities. A KYC system may be used to verify the identity of individuals who are participating in the governance system. This may help prevent fraud, identity theft, or other illegal activities. In some implementations, integrated blockchain technology may be used as a distributed ledger to record and verify transactions or interactions within the governance system. For example, a blockchain-based voting system may be used to ensure the integrity of elections or decision-making processes within the governance system. Another way to use blockchain is to create smart contracts that automatically execute certain actions or decisions within the governance system based on predefined rules. This can help reduce the risk of human error or fraud. Blockchain may also be used to create decentralized autonomous organizations (DAOs), which are organizations that operate based on rules encoded in smart contracts on a blockchain. DAOs may be used to create more democratic and decentralized governance structures, where decisions are made through transparent and decentralized voting processes.

[2788] As mentioned previously, the organizational structure of an enterprise, and especially a large enterprise, means that it is likely that multiple value chains may need to be managed or controlled to perform the objective, goal, or purpose of the enterprise. With this being the case, the control architecture 21000 may enable a primary system 21100 or control tower SOS to control multiple value chains from a central management position. For example, FIG. 164A depicts a single control tower SOS on the control layer 21310 as the overall management hub for the management stack 21300. The primary system 21100 may then manage one or more supporting operations 21322 (e.g., secondary systems 21200 that are operation specific) on the

operational layer 21320. For instance, a first value chain may follow the first path p1 while a second value chain may follow the second path p2. For either value chain, the operational layer 21320 includes a set of supporting operations 21322. In terms of this example, a value chain network refers to a value chain that flows through a particular operational entity. That is, each operational entity or supporting operation has its own network of activities 21332 and services 21342 that enable the operational entity to properly function for the enterprise. For example, each supporting operation 21322 is shown to perform one or more activities 21332a–n on the activity layer 21330 with each activity 21332 supported by a set of services 21342a–n associated with the service layer 21340.

[2789] Referring specifically to the stack 21300 of FIG. 164A, the first path p1 flows through a first supporting operation 21322a. The first supporting operation 21322a includes n number of activities 21332a–n. Each activity 21332 is supported by a set of services 21342. For comparison, the second path p2 may flow through another supporting operation 21322 (e.g., a second supporting operation 21322b) of a set of supporting operations 21322a–n and then have a similar network structure with a corresponding set of activities 21332 performed/enabled by an underlying set of services 21342. In this respect, the stack 21300 is able to accommodate any number of supporting operations indicating that any number of value chains/value chain networks may be deployed with a single instance of a control tower SOS.

[2790] In some implementations, generating the set of at least one CSS may include generating 17426 at least one CSS for each interface layer in a management stack (e.g., management stack 21300). For instance, in some configurations, as shown in FIG. 164A, the functionality of each layer may be orchestrated by one or more SOS units. Meaning that, each layer may have one or more CSS that is capable of configuring the systems to provide the services demanded at each layer. In other words, each layer may have at least one local CSS to ensure the functionality of the layer can occur in an autonomous-oriented manner (e.g., autonomously or semi-autonomously). Each layer may be arranged to manage or control its proximate lower level. In this arrangement, the CSS for a particular layer functions to provision configurations (e.g., inputs, starter materials, connect data pipelines, etc.) that allow a lower level to function. For instance, the operational CSS associated with the operational layer 21320 configures systems that enable the set of activities 2132 to operate. Similarly, the CSSs of the activity layer 21330 configures systems that enable the set of services 21342 to function. At the lowest level, shown as the service layer 21340, the CSSs associated with this service layer 21340 enable the execution of the set of services 21342.

[2791] In some implementations, each layer in the management stack 21300 is capable of communicating with another layer using an interface layer 21350. The interface layer 21350 may include communication tools or protocols that enable one SOS to communicate with another SOS potentially anywhere in the stack 21300. The interface layer 21350 may also function to limit which layers (or SOSs) can communicate with which other layers (or other SOSs). That is, an architect of the stack 21300 may prefer for some communication tools to be limited to higher level control or vice versa (e.g., limited to service layer communication). In

this respect, the interface layer 21350 can apply communication access controls at the layer level.

[2792] In some configurations, the interface layer 21350 includes a range of communication tools that permit one system to communicate with another system. For example, the interface layer 21350 includes a plurality of application programming interfaces (APIs) that allow software associated with one system or SOS to communicate with software of another SOS. An API is a software tool that generally facilitates communication between two platforms (e.g., between two CSSs or between two SOS systems). APIs are typically designed to standardize the way programmers/developers interact with a platform (e.g., a software application). In other words, prior to APIs, programmers/developers would likely have to customize the manner in which they interact or connect with the services of an application. With APIs, there are typically technical specifications in the form of documentation that is associated with the API that specifies how to integrate with the API. When using an application, a user may initiate a task/service from the application that generates a request. The API associated with the application may then make a call that relays the request to a destination or API endpoint (e.g., a uniform resource locator (URL) of a server). Upon receipt of the request, the API endpoint facilitates the execution of the task (e.g., by a third-party application or database that provides the task/service). From that perspective, APIs can ease the development and user experience by connecting disparate system (e.g., disparate software applications). In other words, by using an API, the entity configuring a system or application to perform a service can integrate the functionality of other systems without having to design those systems' functionality in-system. Some examples of APIs that the interface layer 21350 may include are Web APIs used to access web browsers or web-based devices, Simple Object Access Protocol (SOAP) APIs that use extensible markup language (XML) and XML schema to perform calls and structure payloads, Open APIs (also known as public APIs), Representative State Transfer (REST) APIs that use stateless communication protocols, JavaScript Objection Notation (JSON)-Remote Programming Calls (RPC) for asynchronous server calls, and other custom APIs. By making an array of APIs accessible to portions of the stack 21300, the interface layer 21350 helps ensure that the language of one system is capable of being translated to a language of another system. Otherwise, the set of systems deployed in a given instance of the management stack 21300 may have communication compatibility issues or suffer from the inability to cooperatively integrate cross-functionality.

[2793] The interface layer 21350 is also configured to use other communication tools such as a user interface (UI) (e.g., graphical user interfaces (GUI)) and software development kits (SDKs). Here, a GUI may correspond to the interface of an API or refer to another interface designed to curate a user experience and interaction with one or more systems. For instance, a system has a GUI that can receive configuration data from CSSs (e.g., to populate data entry fields provided by the GUI to receive a set of inputs). The GUI generally contains graphical elements with underlying functionality. These graphical elements may enable navigation and/or trigger execution of functions of the system associated with the GUI. It will be appreciated that other

types of UIs may be included (e.g., audio-based UIs, gesture-based UIs, digital twin interface, smart wallet interface, augmented reality interface, virtual reality interface, mixed reality interface, interfaces with embedded marketplaces for assets, services, models, data, interfaces that may provide data stories, smart wallet interface that may provide data stories related to a transaction, an account, a set of accounts, etc., smart wallet interface that may manage receipts, interfaces that may provide recommendations/predictions etc.,) without departing from the scope of the present disclosure. In some implementations, a digital twin interface may facilitate the creation and management of a virtual replica of the physical elements, processes, and entities involved in a value chain network. Users may utilize the interface to visualize, simulate, or analyze operations, workflows, scenarios, or strategies pertaining to the value chain network in a virtual environment. In some implementations, a smart wallet interface may allow for the management of transactions, credentials, and digital assets within a network. It may include mechanisms for creating, amending, or substantiating smart contracts. The smart wallet interface may allow value chain network entities to exchange digital assets in a secure manner by ensuring the authenticity of transactions and their participants.

[2794] An SDK or devkit may refer to the set of building tools (e.g., software building tools) for a specific platform (e.g., system). Often, the tools of an SDK may include resources such as a compiler that translates from one programming language to another, code samples that provide examples of coding for the platform, code libraries with sets of preconfigured code sequences (e.g., common or frequently used coding functions), testing and analytics tools that generate metrics/analytics to quantify the performance of programming in, for example, testing and production environments, documentation that provides information or instructions to programmers/developers (e.g., instructions about other tools of the SDK), debuggers that are capable of identifying coding errors, and one or more APIs to relay calls to other services and systems. By deploying these tools, a new application may be built (e.g., beginning with an integrated development environment (IDE)) or an existing application may be modified. In some examples, for mobile application development, the SDK may be Apple's IOS SDK or Google's Android SDK. On the other hand, for large-scale applications, such as enterprise Software-as-a-Service (SaaS), proprietary web applications, or desktop software applications, the SDK may be open source .NET SDK.

[2795] With a management stack 21300, each layer of the stack 21300 may include one or more SOS units. As shown in FIG. 164A, the management stack 21300 maintains a similar hierarchical arrangement to that of the simple primary and secondary system 21100, 21200 of FIG. 163A. That is, the control layer 21310 that functions to control the value chain includes a control tower SOS as the primary system 21100.

[2796] Referring to FIG. 164B, an example management stack 21300 is shown for a particular enterprise value chain. In this example, the control layer 21310 is a primary system 21100 or enterprise control tower SOS. The operational layer 21320 includes four potential value chain networks corresponding to the supporting operations 2132 of (1) marketing and sales, (2) logistics, (3) service, and (4) operations. As shown by the darkened outline, the particular value

chain depicted in FIG. 164B includes operations as the operational layer 21320. Here, with the operational layer 21320 corresponding to the operations group of the enterprise, the activity 21332 for the activity layer 21330 may be one of several activities 21332 that operations may perform. For instance, FIG. 164B illustrates a menu or set of activities 21332 that are associated with the operations group of the enterprise. Of the set of activities 21332 depicted, the operations group is responsible for performing the activities 21332 of production processes, infrastructure management, and quality control. In this respect, the primary system 21100 of the control layer 21310 may have a value chain dedicated to the management and/or control of each of these activities 21332 in relation to operations as the supporting operation 21322 for the enterprise. That is, the first path p1 of FIG. 164B illustrates a first value chain that corresponds to operations performing the activity 21332 of production processes. The second path p2 illustrates a second value chain that corresponds to operations performing the activity 21332 of infrastructure management. The third path p3 illustrates a third value chain that corresponds to operations performing the activity 21332 of quality control.

[2797] In some configurations, such as FIG. 164B, each enterprise group at the operational layer 21320 may have a corresponding set of activities 21332 that it can perform. For instance, FIG. 164B depicts that the marketing and sales group at the operational layer 21320 may perform the activities 21332 of contracts and information services. The logistics group at the operational layer 21320 may perform the activities 21332 of demand management, supply chain management, and procurement. The service group at the operational layer 21320 may perform the activities 21332 of finance, research and development, and human resource management. In these configurations, each activity flow path p can correspond to a value chain network. In that sense, the enterprise control tower may be simultaneously or sequentially managing upwards of a dozen value chain networks.

[2798] FIG. 164B also depicts that the services layer 21340 of the value chain differs based on the activity 21332 to be executed by one or more services 21342. For example, the value chain portrayed as the first path p1 may include a different set of services for the activity 21332 of production processes than the second path p2 for the activity 21332 of infrastructure management. Likewise, the third path p3 for the activity 21332 may have a completely different set of services than both activities 21332 of production processes and infrastructure management. It will be appreciated that more or less paths may be used.

[2799] Referring to FIG. 164B specifically, the service layer 21340 shows a set of services 21342 that are executed in some combination to perform the production processes activity 21332. The set of services may be a unique mix or combination of service building blocks. A building block generally refers to a system that may be configured individually or in combination with another one or more systems to perform task(s)/service(s) that enable a particular activity 21332 (e.g., autonomously allow the activity 21332 to occur). In this sense, it can be said each building block or service 21342 can have a particular configuration to support CSSs for an SOS. In FIG. 164B, the activity 21332 of production processes may be executed by a set of services 21342 that includes service building blocks A, J, N, and P. Although not

depicted, a similar example would be that the activity 21332 of infrastructure management may include service building blocks A, G, and O. As supported by these examples, a building block, such as A, may be configured in combination with two different sets of services in order to perform different activities 21332 (e.g., production processes services v. infrastructure management services). With this being the case, permutations of building blocks can perform a vast array of activities 21332.

[2800] There may be a variety of service building blocks that may be configured to perform activates/actions for the purpose of the primary task. The building blocks that may be implemented by the control architecture 21000 are not limited to a particular ecosystem, but rather may transcend the ecosystems that they are described in relation to herein to provide a configured function or set of functions for the control architecture 21000. For instance, each of the applications 614, applications 630, the value chain entities 652, demand management applications 824, 1502, supply chain applications 812, 1500, intelligent product applications 1510, asset management applications 1530, and enterprise resource management applications 1520 from the VCNP 604 may be a building block. Other examples of buildings blocks may include adaptive intelligent systems 614, artificial intelligence systems 1160, 10212 (including hybrid artificial intelligence systems 3060), and/or other systematic services, such as artificial intelligence and computational systems 634, robotic process automation (RPA) systems 1442, protocol adaptors 1110, packet acceleration systems 1410, edge compute management systems 1400, edge intelligence systems 1420, edge networking systems 16100, adaptive networking systems 1430, state and event managers 1450, opportunity miners 1460, artificial intelligence systems 1160, digital twin systems 1700, digital twin simulation systems 2020, machine vision systems 1600, entity interaction systems 1920, real time monitoring systems 1520, visual monitoring systems 1930, point of interaction systems 1530, physical process observations systems 1510, robotic-oriented systems (e.g., robotic motion tracking systems), machine state monitoring systems 1940, IoT systems 1172, user feedback systems 1534, location monitoring systems 1532, behavioral monitoring systems 1538, entity discovery systems 1900, classification systems 1610, data processing systems 1612, signal processing systems 1614, prediction systems 1620, configuration systems 1630, control systems 1640, analytic systems 1650, testing/diagnostic systems 1660, security systems 1670, and quantum computing systems 17000. For additive manufacturing, some examples of building blocks include systems/services for the additive manufacturing platform 10110, such as additive manufacturing units 10102, pre-processing systems 10104, post-processing systems 10106, material handling systems 10108, finishing systems 10121, packaging systems 10122, shipping systems 10124, processing systems 10127, data acquisition systems 10602, design and simulation systems 10116, Product Lifecycle management (PLM) systems 10648, maintenance management systems (MMS) 10650, Quality Management systems (QMS) 10652, certification systems 10654, compliance systems 10656, feedstock formulation systems 10706, risk prediction and management systems 10712, marketing and customer service systems 10716, and AI systems 10212. With respect to liquid lens, some examples of building block include systems/services associated with dynamic visions

systems 11200. For robotic fleet management, examples of building blocks include systems/services relating to the fleet management platform 12000, such as fleet operations systems 12002, robot operating units 12040, robot control systems 12150, robot security systems 12170, robotic process automation (RPA) systems 12216, vision and sensing systems 12112, and motion planning systems 12158. For smart containers, examples of building blocks include systems/services relating to the smart intermodal shipping container system 1300, such as smart containers 13026, smart container operating units 13040, logistics systems 13016, maintenance management systems 13028, smart container task assemblies 13050, security systems 13046, communication management systems 13010, remote-control systems 13012, human interface systems 13038, fleet management systems 13002, fleet configuration systems 13020, quantum computing services 13008, and smart container digital twins (e.g., smart container fleet manager digital twin 13328). For digital product networks, examples of building blocks include systems/services relating to the digital product network 14000, such as digital product network services 14002, connected products 14010, digital products 14210, demand aggregation systems 14250, supply chain management systems 14252, new product development systems 14254, customer relationship management systems 14256, PLM systems 14258, digital twin systems 14260, synchronized planning systems 14262, intelligent procurement systems 14264, dynamic fulfillment systems 14266, and digital product network systems 14508. For smart contracts, examples of building blocks include systems/services relating to the smart futures contract system 15000, such as futures systems 15006, smart contract services 15020, demand aggregation services 15022, digital wallets 15024, risk determination services 15026, and RPA services 15028. For biology-based systems, examples of building blocks include systems/services relating to the thalamus service 18001, such as control systems 18002, intake data management systems 18028, and intake controllers 18008. For energy systems, examples of building blocks include systems/services relating to the energy system 19000. For dual process artificial neural networks, examples of building blocks include systems/services relating to the dual process artificial neural network (DPANN) system 20000. Although these systems are specifically enumerated as potential building blocks, this list is non-exhaustive and may include other applications, systems, and/or services described herein or others not specifically described, but of a similar nature to systems/services of this disclosure. As explained previously, one or more of these building blocks may be particularly configured as well as mixed and matched in various combinations to form a set of building blocks capable of performing a target task, activity, or action.

[2801] In some implementations, there may be multiple sets of service building blocks that are capable of performing a given activity 21332, especially in a configuration that may be dictated by CSSs. When this is the case, an SOS, such as a primary system 21100, can (as noted above) identify the candidate sets of service building blocks that are capable of performing an activity 21332 and determine an optimal set from the candidate sets. In some examples, the optimal set of service building blocks is determined by an optimization algorithm that weighs one or more different importance factors. Some examples of importance factors include consumption of

computing resources, duty cycle, response time, estimated time to complete the activity 21332, amount of computing resources consumed by internal resources in relation to third-party resource consumption, training or initiation time, quality metrics, inventory metrics/thresholds, human resource expenditure, overhead, cost, raw material consumption, operational capacity, and resource utilization.

[2802] Although FIG. 164B illustrates twenty-four service building blocks, there may be a greater or a fewer number of service building blocks depending on the services available to an enterprise. In some examples, the number of service building blocks is contingent upon the number of services that systems of the enterprise are capable of performing. Meaning that, an enterprise with five systems capable of performing seven service(s)/task(s) may have seven service building blocks such that the enterprise can deploy a configured instance of some set/subset of the seven service blocks. With this type of structure, a management stack 21300 can focus on optimizing a configuration for a combination of services rather than trying to optimize or configure each service individually.

[2803] FIG. 165A illustrates an example of the functionality of the control architecture 21000. Here, the control architecture 21000 includes a primary system 21100 labeled as an autonomous enterprise control tower SOS1 and a secondary system 21200 labeled as an autonomous enterprise SOS2. As previously mentioned, here, the highest-level SOS is the primary system 21100 while the lower level SOS is the secondary system 21200. With nested or grouped systems, the functionality or characteristics of one particular system (e.g., the primary system 21100) may be unique or differentiable with respect to another system (e.g., the secondary system 21200) due to the types of inputs and/or outputs associated with each system. In other words, a first set of inputs to a system can influence an arrangement of services (e.g., intelligence services) to form a unique configuration of those services for the system.

[2804] In some implementations, configuring the set of one or more computing devices to fulfill the one or more secondary commands may include providing 17416 intelligence received from the at least one CSS to the set of one or more computing devices. For instance, in some examples, such as FIG. 165A, the CSS1 of the primary system 21100 includes a first configured intelligence service CIS1 that, at 21404, receives a directed request to perform intelligent processing for the CSS1. Here, this request may be referred to as an "intelligence request" from the CSS. Intelligent processing may refer to using, at the configured intelligence service (CIS), intelligence capabilities of or similar to the intelligence services system 8800. In some examples, the arrangement of the configured intelligence service CIS is identical to that of the intelligence services system 8800 (e.g., shown in FIG. 106) except that it has an intelligence configuration (e.g., configured by its associated CSSs) that has been adapted to support a particular system service or set of system services. In the case of a control tower or primary system 21100, this intelligent processing at 21404 may perform analysis of one or more of the managerial functions. In some implementations, intelligent decision-making regarding strategy for the primary command may be performed 17428 based upon, at least in part, the CIS. For instance, when the primary system 21100 is determining a strategy to perform the requested task (i.e., the

primary task), the intelligence service is capable of performing intelligent decision-making regarding strategy for the requested task. This decision making may include decomposing the primary task into a set of subtasks, determining secondary systems 21200 that may be capable of performing the primary task, evaluating the availability of one or more secondary systems 21200, predicting an efficient use of resources to perform the primary task, and/or allocating system resources to the primary task or some portion of the primary task.

[2805] In some implementations, the first configured intelligence service CIS1 is supported by other system services. That is, at 21406, one or more other system services may be configured to perform supporting analytics for the intelligence services of the first configured intelligence service CIS1. For example, FIG. 165A illustrates n number of CSSs CSS1-1...CSS1-n to represent the other system services that have been configured to support the first configured intelligence service CIS. As an example, when the first configured intelligence service CIS1 is evaluating the availability of secondary systems 21200, a set of supporting system services may be configured to query various systems to determine system capabilities or resource utilization. In this sense, the CSSs CSS1–n have been configured for resource management and resource reporting.

[2806] In response to performing intelligent processing, the CSS1, at 21408, determines whether the processing has provided adequate intelligence in response to the intelligence request (i.e., has successfully fulfilled the intelligence request). In some implementations, to evaluate whether the intelligent processing is complete, the CSS determines whether the output or decision generated by the configured intelligence system CIS satisfies a threshold (e.g., a decision-making threshold). For instance, the output or decision from the configured intelligence service CIS may be bound by constraints. Here, these constraints may individually or collectively correspond to the decision-making threshold. In some examples, these constraints correspond to the set of inputs 21102 to the primary system 21100. For instance, the constraints are derived from or related to one or more external controls provided to the primary system 21100 as an input 21102.

[2807] In some configurations, the CSS1 determines whether the intelligent processing has provided adequate intelligence for the intelligence request in response to an output from the configured intelligence service CIS. In other configurations, there may be an event which triggers an evaluation of whether the intelligent processing has provided adequate intelligence in response to the intelligence request. For instance, the event may be a time-based event such as an expiration of a set duration after receiving the request or an expiration of a time period based on a set frequency for evaluating the intelligent processing.

[2808] As shown in FIG. 165A, in response to the intelligent processing failing to provide sufficient intelligence for the intelligence request or being incomplete at the time of evaluation, the CSS1 may iteratively repeat the intelligent processing at 21404 and 21406 in furtherance of the intelligence request. When another iteration occurs, that iteration of intelligent processing may also include another iteration of support from one or more of the other system services (e.g., shown as CSSs CSS1–n). In some examples, an iteration may require less (or more)

system services than a prior iteration. In this respect, each iteration may include an operation that identifies which, if any, of the supporting system services are demanded for the present iteration. Moreover, each iteration may demand a different configuration for the supporting system service(s). When a different configuration is requested, the CSS1 can generate configuration data prior to the provision of services by the supporting system services during the present iteration. That is, although the configuration system services CSS of the primary system 21100 may be designed for the requested functionality of the primary system 21100, this configuration may vary to some extent during sequential intelligent processing (e.g., within some expected variance).

[2809] In response to a determination that the intelligent processing of the configured intelligence service CIS has provided adequate intelligence in response to the intelligence request, the CSS is configured to determine at 21410 whether further action is required (e.g., from one or more secondary systems 21200). That is, the CSS of the primary system 21100 is a system designed to perform a particular service or set of services (e.g., based on the primary task). Here, at 21410, if the output of the configured intelligence service CIS satisfies or enables the CSS to perform its own set of services to satisfy the primary task without further input or influence, then the primary system 21100 may complete the request without involving the secondary system 21200.

[2810] However, in some examples, the primary system 21100 requires at least another level of services to perform the primary task. The primary system 21100 may call on any number of secondary systems 21200 (e.g., via an output 21104) to perform a directed set of tasks. To call on the secondary system 21200, the primary system 21100 may generate an output 21104 that functions as an input 21202 to the secondary system 21200. As shown in FIG. 165A, this output 21104 may be a directed action request or some action-configuring information such as parameters, variables, or data. Here, this output 21104 by the primary system 21100 may enable the secondary system 21200 to be configured to perform actions/functions in furtherance of the primary task or to perform according to the directed action request. For example, the directed action request requests that the secondary system 21200 executes or facilitates the execution of one or more subtasks associated with primary request. As an example, the directed action request includes an executable sequence of tasks for the secondary system 21200 to perform.

[2811] In response to the secondary system 21200 receiving the output 21104 of the primary system 21100 (as the input 21202 to the secondary system 21200), the secondary system 21200, at 21412, is configured to evaluate the output 21204. That is, the secondary system 21200 may evaluate the directed action request included in the output 21104 of the primary system 21100. For instance, as shown in FIG. 165A, a CSS2 evaluates the output 21104 from the primary system 21100. In some implementations, the evaluation of the directed action request by the secondary system 21200 includes an evaluation of resource requirements and/or resource options that are available to perform the directed action request.

[2812] Similar to functionality of the primary system 21100, the CSS2 of the secondary system 21100 includes a second configured intelligence service CIS2. In some examples, after

evaluating the directed request included in the output 21104 from the primary system 21100, the CSS2 generates an intelligence request based on, or derived from, that directed request. For example, FIG. 165A, at 21414, depicts the second configured intelligence service CIS2 performing CSS2-directed analysis to represent the execution of the intelligence request based on the directed request.

[2813] In some configurations, to generate the intelligence request, the CSS2 generates configuration data. In some examples, the configuration data provided by the CSSs2 configures all or some portion of the artificial intelligence service or the intelligence system controller (e.g., the analysis modules, the analysis management module, or the governance library) for an intelligence services system (e.g., shown in FIG. 104). Here, by configuring the intelligence services system with the provided configuration data, the intelligence services system may be considered a "configured intelligence service." When generating the configuration data for the intelligence request, the CSS2 may leverage information that it receives from the directed request in order to perform intelligent processing for the CSS1.

[2814] Much like step 21408 for the primary system 21100, the secondary system 21200, at 21416, is configured to determine whether the intelligent processing at 21414 has provided adequate intelligence in response to the intelligence request (i.e., has successfully fulfilled the intelligence request). In some implementations, to evaluate whether the intelligent processing is complete, the CSS2 determines whether the output or decision generated by the second configured intelligence system CIS2 satisfies a threshold (e.g., the decision-making threshold). For instance, the output or decision from the second configured intelligence service CIS2 may be bound by constraints. Here, these constraints may individually or collectively correspond to the decision-making threshold. In some examples, these constraints correspond to the set of inputs 21202 to the secondary system 22100.

[2815] In some configurations, the CSS2 determines whether the intelligent processing has provided adequate intelligence for the intelligence request in response to an output from the second configured intelligence service CIS2. In other configurations, there may be an event which triggers an evaluation of whether the intelligent processing has provided adequate intelligence in response to the intelligence request. For instance, the event may be a time-based event such as an expiration of a set duration after receiving the request or an expiration of a time period based on a set frequency for evaluating the intelligent processing.

[2816] As shown in FIG. 165A, in response to the intelligent processing failing to provide sufficient intelligence for the intelligence request or being incomplete at the time of evaluation, the CSS2 may iteratively repeat the intelligent processing at 21418 and 21414 in furtherance of the intelligence request. When another iteration occurs, that iteration of intelligent processing may also include supporting functionality at 21418 from one or more of the other system services (e.g., shown as CSSs3, CSS4, CSS(n)). In some examples, an iteration may require less (or more) system services than a prior iteration. In this respect, each iteration may include an operation that identifies which, if any, of the supporting system services are demanded for the present iteration. Moreover, each iteration may demand a different configuration for the

supporting system service(s). When a different configuration is requested, the CSS2 can generate configuration data prior to the provision of services by the supporting system services during the present iteration. That is, although the configuration system services CSS of the secondary system 21200 may be designed for the requested functionality of the secondary system 21200, this configuration may vary to some extent during sequential intelligent processing (e.g., within some expected variance).

[2817] In response to a determination at 21416 that the intelligent processing of the second configured intelligence service CIS2 has provided adequate intelligence in response to the intelligence request, the CSS2 is configured to determine at 21420 whether an action is available to fulfill the directed action request from the primary system 21100. When there is an action available to fulfill the directed action request at 21420, the CSS2 proceeds to 21424. On the other hand, if an action is not available at 21420 to fulfill the directed action request, the CSS2 may perform directed action process configuration and/or directed action resource analysis assistance using one or more additional system services at 21422 (e.g., shown as CSS5, CSS6, and CSS(n)). Here, these additional system services may be another SOS or an external service.

[2818] At 21420, when the CSS2 determines that there is an action available to fulfill the directed request, the process proceeds to 21424. Here, at 21424, the CSS2 initiates and/or executes a process determined by or based on the available action and/or the intelligent processing response from the second configured intelligence service CIS2.

[2819] Optionally, as shown at 21426 and 21428, the process that is to be initiated or executed can undergo an optimization operation. For example, at 21428, the second configured intelligence system CIS2 determines whether the directed action process is an optimized process. In some implementations, to determine whether the directed action process is an optimized process, the CSS2 determines whether the process satisfies a set of optimization constraints. In other implementations, the CSS2, at 21428, determines whether the process satisfies a designed objective function. In some instances, the objective function is based on the primary task (e.g., in combination with any external controls included in the primary system input 21102). In other instances, the objective function is based on the secondary task specified by the directed action request from the secondary system input 21202.

[2820] At 21430, the CSS2 reports a response to the directed action request as an output 21204 of the secondary system 21200. For example, the output 21204 is an action plan for the primary task. Additionally and/or alternatively, the output 21204 of the secondary system 21200 being reported to the primary system 21100 is that some set of actions were executed at the secondary system 21200 to support the primary task as directed by the direct action request from the primary system 21100. When reporting the execution of some set of actions, the output 21204 of the secondary system 21200 may include data or information related to the execution of the set of actions. In some configurations, the data or information is monitoring data that characterizes the performance of the set of actions implemented by the secondary system 21200 at some snapshot in time or over a certain period of time.

[2821] Although FIG. 165A illustrates operational details about the inputs and outputs of a single primary system 21100 and a single secondary system 21200 (e.g., as shown in FIG. 163A), there may be any number of secondary systems 21200 managed by either the primary system 21100 or a particular secondary system 21200. When a set of additional secondary systems 21200 are managed by the secondary system 21200, these additional secondary systems 21200 may be referred to as secondary subsystems. When there are multiple secondary systems 21200 for a control architecture 21000 (e.g., as shown in FIG. 163B), each secondary system 21200 may follow a similar set of operations (e.g., operations referenced by 21412–21430) in support of the primary task for the primary system 21100.

MINI CONTROL TOWER FOR VALUE CHAIN NETWORK ENTITIES

[2822] A mini control tower is typically connected to a larger control tower (e.g., a larger secondary computing device, a primary computing device, etc.), which is responsible for managing the overall performance of the VCN. As will be discussed below, the larger control tower integrates data from all of the mini control towers and other sources to provide a comprehensive view of the VCN. This enables the larger control tower to identify trends, predict potential issues, and optimize the performance of the entire supply chain network. In some implementations, the mini control tower(s) and the larger control tower may be connected through a communication network that enables real-time data exchange and collaboration. The mini control tower may provide detailed information on specific areas of the supply chain network, while the larger control tower provides a more holistic view of the entire network. This integration enables the control towers to work together to optimize the performance of the supply chain network and ensure that it operates efficiently and effectively.

[2823] Referring to the example implementation of FIG. 163C, in some implementations, a control architecture 21000' generally includes a primary system 21100' (e.g., a PAO system) and one or more sub-level computing devices 21200'. Each of the primary system 21100' and the sub-level computing devices 21200' may function in the control architecture 21000' as a system of systems (SOS). Here, a "system of systems" refers to a structure that provides cooperative coordination among a set of systems (e.g., already deployed/available systems such as autonomous-oriented systems) that are configurable for the execution of one or more services/tasks. The terminology of "system" of systems therefore indicates that a particular system (e.g., primary or secondary system) is the liaison system for a set of underlying systems. For instance, an SOS is deployed for a particular management or facilitation goal (e.g., to achieve a particular target metric or quantifiable measure of value). This type of SOS structure allows a first SOS to communicate with a second SOS without the need to interface with the set of systems for which an SOS is responsible for.

[2824] By having a first SOS communicate with a second SOS without the need to interface with the set of systems for which the second SOS is responsible, the control architecture 21000' may be able to minimize compatibility issues between all of the systems demanded for execution a primary task (e.g., autonomous execution). For example, if the underling systems

are combinations of different hardware and/or programmable software, being able to have a uniform communication language or protocol to have the systems communicate with each can be incredibly difficult. With the control architecture 21000', systems may be set up in a set or a grouping that is configured by a particular SOS that is capable of communicating with members of the set. In this respect, the SOS of the group/set only needs communication tools for its set of systems and for outside communication with one or more SOSs. For instance, the sub-level computing device 21200' may include communication tools to configure its underlying set of systems and communication tools to interface with the primary system 21100'. The control architecture 21000' therefore can be quite elastic and permit scalability for communication between multiple SOSs without any individual SOS being responsible for all or a substantial portion of communication tools for all systems utilized within a particular implementation (i.e., instance) of the control architecture 21000' as well as control architecture 21000 of FIG. 163A and 163B.

[2825] For instance, in some implementations, a VCN process, such as VCN process 10, may configure 17800 a set of sub-level computing devices (e.g., sub-level computing devices 21200') for communication with a primary computing device (e.g., primary system 2100'), wherein the primary computing device may manage the set of sub-level computing devices to orchestrate performance of a set of value chain network entities. For instance, in the example implementation depicted in FIG. 163C, the primary system 21100' is deployed as a control tower SOS. When a system is arranged as a control tower SOS, the system is typically deployed as a manager or primary facilitator among a set of sub-level computing devices 21200' (e.g., as shown in FIG. 163D). As a manager (or other similar user), the overarching goal of the control tower may be to propagate a strategy (e.g., optimize a set of sub-level computing devices 21200' for a particular primary task or primary service), to provide oversight to a system arrangement (e.g., system monitoring), and/or to control a set of systems (e.g., tune input parameters to sub-level computing devices 21200' to produce a target result).

[2826] In some implementations, VCN process 10 may receive 17802 (e.g., via at least one member of the set of sub-level computing devices) a set of primary commands from the primary computing device, wherein each of the set of commands may be at least one of a task or a request associated with the value chain network. For instance, and referring at least to the example implementation of FIG. 165B, the primary system 21100' receives a set of inputs 21102'. Here, some examples of these inputs 21102' include external data (e.g., similar to external data 21050'), external controls imposed on the system, and/or operational feedback. As a control tower or primary system 21100', upon receipt of the inputs 21102' at 21402, the primary system 21100' (e.g., using a CSS1) identifies that the inputs 21102' correspond to a particular request to perform a primary task. As part of the performance of the primary task, the primary system 21100' may be configured to perform managerial functions. These managerial functions may include: determining a strategy to perform the requested task; providing oversight for execution of the requested task; and/or controlling actions that execute the requested task.

[2827] As shown in FIG. 163C, the sub-level computing device 21200' is also capable of generating a system output 21204' that may be communicated to the primary system 21100'. The primary system 21100' may receive or otherwise obtain the system output 21204' at various times during an instance of the sub-level computing device 21200'. In other words, the generation of a system output 21204' may occur during initialization of the sub-level computing device 21200', during simulation of the sub-level computing device 21200', during operation/implementation of the sub-level computing device 21200', or during some wind-down or final phase of the sub-level computing device 21200' (e.g., in response to the sub-level computing device 21200' completing a task/service).

[2828] In some examples, the system output 21204' functions as a feedback loop. For instance, as a feedback loop, the system output 21204' may inform the intelligence of the CSS. Here, by informing the intelligence of the CSS, the primary system 21100' via its CSS may further tune or fine tune the parameters that are generated and provided to the sub-level computing device 21200' as system inputs 21202'. In other words, in some circumstances, systems inputs 21202' may be provided to the sub-level computing device 21200' on an ongoing basis (e.g., for ongoing product production). In these circumstances, the system outputs 21204' of the sub-level computing device 21200' may impact the next round or iteration of system inputs 21202' provided to the sub-level computing device 21200'. In other words, the system outputs 21204' are capable of updating and/or modifying the system inputs 21202' due to the intelligent functionality of the CSS of the primary system 21100'.

[2829] Referring further to FIG. 163C, the sub-level computing device 21200' is a value chain SOS. In other words, the configuration promoted by the sub-level computing device 21200' is generally optimized for a particular value metric or target metric. The focus and/or dependence on this value metric is therefore generally carried through or applied to the CSS of the sub-level computing device 21200'. For instance, the target metric is profit and therefore the sub-level computing device 21200' performs its functionality with profit as a primary optimization variable when configuring its associated systems.

[2830] As shown in FIG. 163C, in some examples, the CSS configures the set of systems associated with the sub-level computing device 21200'. Here, the set of systems that is configurable by the CSS2 is illustrated by n number of additional CSSs(1–n). In other words, a sub-level computing device 21200' may be responsible for performing some group of subtask(s) or service(s) to execute a primary task/service. Each subtask/service within that group may be associated with one or more systems (e.g., SOA systems). Stated differently, the one or more systems are capable of enabling and/or performing a subtask/service when configured. Meaning that, systems, such as SAO systems, are capable of performing functions that result in the execution of a range of tasks or services. These functions may be parameterized (e.g., according to a configuration) to tune the system to perform a particular task/service within the range or a specialized version of a task/service. In this respect, the CSSs of the sub-level computing device 21200' therefore may enable or configure the set of systems that perform the corresponding subtask(s)/service(s).

[2831] As a simple example, the CSSs2 of the sub-level computing device 21200' includes three systems and a CSS (e.g., CSS3–CSS5) that corresponds to each system (though a one-to-one relationship is described, other relationships are possible). In this example, the CSS2 of the sub-level computing device 21200' would have to configure three CSSs to provide the services/tasks associated with the sub-level computing device 21200'. To illustrate, if the primary task was production of a product, the sub-level computing device 21200' may be responsible for a subtask/service of the production – e.g., logistics. Here, although the sub-level computing device 21200' is responsible for logistics, part of that responsibility may be the management or facilitation of systems associated with three different logistic channels – e.g., trucking logistics, flight logistics, and water vessel logistics. Accordingly, each of those three logistic channels may be configured to have its own CSS such that the sub-level computing device 21200' provides configuration data for the operations of the three CSSs associated with each of those logistic channels. In this respect, the sub-level computing device 21200' is able to generate configuration data that ensures that each CSS associated with each of the logistic channels collectively is optimized for the primary task. For instance, instead of each of the CSSs of the logistic channels only seeking their own self-optimization, the optimization is driven from a higher level. Meaning, that, for example, the water vessel logistics on its own may not seem to be optimized specifically for water vessel logistics of the product, but in the scheme of the entire logistics for the product, it is optimized in conjunction with the, e.g., flight logistics and the trucking logistics, so that the target metric is maximized (or minimized) across all of the logistic systems.

[2832] In some implementations, the primary system 21100' is the system that dictates or determines the set of services/tasks performed by each sub-level computing device 21200'. For example, the intelligence associated with the primary system 21100' determines the number of sub-level computing devices 21200' that may be required for a particular primary task and/or the available systems that would enable the primary task. For instance, the primary system determines a combination of available systems that would enable the primary task. In this situation, the intelligence of the primary system 21100' recognizes that individually configured systems working together in some combination can perform some aspect of the primary task.

[2833] In some implementations, as noted above, VCN process 10 may assign 17804 at least a portion of one or more computing devices capable of fulfilling the primary command as a set of one or more computing devices to be managed by the set of sub-level computing device, wherein the sub-level computing device is a computing device that manages or executes performance of a particular entity or relationship of the value chain network. For instance, a mini control tower in a VCN (supply or demand) may be a sub-level control tower that focuses on a specific area or aspect of the supply chain. It is typically responsible for monitoring and managing the performance of a particular segment (e.g., entity or relationship between multiple entities) of the supply chain, such as a specific warehouse or distribution center, transportation route, or supplier. For example, primary system 21100' as a control tower SOS receives a primary task or service request, as discussed above. In response to the receipt of the primary task

or service request, the primary system 21100' determines a set of systems that can fulfill the request from a pool of available system resources (e.g., a pool of autonomous-oriented systems). In some implementations, the determined set of systems are parsed or classified into groups where each group is assigned to a sub-level computing device 21200'. As will be discussed below, each sub-level computing device 21200' may generate a set of CSSs for the set of systems that are assigned to it. "Mini control towers" may be beneficial to proliferate through the connection of previously siloed operational segments. Disparate solutions of the value chain technology may continue to converge towards the goal of turning these "mini control towers" into enterprise-wide control towers that enable greater automation and visibility throughout a company's supply-chain. Additionally, unlike currently known control towers that are limited to the supply-chain, the control towers (and mini control towers) of the present disclosure are also integrated with the demand side of enterprises. As will be clear after reading the present disclosure, the mini control tower may be considered as the preliminary step before a fully functional control tower (e.g., with a company-wide dashboard as discussed throughout). Generally speaking, the mini control tower may be considered the slot in application partners within the control tower (i.e., the interaction between data aggregation at the control tower).

[2834] In some implementations, VCN process 10 (e.g., via the set of sub-level computing device) may configure 17806 the set of one or more computing devices to fulfill one or more secondary commands based upon, at least in part, the primary command. For instance, with the CSSs (discussed further below) scaled to the assigned set of systems, the sub-level computing device 21200' configures each system of the set using the CSSs so that the set associated with the sub-level computing device 21200' can collectively perform/enable the primary task with execution of its one or more tasks/services.

[2835] In some implementations, as noted above, configuring the set of one or more computing devices to fulfill the one or more secondary commands may include generating 17812 a set of at least one configured system service (CSS). For instance, FIG. 163C depicts a single primary system 21100' as the control tower SOS and a sub-level computing device 21200' as a value chain SOS. Each SOS (e.g., the primary system 21100' or the sub-level computing device 21200') generally includes at least one configured system service (CSS) and a general system service (GSS). For example, the primary system 21100' is shown with a first CSS (CSS1) and a first GSS (GSS1) while the sub-level computing device 21200' is shown with a second CSS (CSS2) and a second GSS (GSS2). In this respect, each CSS and GSS may be tailored or dependent upon the SOS with which it is associated. For example, in some implementations, when the primary system 21100' as the control tower SOS is set up for oversight, the CSS1 and the GSS1 are configured to provide service(s) for oversight.

[2836] It will be appreciated after reading the present disclosure that any individual parts of the present disclosure that use a processor may include some or all of VCN process 10 (and *vice versa*). For example, VCN process 10 may include some or all of a CSS, a GSS, a primary system, a sub-level computing device, a service, an application, etc. That is, any individual parts of the present disclosure that use a processor may be configured to effectuate some or all of the

functionality of VCN process 10 (and *vice versa*). Accordingly, in some implementations, VCN process 10 may be a purely server-side process, a purely client-side process, or a hybrid server-side / client-side process that is cooperatively executed. Furthermore, it will be appreciated after reading the present disclosure that VCN process 10 may apply equally to the demand side as the supply side. That is, VCN process 10 is described with examples of obtaining information and insights for things affecting the supply of an item; however, VCN process 10 may also be used with examples of obtaining information and insights for things affecting the demand of an item. For example, factors that may affect the demand of an item may include, e.g.,: Customer attributes, such as geographic location, historical purchasing habits and preferences, financial capacity, interactions with similar or proximal products, lifetime value; Market trends, such as popularity of particular products or categories of products, activism or social movements (e.g., palm oil is linked to the destruction of biodiversity, deforestation, etc. and demand for products with this ingredient may be suppressed as a result of increasing social awareness of negative impacts), seasonal demand; Competition, such as availability/price/appearance/brand value of competing or substitute products, Economic, such as correlation of item purchases with economic factors such as consumer spending, interest rates, exchange rates, etc.; Governmental/Regulatory, such as trade restrictions, tariffs, regulations related to import/export control or materials/ingredients; Marketing, such as advertising campaign metrics (e.g. website traffic, total page views, bounce rate, engagement rate, cost per click, cost per lead, cost per acquisition, conversion rate, longevity). As such, the description of VCN process 10 being used for the supply side should be taken as example only and not to otherwise limit the scope of the present disclosure.

[2837] The GSS functions to provide general system integration and operations such as data storage, data processing, networking, and other shared functionality (e.g., the GSS may have similar functionality to aspects of data processing systems 1612, 10206, 12030, 12130, 12142, 13024 and/or data storage systems 624). In FIGS. 163C and 163D, the GSS is shown with a dashed-lined perimeter to represent that the GSS may be included locally within a deployed instance of an SOS (e.g., a primary system or a sub-level computing device) or operate remotely yet in communication with an SOS. When deployed locally, the GSS may be configured in dedication to its associated SOS. In that respect, aspects of the GSS may be optimized, programmed, or configured to the instance of the SOS. When functioning remotely, the GSS may operate as a global GSS that one or more systems (e.g., a primary system 21100' and/or a sub-level computing device(s) 21200') can access/utilize. Here, this type of global configuration may be advantageous, depending on the deployment of the control architecture 21000', because data storage and data processing functionality is shared among systems. Meaning that, data format compatibility or other data compliance related aspects are potentially addressed on the front-end (e.g., designed for compatibility).

[2838] In some implementations, generating the set of at least one CSS may include utilizing 17814 an output of a plurality of sources as an input to generate one or more control parameters. For instance, the mini control tower(s) may collect data from various sources, including sensors,

enterprise resource planning (ERP) systems, warehouse management systems (WMS), transportation management systems (TMS), local media, national media, social media, etc. and other sources. The data is analyzed to identify potential issues or bottlenecks in the supply chain and to determine the best course of action to resolve these issues. The CSS for an SOS functions to configure the set of systems corresponding to the SOS to perform a set of tasks or services based on intelligence determined by the CSS. The intelligence performed for the CSSs is generally determined by a configured intelligence system CIS that is a part of (e.g., as shown in FIG. 165B) or associated with the CSSs. More particularly, the configured intelligence service CIS used by the CSS has the intelligence capabilities of or that are similar to the intelligence services system 8800 except that the configured intelligence system CIS is an intelligence services system that is configured, for example, by the CSS to provide intelligence for a particular set of system services. In this respect, the CSSs may act akin to the intelligence service client 8836 in its relationship with the configured intelligence system CIS. For instance, if the primary task of primary system 21100' is to control the production of a product, the intelligence of the CSS identifies system resources that (e.g., a set of systems) are available (e.g., within the enterprise ecosystem) to control production of the product and configures these control-based resources to generate control parameters that downstream production resources demand to produce the product. To extend this example to FIG. 163C, the primary system 21100' generates an output that is provided to the sub-level computing device 22000' as a system input 21202'. If the CSS1 generates control parameters, these control parameters may be fed as output of the primary system 21100' to the sub-level computing device 21200' as system inputs 21202'. The sub-level computing device 21200' may then utilize the system inputs 21202' to configure its own CSS (e.g., the CSS2).

[2839] In some implementations, VCN process 10 may (e.g., via the set of sub-level computing device) fulfill 17808 the primary command based upon, at least in part, the set of one or more computing devices fulfilling the one or more secondary commands. For instance, FIG. 163D is similar to FIG. 163C except that FIG. 163D shows multiple sub-level computing devices 21200'a–n being managed by the primary system 21100'. That is, multiple SOS instances may be coordinated via a single control tower SOS instance. The number of sub-level computing devices 21200' associated with a control tower SOS or primary system 21100' may depend on several variables. Some of these variables may include, e.g., the selected set of systems to fulfill a service/task request, the type of systems selected, the configurable parameters of the selected systems, the communication capabilities of the selected systems, the manner in which the systems may be combined or cooperate, and the structure or characteristics of the enterprise deploying the control architecture 21000'.

[2840] In some configurations, the set of systems selected to fulfill a service/task request (e.g., a request for a primary task) includes one or more third-party systems that the enterprise can access or utilize. For instance, for autonomous generation of a product, the primary system 21100' may inquire about demand for the product using a customer relations management (CRM) system managed by a third party. Here, the primary system 21100' or a sub-level

computing device 21200' may provide the CRM system with data that characterizes the product to be generated in order to query the CRM system to determine an estimated demand forecast from customers who have an interest in the type of product that has been characterized. In some implementations, the CRM system returns an output (e.g., a forecasted demand) based on the input data that is then configured to inform or be communication to one or more other systems. Therefore, when third-party systems are integrated in the configured systems workflow of the control architecture 21000', the SOS can determine acceptable inputs to these third-party systems and expected/anticipated outputs so that outputs can be pipeline data to the appropriate CSS.

[2841] In some implementations, VCN process 10 may send 17810 a generated system output to the primary computing device responding to the primary command based upon, at least in part, the set of one or more computing devices fulfilling the one or more secondary commands. For instance, and to expand on the previous example using FIG. 163D for example purposes only, when the set of systems that fulfill the request are parsed or classified into n groups, the primary system 21100' assigns the first group to the first sub-level computing device 21200'a, the second group to the second sub-level computing device 21200'b, and the nth group to the nth sub-level computing device 21200'n. Here, outputs from the primary system 21100' may be provided to any or all of the sub-level computing devices 21200'a–n to form the system inputs 21200'a–n for the sub-level computing devices 21200'. Much like the single sub-level computing device example of FIG. 163C, each sub-level computing device 21200' is capable of generating system outputs 21204'a–n that are communicated to or obtained by the primary system 21100'. In some implementations, each of these sub-level computing devices 21200', as SOS instances, may include CSSs and/or GSSs. Therefore, each sub-level computing device 21200' generates a set of CSSs for the set of systems that are assigned to it.

[2842] In some implementations, an SOS has the capabilities to interface with entities or resources that are external to the SOS. For instance, FIGS. 163C and 163D illustrate the primary system 21100' as the control tower receiving external data inputs/outputs (I/O) 21050'. Some examples of external data I/Os 21050' include asset indicators (e.g., asset statuses, asset locations, asset time of life, etc.), market data (e.g., for markets impacted/associated with an enterprise asset), weather data, sensor data (e.g., from robotic fleet management, IoT, digital twin, environmental container conditions such as temperature, humidity or light intensity, etc.), enterprise resource planning (ERP) data, network data (e.g., connectivity data), event data (e.g., holidays, event logs, cycle time, running time, etc.), local media, social media, etc. In some examples, the external data I/O 21050' is provided by another control tower SOS. Additionally and/or alternatively, the external data I/O 21050' may be generated by a third-party system that is or is not included in the control architecture 21000' such as a software as a service (SaaS) provider to the enterprise.

[2843] In some implementations, the primary computing device (e.g., via VCN process 10) may be bypassed 17824 to receive external data at the sub-level computing device when the external data is unused by the primary computing device. For example, the control architecture

21000' is not limited to only the primary system 21100' receiving the external data 21050'. In some configurations, it may be more efficient from a data management or data flow approach to feed external data 21050' directly to a sub-level computing device 21200' or to a component of a sub-level computing device 21200' (e.g., a CSS). For instance, a system of the sub-level computing device 21200' rather than a system of the primary system 21100' is the system that consumes the external data 21050'. In some instances, if the external data 21050' is not utilized by the primary system 21100' (e.g., the CSS), then having the primary system 21100' ingest, store, and/or relay the external data 21050' to a sub-level computing device 21200' that consumes the external data 21050' may become burdensome or computationally expensive.

[2844] Referring to the example implementations of FIGS. 164C and 164D, the control architecture 21000' may be adapted to cater to a specific organization of an enterprise. In other words, the SOS structure that includes the CSS may be deployed to provide system management at any business unit level. To illustrate, FIG. 164C depicts a management stack 21300' (also referred to as stack 21300') that includes a control layer 21310', an operational layer 21320', an activity layer 21330', and a service layer 21340'. Although the management stack 21300' is depicted as a 4-layer management stack 21300', the principles of a primary SOS system and a secondary SOS system may be applied to more or less layers (e.g., a 3-layer stack, a 5-layer stack, or a 10-layer stack). As shown in FIG. 164D, one reason for the 4-layer management stack 21300' is that it may track an enterprise's value chain workflow. For instance, in FIG. 164D, an enterprise may have a plurality of enterprise value chain networks that correspond to the operational groups/teams of the enterprise. FIG. 164C has four different operational groups – marketing and sales, logistics, service, and operations. Each operational group may be capable or expected to perform one or more activities for the enterprise. And moreover, each activity may use a set of services to perform the respective activity. In this sense, the service layer 21340' of the management stack 21300' corresponds to the set of services 21342'a-n (e.g., data sourcing services, data processing services, intelligence services, analytics services, smart contracts services, distributed ledger services, governance services, security services, risk management services, etc.) that perform an activity 21332'. The activity layer 21330' corresponds to the activity 21332' performed by an operational group of the enterprise and the operational layer 21320' corresponds to the particular operational team performing the activity 21332' with the set of services 21342'.

[2845] In some implementations, a distributed ledger service may increase traceability of material supply chain to ensure corporate standards are met, as well as lower losses from counterfeit/gray market trading. A distributed ledger service may also improve visibility and compliance over outsourced contract manufacturing, as well as reduce paperwork and administrative costs, strengthen corporate reputation through providing transparency of materials used in products, improve credibility and public trust of data shared, reduce potential public relations risk from supply chain malpractice, and engage stakeholders.

[2846] In some implementations, a governance service may be used for access of a system in a VCN setting, including a set of policies, procedures, and controls that are implemented to ensure

secure access to the system. The governance service may be responsible for managing and controlling access to the system by employees, suppliers, and other stakeholders in the supply chain network. The governance service may define the rules and requirements for accessing the system, including the authentication and authorization processes. This may involve establishing user roles and permissions, defining access levels, and implementing controls to ensure that only authorized individuals can access the system. The governance service may also be responsible for monitoring and auditing system access to detect and prevent unauthorized access or misuse of the system. This may involve regular review of user access logs and other system activity to identify potential security breaches or policy violations. Additionally, the governance service may be responsible for enforcing compliance with regulatory requirements and industry standards for data privacy and security. This may involve establishing and maintaining security protocols and procedures to protect sensitive data and information from unauthorized access or disclosure. In some implementations, innovations such as haptics, biometrics, and AI may be applied to enhance the security and functionality of the governance service. For instance, haptics may be used to provide a multi-factor authentication process that includes physical verification such as fingerprints or facial recognition, in addition to traditional login credentials such as username and password. Biometrics may also be used to enable continuous authentication, which may involve monitoring user behavior and biometric data to detect and prevent unauthorized access or suspicious activity. AI may be used to analyze access logs and other system activity data to identify potential security threats or policy violations in real-time. This may include identifying patterns of access that are outside of normal behavior or detecting unusual activity that could indicate a security breach. A scoring system may be used to assess the performance or behavior of individuals or organizations within the governance system. This may be used to identify areas for improvement or to provide incentives for good behavior. A Know Your Business (KYB) system may be used to verify the identity and legitimacy of businesses that are operating within the governance system. This may help prevent fraud, money laundering, or other illegal activities. A KYC system may be used to verify the identity of individuals who are participating in the governance system. This may help prevent fraud, identity theft, or other illegal activities. In some implementations, integrated blockchain technology may be used as a distributed ledger to record and verify transactions or interactions within the governance system. For example, a blockchain-based voting system may be used to ensure the integrity of elections or decision-making processes within the governance system. Another way to use blockchain is to create smart contracts that automatically execute certain actions or decisions within the governance system based on predefined rules. This can help reduce the risk of human error or fraud. Blockchain may also be used to create decentralized autonomous organizations (DAOs), which are organizations that operate based on rules encoded in smart contracts on a blockchain. DAOs may be used to create more democratic and decentralized governance structures, where decisions are made through transparent and decentralized voting processes.

[2847] As mentioned previously, the organizational structure of an enterprise, and especially a large enterprise, means that it is likely that multiple value chains may need to be managed or controlled to perform the objective, goal, or purpose of the enterprise. With this being the case, the control architecture 21000' may enable a primary system 21100' or control tower SOS to control multiple value chains from a central management position. For example, FIG. 164C depicts a single control tower SOS on the control layer 21310' as the overall management hub for the management stack 21300'. The primary system 21100' may then manage one or more supporting operations 21322' (e.g., sub-level computing devices 21200' that are operation specific) on the operational layer 21320'. For instance, a first value chain may follow the first path p1 while a second value chain may follow the second path p2. For either value chain, the operational layer 21320' includes a set of supporting operations 21322'. In terms of this example, a value chain network refers to a value chain that flows through a particular operational entity. That is, each operational entity or supporting operation has its own network of activities 21332' and services 21342' that enable the operational entity to properly function for the enterprise. For example, each supporting operation 21322' is shown to perform one or more activities 21332'a–n on the activity layer 21330' with each activity 21332' supported by a set of services 21342'a–n associated with the service layer 21340'.

[2848] Referring specifically to the stack 21300' of FIG. 164C, the first path p1 flows through a first supporting operation 21322'a. The first supporting operation 21322'a includes n number of activities 21332'a–n. Each activity 21332' is supported by a set of services 21342'. For comparison, the second path p2 may flow through another supporting operation 21322' (e.g., a second supporting operation 21322'b) of a set of supporting operations 21322'a–n and then have a similar network structure with a corresponding set of activities 21332' performed/enabled by an underlying set of services 21342'. In this respect, the stack 21300' is able to accommodate any number of supporting operations indicating that any number of value chains/value chain networks may be deployed with a single instance of a control tower SOS.

[2849] In some implementations, generating the set of at least one CSS may include generating 17826 at least one CSS for each interface layer in a management stack (e.g., management stack 21300'). For instance, in some configurations, as shown in FIG. 164C, the functionality of each layer may be orchestrated by one or more SOS units. Meaning that, each layer may have one or more CSS that is capable of configuring the systems to provide the services demanded at each layer. In other words, each layer may have at least one local CSS to ensure the functionality of the layer can occur in an autonomous-oriented manner (e.g., autonomously or semi-autonomously). Each layer may be arranged to manage or control its proximate lower level. In this arrangement, the CSS for a particular layer functions to provision configurations (e.g., inputs, starter materials, connect data pipelines, etc.) that allow a lower level to function. For instance, the operational CSS associated with the operational layer 21320' configures systems that enable the set of activities 21332' to operate. Similarly, the CSSs of the activity layer 21330' configures systems that enable the set of services 21342' to function. At the lowest level,

shown as the service layer 21340', the CSSs associated with this layer 21340' enable the execution of the set of services 21342'.

[2850] In some implementations, each layer in the management stack 21300' is capable of communicating with another layer using an interface layer 21350'. The interface layer 21350' may include communication tools or protocols that enable one SOS to communicate with another SOS potentially anywhere in the stack 21300'. The interface layer 21350' may also function to limit which layers (or SOSs) can communicate with which other layers (or other SOSs). That is, an architect of the stack 21300' may prefer for some communication tools to be limited to higher level control or vice versa (e.g., limited to service layer communication). In this respect, the interface layer 21350' can apply communication access controls at the layer level.

[2851] In some configurations, the interface layer 21350' includes a range of communication tools that permit one system to communicate with another system. For example, the interface layer 21350' includes a plurality of application programming interfaces (APIs) that allow software associated with one system or SOS to communicate with software of another SOS. An API is a software tool that generally facilitates communication between two platforms (e.g., between two CSSs or between two SOS systems). APIs are typically designed to standardize the way programmers/developers interact with a platform (e.g., a software application). In other words, prior to APIs, programmers/developers would likely have to customize the manner in which they interact or connect with the services of an application. With APIs, there are typically technical specifications in the form of documentation that is associated with the API that specifies how to integrate with the API. When using an application, a user may initiate a task/service from the application that generates a request. The API associated with the application may then make a call that relays the request to a destination or API endpoint (e.g., a uniform resource locator (URL) of a server). Upon receipt of the request, the API endpoint facilitates the execution of the task (e.g., by a third-party application or database that provides the task/service). From that perspective, APIs can ease the development and user experience by connecting disparate system (e.g., disparate software applications). In other words, by using an API, the entity configuring a system or application to perform a service can integrate the functionality of other systems without having to design those systems' functionality in-system. Some examples of APIs that the interface layer 21350' may include are Web APIs used to access web browsers or web-based devices, Simple Object Access Protocol (SOAP) APIs that use extensible markup language (XML) and XML schema to perform calls and structure payloads, Open APIs (also known as public APIs), Representative State Transfer (REST) APIs that use stateless communication protocols, JavaScript Objection Notation (JSON)-Remote Programming Calls (RPC) for asynchronous server calls, and other custom APIs. By making an array of APIs accessible to portions of the stack 21300', the interface layer 21350' helps ensure that the language of one system is capable of being translated to a language of another system. Otherwise, the set of systems deployed in a given instance of the management stack 21300' may

have communication compatibility issues or suffer from the inability to cooperatively integrate cross-functionality.

[2852] The interface layer 21350' is also configured to use other communication tools such as a user interface (UI) (e.g., graphical user interfaces (GUI)) and software development kits (SDKs). Here, a GUI may correspond to the interface of an API or refer to another interface designed to curate a user experience and interaction with one or more systems. For instance, a system has a GUI that can receive configuration data from CSSs (e.g., to populate data entry fields provided by the GUI to receive a set of inputs). The GUI generally contains graphical elements with underlying functionality. These graphical elements may enable navigation and/or trigger execution of functions of the system associated with the GUI. It will be appreciated that other types of UIs may be included (e.g., audio-based UIs, gesture-based UIs, digital twin interface (as discussed throughout), smart wallet interface (as discussed throughout), etc.) without departing from the scope of the present disclosure.

[2853] An SDK or devkit may refer to the set of building tools (e.g., software building tools) for a specific platform (e.g., system). Often, the tools of an SDK may include resources such as a compiler that translates from one programming language to another, code samples that provide examples of coding for the platform, code libraries with sets of preconfigured code sequences (e.g., common or frequently used coding functions), testing and analytics tools that generate metrics/analytics to quantify the performance of programming in, for example, testing and production environments, documentation that provides information or instructions to programmers/developers (e.g., instructions about other tools of the SDK), debuggers that are capable of identifying coding errors, and one or more APIs to relay calls to other services and systems. By deploying these tools, a new application may be built (e.g., beginning with an integrated development environment (IDE)) or an existing application may be modified. In some examples, for mobile application development, the SDK may be Apple's IOS SDK or Google's Android SDK. On the other hand, for large-scale applications, such as enterprise Software-as-a-Service (SaaS), proprietary web applications, or desktop software applications, the SDK may be open source .NET SDK.

[2854] With a management stack 21300', each layer of the stack 21300' may include one or more SOS units. As shown in FIG. 164C, the management stack 21300' maintains a similar hierarchical arrangement to that of the simple primary and sub-level computing device 21100', 21200' of FIG. 163C. That is, the control layer 21310' that functions to control the value chain includes a control tower SOS as the primary system 21100'.

[2855] Referring to FIG. 164D, an example management stack 21300' is shown for a particular enterprise value chain. In this example, the control layer 21310' is a primary system 21100' or enterprise control tower SOS. The operational layer 21320' includes four potential value chain networks corresponding to the supporting operations of (1) marketing and sales, (2) logistics, (3) service, and (4) operations. As shown by the darkened outline, the particular value chain depicted in FIG. 164D includes operations as the operational layer 21320'. Here, with the operational layer 21320' corresponding to the operations group of the enterprise, the activity

21332' for the activity layer 21330' may be one of several activities 21332' that operations may perform. For instance, FIG. 164D illustrates a menu or set of activities 21332' that are associated with the operations group of the enterprise. Of the set of activities 21332' depicted, the operations group is responsible for performing the activities 21332' of production processes, infrastructure management, and quality control. In this respect, the primary system 21100' of the control layer 21310' may have a value chain dedicated to the management and/or control of each of these activities 21332' in relation to operations as the supporting operation 21322' for the enterprise. That is, the first path p1 of FIG. 164D illustrates a first value chain that corresponds to operations performing the activity 21332' of production processes. The second path p2 illustrates a second value chain that corresponds to operations performing the activity 21332' of infrastructure management. The third path p3 illustrates a third value chain that corresponds to operations performing the activity 21332' of quality control.

[2856] In some configurations, such as FIG. 164D, each enterprise group at the operational layer 21320' may have a corresponding set of activities 21332' that it can perform. For instance, FIG. 164D depicts that the marketing and sales group at the operational layer 21320' may perform the activities 21332' of contracts and information services. The logistics group at the operational layer 21320' may perform the activities 21332' of demand management, supply chain management, and procurement. The service group at the operational layer 21320' may perform the activities 21332' of finance, research and development, and human resource management. In these configurations, each activity flow path p can correspond to a value chain network. In that sense, the enterprise control tower may be simultaneously or sequentially managing upwards of a dozen value chain networks.

[2857] FIG. 164D also depicts that the services layer 21340' of the value chain differs based on the activity 21332' to be executed by one or more services 21342'. For example, the value chain portrayed as the first path p1 may include a different set of services for the activity 21332' of production processes than the second path p2 for the activity 21332' of infrastructure management. Likewise, the third path p3 for the activity 21332' may have a completely different set of services than both activities 21332' of production processes and infrastructure management. It will be appreciated that more or less paths may be used.

[2858] Referring to FIG. 164D specifically, the service layer 21340' shows a set of services 21342' that are executed in some combination to perform the production processes activity 21332'. The set of services may be a unique mix or combination of service building blocks. A building block generally refers to a system that may be configured individually or in combination with another one or more systems to perform task(s)/service(s) that enable a particular activity 21332' (e.g., autonomously allow the activity 21332' to occur). In this sense, it can be said each building block or service 21342' can have a particular configuration to support CSSs for an SOS. In FIG. 164D, the activity 21332' of production processes may be executed by a set of services 21342' that includes service building blocks A, J, N, and P. Although not depicted, a similar example would be that the activity 21332' of infrastructure management may include service building blocks A, G, and O. As supported by these examples,

a building block, such as A, may be configured in combination with two different sets of services in order to perform different activities 21332' (e.g., production processes services v. infrastructure management services). With this being the case, permutations of building blocks can perform a vast array of activities 21332'.

[2859] There may be a variety of service building blocks that may be configured to perform activates/actions for the purpose of the primary task. The building blocks that may be implemented by the control architecture 21000' are not limited to a particular ecosystem, but rather may transcend the ecosystems that they are described in relation to herein to provide a configured function or set of functions for the control architecture 21000'. For instance, each of the applications 614, applications 630, the value chain entities 652, demand management applications 824, 1502, supply chain applications 812, 1500, intelligent product applications 1510, asset management applications 1530, and enterprise resource management applications 1520 from the VCNP 604 may be a building block. Other examples of buildings blocks may include adaptive intelligent systems 614, artificial intelligence systems 1160, 10212 (including hybrid artificial intelligence systems 3060), and/or other systematic services, such as artificial intelligence and computational systems 634, robotic process automation (RPA) systems 1442, protocol adaptors 1110, packet acceleration systems 1410, edge compute management systems 1400, edge intelligence systems 1420, edge networking systems 16100, adaptive networking systems 1430, state and event managers 1450, opportunity miners 1460, artificial intelligence systems 1160, digital twin systems 1700, digital twin simulation systems 2020, machine vision systems 1600, entity interaction systems 1920, real time monitoring systems 1520, visual monitoring systems 1930, point of interaction systems 1530, physical process observations systems 1510, robotic-oriented systems (e.g., robotic motion tracking systems), machine state monitoring systems 1940, IoT systems 1172, user feedback systems 1534, location monitoring systems 1532, behavioral monitoring systems 1538, entity discovery systems 1900, classification systems 1610, data processing systems 1612, signal processing systems 1614, prediction systems 1620, configuration systems 1630, control systems 1640, analytic systems 1650, testing/diagnostic systems 1660, security systems 1670, and quantum computing systems 17000. For additive manufacturing, some examples of building blocks include systems/services for the additive manufacturing platform 10110, such as additive manufacturing units 10102, pre-processing systems 10104, post-processing systems 10106, material handling systems 10108, finishing systems 10121, packaging systems 10122, shipping systems 10124, processing systems 10127, data acquisition systems 10602, design and simulation systems 10116, Product Lifecycle management (PLM) systems 10648, maintenance management systems (MMS) 10650, Quality Management systems (QMS) 10652, certification systems 10654, compliance systems 10656, feedstock formulation systems 10706, risk prediction and management systems 10712, marketing and customer service systems 10716, and AI systems 10212. With respect to liquid lens, some examples of building block include systems/services associated with dynamic visions systems 11200. For robotic fleet management, examples of building blocks include systems/services relating to the fleet management platform 12000, such as fleet operations

systems 12002, robot operating units 12040, robot control systems 12150, robot security systems 12170, robotic process automation (RPA) systems 12216, vision and sensing systems 12112, and motion planning systems 12158. For smart containers, examples of building blocks include systems/services relating to the smart intermodal shipping container system 1300, such as smart containers 13026, smart container operating units 13040, logistics systems 13016, maintenance management systems 13028, smart container task assemblies 13050, security systems 13046, communication management systems 13010, remote-control systems 13012, human interface systems 13038, fleet management systems 13002, fleet configuration systems 13020, quantum computing services 13008, and smart container digital twins (e.g., smart container fleet manager digital twin 13328). For digital product networks, examples of building blocks include systems/services relating to the digital product network 14000, such as digital product network services 14002, connected products 14010, digital products 14210, demand aggregation systems 14250, supply chain management systems 14252, new product development systems 14254, customer relationship management systems 14256, PLM systems 14258, digital twin systems 14260, synchronized planning systems 14262, intelligent procurement systems 14264, dynamic fulfillment systems 14266, and digital product network systems 14508. For smart contracts, examples of building blocks include systems/services relating to the smart futures contract system 15000, such as futures systems 15006, smart contract services 15020, demand aggregation services 15022, digital wallets 15024, risk determination services 15026, and RPA services 15028. For biology-based systems, examples of building blocks include systems/services relating to the thalamus service 18001, such as control systems 18002, intake data management systems 18028, and intake controllers 18008. For energy systems, examples of building blocks include systems/services relating to the energy system 19000. For dual process artificial neural networks, examples of building blocks include systems/services relating to the dual process artificial neural network (DPANN) system 20000. Although these systems are specifically enumerated as potential building blocks, this list is non-exhaustive and may include other applications, systems, and/or services described herein or others not specifically described, but of a similar nature to systems/services of this disclosure. As explained previously, one or more of these building blocks may be particularly configured as well as mixed and matched in various combinations to form a set of building blocks capable of performing a target task, activity, or action.

[2860] In some implementations, there may be multiple sets of service building blocks that are capable of performing a given activity 21332', especially in a configuration that may be dictated by CSSs. When this is the case, an SOS, such as a primary system 21100', can (as noted above) identify the candidate sets of service building blocks that are capable of performing an activity 21332' and determine an optimal set from the candidate sets. In some examples, the optimal set of service building blocks is determined by an optimization algorithm that weighs one or more different importance factors. Some examples of importance factors include consumption of computing resources, duty cycle, response time, estimated time to complete the activity 21332', amount of computing resources consumed by internal resources in relation to third-party

resource consumption, training or initiation time, quality metrics, inventory metrics/thresholds, human resource expenditure, overhead, cost, raw material consumption, operational capacity, and resource utilization.

[2861] Although FIG. 164D illustrates twenty-four service building blocks, there may be a greater or a fewer number of service building blocks depending on the services available to an enterprise. In some examples, the number of service building blocks is contingent upon the number of services that systems of the enterprise are capable of performing. Meaning that, an enterprise with five systems capable of performing seven service(s)/task(s) may have seven service building blocks such that the enterprise can deploy a configured instance of some set/subset of the seven service blocks. With this type of structure, a management stack 21300' can focus on optimizing a configuration for a combination of services rather than trying to optimize or configure each service individually.

[2862] FIGS. 165B illustrates an example of the functionality of the control architecture 21000'. Here, the control architecture 21000' includes a primary system 21100' labeled as an autonomous enterprise control tower SOS1 and a sub-level computing device 21200' labeled as an autonomous enterprise SOS2. As previously mentioned, here, the highest-level SOS is the primary system 21100' while the lower level SOS is the sub-level computing device 21200'. With nested or grouped systems, the functionality or characteristics of one particular system (e.g., the primary system 21100') may be unique or differentiable with respect to another system (e.g., the sub-level computing device 21200') due to the types of inputs and/or outputs associated with each system. In other words, a first set of inputs to a system can influence an arrangement of services (e.g., intelligence services) to form a unique configuration of those services for the system.

[2863] In some implementations, configuring the set of one or more computing devices to fulfill the one or more secondary commands may include providing 17816 intelligence received from the at least one CSS to the set of one or more computing devices. For instance, in some examples, such as FIG. 165B, the CSS1 of the primary system 21100' includes a first configured intelligence service CIS1 that, at 21404', receives a directed request to perform intelligent processing for the CSS1. Here, this request may be referred to as an "intelligence request" from the CSS. Intelligent processing may refer to using, at the configured intelligence service (CIS), intelligence capabilities of or similar to the intelligence services system 8800. In some examples, the arrangement of the configured intelligence service CIS is identical to that of the intelligence services system 8800 (e.g., shown in FIG. 106) except that it has an intelligence configuration (e.g., configured by its associated CSSs) that has been adapted to support a particular system service or set of system services. In the case of a control tower or primary system 21100', this intelligent processing at 21404' may perform analysis of one or more of the managerial functions. In some implementations, intelligent decision-making regarding strategy for the primary command may be performed 17828 based upon, at least in part, the CIS. For instance, when the primary system 21100' is determining a strategy to perform the requested task (i.e., the primary task), the intelligence service is capable of performing intelligent decision-making

regarding strategy for the requested task. This decision making may include decomposing the primary task into a set of subtasks, determining sub-level computing devices 21200' that may be capable of performing the primary task, evaluating the availability of one or more sub-level computing devices 21200', predicting an efficient use of resources to perform the primary task, and/or allocating system resources to the primary task or some portion of the primary task.

[2864] In some implementations, the first configured intelligence service CIS1 is supported by other system services. That is, at 21406', one or more other system services may be configured to perform supporting analytics for the intelligence services of the first configured intelligence service CIS1. For example, FIG. 165B illustrates n number of CSSs CSS1-1...CSS1-n to represent the other system services that have been configured to support the first configured intelligence service CIS. As an example, when the first configured intelligence service CIS1 is evaluating the availability of sub-level computing devices 21200', a set of supporting system services may be configured to query various systems to determine system capabilities or resource utilization. In this sense, the CSSs CSS1–n have been configured for resource management and resource reporting.

[2865] In response to performing intelligent processing, the CSS1, at 21408', determines whether the processing has provided adequate intelligence in response to the intelligence request (i.e., has successfully fulfilled the intelligence request). In some implementations, to evaluate whether the intelligent processing is complete, the CSS determines whether the output or decision generated by the configured intelligence system CIS satisfies a threshold (e.g., a decision-making threshold). For instance, the output or decision from the configured intelligence service CIS may be bound by constraints. Here, these constraints may individually or collectively correspond to the decision-making threshold. In some examples, these constraints correspond to the set of inputs 21102' to the primary system 21100'. For instance, the constraints are derived from or related to one or more external controls provided to the primary system 21100' as an input 21102'.

[2866] In some configurations, the CSS1 determines whether the intelligent processing has provided adequate intelligence for the intelligence request in response to an output from the configured intelligence service CIS. In other configurations, there may be an event which triggers an evaluation of whether the intelligent processing has provided adequate intelligence in response to the intelligence request. For instance, the event may be a time-based event such as an expiration of a set duration after receiving the request or an expiration of a time period based on a set frequency for evaluating the intelligent processing.

[2867] As shown in FIG. 165B, in response to the intelligent processing failing to provide sufficient intelligence for the intelligence request or being incomplete at the time of evaluation, the CSS1 may iteratively repeat the intelligent processing at 21404' and 21406' in furtherance of the intelligence request. When another iteration occurs, that iteration of intelligent processing may also include another iteration of support from one or more of the other system services (e.g., shown as CSSs CSS1–n). In some examples, an iteration may require less (or more) system services than a prior iteration. In this respect, each iteration may include an operation

that identifies which, if any, of the supporting system services are demanded for the present iteration. Moreover, each iteration may demand a different configuration for the supporting system service(s). When a different configuration is requested, the CSS1 can generate configuration data prior to the provision of services by the supporting system services during the present iteration. That is, although the configuration system services CSS of the primary system 21100' may be designed for the requested functionality of the primary system 21100', this configuration may vary to some extent during sequential intelligent processing (e.g., within some expected variance).

[2868] In response to a determination that the intelligent processing of the configured intelligence service CIS has provided adequate intelligence in response to the intelligence request, the CSS is configured to determine at 21410' whether further action is required (e.g., from one or more sub-level computing devices 21200'). That is, the CSS of the primary system 21100' is a system designed to perform a particular service or set of services (e.g., based on the primary task). Here, at 21410', if the output of the configured intelligence service CIS satisfies or enables the CSS to perform its own set of services to satisfy the primary task without further input or influence, then the primary system 21100' may complete the request without involving the sub-level computing device 21200'.

[2869] However, in some examples, the primary system 21100' requires at least another level of services to perform the primary task. The primary system 21100' may call on any number of sub-level computing devices 21200' (e.g., via an output 21104') to perform a directed set of tasks. To call on the sub-level computing device 21200', the primary system 21100' may generate an output 21104' that functions as an input 21202' to the sub-level computing device 21200'. As shown in FIG. 165B, this output 21104' may be a directed action request or some action-configuring information such as parameters, variables, or data. Here, this output 21104' by the primary system 21100' may enable the sub-level computing device 21200' to be configured to perform actions/functions in furtherance of the primary task or to perform according to the directed action request. For example, the directed action request requests that the sub-level computing device 21200' executes or facilitates the execution of one or more subtasks associated with primary request. As an example, the directed action request includes an executable sequence of tasks for the sub-level computing device 21200' to perform.

[2870] In response to the sub-level computing device 21200' receiving the output 21104' of the primary system 21100' (as the input 21202' to the sub-level computing device 21200'), the sub-level computing device 21200', at 21412', is configured to evaluate the output 21204'. That is, the sub-level computing device 21200' may evaluate the directed action request included in the output 21104' of the primary system 21100'. For instance, as shown in FIG. 165B, a CSS2 evaluates the output 21104' from the primary system 21100'. In some implementations, the evaluation of the directed action request by the sub-level computing device 21200' includes an evaluation of resource requirements and/or resource options that are available to perform the directed action request.

[2871] Similar to functionality of the primary system 21100', the CSS2 of the sub-level computing device 21100' includes a second configured intelligence service CIS2. In some examples, after evaluating the directed request included in the output 21104' from the primary system 21100', the CSS2 generates an intelligence request based on, or derived from, that directed request. For example, FIG. 165B, at 21414', depicts the second configured intelligence service CIS2 performing CSS2-directed analysis to represent the execution of the intelligence request based on the directed request.

[2872] In some configurations, to generate the intelligence request, the CSS2 generates configuration data. In some examples, the configuration data provided by the CSSs2 configures all or some portion of the artificial intelligence service or the intelligence system controller (e.g., the analysis modules, the analysis management module, or the governance library) for an intelligence services system (e.g., shown in FIG. 104). Here, by configuring the intelligence services system with the provided configuration data, the intelligence services system may be considered a "configured intelligence service." When generating the configuration data for the intelligence request, the CSS2 may leverage information that it receives from the directed request in order to perform intelligent processing for the CSS1.

[2873] Much like step 21408' for the primary system 21100', the sub-level computing device 21200', at 21416', is configured to determine whether the intelligent processing at 21414' has provided adequate intelligence in response to the intelligence request (i.e., has successfully fulfilled the intelligence request). In some implementations, to evaluate whether the intelligent processing is complete, the CSS2 determines whether the output or decision generated by the second configured intelligence system CIS2 satisfies a threshold (e.g., the decision-making threshold). For instance, the output or decision from the second configured intelligence service CIS2 may be bound by constraints. Here, these constraints may individually or collectively correspond to the decision-making threshold. In some examples, these constraints correspond to the set of inputs 21202' to the sub-level computing device 22100'.

[2874] In some configurations, the CSS2 determines whether the intelligent processing has provided adequate intelligence for the intelligence request in response to an output from the second configured intelligence service CIS2. In other configurations, there may be an event which triggers an evaluation of whether the intelligent processing has provided adequate intelligence in response to the intelligence request. For instance, the event may be a time-based event such as an expiration of a set duration after receiving the request or an expiration of a time period based on a set frequency for evaluating the intelligent processing.

[2875] As shown in FIG. 165B, in response to the intelligent processing failing to provide sufficient intelligence for the intelligence request or being incomplete at the time of evaluation, the CSS2 may iteratively repeat the intelligent processing at 21418' and 21414' in furtherance of the intelligence request. When another iteration occurs, that iteration of intelligent processing may also include supporting functionality at 21418' from one or more of the other system services (e.g., shown as CSSs3, CSS4, CSS(n)). In some examples, an iteration may require less (or more) system services than a prior iteration. In this respect, each iteration may include an

operation that identifies which, if any, of the supporting system services are demanded for the present iteration. Moreover, each iteration may demand a different configuration for the supporting system service(s). When a different configuration is requested, the CSS2 can generate configuration data prior to the provision of services by the supporting system services during the present iteration. That is, although the configuration system services CSS of the sub-level computing device 21200' may be designed for the requested functionality of the sub-level computing device 21200', this configuration may vary to some extent during sequential intelligent processing (e.g., within some expected variance).

[2876] In response to a determination at 21416' that the intelligent processing of the second configured intelligence service CIS2 has provided adequate intelligence in response to the intelligence request, the CSS2 is configured to determine at 21420' whether an action is available to fulfill the directed action request from the primary system 21100'. When there is an action available to fulfill the directed action request at 21420', the CSS2 proceeds to 21424'. On the other hand, if an action is not available at 21420' to fulfill the directed action request, the CSS2 may perform directed action process configuration and/or directed action resource analysis assistance using one or more additional system services at 21422' (e.g., shown as CSS5, CSS6, and CSS(n)). Here, these additional system services may be another SOS or an external service.

[2877] At 21420', when the CSS2 determines that there is an action available to fulfill the directed request, the process proceeds to 21424'. Here, at 21424', the CSS2 initiates and/or executes a process determined by or based on the available action and/or the intelligent processing response from the second configured intelligence service CIS2.

[2878] Optionally, as shown at 21426' and 21428', the process that is to be initiated or executed can undergo an optimization operation. For example, at 21428', the second configured intelligence system CIS2 determines whether the directed action process is an optimized process. In some implementations, to determine whether the directed action process is an optimized process, the CSS2 determines whether the process satisfies a set of optimization constraints. In other implementations, the CSS2, at 21428', determines whether the process satisfies a designed objective function. In some instances, the objective function is based on the primary task (e.g., in combination with any external controls included in the primary system input 21102'). In other instances, the objective function is based on the secondary task specified by the directed action request from the sub-level computing device input 21202'.

[2879] At 21430', the CSS2 reports a response to the directed action request as an output 21204' of the sub-level computing device 21200'. For example, the output 21204' is an action plan for the primary task. Additionally or alternatively, the output 21204' of the sub-level computing device 21200' being reported to the primary system 21100' is that some set of actions were executed at the sub-level computing device 21200' to support the primary task as directed by the direct action request from the primary system 21100'. When reporting the execution of some set of actions, the output 21204' of the sub-level computing device 21200' may include data or information related to the execution of the set of actions. In some

configurations, the data or information is monitoring data that characterizes the performance of the set of actions implemented by the sub-level computing device 21200' at some snapshot in time or over a certain period of time.

[2880] Although FIG. 165B illustrates operational details about the inputs and outputs of a single primary system 21100' and a single sub-level computing device 21200' (e.g., as shown in FIG. 163C), there may be any number of sub-level computing devices 21200' managed by either the primary system 21100' or a particular sub-level computing device 21200'. When a set of additional sub-level computing devices 21200' are managed by the sub-level computing device 21200', these additional sub-level computing devices 21200' may be referred to as secondary subsystems. When there are multiple sub-level computing devices 21200' for a control architecture 21000' (e.g., as shown in FIG. 165B), each sub-level computing device 21200' may follow a similar set of operations (e.g., operations referenced by 21412'–21430') in support of the primary task for the primary system 21100'.

[2881] In some implementations, VCN process 10 may include a VCN autonomous mobile infrastructure network, which may provide modular, adaptive, and mobile resources that deliver responsive and optimized on-site production as directed by the agile demand response resource network. This network may also provide local granular data to further refine demand response modeling and production. Each of these networks comprise a unique combination of capabilities and applications that are purpose-built using a common set of constituent building block elements and generalized services such as intelligence, distributed ledger, smart contracts, analytics, data sourcing and processing, sensors, etc. Resulting sets of capabilities and applications may be collectively managed by their respective networks, while orchestration of the set of networks may be provided at the highest level by the VCN SOS.

[2882] In some implementations, VCN process 10 may include a VCN autonomous fixed infrastructure network. For instance, this network may be similar to a mobile network and may use some of the same configured system services, but it also incorporates a wider set of data and capabilities made available by greater access varied resources such as, e.g., ERP and Industry 4.0 integration, processing power, fewer energy and space limitations, the ability to optimize for location, etc. Each of these networks may include a unique combination of capabilities and applications that are purpose-built using a common set of constituent building block elements and generalized services such as intelligence, distributed ledger, smart contracts, analytics, data sourcing and processing, sensors, etc. Resulting sets of capabilities and applications may be collectively managed by their respective networks, while orchestration of the set of networks may be provided at the highest level by the VCN SOS.

[2883] In some implementations, VCN process 10 may include a VCN agile demand response resource network, which may provide configured system services and assemblies of services that simulate and visualize demand scenarios, produce synchronized planning and dynamic fulfillment, etc. One example is Peer-to-Peer (P2P) cognitive matching of supply and demand. Each of these networks may include a unique combination of capabilities and applications that are purpose-built using a common set of constituent building block elements and generalized

services such as intelligence, distributed ledger, smart contracts, analytics, data sourcing and processing, sensors, etc. Resulting sets of capabilities and applications may be collectively managed by their respective networks, while orchestration of the set of networks may be provided at the highest level by the VCN SOS.

ML/AI TO FLAG AND RESPOND TO POTENTIAL DISRUPTIONS IN THE VALUE CHAIN

[2884] As also discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may receive 17900, by a computing device, information associated with a set of value chain network entities (such as those discussed above) of a value chain network. For instance, as discussed throughout, a unified database (e.g., via platform 604) may (e.g., via VCN process 10) receive information associated with a set of value chain network entities of a value chain. The information may be collected in a variety of ways, including (by example only) via the unified data collections systems discussed throughout.

[2885] In some implementations, the information may be generated by a set of sensors of the set of value chain network entities. For instance, example sensors and/or a set of APIs configured to publish data relating to the set of value chain network entities may include those discussed regarding the adaptive intelligent systems and monitoring layers of platform 604. In some implementations, the information generated by a set of IoT devices configured to collect data relating to the set of value chain network entities. For instance, unified IoT monitoring systems (such as those discussed regarding at least the example implementation of FIG. 33) may be used to generate information from a set of IoT devices. It will be appreciated after reading the present disclosure that various other types of methods may be used for information generation without departing from the scope of the present disclosure. As such, the example use of the techniques and methods of information generation described throughout should be taken as example only and not to otherwise limit the scope of the present disclosure.

[2886] In some implementations, VCN process 10 may provide 17902 the information to a set of Artificial Intelligence (AI)-based learning models, wherein at least one member of the set of AI-based learning models may be trained on a training data set of a set of value chain network entities operating data to classify at least one of: an operating state, a fault condition, an operating flow, or a behavior of at least one value chain entity of the set of value chain network entities. For instance, in embodiments, an intelligence services (such as those discussed in the example implementation of FIG. 104) may include an intelligence service controller and AI modules. In embodiments, an artificial intelligence services receives an intelligence request from an intelligence service client and any required data to process the request from the intelligence service client. In response to the request and the specific data, one or more implicated artificial intelligence modules perform the intelligence task and output an "intelligence response". Examples of intelligence modules responses may include a decision (e.g., a control instruction, a proposed action, machine-generated text, and/or the like), a prediction (e.g., a predicted meaning

of a text snippet, a predicted outcome associated with a proposed action, a predicted fault condition, a predicted disruption or risk in the value chain network, a prediction of future demand, and/or the like), a classification (e.g., a classification of an object in an image, a classification of a spoken utterance, a classified fault condition based on sensor data, and/or the like), and/or other suitable outputs of an AI system. In some implementations, the operating state of a machine may be the current condition of the machine. Some examples of operating states may include, e.g., Running - the machine is in normal operation; Idle - the machine is not in operation, but it is ready to be started; Stopped - the machine is not in operation and is not ready to be started; Malfunctioning/Faulted - the machine has malfunctioned and is not operating properly; Under maintenance - the machine is being serviced or repaired.

[2887] In some implementations, the set of AI-based learning models may include at least one of a transformer model, a convolutional neural network, a deep learning model trained on a set of outcomes of the value chain network entity, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model, and the training data set for the set of AI-based learning models may include one of a set of objects or events that are labeled to classify the set of objects or events according to a classification taxonomy that may include at least one of the above-noted operating state, the fault condition, the operating flow, or the behavior. Other examples of AI-based learning models (e.g., machine learning models) may include neural networks in general (e.g., deep neural networks, convolution neural networks, and many others), regression based models, decision trees, hidden forests, Hidden Markov models, Bayesian models, and the like. In some implementations, VCN process 10 may include combinations where an expert system uses one neural network for classifying an item (e.g., identifying a machine, a component, or an operational mode) and a different (or the same) neural network for predicting a state of the item (e.g., a fault state, an operational state, an anticipated state, a maintenance state, or the like).

[2888] In some implementations, VCN process 10 may determine 17904 a potential risk in the value chain based upon, at least in part, an output of the AI-based learning classification. For instance, an example of a potential risk may be a supply chain disruption. A supply chain disruption may occur when there is a break in the flow of goods or services from the supplier to the customer. This can be caused by a variety of factors, such as natural disasters, political instability, or pandemics. A value chain risk (e.g., disruption) is a broader term that refers to any disruption that affects the flow of goods or services within a company or organization. This can include disruptions to production, distribution, or sales. Therefore, VCN process 10 may utilize an AI system that can track and predict potential supply chain risks (or other types of disruptions) and generate predictive insights based upon the above-noted generated information provided to the AI-based learning models. In some implementations, the determination may be a prediction of a future potential risk, or predicted current potential risk.

[2889] In some implementations, VCN process 10 may execute 17906 an action to mitigate the potential risk in the value chain network. For instance, once a potential risk has been predicted (or determined/identified), VCN process 10 may execute an action to mitigate that potential risk.

In some implementations, the action may be automatically executed without human interaction, or manually executed (e.g., approving an action suggested by VCN process 10). In some implementations, the action taken may be recorded in a log or a feed for viewing.

[2890] In some implementations, executing the action to mitigate the potential risk in the value chain network may include flagging 17908 the potential risk in the value chain network. For instance, in some implementations, VCN process 10 may use AI-based learning models to automatically draft and send communications (e.g., text, email, pop-ups, notification feed, chat, etc.) explaining what the predicted risk is, what information was used to predict the risk, and potential recommendations to mitigate the potential risk. This may allow a user to verify whether the potential risk is an actual risk, and take the appropriate action. In some implementations, the potential risk may also be flagged in an application's user interface (UI), such as the above-noted control tower UI.

[2891] In some implementations, executing the action to mitigate the potential risk in the value chain network may include responding 17910 to the potential risk in the value chain network. For example, VCN process 10 may suggest diversifying suppliers, which means having multiple suppliers for the same product or service. This can help to reduce the risk of a disruption from one supplier affecting the entire supply chain. Another example suggestion from VCN process 10 may be building inventory buffers, which means having more inventory than is normally needed. This can help to ensure that there is enough product available to meet demand even if there is a disruption. Another example suggestion from VCN process 10 may be using alternative transportation methods, which means using different modes of transportation, such as air freight or rail, if there are disruptions to road or sea transportation. Another example suggestion from VCN process 10 may be renegotiating contracts, which means negotiating with suppliers to change the terms of contracts, such as delivery dates or pricing, if there are disruptions or other risks. Another example suggestion from VCN process 10 may be using technology, meaning the use of technology to track shipments, manage inventory, and communicate with suppliers about the potential risk. This can help to improve visibility and coordination in the supply chain and make it easier to respond to disruptions or other risks. Another example suggestion from VCN process 10 may be additional innovation, such as flagging/responding in a digital twin (e.g., a value chain network digital twin as discussed throughout), where the response may involve, e.g., placing an order in an embedded marketplace of the digital twin.

[2892] In some implementations, executing the action to mitigate the potential risk in the value chain network may include resolving 17912 an out-of-stock situation. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by resolving an out-of-stock situation. As an example, VCN process may determine that a particular product (e.g., an engine part) is out-of-stock or will soon be out-of-stock based upon the AI-based learning models. In some implementations, VCN process 10 may resolve this situation by automatically executing

(without human interaction) a reordering of the engine part, or providing a suggestion on a user interface to reorder the engine part, which may be manually executed (e.g., receiving a user input to approve the suggested action).

[2893] Resolving an out-of-stock situation may also be achieved by VCN process 10 monitoring inventory levels in real-time across various locations by integrating data from, e.g., IoT devices, edge devices, cameras, RFID tags, or other inventory tracking technologies. The process may utilize this real-time stock level information to predict or ascertain an out-of-stock situation and attempt to ameliorate the problem by, e.g., automatically purchasing new inventory, implementing a dynamic pricing strategy wherein real-time stock levels and customer demand are used as inputs to determine the dynamic price of a product, using drop shipping to fulfill orders by automatically identifying suppliers with stock of the item and placing an order with that supplier and having the item shipped directly to the customer, using an AI-based model to perform a root cause analysis to understand the reasons behind the occurrence of the out-of-stock situation and provide recommendations on how to prevent similar situations from happening in the future, automatically notifying customers about stock levels and the potential for delays and offer a discount, backordering option, alternative products, or other incentive, etc.

[2894] In some implementations, executing the action to mitigate the potential risk in the value chain network may include predicting 17914 when to place an order based upon, at least in part, upstream data. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by using upstream data to predict when to place an order (e.g., demand enhancement/planning). As an example, VCN process 10 may include or interact with a demand planning application that may automatically calculate demand (demand sensing) and stock forecasts based on upstream data (e.g., sales forecasts, warehouse data, etc.). This may allow a precise view of when to place optimal orders that cover specific product demands. In some implementations, VCN process 10 may resolve this situation by automatically executing (without human interaction) a reordering of the engine part, or providing a suggestion on a user interface to reorder the engine part at the optimal time, which may be manually executed (e.g., receiving a user input to approve the suggested action).

[2895] As an example, VCN process 10 may determine potential risk in the stocking of an engine part. Data obtained from suppliers, distributors, manufacturers, or other upstream value chain network entities may be analyzed by one or more AI-based learning models to generate a risk assessment for immediate or future procurement of the engine part. In some implementations, the VCN process may mitigate this risk by adjusting the timing or quantity of the part procurement. In some implementations, the VCN process may mitigate risk by automatically identifying alternate suppliers for the engine part and placing an order for the part with the identified supplier.

[2896] In some implementations, executing the action to mitigate the potential risk in the value chain network may include supply planning 17916. Generally, supply planning ensures that

products, materials, and resources will have optimal availability in order to meet current and anticipated demand while minimizing costs and preventing delays in delivery. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by using upstream data for supply planning. As an example, VCN process 10 may include or interact with a supply planning application that may automatically calculate supply (supply sensing) and stock forecasts based on upstream data (e.g., sales forecasts, warehouse data, etc.). This may allow a precise view of when to place optimal orders that cover specific product supplies. In some implementations, VCN process 10 may resolve this situation by automatically executing (without human interaction) a reordering of the engine part, or providing a suggestion on a user interface to reorder the engine part at the optimal time, which may be manually executed (e.g., receiving a user input to approve the suggested action).

[2897] In another example embodiment, an automotive manufacturer may use supply planning of VCN process 10 to mitigate risks associated with component availability and anticipated demand. Consider an automotive manufacturer that anticipates an increase in demand for a specific car model in the upcoming quarter based on analysis that takes into account data including, but not limited to, historical sales, current market trends, and planned promotional initiatives. The manufacturer projects that an additional 10,000 cars will need to be manufactured during the next quarter in order to meet the predicted demand. The manufacturer assesses their current inventory and finds that they only have enough engine parts to manufacture 2,000 cars and therefore needs to order additional stock from their suppliers. A first supplier is able to commit to delivering engine parts sufficient for the manufacturing of 5,000 cars within a one month time frame. A second supplier is able to commit to delivering engine parts sufficient for the manufacturing of 3,000 cars with a two month lead time. A third supplier is able to deliver any requested volume of engine parts with a delivery time of only two weeks, but charges a premium for the expedited delivery. The automotive manufacturer uses this supplier information to plan production scheduling such that car production ramps up after 1.5 months to ensure that component availability is adequate and demand is met in time. The third supplier is used as an auxiliary supplier to mitigate risk in the event that delays are encountered with the primary suppliers. In this manner, the automotive manufacturer uses supply planning to maximize production efficiency and optimize expenses while ensuring sufficient supply to meet anticipated demand.

[2898] In some implementations, executing the action to mitigate the potential risk in the value chain network may include optimizing 17918 an inventory mix. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by using upstream data to optimize an inventory mix. Generally, an inventory mix is the composition of a company's inventory. Inventory mix may be calculated by VCN process 10 dividing the value of each product

category by the total value of the inventory. For instance, assume for example purposes only that there is a local sporting goods store that learns via VCN process 10 that it needs to optimize its inventory mix. In the example, the store's sales data shows (e.g., via VCN process 10) that basketballs are the most popular product in the store. The store also knows from VCN process 10 that basketball season is coming up, so VCN process 10 recommends to increase their stock of basketballs. VCN process 10 also recommends to stock a wider variety of basketballs, including different sizes, colors, and brands. This will help to appeal to a wider range of customers. VCN process 10 may also know that baseball season is ending, so VCN process 10 may recommend reducing their stock of baseball bats and gloves. VCN process 10 may also recommend that the store sell off any remaining inventory at a discount. This will help to clear out space for new inventory and reduce the amount of obsolete inventory.

[2899] In some implementations, VCN process 10 may receive 17920 external data, and VCN process 10 may determine 17922 a strategy to reduce transportation costs based upon, at least in part, the external data. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential to reduce transportation costs in the value chain network based upon received data. In the example, VCN process 10 may receive the external data to both determine that there is the potential to reduce transportation costs, and determine how to do so. As an example, VCN process 10 may include or interact with a transportation application that may automatically calculate the fastest or most optimal route and transportation method (e.g., air, boat, truck, etc.) based on external data (e.g., gas prices, traffic data, transportation time, sales forecasts, warehouse data, etc.) for past behavior over time, historical data, and/or current data. This may allow a precise view of when to ship orders, what mode of transportation to do so, and the optimal route. In some implementations, the external data may be received and analyzed in real-time or near real-time, enabling rapid time-to-value by collaborating globally with carriers to reduce transportation costs. Time-to-value here may refer to the amount of time it takes for a company to see a return on its investment in real-time data collaboration with global carriers. In some implementations, VCN process 10 may resolve this situation by automatically executing (without human interaction) a change in transportation logistics (e.g., shipping time/date, shipping mode, shipping route, etc.), or providing a suggestion on a user interface to change the transportation logistics, which may be manually executed (e.g., receiving a user input to approve the suggested action). Other examples of external data that may be used to help reduce transportation costs may include, e.g., demand forecasting data (e.g., market trends, sales data, promotional events, seasonal trends, economic indicators, mobile analytics, website analytics, etc.) that may be used to predict regional demand allowing for the consolidation of shipments or ordering of bulk shipments to reduce per-unit transportation costs; fuel price and futures data (e.g., current fuel prices, futures markets data, news media regarding geopolitical events that may affect oil prices) that may be used to provide recommendations on when to purchase fuel or to purchase futures contracts to hedge prices against predicted price increases.

[2900] As such, VCN process 10 may help a business select the optimal mode of shipment and the best carrier, based on, e.g., cost, efficiency, and distance, including optimizing multi-leg carrier routes. VCN process 10 may provide visibility into every stage of the supply chain, and together with global trade management functionality of VCN process 10, may also provide information on trade and tariffs, and if there are any potential delays that may happen because of customs and other trade regulations. In some implementations, VCN process 10 may match loads and communicating with carriers, document and track shipments, and assist with freight billing and settlement, provide track and trace services (e.g., enabling real-time information exchange among carriers, distributors, warehouses, and customers), handle complex international logistics, including providing proper import and export documentation making sure shipments are trade compliant.

[2901] In some implementations, other ways for VCN process 10 to reduce transportation costs may include, e.g., Route optimization - by tracking the location and availability of carriers in real time, companies can optimize their shipping routes to reduce fuel costs and transit times; Mode selection - companies can also use real-time data to select the most cost-effective mode of transportation for their shipments. For example, if a shipment is not urgent, the company may be able to save money by shipping it via ground transportation instead of air freight; Negotiation - companies can use real-time data to negotiate better rates with carriers. For example, if a company has a large volume of shipments, they may be able to negotiate a lower rate with a carrier; Tracking and Tracing - real-time data can also be used to track and trace shipments in real time. This can help to identify and resolve problems quickly, which can reduce costs and improve customer satisfaction. For instance, assume for example purposes only that a company is shipping a product from China to the United States. Further assume that the company uses a real-time data platform (such as VCN process 10) to track the location and availability of carriers. The platform may also provide information on fuel costs and transit times. Further assume VCN process 10 uses this information to recommend to the company to optimize its shipping route. VCN process 10 may recommend one or more carriers for the company to select (of that VCN process 10 may select automatically) that is located near the shipper and that has a good reputation for on-time delivery. VCN process 10 may recommend that the company also select a mode of transportation that is cost-effective for the shipment.

[2902] In some implementations, VCN process 10 may unify 17924 data associated with warehouse management, inventory management, order management, and analytics to optimize an omnichannel fulfillment. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential to optimize an omnichannel fulfillment in the value chain network based upon received data (e.g., warehouse management, inventory management, order management, and analytics). Omnichannel may generally refer to the integration of all sales and fulfillment channels, including such examples as internet/e-commerce, physical stores, and mobile apps, such as to provide a seamless customer journey. Generally, dynamic fulfillment considers the value of inventory according to the location where it is maintained. For example, if a store is in an

overstock position anticipating mark-downs to move the excess, these items can be given priority for on-line orders. The net result is higher profit and customer satisfaction. Thus, in some implementations, VCN process 10 may provide a single platform that unifies warehouse management, inventory management, order management, analytics, and more for full network visibility.

[2903] In some implementations, VCN process 10 may provide 17926 a platform with a plurality of AI-based learning models for download. For instance, VCN process 10 may be enabled as a models-as-a-service system. For instance, in the context of value chain networks, models-as-a-service may generally refer to the practice of providing access to machine learning (or other type of AI-based learning) models as a service, which may be integrated into different stages of the value chain. Value chain networks can consist of a series of interconnected activities that create value for customers, and these activities may include everything from raw material sourcing and production to marketing and distribution. By providing access to AI-based learning models as a service, businesses may enhance their ability to optimize and automate these activities, improving efficiency, reducing costs, and ultimately delivering better products or services to customers.

[2904] For example, a company may provide access to an AI-based learning model that can predict demand for a particular product. This model may be integrated into the planning stage of the value chain, allowing the company to better anticipate customer demand and adjust production accordingly. Similarly, a machine learning model that analyzes customer data may be used in the marketing stage to better understand customer preferences and tailor marketing campaigns to specific customer segments. Overall, models-as-a-service may help businesses in value chain networks to stay competitive by leveraging the power of AI-based learning to optimize and automate their operations. In some implementations, each of the AI-based learning models may be available in an AI marketplace, where users may browse, select, and download individual AI-based learning models for a fee and as needed.

[2905] In some implementations, VCN process 10 may use example systems and processes that provide logistics-as-a-service that may be configured as a platform for retail). This platform may transform unused or underutilized space within retail centers into technologically advanced micro distribution hubs. In example embodiments, this may enhance operational efficiency for both retailers and parcel carriers. This may result in cost reduction and improved service quality by reducing the time it takes to fulfill orders.

[2906] In some implementations, VCN process 10 may use an AI-based learning model to synchronize the supply chain.

[2907] In some implementations, VCN process 10 may use an AI-based learning model for allocation and order promising.

[2908] In some implementations, VCN process 10 may use an AI-based learning model for distribution planning.

[2909] In some implementations, VCN process 10 may use an AI-based learning model for sales and operations planning.

[2910] In some implementations, VCN process 10 may use an AI-based learning model to identify and/or track seasonality patterns and trends.

[2911] In some implementations, VCN process 10 may use an AI-based learning model to generate insights related to supply and/or demand.

[2912] In some implementations, VCN process 10 may use an AI-based learning model to provide product-level transparency into supply and/or demand metrics.

[2913] In some implementations, VCN process 10 may use an AI-based learning model.

[2914] to provide material-level transparency into supply and/or demand metrics.

[2915] In some implementations, VCN process 10 may use an AI-based learning model to provide dynamic fulfillment. For instance, VCN process 10 may provide a platform to realize the full potential of the supply chain infrastructure in terms of maximum revenue, maximum profit, minimum cost and best in class service. VCN process 10 may provide a dynamic fulfillment network, which may generally be described as an interconnected cross-enterprise system that enhances the customer experience by getting the right product and service to the right customer or node at the right time and in the right quantity, quality and condition, while providing supply networks with the desired level of logistics visibility, responsiveness, scalability and flexibility through the application of leading practices, empowering technologies and cross-functional collaboration.

AUTOMATED, INTELLIGENT PROCUREMENT SYSTEM FOR VALUE CHAIN NETWORK ENTITIES

[2916] As also discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may 18000 receive, by a computing device, information associated with a set of value chain network entities (such as those discussed above) of a value chain network. For instance, as discussed throughout, a unified database (e.g., via platform 604) may (e.g., via VCN process 10) receive information associated with a set of value chain network entities of a value chain. The information may be collected in a variety of ways, including (by example only) via the unified data collections systems discussed throughout.

[2917] In some implementations, the information may be generated by a set of sensors of the set of value chain network entities, or a set of APIs configured to publish data relating to the set of value chain network entities. For instance, example sensors and/or a set of APIs configured to publish data relating to the set of value chain network entities may include those discussed regarding the adaptive intelligent systems and monitoring layers of platform 604. In some implementations, the information generated by a set of IoT devices configured to collect data relating to the set of value chain network entities. For instance, unified IoT monitoring systems (such as those discussed regarding at least the example implementation of FIG. 33) may be used to generate information from a set of IoT devices. It will be appreciated after reading the present disclosure that various other types of methods may be used for information generation without departing from the scope of the present disclosure. As such, the example use of the techniques

and methods of information generation described throughout should be taken as example only and not to otherwise limit the scope of the present disclosure.

[2918] In some implementations, VCN process 10 may provide 18003 the information to a set of Artificial Intelligence (AI)-based learning models, wherein at least one member of the set of AI-based learning models may be trained on a training data set of a set of value chain network entities operating data to classify at least one of: an operating state, a fault condition, an operating flow, or a behavior of at least one value chain entity of the set of value chain network entities. For instance, in embodiments, an intelligence services (such as those discussed in the example implementation of FIG. 104) may include an intelligence service controller and AI modules. In embodiments, an artificial intelligence services receives an intelligence request from an intelligence service client and any required data to process the request from the intelligence service client. In response to the request and the specific data, one or more implicated artificial intelligence modules perform the intelligence task and output an "intelligence response". Examples of intelligence modules responses may include a decision (e.g., a control instruction, a proposed action, machine-generated text, and/or the like), a prediction (e.g., a predicted meaning of a text snippet, a predicted outcome associated with a proposed action, a predicted fault condition, a predicted disruption or risk in the value chain network, and/or the like), a classification (e.g., a classification of an object in an image, a classification of a spoken utterance, a classified fault condition based on sensor data, and/or the like), and/or other suitable outputs of an AI system.

[2919] In some implementations, the set of AI-based learning models may include at least one of a transformer model, a convolutional neural network, a deep learning model trained on a set of outcomes of the value chain network entity, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model, and the training data set for the set of AI-based learning models may include one of a set of objects or events that are labeled to classify the set of objects or events according to a classification taxonomy that may include at least one of the above-noted operating state, the fault condition, the operating flow, or the behavior. Other examples of AI-based learning models (e.g., machine learning models) may include neural networks in general (e.g., deep neural networks, convolution neural networks, and many others), regression based models, decision trees, hidden forests, Hidden Markov models, Bayesian models, and the like. In some implementations, VCN process 10 may include combinations where an expert system uses one neural network for classifying an item (e.g., identifying a machine, a component, or an operational mode) and a different (or the same) neural network for predicting a state of the item (e.g., a fault state, an operational state, an anticipated state, a maintenance state, or the like).

[2920] In some implementations, VCN process 10 may determine 18005 a procurement action to be taken in the value chain network based upon, at least in part, an output of the set of AI-based learning models. For instance, procurement actions may generally be described as a set of one or more activities that organizations undertake (e.g., via VCN process 10) to acquire the goods and services they need to operate. In a value chain network, procurement actions may

include but are not limited to: (1) identifying suppliers – finding suppliers who can provide the goods and services needed at a competitive price and with the required quality; (2) negotiating (or renegotiating) contracts – negotiating the terms of contracts with suppliers, such as price, delivery terms, and quality standards; (3) ordering goods and services – placing orders with suppliers for the goods and services needed; (4) receiving and inspecting goods and services – receiving goods and services from suppliers and inspecting them to ensure that they meet the agreed-upon specifications; (5) paying suppliers - paying suppliers for the goods and services they have provided; and (6) managing supplier relationships – building and maintaining relationships with suppliers to ensure that they are reliable and responsive to the organization's needs. Additional considerations (data points) that may be included in the analysis of VCN process 10 may include, e.g.,: the cost of procurement – organizations need to find ways to procure goods and services at a competitive price without sacrificing quality; the quality of goods and services – organizations need to ensure that the goods and services they procure meet their specifications and meet the needs of their customers; the timeliness of procurement – organizations need to ensure that they procure goods and services in a timely manner to meet their production or operational needs; the risk involved -organizations may benefit from identifying and managing the risks associated with procurement, such as the risk of supply disruptions or the risk of quality problems; compliance – organizations need to comply with all applicable laws and regulations when procuring goods and services, which may include such things as laws and regulations related to labor, environmental protection, and product safety. The procurement process of VCN process 10 may also include such things as, e.g., developing standards of quality, financing purchases, creating purchase orders, negotiating price, buying goods, inventory control, inventory management, disposal of waste products (e.g., packaging), cost-benefit analysis or cost-utility analysis, finding new suppliers, locating and acquiring goods and services, overseeing sourcing activities, negotiating terms and conditions, monitoring supplier performance and inventory levels, drive cost-saving initiatives, and make buying decisions under conditions of scarcity.

[2921] Thus, intelligent procurement in a value chain network may generally refer to the use of advanced technologies and data analytics (such as those provided by VCN process 10, which may include at least a portion of intelligent procurement module 14244 and/or intelligent procurement system 14264) to optimize procurement processes and improve value chain efficiency (e.g., from the C-suite to the production lines). As intelligent procurement is built on cognitive intelligence, which is a system that learns from information (e.g., human behavior over time, historical data, current data) and then may formulate recommendations and behaviors to mirror what a human expert would do. Intelligent procurement systems (which may be included as at least a portion of VCN process 10) may be able to learn from past behavior over time, analyze historical and current data, and make a decision based on that data. As a result, instead of needing a human to identify a potential problem and then to make a change to avoid that problem, VCN process 10 may automatically implement this change and flag administrators to alert them of the decision.

[2922] Generally, in some implementations, the key components of VCN processes' 10 intelligent procurement abilities may include but are not limited to, e.g., data analytics – as intelligent procurement may rely on data analytics to gain insights into supplier performance, market trends, and other factors that impact procurement decisions, which may be used to identify cost savings opportunities and optimize procurement strategies; automated processes – as intelligent procurement systems may automate such things as purchase order creation and invoice processing, which not only reduces the workload for procurement teams, but also reduces errors and delays in the procurement process; contract management – as an intelligent procurement system may streamline contract management by providing easy access to contract terms and monitoring compliance, which may help to ensure that suppliers are meeting their contractual obligations and that procurement teams are getting the best possible value from their suppliers.

[2923] In some implementations, VCN process 10 may execute 18007 the procurement action to facilitate an improvement of at least one of the operating state, the fault condition, the operating flow, or the behavior of at least the one entity of the set of value chain network entities. For instance, once a procurement action (such as those discussed above) has been determined (identified), VCN process 10 may execute the procurement action an action to improve either the operating state, the fault condition, the operating flow, or the behavior of one or more value chain network entities. For instance, assume for example purposes only that VCN process 10 determines there is a risk of significant inflation of copper (a component used in semiconductor devices) for a supplier that is currently supplying semiconductor devices. In the example, VCN process 10 may execute a procurement action of proactively renegotiating with the supplier for a lower price of semiconductors or even renewing the current contract for a longer term, in anticipation of the supplier raising its prices due to inflation. In some implementations, the action may be automatically executed without human interaction, or manually executed (e.g., approving an action suggested by VCN process 10). In some implementations, the action taken may be recorded in a log or a feed for viewing.

[2924] Another example of a procurement action may include VCN process 10 determining that there is a need to select a new supplier for a quantity of product required to fulfill a contract. In the example, the product should conform to required quality standards, while also being made available at a competitive price. Additionally, the product should be supplied in sufficient quantity and within a defined timeframe. In this example, VCN process 10 may execute a procurement action of identifying suppliers by collecting and analyzing bids for products meeting the requirements of the contract. These bids should include product information relevant to the specifications set forth in the contract, such as pricing, quality metrics, available quantity, delivery timeframe, and/or other factors. VCN process 10 may also reference information documenting the supplier's history, including quantity of previous transactions, likelihood of successful fulfillment, or other data that can support the selection of a particular supplier and their offered product(s). In some Implementations, the action may be automatically executed without human interaction, or manually executed (e.g., approving an action suggested

by VCN process 10). In some implementations, the action taken may be recorded in a log or a feed for viewing.

[2925] In some implementations, another example procurement action may include VCN process 10, e.g., identifying needs, researching suppliers, placing orders, receiving and inspecting goods, making payments, issuing a purchase order to a supplier for a new batch of widgets, signing a contract with a logistics provider to transport goods from its warehouse to its customers, negotiating a new pricing agreement with a supplier of raw materials, conducting a competitive bidding process to select a new vendor for its IT services, developing a new supplier onboarding process to ensure that new suppliers are meeting its standards, etc.

[2926] In some implementations, executing the procurement action may include resolving 18009 an out-of-stock situation. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by resolving an out-of-stock situation with a procurement action. As an example, VCN process may determine that a particular concern, such as a lack of semiconductor devices of a particular supplier being used by a value chain network entity is out-of-stock or will soon be out-of-stock based upon the AI-based learning models. In some implementations, VCN process 10 may resolve this situation by automatically executing (without human interaction) a negotiation of a contract with another supplier that does have semiconductor devices in stock, or providing a suggestion on a user interface to negotiate a contract with another supplier that does have semiconductor devices in stock, which may be manually executed (e.g., receiving a user input to approve the suggested action).

[2927] In some implementations, executing the procurement action may include predicting 18011 when to place an order based upon, at least in part, upstream data. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by using upstream data to predict when to place an order (e.g., demand enhancement/planning). As an example, VCN process 10 may include or interact with a demand planning application that may automatically calculate demand (demand sensing) and stock forecasts based on upstream data (e.g., sales forecasts, warehouse data, etc.). This may allow a precise view of when to place optimal orders that cover specific product demands. For instance, VCN process 10 may use upstream and/or external data to determine there is a risk of significant inflation of copper (a component used in semiconductor devices) for a supplier that is currently supplying semiconductor devices. In the example, VCN process 10 may execute a procurement action of proactively order semiconductor devices from the supplier prior to an anticipated price hike by the supplier resulting from the predicted or actual inflation. In some implementations, VCN process 10 may accomplish this by automatically executing (without human interaction) a reordering of the semiconductor devices, or providing a suggestion on a user interface to reorder the semiconductor devices at the optimal

time, which may be manually executed (e.g., receiving a user input to approve the suggested action).

[2928] In some implementations, VCN process 10 may provide 18013 an alert describing the procurement action that was executed. For instance, in some implementations, VCN process 10 may use AI-based learning models to automatically draft and send communications (e.g., text, email, pop-ups, notification feed, chat, etc.) explaining what the determined procurement action(s) may be/are, what information was used to determine the procurement action, and the intended result of executing the procurement action (e.g., faster delivery, lower costs, better quality, etc.). This may allow a user to verify whether the procurement action should be confirmed, and take any additional appropriate action. In some implementations, the potential risk may also be flagged in an application's user interface (UI), such as the above-noted control tower UI.

[2929] In some implementations, VCN process 10 may provide 18015 real-time information on supplier performance. For example, in some implementations, VCN process 10 may monitor 18017 compliance of suppliers and procurement teams. For instance, VCN process 10 may include supplier management functionality, which may include an intelligent procurement system that enable effective supplier management by providing real-time information on supplier performance, including delivery times, quality metrics, and pricing. This information, as noted above, may be used to make informed decisions about supplier selection, performance management, or other procurement actions. In some implementations, the real-time information may also be flagged or otherwise displayed in an application's user interface (UI), such as the above-noted control tower UI.

[2930] For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential to reduce transportation costs in the value chain network based upon received data. In the example, VCN process 10 may receive the external data to both determine that there is the potential to reduce transportation costs, and determine how to do so. As an example, VCN process 10 may include or interact with a transportation application that may automatically calculate the fastest or most optimal route and transportation method (e.g., air, boat, truck, etc.) based on external data (e.g., gas prices, traffic data, transportation time, sales forecasts, warehouse data, etc.) for past behavior over time, historical data, and/or current data. This may allow a precise view of such procurement actions including, e.g., when to order, when to pay invoices, etc. In some implementations, the external data may be received and analyzed in real-time or near real-time, enabling rapid time-to-value by collaborating globally with carriers to reduce transportation costs. In some implementations, VCN process 10 may resolve this situation by automatically executing (without human interaction) a request to change contract terms (e.g., price, delivery terms, and quality standards, etc.), or providing a suggestion on a user interface to change contract terms, which may be manually executed (e.g., receiving a user input to approve the suggested action).

[2931] In some implementations, VCN process 10 may automatically generate 18019 purchase orders associated with the procurement action, and in some implementations, VCN process 10

may automatically process 18021 invoice processing associated with the procurement action. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by using upstream data to predict when to place an order (e.g., demand enhancement/planning). As an example, VCN process 10 may include or interact with a demand planning application that may automatically calculate demand (demand sensing) and stock forecasts based on upstream data (e.g., sales forecasts, warehouse data, etc.). This may allow a precise view of when to generate purchase orders that cover specific product demands and when to process invoice processing for the purchase orders. For instance, VCN process 10 may use upstream and/or external data to determine there is a risk of significant inflation of copper (a component used in semiconductor devices) for a supplier that is currently supplying semiconductor devices. In the example, VCN process 10 may execute a procurement action of proactively generating purchase orders for semiconductor devices from the supplier prior to an anticipated price hike by the supplier resulting from the predicted or actual inflation. In some implementations, VCN process 10 may accomplish this by automatically executing (without human interaction) a reordering of the semiconductor devices through purchase order generation and/or submission, or providing a suggestion on a user interface to reorder the semiconductor devices through purchase order generation and/or submission at the optimal time, which may be manually executed (e.g., receiving a user input to approve the suggested action).

[2932] In some implementations, VCN process 10 may unify 18023 data associated with warehouse management, inventory management, order management, analytics to optimize an omnichannel fulfillment. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential to optimize an omnichannel fulfillment in the value chain network based upon received data (e.g., warehouse management, inventory management, order management, and analytics). Generally, dynamic fulfillment considers the value of inventory according to the location where it is maintained. For example, if a store is in an overstock position anticipating mark-downs to move the excess, these items can be given priority for on-line orders. The net result is higher profit and customer satisfaction. Thus, in some implementations, VCN process 10 may provide a single platform that unifies warehouse management, inventory management, order management, analytics, and more for full network visibility.

[2933] In some implementations, VCN process 10 may execute the procurement action by a value chain network digital twin. For example, VCN process 10 may suggest diversifying suppliers, which means having multiple suppliers for the same product or service. This can help to reduce the risk of a disruption from one supplier affecting the entire supply chain. Another example suggestion from VCN process 10 may be building inventory buffers, which means having more inventory than is normally needed. This can help to ensure that there is enough product available to meet demand even if there is a disruption or other issues. Another example suggestion from VCN process 10 may be identifying suppliers that use alternative transportation

methods, which means using different modes of transportation, such as air freight or rail, if there are disruptions to road or sea transportation. Another example suggestion from VCN process 10 may be renegotiating contracts, which means negotiating with suppliers to change the terms of contracts, such as delivery dates or pricing, if there are disruptions or other risks. Another example suggestion from VCN process 10 may be using technology, meaning the use of technology to track shipments, manage inventory, and communicate with suppliers about the potential risk. This can help to improve visibility and coordination in the supply chain and make it easier to respond to disruptions or other risks. Another example suggestion from VCN process 10 may be additional innovation, such as flagging/responding in a digital twin (e.g., a value chain network digital twin as discussed throughout), where the response may involve, e.g., placing an order in an embedded marketplace of the digital twin.

[2934] In some implementations, the control tower UI (or other type of UI) may be considered as something of a command and control center that provides intelligent and automated control over operations, enabling more efficient risk management to cope with increasing volatility. Example control tower UI features may include, e.g.,: Dashboards with interactive widgets to provide an at-a-glance view of key performance indicators (KPIs) such as stock levels, in-transit goods, and supplier performance; Notification Panel for real-time alerts for any disruptions, pending tasks, or anomalies in the supply chain; Digital twin with 3D Visualizations, such as an interactive three-dimensional representation of the entire supply chain, from suppliers to end-users, Layered Views, such as a toggle between different aspects of the supply chain (e.g., transportation, warehousing) on the digital twin to drill down into reduced dimensionality views to reveal higher levels of detail, or zoom out to lower dimensionality views, Simulation Controls for tools to run various scenarios and forecasts on the digital twin, like potential supply disruptions or demand spikes, Logistics, such as interactive maps to display real-time movement of goods, allowing users to zoom, pan, or click on specific routes or shipments for detailed information, Timeline Views for a chronological representation of the supply chain process, from order placement to delivery, Heatmaps for a visual representation of data densities, such as areas with the highest sales or locations of frequent supply disruptions, real-time data, such as Live Data Feeds for continuous updating of data as it comes in, be it from IoT devices, supplier inputs, or point-of-sale systems, a Historical Data Toggle to compare real-time data with historical data to identify trends or anomalies, a search functionality for dynamic searching to allow users to quickly locate specific products, shipments, or suppliers, customizable filters to refine views based on criteria like date range, product type, or transportation mode, an Intelligent chatbot, such as an AI Chatbot Interface to allow users to chat with the control tower in natural language utterances to obtain information related to supply chain activities or internal business processes, Reporting and Analytics, Custom Report Builder that allows users to generate detailed reports based on selected data sets, Trend Analysis for graphical tools to identify and analyze supply chain trends over time, Predictive Analytics to utilize AI algorithms to predict future supply chain scenarios based on current and historical data and present the results to the user in a visual framework, Summary Widgets for quick stats on the total number

of shipments, those in-transit, delayed, received, dispatched, etc., a Notification Panel for real-time alerts for pending shipments, potential delays, or any anomalies, Interactive Shipment Map for visualizing the real-time location and status of each shipment (e.g., which may enable hovering/clicking/touching, etc. on shipment icons for detailed information), Dynamic Search for quickly locating a specific shipment using shipment ID, sender/receiver name, etc., Advanced Filters for shipments by status (e.g., in-transit, delivered), date range, carrier, destination, etc., Shipment Details for comprehensive information about a specific shipment, including items, quantity, origin, destination, carrier details, and expected vs. actual delivery times, attachments like bill of lading, invoice, or any other relevant documents, Carrier Performance Metrics for insights into the performance of various carriers based on delivery time, damages, and other relevant metrics.

[2935] As will be discussed in greater detail, VCN process 10 may be enabled with predictive sourcing capabilities, and may also include, in some implementations, a no login, no application, no hassle, seamless, one-click sourcing events in a supplier's inbox, embedded with real-time predictive data.

PREDICTIVE SOURCING SYSTEM

[2936] As also discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may receive 18101, by a computing device, information associated with a set of value chain network entities (such as those noted throughout) of a value chain network. For instance, as discussed throughout, a unified database (e.g., via platform 604) may (e.g., via VCN process 10) receive information associated with a set of value chain network entities of a value chain network. The information may be collected in a variety of ways, including (by example only) via the unified data collections systems discussed throughout.

[2937] In some implementations, VCN process 10 may include the ability to synchronize planning and predictive sourcing, which may be two components of supply chain management that may help improve supply chain efficiency and reduce costs. For instance, VCN processes' 10 synchronized planning may be generally described as the process of aligning some or all of the activities and functions within the supply (or demand) chain to work together towards a common goal. This may include, e.g., demand planning/sensing for highly accurate forecasts, production planning, inventory management, and logistics planning. By VCN process 10 coordinating these activities, companies may ensure that they are efficiently using their resources to meet customer demand while minimizing costs. As an example, as will be discussed below, if a company knows that demand for a particular product is going to increase, they can use VCN processes' 10 synchronized planning to ensure that they have enough inventory on hand to meet that demand, while also ensuring that production and logistics are prepared to handle the increased volume. VCN processes' 10 predictive sourcing may be generally described as the use of data analytics and predictive modeling to forecast future demand and identify potential supply chain disruptions. By VCN process 10 analyzing historical data and

current trends, companies can use VCN process 10 to identify potential risks and take proactive measures to mitigate them. For example, if a company knows (e.g., via VCN process 10) that a particular supplier has a history of delivery delays, they can use VCN processes' 10 predictive sourcing to identify the likelihood of future delays and take steps to ensure that they have alternative suppliers lined up or extra inventory on hand to avoid any disruption in the supply chain.

[2938] In some implementations, the information may be generated by a set of sensors of the set of value chain network entities. For instance, example sensors and/or a set of APIs configured to publish data relating to the set of value chain network entities may include those discussed regarding the adaptive intelligent systems and monitoring layers of platform 604. In some implementations, the information generated by a set of IoT devices configured to collect data relating to the set of value chain network entities. For instance, unified IoT monitoring systems (such as those discussed regarding at least the example implementation of FIG. 33) may be used to generate information from a set of IoT devices. It will be appreciated after reading the present disclosure that various other types of methods may be used for information generation without departing from the scope of the present disclosure. As such, the example use of the techniques and methods of information generation described throughout should be taken as example only and not to otherwise limit the scope of the present disclosure.

[2939] In some implementations, VCN process 10 may provide 18103 the information to a first set of Artificial Intelligence (AI)-based learning models, wherein at least one member of the first set of AI-based learning models may be trained on a training data set of value chain network data to generate a prediction of future demand for an item in the value chain network. For instance, in embodiments, one or more intelligence services (such as those discussed in the example implementation of FIG. 104) may include an intelligence service controller and AI modules. In embodiments, an artificial intelligence services receives an intelligence request from an intelligence service client and any required data to process the request from the intelligence service client. In response to the request and the specific data, one or more implicated artificial intelligence modules perform the intelligence task and output an "intelligence response". Examples of intelligence modules responses may include a decision (e.g., a control instruction, a proposed action, machine-generated text, and/or the like), a prediction (e.g., a predicted meaning of a text snippet, a predicted outcome associated with a proposed action, a predicted fault condition, a predicted disruption or risk in the value chain network, a prediction of future demand, and/or the like), a classification (e.g., a classification of an object in an image, a classification of a spoken utterance, a classified fault condition based on sensor data, and/or the like), and/or other suitable outputs of an AI system. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by using upstream data to predict demand for a product (e.g., demand enhancement/planning). As an example, VCN process 10 may include or interact with a demand planning application that may automatically calculate demand

(demand sensing) and stock forecasts based on upstream data (e.g., sales forecasts, warehouse data, etc.). This may allow a precise view of when to place optimal orders that cover specific product demands.

[2940] In some implementations, VCN process 10 may provide 18105 the information to a second set of AI-based learning models, wherein at least one member of the second set of AI-based learning models may be trained on a training data set of a set of value chain network entities operating data to classify at least one of: an operating state, a fault condition, an operating flow, or a behavior of at least one value chain entity of the set of value chain network entities. For instance, similar to first set of AI-based learning models noted above, one or more intelligence services (such as those discussed in the example implementation of FIG. 104, which may be from the same system or various sources) may include an intelligence service controller and AI modules. In embodiments, an artificial intelligence services receives an intelligence request from an intelligence service client and any required data to process the request from the intelligence service client. In response to the request and the specific data, one or more implicated artificial intelligence modules perform the intelligence task and output an "intelligence response". Examples of intelligence modules responses may include a decision (e.g., a control instruction, a proposed action, machine-generated text, and/or the like), a prediction (e.g., a predicted meaning of a text snippet, a predicted outcome associated with a proposed action, a predicted fault condition, a predicted disruption or risk in the value chain network, a prediction of future demand, and/or the like), a classification (e.g., a classification of an object in an image, a classification of a spoken utterance, a classified fault condition based on sensor data, and/or the like), and/or other suitable outputs of an AI system. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by using upstream data to predict demand for a product (e.g., demand enhancement/planning). As an example, VCN process 10 may include or interact with a demand planning application that may automatically calculate demand (demand sensing) and stock forecasts based on upstream data (e.g., sales forecasts, warehouse data, etc.). This may allow a precise view of when to place optimal orders that cover specific product demands.

[2941] In some implementations, the set of AI-based learning models may include at least one of a transformer model, a convolutional neural network, a deep learning model trained on a set of outcomes of the value chain network entity, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model, and the training data set for the set of AI-based learning models may include one of a set of objects or events that are labeled to classify the set of objects or events according to a classification taxonomy that may include at least one of the above-noted operating state, the fault condition, the operating flow, or the behavior. Other examples of AI-based learning models (e.g., machine learning models) may include neural networks in general (e.g., deep neural networks, convolution neural networks, and many others), regression based models, decision trees, hidden forests, Hidden Markov models, Bayesian

models, and the like. In some implementations, VCN process 10 may include combinations where an expert system uses one neural network for classifying an item (e.g., identifying a machine, a component, or an operational mode) and a different (or the same) neural network for predicting a state of the item (e.g., a fault state, an operational state, an anticipated state, a maintenance state, or the like).

[2942] In some implementations, VCN process 10 may determine 18107 a potential risk in the value chain network associated with the at least one value chain network entity based upon, at least in part, an output of the AI-based learning models. For instance, in some implementations, VCN process 10 may information that leverages a highly accurate daily forecast for every (desired) item at every (known) location, processing hundreds of internal and external signals to arrive at unbiased predictions and deliver profitable business decisions. VCN process 10 may use automation, AI and AI-based learning models to analyze real-time supply chain data and determine the influence of new demand signals. For example, VCN processes' 10 predictive sourcing may allow procurement teams to be proactive to market changes and know when to source to avoid higher prices. For example, predictive sourcing may have seen a global semiconductor shortage and its impact on, e.g., the automobile industry. As there were only several dozen chip fabrication plants in operation, with a few companies dominating making semiconductors under contract for other companies, which in turn sell chips through the supply chain, VCN processes' 10 predictive analytics in procurement would have seen the warning signs converging based upon information such as, e.g., increased demand for high-tech products across multiple sectors; a new generation of game console launching; geopolitical tensions resulting in Chinese companies buying up microprocessor stockpiles; and chip fabrication plants starting to reach their maximum production capacity. This information may be sent to or actively retrieved by VCN process 10 using multiple example sources, and may include such things as internal data assets and external data assets. Internal data assets may include, e.g., supplier provided data - such as invoices and purchase orders; transactional (ERP) data; tactical data – such as Excel and SharePoint, and external data assets may include, e.g., Public internet data – such as supplier information, currency rates, publicity traded commodities; 3rd party proprietary data - such as supplier industry codes, risk and CSR profiles, and certain indexes, procurement benchmarking and supplier discover.

[2943] Some non-limiting examples of procurement analytics used by VCN process 10 may include, e.g., spend analytics (procurement spend data from internal or external data sources), invoice analytics (invoice data and payment cycles from internal or external data sources), purchase order analytics (purchase order (PO) coverage, maverick spend, and PO cycle times from internal or external data sources), payment term analytics (identify and act on working capital improvement opportunities), supplier analytics (individual suppliers' performance, comparison of supplier performance, analysis of supplier risk, sustainability or diversity, or analysis of supplier base), diversity analytics (social responsibility and diversity in the supply base, on category and individual supplier level), sustainability analytics (Environmental, Labor & Human Rights, Ethics, and Sustainable Procurement targets from the supply chain), supplier

risk analytics (external risk factors negatively impacting the supply chain), contract analytics (supplier contracts and their meta-data, such as payment terms and expiration dates).

[2944] In some implementations, an example potential risk may be a supply chain disruption. A supply chain disruption may occur when there is a break in the flow of goods or services from the supplier to the customer. This can be caused by a variety of factors, such as natural disasters, political instability, or pandemics. A value chain risk (e.g., disruption) is a broader term that refers to any disruption that affects the flow of goods or services within a company or organization. This can include disruptions to production, distribution, or sales. Therefore, VCN process 10 may utilize an AI system that can track and predict potential supply chain risks (or other types of disruptions) and generate predictive insights based upon the above-noted generated information provided to the AI-based learning models. In some implementations, the determination may be a prediction of a future potential risk, or predicted current potential risk.

[2945] In some implementations, VCN process 10 may either output 18109 a recommendation to mitigate the potential risk in the value chain network and/or may automatically execute 18111 an action to mitigate the potential risk in the value chain network. For instance, once a potential risk has been predicted (or determined/identified), VCN process 10 may execute an action to mitigate that potential risk. In some implementations, the action may be automatically executed without human interaction, or manually executed (e.g., approving an action suggested by VCN process 10 that was output via a UI, such as the control tower UI discussed throughout). In some implementations, the action taken may be recorded in a log or a feed for viewing. In some implementations, the action may be VCN process 10 suggesting diversifying suppliers, which means having multiple suppliers for the same product or service. This may help to reduce the risk of a disruption from one supplier affecting the entire supply chain. Another example suggestion from VCN process 10 may be building inventory buffers, which means having more inventory than is normally needed. This can help to ensure that there is enough product available to meet demand even if there is a disruption or other issues. Another example suggestion from VCN process 10 may be identifying suppliers that use alternative transportation methods, which means using different modes of transportation, such as air freight or rail, if there are disruptions to road or sea transportation. Another example suggestion from VCN process 10 may be renegotiating contracts, which means negotiating with suppliers to change the terms of contracts, such as delivery dates or pricing, if there are disruptions or other risks. Another example suggestion from VCN process 10 may be using technology, meaning the use of technology to track shipments, manage inventory, and communicate with suppliers about the potential risk. This can help to improve visibility and coordination in the supply chain and make it easier to respond to disruptions or other risks. Another example suggestion from VCN process 10 may be additional innovation, such as predictive sourcing in an AI-driven digital twin (e.g., a value chain network digital twin as discussed throughout), where the response may involve, e.g., placing an order in an embedded marketplace of the digital twin.

[2946] As another example, using the above-noted synchronized planning of VCN process 10, a company may be enabled to automate the planning process and create an improved inventory

mix over a widespread network (as noted throughout). In some implementations, VCN process 10 may use its AI and cluster analysis, helping to identify and track seasonality patterns and trends not easily uncovered via traditional methods.

[2947] In some implementations, executing the action to mitigate the potential risk in the value chain network associated with the item may include flagging 18113 the potential risk in the value chain network associated with the item. For instance, in some implementations, VCN process 10 may use AI-based learning models to automatically draft and send communications (e.g., text, email, pop-ups, notification feed, chat, etc.) explaining what the predicted risk is, what information was used to predict the risk, and potential recommendations to mitigate the potential risk. This may allow a user to verify whether the potential risk is an actual risk, and take the appropriate action. In some implementations, the potential risk may also be flagged in an application's user interface (UI), such as the above-noted control tower UI.

[2948] In some implementations, executing the action to mitigate the potential risk in the value chain network associated with the item may include responding 18115 to the potential risk in the value chain network associated with the item. For example, VCN process 10 may suggest diversifying suppliers, which means having multiple suppliers for the same product or service. This can help to reduce the risk of a disruption from one supplier affecting the entire supply chain. Another example suggestion from VCN process 10 may be building inventory buffers, which means having more inventory than is normally needed. This can help to ensure that there is enough product available to meet demand even if there is a disruption. Another example suggestion from VCN process 10 may be using alternative transportation methods, which means using different modes of transportation, such as air freight or rail, if there are disruptions to road or sea transportation. Another example suggestion from VCN process 10 may be renegotiating contracts, which means negotiating with suppliers to change the terms of contracts, such as delivery dates or pricing, if there are disruptions or other risks. Another example suggestion from VCN process 10 may be using technology, meaning the use of technology to track shipments, manage inventory, and communicate with suppliers about the potential risk. This can help to improve visibility and coordination in the supply chain and make it easier to respond to disruptions or other risks. Another example suggestion from VCN process 10 may be additional innovation, such as flagging/responding in a digital twin (e.g., a value chain network digital twin as discussed throughout), where the response may involve, e.g., placing an order in an embedded marketplace of the digital twin.

[2949] In some implementations, executing the action to mitigate the potential risk in the value chain network associated with the item may include resolving 18117 an out-of-stock situation. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by resolving an out-of-stock situation with a procurement action. As an example, VCN process may determine that a particular concern, such as a lack of semiconductor devices of a particular supplier being used by a value chain network entity is out-of-stock or will soon be out-of-stock

based upon the AI-based learning models. In some implementations, VCN process 10 may resolve this situation by automatically executing (without human interaction) a negotiation of a contract with another supplier that does have semiconductor devices in stock, or providing a suggestion on a user interface to negotiate a contract with another supplier that does have semiconductor devices in stock, which may be manually executed (e.g., receiving a user input to approve the suggested action).

[2950] In some implementations, executing the action to mitigate the potential risk in the value chain network associated with the item may include predicting 18119 when to place an order based upon, at least in part, upstream data. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by using upstream data to predict when to place an order (e.g., demand enhancement/planning). As an example, VCN process 10 may include or interact with a demand planning application that may automatically calculate demand (demand sensing) and stock forecasts based on upstream data (e.g., sales forecasts, warehouse data, etc.). This may allow a precise view of when to place optimal orders that cover specific product demands. In some implementations, VCN process 10 may resolve this situation by automatically executing (without human interaction) a reordering of the engine part, or providing a suggestion on a user interface to reorder the engine part at the optimal time, which may be manually executed (e.g., receiving a user input to approve the suggested action).

[2951] In some implementations, VCN process 10 may unify 18121 data associated with warehouse management, inventory management, order management, analytics to optimize an omnichannel fulfillment. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential to optimize an omnichannel fulfillment in the value chain network based upon received data (e.g., warehouse management, inventory management, order management, and analytics). Generally, dynamic fulfillment considers the value of inventory according to the location where it is maintained. For example, if a store is in an overstock position anticipating mark-downs to move the excess, these items can be given priority for on-line orders. The net result is higher profit and customer satisfaction. Thus, in some implementations, VCN process 10 may provide a single platform that unifies warehouse management, inventory management, order management, analytics, and more for full network visibility.

[2952] In some implementations, VCN process 10 may provide 18123 an alert describing the action to mitigate the potential risk in the value chain network associated with the item that was executed. For instance, in some implementations, VCN process 10 may use AI-based learning models to automatically draft and send communications (e.g., text, email, pop-ups, notification feed, chat, etc.) explaining what the determined procurement action(s) may be/are, what information was used to determine the procurement action, and the intended result of executing the procurement action (e.g., faster delivery, lower costs, better quality, etc.). This may allow a user to verify whether the procurement action should be confirmed, and take any additional

appropriate action. In some implementations, the potential risk may also be flagged in an application's user interface (UI), such as the above-noted control tower UI.

[2953] In some implementations, the information may include past behavior over time, historical data, and current data. For instance, VCN process 10 may include supplier management functionality, which may include an intelligent procurement system that enable effective supplier management by providing real-time information on supplier performance, including delivery times, quality metrics, and pricing. This information, as noted above, may be used to make informed decisions about supplier selection, performance management, or other procurement actions. In some implementations, the real-time information may also be flagged or otherwise displayed in an application's user interface (UI), such as the above-noted control tower UI.

[2954] For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential to reduce transportation costs in the value chain network based upon received data. In the example, VCN process 10 may receive the external data to both determine that there is the potential to reduce transportation costs, and determine how to do so. As an example, VCN process 10 may include or interact with a transportation application that may automatically calculate the fastest or most optimal route and transportation method (e.g., air, boat, truck, etc.) based on external data (e.g., gas prices, traffic data, transportation time, sales forecasts, warehouse data, etc.) for past behavior over time, historical data, and/or current data. This may allow a precise view of such procurement actions including, e.g., when to order, when to pay invoices, etc. In some implementations, the external data may be received and analyzed in real-time or near real-time, enabling rapid time-to-value by collaborating globally with carriers to reduce transportation costs. In some implementations, VCN process 10 may resolve this situation by automatically executing (without human interaction) a request to change contract terms (e.g., price, delivery terms, and quality standards, etc.), or providing a suggestion on a user interface to change contract terms, which may be manually executed (e.g., receiving a user input to approve the suggested action).

[2955] In some implementations, VCN process 10 may render 18125 a visualization associated with at least one of inbound or outbound shipments associated with the item, which, in some implementations, may be based upon VCN processes' 10 AI-based learning models, may be related to the VCN, and may be related to the VCN using VCN processes' 10 AI-based learning models. For instance, example features/widgets/windows, etc. of the example control tower UI discussed throughout may include, e.g., Summary Widgets for quick stats on the total number of shipments, those in-transit, delayed, received, dispatched, etc., a Notification Panel for real-time alerts for pending shipments, potential delays, or any anomalies, Interactive Shipment Map for visualizing the real-time location and status of each shipment (e.g., which may enable hovering/clicking/touching, etc. on shipment icons for detailed information), Dynamic Search for quickly locating a specific shipment using shipment ID, sender/receiver name, etc., Advanced Filters for shipments by status (e.g., in-transit, delivered), date range, carrier, destination, etc., Shipment Details for comprehensive information about a specific shipment,

including items, quantity, origin, destination, carrier details, and expected vs. actual delivery times, attachments like bill of lading, invoice, or any other relevant documents, Carrier Performance Metrics for insights into the performance of various carriers based on delivery time, damages, and other relevant metrics.

[2956] In some implementations, VCN process 10 may be enabled with predictive sourcing capabilities, and may also include, in some implementations, a no login, no application, no hassle, seamless, one-click sourcing events in a supplier's inbox, embedded with real-time predictive data. For instance, predictive sourcing capabilities may be used by VCN process 10 to identify potential suppliers, predict their prices, and assess their risk. This can help companies to save time and money when sourcing goods and services. In some implementations, VCN process 10 may include a no login, no application, no hassle, seamless, one-click sourcing events in a supplier's inbox, embedded with real-time predictive data, which allows suppliers to participate in sourcing events with minimal effort. Suppliers may click on a link in their inbox to participate in an event, and they may be able to see real-time predictive data about the event, such as the estimated demand for the goods or services being sourced. For instance, assume for example purposes only that a retail company is looking to source new products for its upcoming holiday season. In the example, the company uses predictive sourcing capabilities of VCN process 10 to identify a list of potential suppliers for each product category. The company may then send out (e.g., via VCN process 10) one-click sourcing event invitations to the suppliers on the list. In the invitation, the company may specify the estimated demand for each product category. The suppliers click on the link in the invitation to participate in the event. The suppliers can see real-time predictive data about the event, such as the estimated demand for each product category and the current prices of competing suppliers. The suppliers submit their bids to the company, and the company then selects the supplier with the most competitive bid for each product category.

ML/AI FOR AUTOMATION OF A SET OF VALUE CHAIN NETWORK ENTITIES

[2957] As will be discussed in greater detail below, as discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may receive 18200, by a computing device, information associated with a value chain network. For instance, as similarly discussed throughout, a unified database (e.g., via platform 604) may (e.g., via VCN process 10) receive information associated with a set of value chain network entities of a value chain network, as well as a value chain network itself. The information may be collected in a variety of ways, including (by example only) via the unified data collections systems discussed throughout.

[2958] In some implementations, the information may be generated by a set of sensors of the set of value chain network entities (such as the example value chain network entities discussed throughout). For instance, in some implementations, the information generated by a set of IoT devices configured to collect data relating to the set of value chain network entities. As an example, unified IoT monitoring systems (such as those discussed regarding at least the example

implementation of FIG. 33) may be used to generate information from a set of IoT devices. As another example, a set of APIs configured to publish data relating to the set of value chain network entities or a particular item (e.g., an engine part) may include those discussed regarding the adaptive intelligent systems and monitoring layers of platform 604. In some implementations, the information may include one or more of historical sales data and market trends associated with the item. As yet another example, some example sensors may be configured to publish data relating to the set of value chain network entities may include those discussed regarding the adaptive intelligent systems and monitoring layers of platform 604. As discussed in greater detail throughout, some example sensors associated with a particular item may also be able to monitor and gather information associated with that item. It will be appreciated after reading the present disclosure that various other types of methods may be used for information generation without departing from the scope of the present disclosure. As such, the example use of the techniques and methods of information generation described throughout should be taken as example only and not to otherwise limit the scope of the present disclosure.

[2959] In some implementations, VCN process 10 may provide 18202 the information to a set of Artificial Intelligence (AI)-based learning models, wherein at least one member of the set of AI-based learning models may be trained on a training data set of a set of value chain network entities operating data to classify at least one of: an operating state, a fault condition, an operating flow, or a behavior of at least one value chain entity of the set of value chain network entities. For instance, in embodiments, one or more intelligence services (such as those discussed in the example implementation of FIG. 104) may include an intelligence service controller and AI modules. In embodiments, an artificial intelligence services receives an intelligence request from an intelligence service client and any required data to process the request from the intelligence service client. In response to the request and the specific data, one or more implicated artificial intelligence modules perform the intelligence task and output an "intelligence response". Examples of intelligence modules responses may include a decision (e.g., a control instruction, a proposed action, machine-generated text, and/or the like), a prediction (e.g., a predicted meaning of a text snippet, a predicted outcome associated with a proposed action, a predicted fault condition, a predicted disruption or risk in the value chain network, a prediction of future demand, and/or the like), a classification (e.g., a classification of an object in an image, a classification of a spoken utterance, a classified fault condition based on sensor data, and/or the like), and/or other suitable outputs of an AI system. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by using upstream data to predict demand for a product (e.g., demand enhancement/planning). As an example, VCN process 10 may include or interact with a demand planning application that may automatically calculate demand (demand sensing) and stock forecasts based on upstream data (e.g., sales forecasts, warehouse data, etc.). This may allow a precise view of when to place optimal orders that cover specific product demands.

[2960] In some implementations, the set of AI-based learning models may include at least one of a transformer model, a convolutional neural network, a deep learning model trained on a set of outcomes of the value chain network entity, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model, and the training data set for the set of AI-based learning models may include one of a set of objects or events that are labeled to classify the set of objects or events according to a classification taxonomy that may include at least one of the above-noted operating state, the fault condition, the operating flow, or the behavior. Other examples of AI-based learning models (e.g., machine learning models) may include neural networks in general (e.g., deep neural networks, convolution neural networks, and many others), regression based models, decision trees, hidden forests, Hidden Markov models, Bayesian models, and the like. In some implementations, VCN process 10 may include combinations where an expert system uses one neural network for classifying an item (e.g., identifying a machine, a component, or an operational mode) and a different (or the same) neural network for predicting a state of the item (e.g., a fault state, an operational state, an anticipated state, a maintenance state, or the like).

[2961] In some implementations, VCN process 10 may determine 18204 a task to be completed for the value chain network based upon, at least in part, on an output of the set of AI-based learning models, and in some implementations, VCN process 10 may execute 18206 the task to facilitate an improvement in the value chain network. For instance, in some embodiments, VCN process 10 may provide automated recommendations for a set of one or more value chain process tasks involving a wide range of types of activities, such as, without limitation, product configuration activities, product selection activities for a customer, supplier selection activities, shipper selection activities, route selection activities, factory selection activities, product assortment activities, product management activities, logistics activities, reverse logistics activities, artificial intelligence configuration activities, maintenance activities, product support activities, product recommendation activities, demand prediction, defect and quality issue detection, item failure prediction, optimization identification and execution, and many others. For example, in some implementations, executing the task may include predicting 18208 future demand for an item in the value chain network. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used to analyze historical sales data, market trends, and other factors to predict future demand for products (such as the engine part). This may help companies optimize inventory levels, production schedules, and pricing strategies to meet customer demand and maximize revenue.

[2962] In some implementations, executing the task may include detecting 18210 defects and quality issues in an item in the value chain network. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used to detect defects and quality issues in an item. For instance, assume for example purposes only that the above-noted information includes a video and/or a photo associated with the item (as well as other data). In the example, the video/photo of the actual item may be analyzed by VCN process 10 to identify any imperfections in the item itself. An example imperfection may include an anomaly in the shape

of the item, such as a crack or warped portion of the item, dimensional inconsistencies of items or their packaging, such as those resulting from crushing, impact, or other physical damage, surface blemishes such as a chip, scuff, abrasion, or other surface anomaly, defects or quality issues such as an item's exposure to potentially damaging temperatures, extreme pressures, impacts, visible or UV light, toxic materials (e.g., chemicals, pathogenic organisms, or other dangerous contaminants), or intentional product adulterations / sabotage, discoloration, mislabels or misprints, water damage as evidenced by leaks or seepage, mold, corrosion or rust, foreign object detection. The presence of these defects may be detected by sensors that are directly contacting the item or are monitoring the item's environment(s). This may help companies identify and address quality issues early in the production process (or even in use), reducing waste and improving customer satisfaction. The information may include data from one or more sensors associated with the item. For instance, a temperature sensor, magnetic sensor, pressure monitoring sensor, vibration monitoring sensor, heat flow monitoring sensor, or any other type of sensor is contemplated, which may also be used by a digital twin (or otherwise) to help detect defects and quality issues in an item.

[2963] In some implementations, executing the task may include predicting 18212 when an item in the value chain network will fail. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used to predict when equipment is likely to fail. This may help companies schedule maintenance proactively, reducing downtime and maintenance costs. As an example, the above-noted platform 604 may (e.g., via VCN process 10) include the ability of performing condition monitoring, anomaly detection, failure forecasting and predictive maintenance of an item/equipment. Some examples of questions that the predictive model may answer may include, e.g., when will the item fail, what type of failure it will be, what is the probability that a failure will occur within the next X hours or other given time window, what is the remaining useful life of the item, is the item behaving in an uncharacteristic manner, which item requires maintenance most urgently and the like. In some implementations, the information associated with the predictions may be received by a digital twin.

[2964] In some implementations, executing the task may include identifying 18214 a value chain process capable of optimization based upon, at least in part, analyzing the information associated with the value chain network, and optimizing 18216 the value chain process. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used to optimize supply chain processes/tasks, such as transportation routing and management, inventory management, supplier selection, scheduling production, tracking production costs, packing and shipping goods, tracking delivery status, identifying suppliers, negotiating contracts, configuring a smart contract, ordering goods and services, and receiving and inspecting goods and services. Information may be analyzed from various sources, such as inventory levels, transportation schedules, and supplier performance, to optimize supply chain operations. For instance, regarding inventory levels, assume for example purposes only that a large e-commerce company sells a wide range of products to customers worldwide. Further assume the company faces challenges in managing its inventory efficiently due to fluctuating

customer demands, seasonal trends, supplier lead times, and other factors. After gathering historical data on sales, customer orders, supplier deliveries, market trends, and other relevant variables, the data can be processed and fed into an AI-based predictive analytics system of VCN process 10 that also considers historical and current inventory levels. VCN process 10 may then facilitate decision making processes concerning reorder points, safety stock levels, and order quantities by forecasting supply and demand side factors that determine optimal inventory levels. Regarding transportation schedules, assume for example purposes only that an organic produce distributor relies heavily on timely shipments to ensure freshness of their product. The distributor (e.g., via VCN process 10) may analyze historical transportation schedules and bottlenecks to choose the most reliable carriers and optimized routes to reduce transit times so that fresher products make their way onto store shelves quicker and with fewer wasted perishables. Regarding supplier performance, assume for example purposes only that a luxury fashion retailer with a reputation for quality and timely deliveries regularly assesses their supplier performance metrics, such as delivery punctuality and defect rates. When a primary fabric supplier begins showing (e.g., via VCN process 10) inconsistent delivery times and increased defects, VCN process 10 may proactively recommend sources for the fashion retailer for an alternate supplier, ensuring continuity in production and upholding their high-quality reputation. Other types of optimizations may include configuring and/or deploying robotic fleets, container fleets, additive manufacturing/3D printer fleets, loading/unloading containers, etc. This may help companies reduce costs, improve efficiency, and increase flexibility in their supply chain operations.

[2965] In some implementations, executing the task may include analyzing 18218 user data of a user from at least one source, and identifying 18220 one or more attributes of the user based upon, at least in part, the user data. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used to analyze customer data, such as purchase history, social media activity, and demographic information, to gain insights into attributes such as customer behavior and preferences. This may help companies improve their product offerings, marketing strategies, and customer service.

[2966] In some implementations, the value chain process may include transportation routing. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential to reduce transportation costs in the value chain network based upon received data. In the example, VCN process 10 may receive the external data to both determine that there is the potential to reduce transportation costs, and determine how to do so. As an example, VCN process 10 may include or interact with a transportation application that may automatically calculate the fastest or most optimal route and transportation method (e.g., air, boat, truck, etc.) based on external data (e.g., gas prices, traffic data, transportation time, sales forecasts, warehouse data, etc.) for past behavior over time, historical data, and/or current data. This may allow a precise view of when to ship orders, what mode of transportation to do so, and the optimal route. In some implementations, the external data may be received and analyzed in real-time or near real-time, enabling rapid time-to-value

by collaborating globally with carriers to reduce transportation costs. In some implementations, VCN process 10 may resolve this situation by automatically executing (without human interaction) a change in transportation logistics (e.g., shipping time/date, shipping mode, shipping route, etc.), or providing a suggestion on a user interface to change the transportation logistics, which may be manually executed (e.g., receiving a user input to approve the suggested action).

[2967] In some implementations, the value chain process may include inventory management. For example, as discussed throughout, a supply chain or inventory management application (e.g., via VCN process 10) in the value chain management platform 604, such as one for ordering replacement parts for a machine or item of equipment, may access the same data set about what parts have been replaced for a set of machines as a predictive maintenance application that is used to predict whether a component of a ship, or facility of a port is likely to require replacement parts. Similarly, prediction may be used with respect to resupply of items.

[2968] In some implementations, the value chain process may include supplier selection. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used to select the optimal supplier. Example data points that may be used for determining what makes a supplier optimal may include, e.g., Reliability - ability to consistently meet delivery schedules and fulfill orders as requested; On-time delivery rate, order fulfillment rate, number of backorders, number of late deliveries, customer satisfaction surveys; Quality - providing products and services that meet or exceed required standards; Number of product defects, number of customer returns and complaints, product inspection results, quality certifications and awards; Cost-effectiveness - offering competitive prices; Price of goods and services, volume discounts, payment terms, hidden costs shipping/handling fees, etc.); Scalability - ability to meet increased or decreased demands as necessary; Production capacity, ability to quickly add or remove resources, track record of meeting increased or decreased demand; Location - located near the purchaser or end consumer to minimize transportation costs and lead times; Distance from the purchaser or end consumer; Transportation costs; Lead times; Financial Stability - is in good financial standing and is not likely to be at risk of bankruptcy; Credit rating; Debt-to-equity ratio; Net income; Innovative - continuously offering improvements to existing solutions and develops new products that offer operational advantages; Number of new products or services developed (e.g., in the past year); Number of patents; Customer satisfaction surveys with respect to product innovation, etc.

[2969] In some implementations, the value chain process may include warehouse management. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used for warehouse management.

ML TO INSTRUCT SMART MACHINES FOR A VALUE CHAIN NETWORK

[2970] As also discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may receive 18300, by a computing device, information associated with a value chain network. For instance, as similarly discussed

throughout, a unified database (e.g., via platform 604) may (e.g., via VCN process 10) receive information associated with a set of value chain network entities (such as those discussed throughout) of a value chain network, as well as a value chain network itself. The information may be collected in a variety of ways, including (by example only) via the unified data collections systems discussed throughout.

[2971] In some implementations, the information may be generated by a set of sensors of the set of value chain network entities. For instance, in some implementations, the information generated by a set of IoT devices configured to collect data relating to the set of value chain network entities. As an example, unified IoT monitoring systems (such as those discussed regarding at least the example implementation of FIG. 33) may be used to generate information from a set of IoT devices. As another example, a set of APIs configured to publish data relating to the set of value chain network entities or a particular item (e.g., an engine part) may include those discussed regarding the adaptive intelligent systems and monitoring layers of platform 604. In some implementations, the information may include one or more of historical sales data and market trends associated with the item. As yet another example, some example sensors may be configured to publish data relating to the set of value chain network entities may include those discussed regarding the adaptive intelligent systems and monitoring layers of platform 604. As discussed in greater detail throughout, some example sensors associated with a particular item may also be able to monitor and gather information associated with that item. It will be appreciated after reading the present disclosure that various other types of methods may be used for information generation without departing from the scope of the present disclosure. As such, the example use of the techniques and methods of information generation described throughout should be taken as example only and not to otherwise limit the scope of the present disclosure.

[2972] In some implementations, VCN process 10 may provide 18302 the information to a set of Artificial Intelligence (AI)-based learning models, wherein at least one member of the set of AI-based learning models may be trained on a training data set of a set of value chain network entities operating data to classify at least one of: an operating state, a fault condition, an operating flow, or a behavior of the value chain network. For instance, in embodiments, one or more intelligence services (such as those discussed in the example implementation of FIG. 104) may include an intelligence service controller and AI modules. In embodiments, an artificial intelligence services receives an intelligence request from an intelligence service client and any required data to process the request from the intelligence service client. In response to the request and the specific data, one or more implicated artificial intelligence modules perform the intelligence task and output an "intelligence response". Examples of intelligence modules responses may include a decision (e.g., a control instruction, a proposed action, machine-generated text, and/or the like), a prediction (e.g., a predicted meaning of a text snippet, a predicted outcome associated with a proposed action, a predicted fault condition, a predicted disruption or risk in the value chain network, a prediction of future demand, and/or the like), a classification (e.g., a classification of an object in an image, a classification of a spoken

utterance, a classified fault condition based on sensor data, and/or the like), and/or other suitable outputs of an AI system. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by using upstream data to predict demand for a product (e.g., demand enhancement/planning). As an example, VCN process 10 may include or interact with a demand planning application that may automatically calculate demand (demand sensing) and stock forecasts based on upstream data (e.g., sales forecasts, warehouse data, etc.). This may allow a precise view of when to place optimal orders that cover specific product demands.

[2973] In some implementations, the set of AI-based learning models may include at least one of a transformer model, a convolutional neural network, a deep learning model trained on a set of outcomes of the value chain network entity, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model, and the training data set for the set of AI-based learning models may include one of a set of objects or events that are labeled to classify the set of objects or events according to a classification taxonomy that may include at least one of the above-noted operating state, the fault condition, the operating flow, or the behavior. Other examples of AI-based learning models (e.g., machine learning models) may include neural networks in general (e.g., deep neural networks, convolution neural networks, and many others), regression based models, decision trees, hidden forests, Hidden Markov models, Bayesian models, and the like. In some implementations, VCN process 10 may include combinations where an expert system uses one neural network for classifying an item (e.g., identifying a machine, a component, or an operational mode) and a different (or the same) neural network for predicting a state of the item (e.g., a fault state, an operational state, an anticipated state, a maintenance state, or the like).

[2974] In some implementations, at least one member of the set of AI-based learning models may be trained on the training data set to determine, upon receiving the classification, a task to be completed for the value chain network. For instance, in some embodiments, VCN process 10 may provide automated recommendations for a set of one or more value chain process tasks involving a wide range of types of activities, such as, without limitation, product configuration activities, product selection activities for a customer, supplier selection activities, shipper selection activities, route selection activities, factory selection activities, product assortment activities, product management activities, logistics activities, reverse logistics activities, artificial intelligence configuration activities, maintenance activities, product support activities, product recommendation activities, demand prediction, defect and quality issue detection, item failure prediction, optimization identification and execution, and many others such as those discussed throughout. For example, in some implementations, executing the task may include predicting future demand for an item in the value chain network. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used to analyze historical sales data, market trends, and other factors to predict future demand for products (such as the engine part).

This may help companies optimize inventory levels, production schedules, and pricing strategies to meet customer demand and maximize revenue.

[2975] In some implementations, VCN process 10 may provide 18304 a computer code instruction set to a (e.g., a smart) machine to execute the task to facilitate an improvement in the operation of the value chain network. A smart machine may generally be described as a device embedded with machine-to-machine (M2M) and/or cognitive computing technologies, such as AI, AI-based learning or deep learning, etc. all of which it may use to reason, problem-solve, make decisions and take action. For instance, the smart machine may include one or more of a robot, an automated guided vehicle (AGV), a smart container, a 3D printer, or a drone. As an example, machines (e.g., smart machines that may include at least a portion of VCN process 10) such as robots, AGVs, smart containers, 3D printers, and drones may be provided with computer code instructions to move materials and products throughout the supply chain. As another example, smart shop floor equipment may include fixed automations or robots on an assembly line to perform repetitive actions to speed up production. As another example, smart robots may be used for other repetitive tasks such as welding and painting, while also being more efficient and precise. Smart machines may be enabled to read barcodes or RFID tags to update inventory records, pick items up from storage and package them for shipping without human intervention, or use a self-driving vehicle to transport goods within a warehouse or distribution center, extract order information from emails or electronic documents and enter them into a processing system of VCN process 10, check invoices for accuracy and process payments, monitor inventory levels and trigger reorder requests when a threshold inventory level is reached, deliver (small) packages directly to customers, or perform inventory checks in a large warehouse or outdoor storage area, as well as any of the other tasks described throughout. Smart machines may also use the information to assign delivery drivers to specific routes to assist with last-mile delivery, scan goods and automatically send manifests to warehouses before delivery, and send delay alerts by, e.g., tracking the GPS location of vehicles, although other tracking methods may also be used (e.g., cell tower triangulation). As another example, VCN process 10 may include a Computer-Aided Design (CAD) software to help designers create product designs and prototypes more quickly and accurately. These may help companies reduce labor costs, improve safety, and increase efficiency. It will be appreciated that while examples are described as a "smart" machine, this should not be taken to exclude similar types of machines that may also be used without departing from the scope of the present disclosure.

[2976] In some implementations, providing the computer code instruction set to the smart machine to execute the task may include instructing 18308 the smart machine to detect defects and quality issues in an item in the value chain network. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used to detect defects and quality issues in an item. For instance, assume for example purposes only that the above-noted information includes a video and/or a photo associated with the item (as well as other data). In the example, the video/photo of the actual item may be analyzed by VCN process 10 to identify any imperfections in the item itself. An example imperfection may include an anomaly in the shape

of the item, such as a crack or warped portion of the item. This may help companies identify and address quality issues early in the production process (or even in use), reducing waste and improving customer satisfaction. The information may include data from one or more sensors associated with the item to predict when the item in the value chain network will fail. For instance, a temperature sensor, magnetic sensor, pressure monitoring sensor, vibration monitoring sensor, heat flow monitoring sensor, or any other type of sensor is contemplated, which may also be used by a digital twin (or otherwise) to help detect defects and quality issues in an item.

[2977] In some implementations, providing the computer code instruction set to the smart machine to execute the task may include instructing 18310 the smart machine to predict when an item in the value chain network will fail. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used to predict when equipment is likely to fail. Information used to make the prediction may come from, e.g., smart machines equipped with sensors and other monitoring devices to predict when equipment is likely to fail or predict when to perform maintenance. For instance, rather than performing maintenance at a predetermined interval, maintenance can be performed as-needed based upon VCN processes' 10 determination. Thus, in this example, maintenance staff (or other user) may use VCN processes' 10 AI-based learning models to understand performance signals from smart devices and improve predictive maintenance. This may help companies schedule maintenance proactively, reducing downtime and maintenance costs. As an example, the above-noted platform 604 may (e.g., via VCN process 10) include the ability of performing condition monitoring, anomaly detection, failure forecasting and predictive maintenance of an item/equipment. Some examples of questions that the predictive model may answer may include, e.g., when will the item fail, what type of failure it will be, what is the probability that a failure will occur within the next X hours or other given time window, what is the remaining useful life of the item, is the item behaving in an uncharacteristic manner, which item requires maintenance most urgently and the like. In some implementations, the information associated with the predictions may be received by a digital twin.

[2978] In some implementations, providing the computer code instruction set to the smart machine to execute the task may include instructing 18312 the smart machine to identify a value chain process capable of optimization based upon, at least in part, analyzing the information associated with the value chain network, and optimize the value chain process. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used to optimize supply chain processes/tasks, such as transportation routing and management, inventory management, supplier selection, scheduling production, tracking production costs, packing and shipping goods, tracking delivery status, identifying suppliers, negotiating contracts, configuring a smart contract, ordering goods and services, and receiving and inspecting goods and services. Information may be analyzed from various sources, such as inventory levels, transportation schedules, and supplier performance, to optimize supply chain operations. Other types of optimizations may include configuring and/or deploying robotic fleets, container fleets, additive

manufacturing/3D printer fleets, loading/unloading containers, etc. Thus, in the examples, automated reports for management generated by VCN process 10 based upon the information may provide greater visibility and help teams course correct when issues arise. This may help companies reduce costs, improve efficiency, and increase flexibility in their supply chain operations.

[2979] In some implementations, executing the task may include analyzing user data of a user from at least one source, and identifying one or more attributes of the user based upon, at least in part, the user data. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used to analyze customer data, such as purchase history, social media activity, and demographic information, to gain insights into attributes such as customer behavior and preferences. This may help companies improve their product offerings, marketing strategies, and customer service.

[2980] In some implementations, the value chain process may include transportation routing. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential to reduce transportation costs in the value chain network based upon received data. In the example, VCN process 10 may receive the external data to both determine that there is the potential to reduce transportation costs, and determine how to do so. As an example, VCN process 10 may include or interact with a transportation application that may automatically calculate the fastest or most optimal route and transportation method (e.g., air, boat, truck, etc.) based on external data (e.g., gas prices, traffic data, transportation time, sales forecasts, warehouse data, etc.) for past behavior over time, historical data, and/or current data. This may allow a precise view of when to ship orders, what mode of transportation to do so, and the optimal route. In some implementations, the external data may be received and analyzed in real-time or near real-time, enabling rapid time-to-value by collaborating globally with carriers to reduce transportation costs. In some implementations, VCN process 10 may resolve this situation by automatically executing (without human interaction) a change in transportation logistics (e.g., shipping time/date, shipping mode, shipping route, etc.), or providing a suggestion on a user interface to change the transportation logistics, which may be manually executed (e.g., receiving a user input to approve the suggested action).

[2981] In some implementations, the value chain process may include inventory management. For example, as discussed throughout, a supply chain or inventory management application (e.g., via VCN process 10) in the value chain management platform 604, such as one for ordering replacement parts for a machine or item of equipment, may access the same data set about what parts have been replaced for a set of machines as a predictive maintenance application that is used to predict whether a component of a ship, or facility of a port is likely to require replacement parts. Similarly, prediction may be used with respect to resupply of items.

[2982] In some implementations, the value chain process may include supplier selection. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used to select the optimal supplier.

[2983] In some implementations, the value chain process may include warehouse management. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used for warehouse management.

[2984] In some implementations, providing the computer code instruction set to the smart machine to execute the task may include instructing 18306 the smart machine to move an item throughout the value chain network. For example, computer code instructions for smart machines (such as automated storage and retrieval systems (AS/RS) and warehouse management systems (WMS)) may (e.g., via VCN process 10) be used to optimize warehouse operations. This may help companies reduce labor costs, improve inventory management, and increase efficiency. As an example, smart machines (e.g., via VCN process 10) may be enabled to read barcodes or RFID tags to update inventory records, pick items up from storage and package them for shipping without human intervention, or use a self-driving vehicle to transport goods within a warehouse or distribution center, extract order information from emails or electronic documents and enter them into a processing system of VCN process 10, check invoices for accuracy and process payments, monitor inventory levels and trigger reorder requests when a threshold inventory level is reached, deliver (small) packages directly to customers, or perform inventory checks in a large warehouse or outdoor storage area, as well as any of the other tasks described throughout. As another example, intermodal smart containers may be used to transport items across the world. As another example, in warehouses and factories, robots may be used to pick and place items, palletize and de-palletize items, and transport items between different areas of the facility. As another example, in distribution centers, robots may be used to sort and pack items, and to load and unload trucks. As another example, in ports and rail terminals, robots may be used to load and unload ships and trains. As another example, in delivery fleets, robots may be used to deliver goods to customers' homes and businesses.

[2985] In some implementations, providing the computer code instruction set to the smart machine to execute the task may include instructing 18314 the smart machine to transport the item between locations. For instance, computer code instructions for smart machines (such as autonomous trucks, ships, drones, aircraft, etc.) may be used to transport goods between locations (e.g., warehouses, distribution facilities, to a customer, etc.) without the need for human drivers or operators. This may help companies reduce labor costs, improve safety, and increase efficiency.

[2986] It will be appreciated after reading the present disclosure that smart machines, rather than people, make more and more decisions about what to buy, and at what price, and complete the transactions without a middleman (which may be in conjunction with a blockchain distributed ledger.) For instance, a smart machine may be responsible for molding a specific engine component constantly monitors the wear and tear of its molding dies and predicts their lifecycle. As a die approaches the end of its lifespan, the machine's AI component (e.g., via VCN process 10) may scan one or more marketplaces for replacements. VCN process 10 may evaluate suppliers based on price, lead time, quality certifications, and past performance and identifies an optimal supplier. The machine (e.g., via VCN process 10) may then initiate a smart

contract for procurement of the replacement molding dies. The terms of purchase, which may include but are not limited to the price of replacements, expected delivery date, or quality specifications, may be encoded on a blockchain distributed ledger by VCN process 10. When the terms of the smart contract are met, payment may be automatically triggered by VCN process 10 causing a release of funds from the machine or factory's digital wallet to the supplier's account in the form of tokenized currency or cryptocurrency. All transaction details may be recorded on the blockchain distributed ledger by VCN process 10.

ROBOTIC PROCESS AUTOMATION

[2987] As also discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may receive 18400, by a computing device, information associated with a value chain network, For instance, as similarly discussed throughout, a unified database (e.g., via platform 604) may (e.g., via VCN process 10) receive information associated with a set of value chain network entities (such as those discussed throughout) of a value chain network, as well as a value chain network itself. The information may be collected in a variety of ways, including (by example only) via the unified data collections systems discussed throughout.

[2988] In some implementations, the information may be generated by a set of sensors of the set of value chain network entities. For instance, in some implementations, the information generated by a set of IoT devices configured to collect data relating to the set of value chain network entities. As an example, unified IoT monitoring systems (such as those discussed regarding at least the example implementation of FIG. 33) may be used to generate information from a set of IoT devices. As another example, a set of APIs configured to publish data relating to the set of value chain network entities or a particular item (e.g., an engine part) may include those discussed regarding the adaptive intelligent systems and monitoring layers of platform 604. In some implementations, the information may include one or more of historical sales data and market trends associated with the item. As yet another example, some example sensors may be configured to publish data relating to the set of value chain network entities may include those discussed regarding the adaptive intelligent systems and monitoring layers of platform 604. As discussed in greater detail throughout, some example sensors associated with a particular item may also be able to monitor and gather information associated with that item. It will be appreciated after reading the present disclosure that various other types of methods may be used for information generation without departing from the scope of the present disclosure. As such, the example use of the techniques and methods of information generation described throughout should be taken as example only and not to otherwise limit the scope of the present disclosure.

[2989] In some implementations, VCN process 10 may provide 18402 the information to a set of Artificial Intelligence (AI)-based learning models, wherein at least one member of the set of AI-based learning models may be trained on a training data set of a set of value chain network entities operating data to classify at least one of: an operating state, a fault condition, an

operating flow, or a behavior of the value chain network. For instance, in embodiments, one or more intelligence services (such as those discussed in the example implementation of FIG. 104) may include an intelligence service controller and AI modules. In embodiments, an artificial intelligence services receives an intelligence request from an intelligence service client and any required data to process the request from the intelligence service client. In response to the request and the specific data, one or more implicated artificial intelligence modules perform the intelligence task and output an "intelligence response". Examples of intelligence modules responses may include a decision (e.g., a control instruction, a proposed action, machine-generated text, and/or the like), a prediction (e.g., a predicted meaning of a text snippet, a predicted outcome associated with a proposed action, a predicted fault condition, a predicted disruption or risk in the value chain network, a prediction of future demand, and/or the like), a classification (e.g., a classification of an object in an image, a classification of a spoken utterance, a classified fault condition based on sensor data, and/or the like), and/or other suitable outputs of an AI system. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by using upstream data to predict demand for a product (e.g., demand enhancement/planning). As an example, VCN process 10 may include or interact with a demand planning application that may automatically calculate demand (demand sensing) and stock forecasts based on upstream data (e.g., sales forecasts, warehouse data, etc.). This may allow a precise view of when to place optimal orders that cover specific product demands.

[2990] In some implementations, the set of AI-based learning models may include at least one of a transformer model, a convolutional neural network, a deep learning model trained on a set of outcomes of the value chain network entity, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model, and the training data set for the set of AI-based learning models may include one of a set of objects or events that are labeled to classify the set of objects or events according to a classification taxonomy that may include at least one of the above-noted operating state, the fault condition, the operating flow, or the behavior. Other examples of AI-based learning models (e.g., machine learning models) may include neural networks in general (e.g., deep neural networks, convolution neural networks, and many others), regression based models, decision trees, hidden forests, Hidden Markov models, Bayesian models, and the like. In some implementations, VCN process 10 may include combinations where an expert system uses one neural network for classifying an item (e.g., identifying a machine, a component, or an operational mode) and a different (or the same) neural network for predicting a state of the item (e.g., a fault state, an operational state, an anticipated state, a maintenance state, or the like).

[2991] In some implementations, at least one member of the set of AI-based learning models may be trained on the training data set to determine, upon receiving the classification, a task to be completed for the value chain network. For instance, in some embodiments, VCN process 10 may provide automated recommendations for a set of one or more value chain process tasks

involving a wide range of types of activities, such as, without limitation, product configuration activities, product selection activities for a customer, supplier selection activities, shipper selection activities, route selection activities, factory selection activities, product assortment activities, product management activities, logistics activities, reverse logistics activities, artificial intelligence configuration activities, maintenance activities, product support activities, product recommendation activities, demand prediction, defect and quality issue detection, item failure prediction, optimization identification and execution, and many others such as those discussed throughout. For example, in some implementations, executing the task may include predicting future demand for an item in the value chain network. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used to analyze historical sales data, market trends, and other factors to predict future demand for products (such as the engine part). This may help companies optimize inventory levels, production schedules, and pricing strategies to meet customer demand and maximize revenue.

[2992] In some implementations, VCN process 10 may (e.g., via a robotic process automation (RPA) system) configure 18404 the robotic process automation system to execute the task to facilitate an improvement in the value chain network. For instance, in some implementations, the task may include automatically processing 18406 one or more orders for an item in the value chain network based upon, at least in part, the information, wherein automatically processing the one or more orders for the item in the value chain network may include extracting 18408 order data of the one or more orders from one or more sources and automatically inputting 18410 the order data extracted from the one or more sources into an order management system. For instance, a robotic process automation system (e.g., via VCN process 10) may be enabled to access communications such as emails, text, spreadsheets, Pdfs, other documents, etc. or directly communicate via an order management system (or the like) and use, e.g., natural language processing (NLP) to determine that a communication (e.g., from a customer, supplier, other stakeholder in the VCN) is an order (e.g., a purchase order) for an item in the VCN. Upon such a determination, the robotic process automation system (e.g., via VCN process 10) may extract order information from emails or other electronic documents and enter the associated data into an order management system of VCN process 10, as well as check invoices for accuracy and process payments.

[2993] In some implementations, the task may include monitoring 18412 an inventory level for an item in the value chain network and automatically generating 18414 one or more purchase orders for the item when the inventory level for the item in the value chain network falls below a threshold. For instance, assume for example purposes only that the robotic process automation system (e.g., via VCN process 10) updates inventory records based upon, e.g., reading barcodes or RFID tags and uses this and/or the above-noted information to monitor inventory levels to determine that only a threshold number of items is available in the inventory. As a result, this may automatically trigger VCN process 10 to execute reorder requests from a supplier to obtain more of that item. In some implementations, the demand sensing aspects of VCN process 10 may be used to dynamically adjust the threshold based upon changing information.

[2994] In some implementations, VCN process 10 may track 18416 a shipment of the item in real-time and the inventory level for the item in the value chain network may be automatically updated 18418 based upon, at least in part, tracking the shipment of the item in real-time. For instance, a robotic process automation system (e.g., via VCN process 10) may be enabled to track shipments in real-time using any known tracking techniques (e.g., GPS) and may automatically update an associated company's inventory and order management systems with the latest information. This may help the company quickly identify any delays or issues with shipments and take corrective action (e.g., such as recommending or automatically placing an alternative order from a different supplier).

[2995] In some implementations, the task may include VCN process 10 extracting 18420 invoice data of the one or more invoices from one or more sources and automatically inputting 18422 the invoice data extracted from the one or more sources into an accounting system. For instance, a robotic process automation system (e.g., via VCN process 10) may be enabled to access communications such as emails, text, spreadsheets, Pdfs, other documents, etc. or directly communicate via an accounting management system (or the like) and use, e.g., natural language processing (NLP) to determine that a communication (e.g., to a customer, supplier, other stakeholder in the VCN) is an invoice for an item in the VCN. Upon such a determination, the robotic process automation system (e.g., via VCN process 10) may extract the invoice information from the emails or other electronic documents and enter the associated data into an accounting management system of VCN process 10, as well as check invoices for accuracy and process payments. This may help streamline the invoicing process and reduce errors.

[2996] Similarly, a robotic process automation system (e.g., via VCN process 10) may be used for after-sales service as well. For instance, reading data from service request documents, coordinating with other systems to capture and maintain service ticket data, so that if a customer needs to make a return or request a repair, VCN process 10 may use one or more of the UIs discussed throughout to improve visibility on location, time of arrival and duration to complete work, track orders in real-time and send acknowledgement emails to customers automatically.

[2997] In some implementations, VCN process 10 may render 18424 a user interface enabling a user to visually design automation workflows. For instance, VCN process 10 may render a UI (e.g., the control tower UI discussed throughout) that enables a user to visually design automation workflows. In some implementations, this UI may be an integrated development environment that allows users to create automation processes using a drag-and-drop interface, and may include a library of pre-built activities that may be used to automate tasks. In some implementations, the UI of VCN process 10 may integrate with value chain data sources, such as ERP systems and transportation management systems. This may allow users to access the data they need to design and optimize their value chains. In some implementations, the UI may provide users with value chain analytics tools that can help users to identify areas where their value chains can be improved. In some implementations, the UI may provide users with value chain modeling tools for simulating different scenarios and to identify the best way to design their value chains. In some implementations, the UI may provide users with value chain

collaboration tools that can help users to collaborate with their suppliers and customers. In some implementations, the UI may allow users to test their workflows before they implement them. Users may be able to step through their workflows and see how the different elements interact with each other. In some implementations, the UI may help users identify and correct any errors in their workflows. In some implementations, the UI may include pre-built templates that may provide users with a starting point for designing their workflows. In some implementations, the UI may enable users to modify these templates to meet their specific needs. In some implementations, the UI may include version controls, collaboration tools, and enable integrations with other systems that may allow users to automate tasks that are performed in those systems.

[2998] In some implementations, VCN process 10 may render 18426 a user interface enabling a user to manage automation processes. For instance, VCN process 10 may render a UI (e.g., the control tower UI discussed throughout) that enables a user to deploy, manage, and monitor automation processes from a central location. It may provide a dashboard for real-time monitoring of automation performance, as well as tools for managing user access, scheduling, and logging. In some implementations, the UI may be a web-based management platform. In some implementations, the UI may provide users with visibility into the entire value chain workflow and see the status of all tasks, orders, and shipments in real time. In some implementations, the UI may provide real-time updates on the status of their value chains, which may allow users to identify and respond to problems quickly. In some implementations, the UI may be able to send alerts and notifications to users when there are problems or changes in the value chain. In some implementations, the UI may provide users with collaboration tools that allow them to work with their suppliers and customers to manage the value chain. In some implementations, the UI may provide users with reporting and analytics tools that allow them to track the performance of their value chains and to identify areas where improvements can be made.

[2999] In some implementations, VCN process 10 may render 18428 a user interface enabling a user to create a plurality of AI-based learning models and select a plurality of application programming interfaces to integrate the plurality of AI models into one or more automation workflows. For instance, VCN process 10 may render a UI (e.g., the control tower UI discussed throughout) that enables a user to build, train, and deploy custom machine learning models within their automation workflows. It may provide an interface for creating and managing AI-based learning models (e.g., machine learning models), as well as a set of APIs that may be used to integrate the models into automation workflows.

[3000] In some implementations, VCN process 10 may render 18430 a user interface enabling a user to track automation performance and generate custom dashboards based upon, at least in part, the automation performance. For instance, VCN process 10 may render a UI (e.g., the control tower UI discussed throughout) that provides analytics and reporting capabilities for automation processes. It may allow users to track automation performance, identify bottlenecks and opportunities for optimization, and generate custom reports and dashboards.

[3001] In some implementations, VCN process 10 may render a UI (e.g., the control tower UI discussed throughout) that enables users to capture and document the steps of manual processes, which may then be used to automate those processes as discussed throughout. It may provide a simple and intuitive interface for creating process documentation, and may include features for collaborating with team members and tracking progress. In some implementations, any of the UI's discussed throughout may be used with various supporting infrastructures, such as IoT, intelligent document processing, chatbots, mobile applications, blockchain, etc.

ML-DRIVEN DIGITAL TWINS FOR A VALUE CHAIN NETWORK CONTROL TOWER

[3002] As will be discussed in greater detail below, as discussed throughout and referring also at least to the example implementations of FIGS. 161-173, a VCN process, such as VCN process 10, may receive 18500, by a value chain network digital twin, information associated with a value chain network, wherein the information may include a virtual representation of a plurality of associations between physical data items of the value chain network, and wherein the information may be dynamic, real-time and time-phased. Generally, time-phased may be described as the representation showing the associations between data items over time and that the information provided may be used to track the evolution of the value chain network over time. For example, simply put, a value chain network digital twin (which may include at least a portion of VCN process 10) may be a representation of the various associations between the data objects of the physical (and often multi-enterprise) supply chain, as a basis for local and end-to-end aligned decision making. Put another way, value chain network digital twins may represent a set of value chain network entities (such as those described throughout). The digital twins may be configured to simulate properties, states, operations, behaviors and other aspects of the value chain network entities. The digital twins may have a visual user interface, e.g., in the form of 3D models, or may consist of system specifications or ontologies describing the architecture, including components and their interfaces, of the value chain network entities. The digital twins may include configuration data or condition data of the value chain network entities, including data records of the past and current state of the value chain network entities, such as captured through sensors, through user input, and/or determined by outputs of AI-based models (e.g., AI-based behavioral models) that describe the behavior of the value chain network entities. The digital twins may be updated continuously or periodically with dynamic, real-time and time-phased data to reflect the current condition of the value chain network entities, based on sensor data, test and inspection results, conducted maintenance, modifications, etc. The digital twins may also be configured to communicate with a user via multiple communication channels, such as speech, text, gestures, and the like. For example, a digital twin may receive queries from a user about the value chain network entities, generate responses for the queries, and communicate such responses to the user. Additionally and/or alternatively, digital twins may communicate with one another to learn from and identify similar operating patterns and issues in other value chain network entities, as well as steps taken to resolve those issues. The digital twins may be

used for monitoring, diagnostics, simulation, management, remote control, and prognostics, such as to optimize the individual and collective performance and utilization of value chain network entities.

[3003] In some implementations, the set of value chain network digital twins may include, for example and without limitation, distribution value chain network digital twins, warehousing value chain network digital twins, port infrastructure value chain network digital twins, shipping facility value chain network digital twins, operating facility value chain network digital twins, customer value chain network digital twins, worker value chain network digital twins, wearable device value chain network digital twins, portable device value chain network digital twins, mobile device value chain network digital twins, process value chain network digital twins, machine value chain network digital twins, asset value chain network digital twins, product value chain network digital twins, point of origin value chain network digital twins, point of destination value chain network digital twins, supply factor value chain network digital twins, maritime facility value chain network digital twins, floating asset value chain network digital twins, shipyard value chain network digital twins, fulfillment value chain network digital twins, delivery system value chain network digital twins, demand factors value chain network digital twins, retailer value chain network digital twins, ecommerce value chain network digital twins, online value chain network digital twins, waterway value chain network digital twins, roadway value chain network digital twins, roadway value chain network digital twins, railway value chain network digital twins, air facility value chain network digital twins, aircraft value chain network digital twins, ship value chain network digital twins, vehicle value chain network digital twins, train value chain network digital twins, autonomous vehicle value chain network digital twins, robotic system value chain network digital twins, drone value chain network digital twins, logistics factor value chain network digital twins and many others.

[3004] In some implementations, as similarly discussed throughout, a unified database (e.g., via platform 604) may (e.g., via VCN process 10) receive information associated with one or more value chain network digital twins that represent a set of digital twin value chain network entities (such as the example value chain network entities discussed throughout) of a value chain network, as well as a value chain network itself. The information may be collected in a variety of ways, including (by example only) via the unified data collections systems discussed throughout.

[3005] For instance, in some implementations, the information generated by a set of IoT devices configured to collect data relating to the value chain network digital twins. As an example, unified IoT monitoring systems (such as those discussed regarding at least the example implementation of FIG. 33) may be used to generate information from a set of IoT devices. As another example, a set of APIs configured to publish data relating to the value chain network digital twins or a particular item (e.g., an engine part) may include those discussed regarding the adaptive intelligent systems and monitoring layers of platform 604. In some implementations, the information may include one or more of historical sales data and market trends associated with the item. As yet another example, some example sensors may be configured to publish data

relating to the value chain network digital twins may include those discussed regarding the adaptive intelligent systems and monitoring layers of platform 604. As discussed in greater detail throughout, some example sensors associated with a particular item may also be able to monitor and gather information associated with that item or value chain network entity. It will be appreciated after reading the present disclosure that various other types of methods may be used for information generation without departing from the scope of the present disclosure. As such, the example use of the techniques and methods of information generation described throughout should be taken as example only and not to otherwise limit the scope of the present disclosure.

[3006] In some implementations, VCN process 10 may provide 18502 the information to a set of Artificial Intelligence (AI)-based learning models, wherein at least one member of the set of AI-based learning models may be trained on a training data set of a set of value chain network entities operating data to classify at least one of: an operating state, a fault condition, an operating flow, or a behavior of the value chain network. For instance, in embodiments, one or more intelligence services (such as those discussed in the example implementation of FIG. 104) may include an intelligence service controller and AI modules. In embodiments, an artificial intelligence services receives an intelligence request from an intelligence service client and any required data to process the request from the intelligence service client. In response to the request and the specific data, one or more implicated artificial intelligence modules perform the intelligence task and output an "intelligence response". Examples of intelligence modules responses may include a decision (e.g., a control instruction, a proposed action, machine-generated text, and/or the like), a prediction (e.g., a predicted meaning of a text snippet, a predicted outcome associated with a proposed action, a predicted fault condition, a predicted disruption or risk in the value chain network, a prediction of future demand, and/or the like), a classification (e.g., a classification of an object in an image, a classification of a spoken utterance, a classified fault condition based on sensor data, and/or the like), and/or other suitable outputs of an AI system. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by using upstream data to predict demand for a product (e.g., demand enhancement/planning). As an example, VCN process 10 may include or interact with a demand planning application that may automatically calculate demand (demand sensing) and stock forecasts based on upstream data (e.g., sales forecasts, warehouse data, etc.). This may allow a precise view of when to place optimal orders that cover specific product demands.

[3007] In some implementations, the set of AI-based learning models may include at least one of a transformer model, a convolutional neural network, a deep learning model trained on a set of outcomes of the value chain network entity, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model, and the training data set for the set of AI-based learning models may include one of a set of objects or events that are labeled to classify the set of objects or events according to a classification taxonomy that may include at least one of the

above-noted operating state, the fault condition, the operating flow, or the behavior. Other examples of AI-based learning models (e.g., machine learning models) may include neural networks in general (e.g., deep neural networks, convolution neural networks, and many others), regression based models, decision trees, hidden forests, Hidden Markov models, Bayesian models, and the like. In some implementations, VCN process 10 may include combinations where an expert system uses one neural network for classifying an item (e.g., identifying a machine, a component, or an operational mode) and a different (or the same) neural network for predicting a state of the item (e.g., a fault state, an operational state, an anticipated state, a maintenance state, or the like).

[3008] In some implementations, at least one member of the set of AI-based learning models may be trained on the training data set to determine, upon receiving the classification, a task to be completed for the value chain network. For instance, in some embodiments, VCN process 10 may provide automated recommendations for a set of one or more value chain process tasks involving a wide range of types of activities, such as, without limitation, product configuration activities, product selection activities for a customer, supplier selection activities, shipper selection activities, route selection activities, factory selection activities, product assortment activities, product management activities, logistics activities, reverse logistics activities, artificial intelligence configuration activities, maintenance activities, product support activities, product recommendation activities, demand prediction, defect and quality issue detection, item failure prediction, optimization identification and execution, and many others such as those discussed throughout. For example, in some implementations, executing the task may include predicting future demand for an item in the value chain network. For instance, as discussed throughout, VCN processes' 10 AI-based learning models may be used to analyze historical sales data, market trends, and other factors to predict future demand for products (such as the engine part). This may help companies optimize inventory levels, production schedules, and pricing strategies to meet customer demand and maximize revenue.

[3009] In some implementations, VCN process 10 may provide 18504 at least one of an instruction for executing the task in the value chain network digital twin or provide 18506 a recommendation for executing the task in the value chain network digital twin may be provided. For instance, once a task has been determined, VCN process 10 may provide instructions to execute that task. In some implementations, the task may be automatically executed without human interaction, or manually executed (e.g., approving an action to execute the task as suggested by VCN process 10 that was output via a UI, such as the control tower UI discussed throughout). In some implementations, the task executed may be recorded in a log or a feed for viewing. In some implementations, the task may be VCN process 10 suggesting diversifying suppliers in the value chain network digital twin, which means having multiple suppliers for the same product or service. This may help to reduce the risk of a disruption from one supplier affecting the entire supply chain. Another example suggested task from VCN process 10 may be building inventory buffers in the value chain network digital twin, which means having more inventory than is normally needed. This may help to ensure that there are enough products

available to meet demand even if there is a disruption or other issues. Another example suggested task from VCN process 10 may be identifying suppliers in the value chain network digital twin that use alternative transportation methods, which means using different modes of transportation, such as air freight or rail, if there are disruptions to road or sea transportation. Another example suggested task from VCN process 10 may be renegotiating contracts in the value chain network digital twin, which means negotiating with suppliers to change the terms of contracts, such as delivery dates or pricing, if there are disruptions or other risks. Another example suggested task from VCN process 10 may be using technology in the value chain network digital twin, meaning the use of technology to track shipments, manage inventory, and communicate with suppliers about a potential risk, which may be similarly determined as discussed throughout. This may help to improve visibility and coordination in the supply chain and make it easier to respond to disruptions or other risks. Another example suggested task from VCN process 10 may be using predictive sourcing in the AI-driven digital twin (e.g., the value chain network digital twin as discussed throughout), where the response may involve, e.g., placing an order in an embedded marketplace of the value chain network digital twin.

[3010] As another example, using the above-noted synchronized planning of VCN process 10, a company may be enabled to automate the planning process and create an improved inventory mix over a widespread network (as noted throughout). In some implementations, VCN process 10 may use its AI and cluster analysis in the value chain network digital twin, helping to identify and track seasonality patterns and trends not easily uncovered via traditional methods.

[3011] In some implementations, receiving the information associated with the value chain network may include receiving 18508 sensor data indicative of inbound and outbound shipment conditions. For instance, the value chain network digital twin may (e.g., via VCN process 10) receive information from various sources to monitor inbound/outbound shipping conditions such as temperature, condition, pressure, location, estimated time of arrival, moisture levels, power levels of any equipment used, as well as any of the other example conditions discussed throughout. As an example, the value chain network digital twin may (e.g., via VCN process 10) may monitor the condition of the truckload shipments to prevent costly spoilage and ensure the perishable products remain safe and compliant. In some implementations, this information may also be supplied (e.g., via a UI) to the driver of the vehicle, so that the driver may take any actions to mitigate any issues (e.g., failure of a refrigerator unit carrying supplies).

[3012] In some implementations, VCN process 10 may render 18510 one of a virtual reality (VR) environment, an augmented reality (AR) environment, a mixed reality (MR) environment, or a diminished reality (DR) environment for a user to interact with the sensor-based virtual representation of the plurality of associations between the physical data items of the value chain network. For instance, VCN process 10 may enable users to access the value chain network entity digital twin using VR, AR, MR, and DR. This may enable users (including customers and employees) to perceive the virtual world through an advanced experience. For instance, AR may be used to provide users with real-time information about the products they are working on. For example, users may use AR glasses to see product schematics or assembly instructions overlaid

onto the physical product, reducing the need for printed instructions, and improving accuracy. In other examples, users may use an AR overlay that could be used to show information related to a smart container (e.g., financial metrics related to the contents of the smart container, destination information, temperature information, and the like), status information for a fleet of 3D printers, or performance information associated with a robot. As another example, users may use VR to simulate complex manufacturing or assembly processes, allowing users to practice and train in a virtual environment before working on the actual product. This may reduce errors, improve safety, and increase efficiency. In other examples, users may use VR to inspect items in a smart container, inspect a 3D printing process, or visualize a fleet of robots executing a job. As another example, extended reality (XR) also known as mixed reality (MR) may be used to combine elements of both AR and VR to create a mixed reality environment for users of the value chain network entity digital twin. This may be used to provide users with a more immersive and interactive training experience, allowing them to practice complex tasks in a simulated environment. In another example, MR could be used to create virtual simulations of entities in value chain networks (e.g., simulations of product usage, simulations of robotic fleet job execution, simulations of item moving through a factory, and the like). As another example, MR visualizations could be used to overlay inventory levels onto warehouse shelves. Yet another example, DR may be used to remove distracting elements from a user's field of view, allowing them to focus on the task at hand. For example, a worker may use DR glasses to remove clutter from their workspace, making it easier to focus on the assembly process. In another example, DR may be used to visualize a warehouse in a way that removes everything but warehouse robots, making it easier to focus on the movement of the robots.

[3013] In some implementations, the information may include real-time data about one of inbound prepaid shipments from suppliers linked to orders or inventory coming into a network associated with the value chain network. For instance, the value chain network entity (e.g., via VCN process 10) may receive sufficient information to provide visibility of inbound and outbound shipments. For example, VCN process 10 may receive real-time information about inbound prepaid shipments from suppliers linked to orders and inventory coming into the network. For instance, the value chain network digital twin may (e.g., via VCN process 10) receive information from various sources to monitor inbound/outbound shipping conditions such as temperature, condition, pressure, location, estimated time of arrival, moisture levels, power levels of any equipment used, as well as any of the other example conditions discussed throughout. As an example, the value chain network digital twin may (e.g., via VCN process 10) may monitor the condition of the truckload shipments to prevent costly spoilage and ensure the perishable products remain safe and compliant. In some implementations, this information may also be supplied (e.g., via a UI) to the driver of the vehicle, so that the driver may take any actions to mitigate any issues (e.g., failure of a refrigerator unit carrying supplies). As such, shippers may better manage inventory levels and carrying costs while breaking down internal silos between transportation and demand chain departments.

[3014] In some implementations, VCN process 10 may generate 18512 simulations for the value chain network digital twin, wherein the simulations for the value chain network digital twin may be generated with a graphical neural network (GNN). For instance, as will be discussed in greater detail below, VCN process 10 may use a neural network (e.g., a set GNNs) for generating simulations for value chain network digital twins and/or optimizing interactions in value chain network digital twins. For example, in some implementations, the value chain network digital twin may operate within a digital twin system having one or more sets of one or more digital twins, wherein each digital twin of the one or more sets may include an embedded marketplace for digital twin simulations. For instance, the digital twin system may be similar to the ones described throughout (e.g., at FIG 52). VCN process 10 may be enabled as a simulation-as-a-service system. For instance, in the context of value chain network digital twin, simulation-as-a-service may generally refer to the practice of providing access to simulations (such as value chain network digital twin simulations) as a service, which may be integrated into different stages of the value chain. Value chain network digital twins may consist of a series of interconnected activities that create value for customers, and these activities may include everything from raw material sourcing and production to marketing and distribution. By providing access to AI-based simulations as a service, businesses may enhance their ability to optimize and automate these activities, improving efficiency, reducing costs, and ultimately delivering better products or services to customers.

[3015] For example, a company may provide access to a simulation that can predict demand for a particular product. This simulation may be integrated into the planning stage of the digital twin value chain, allowing the company to better anticipate customer demand and adjust production accordingly. Similarly, a simulation that analyzes customer data may be used in the marketing stage to better understand customer preferences and tailor marketing campaigns to specific customer segments. Overall, simulations-as-a-service may help businesses in value chain network digital twin to stay competitive by leveraging the power of AI-based simulations to optimize and automate their operations. In some implementations, each of the value chain network digital twins may include an AI marketplace for AI-based simulations, where users may browse, select, and download individual AI-based simulations for a fee and as needed.

[3016] In some implementations, the value chain network digital twin may operate within a digital twin system having one or more sets of one or more digital twins, wherein each digital twin of the one or more sets may include an embedded marketplace for one of artificial intelligence-based learning models or artificial intelligence-based algorithms. For instance, VCN process 10 may be enabled as a models-as-a-service system. For instance, in the context of value chain network digital twin, models-as-a-service may generally refer to the practice of providing access to machine learning/algorithms (or other type of AI-based learning/algorithm) models as a service, which may be integrated into different stages of the value chain. Value chain network digital twins may consist of a series of interconnected activities that create value for customers, and these activities may include everything from raw material sourcing and production to marketing and distribution. By providing access to AI-based learning/algorithm models as a

service, businesses may enhance their ability to optimize and automate these activities, improving efficiency, reducing costs, and ultimately delivering better products or services to customers.

[3017] For example, a company may provide access to an AI-based learning model that can predict demand for a particular product. This model may be integrated into the planning stage of the digital twin value chain, allowing the company to better anticipate customer demand and adjust production accordingly. Similarly, a machine learning model that analyzes customer data may be used in the marketing stage to better understand customer preferences and tailor marketing campaigns to specific customer segments. Overall, models-as-a-service may help businesses in value chain network digital twin to stay competitive by leveraging the power of AI-based learning to optimize and automate their operations. In some implementations, each of the value chain network digital twins may include an AI marketplace for the AI-based learning models, where users may browse, select, and download individual AI-based learning models for a fee and as needed.

[3018] In some implementations, the value chain network digital twin may operate within a digital twin system having one or more sets of one or more digital twins, wherein each digital twin of the one or more sets may include an embedded marketplace for data. For instance, the digital twin system may be similar to the ones described throughout (e.g., at least the example implementation of FIG 52). VCN process 10 may be enabled as a data-as-a-service system. For instance, in the context of value chain network digital twin, data-as-a-service may generally refer to the practice of providing access to data (such as value chain network digital twin data) as a service, which may be integrated into different stages of the value chain. Value chain network digital twins may consist of a series of interconnected activities that create value for customers, and these activities may include everything from raw material sourcing and production to marketing and distribution. By providing access to AI-based data as a service, businesses may enhance their ability to optimize and automate these activities, improving efficiency, reducing costs, and ultimately delivering better products or services to customers.

[3019] For example, a company may provide access to data that can predict demand for a particular product. This data may be integrated into the planning stage of the digital twin value chain (including the above-noted simulations/models/algorithms and *vice versa*), allowing the company to better anticipate customer demand and adjust production accordingly. Similarly, the digital twin value chain data that analyzes customer data may be used in the marketing stage to better understand customer preferences and tailor marketing campaigns to specific customer segments. Overall, data-as-a-service may help businesses in value chain network digital twin to stay competitive by leveraging the power of AI-based data (e.g., digital twin value chain AI-based training data) to optimize and automate their operations. In some implementations, each of the value chain network digital twins may include an AI marketplace for AI-based data, where users may browse, select, and download individual AI-based data for a fee (e.g., a one time and/or subscription fee) and as needed.

[3020] In some implementations, VCN process 10 may generate 18514 optimizations for the value chain network digital twin, wherein the simulations for the value chain network digital twin may be generated with a graphical neural network (GNN). For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models of a value chain network digital twin to determine that there is a potential risk in the value chain network. In the example, VCN process 10 may mitigate the potential risk in the value chain network by using upstream data to optimize an inventory mix. For instance, assume for example purposes only that VCN process 10 has used one or more AI-based learning models of a value chain network digital twin to determine that there is a potential to optimize an omnichannel fulfillment in the value chain network based upon received data (e.g., warehouse management, inventory management, order management, and analytics). Generally, dynamic fulfillment considers the value of inventory according to the location where it is maintained. For example, if a store is in an overstock position anticipating mark-downs to move the excess, these items can be given priority for on-line orders. The net result is higher profit and customer satisfaction. Thus, in some implementations, VCN process 10 may provide a single platform that unifies warehouse management, inventory management, order management, analytics, and more for full network visibility, which may help optimize procurement processes and improve value chain efficiency.

[3021] In some implementations, a robotic operating system may enable the value chain network digital twin. For instance, in some implementations, the robotic operating system (e.g., which may include at least a portion of VCN process 10) may include automatically processing one or more orders for an item in the value chain network based upon, at least in part, the information, wherein automatically processing the one or more orders for the item in the value chain network may include extracting order data of the one or more orders from one or more sources and automatically inputting the order data extracted from the one or more sources into an order management system. For instance, a robotic process automation system of the value chain network digital twin (e.g., via VCN process 10) may be enabled to access communications such as emails, text, spreadsheets, Pdfs, other documents, etc. or directly communicate via an order management system (or the like) and use, e.g., natural language processing (NLP) to determine that a communication (e.g., from a customer, supplier, other stakeholder in the VCN) is an order (e.g., a purchase order) for an item in the VCN. Upon such a determination, the robotic process automation system of the value chain network digital twin (e.g., via VCN process 10) may extract order information from emails or other electronic documents and enter the associated data into an order management system of VCN process 10, as well as check invoices for accuracy and process payments.

[3022] In some implementations, the task may include monitoring an inventory level for an item in the value chain network and automatically generating one or more purchase orders for the item when the inventory level for the item in the value chain network falls below a threshold. For instance, assume for example purposes only that the robotic process automation system of the value chain network digital twin (e.g., via VCN process 10) updates inventory records based

upon, e.g., reading barcodes or RFID tags and uses this and/or the above-noted information to monitor inventory levels to determine that only a threshold number of items is available in the inventory. As a result, this may automatically trigger VCN process 10 to execute reorder requests from a supplier to obtain more of that item. In some implementations, the demand sensing aspects of VCN process 10 may be used to dynamically adjust the threshold based upon changing information.

[3023] In some implementations, VCN process 10 may track a shipment of the item in real-time and the inventory level for the item in the value chain network may be automatically updated based upon, at least in part, tracking the shipment of the item in real-time. For instance, a robotic process automation system of the value chain network digital twin (e.g., via VCN process 10) may be enabled to track shipments in real-time using any known tracking techniques (e.g., GPS) and may automatically update an associated company's inventory and order management systems with the latest information. This may help the company quickly identify any delays or issues with shipments and take corrective action (e.g., such as recommending or automatically placing an alternative order from a different supplier).

[3024] In some implementations, the task may include VCN process 10 extracting invoice data of the one or more invoices from one or more sources and automatically inputting the invoice data extracted from the one or more sources into an accounting system. For instance, a robotic process automation system of the value chain network digital twin (e.g., via VCN process 10) may be enabled to access communications such as emails, text, spreadsheets, Pdfs, other documents, etc. or directly communicate via an accounting management system (or the like) and use, e.g., natural language processing (NLP) to determine that a communication (e.g., to a customer, supplier, other stakeholder in the VCN) is an invoice for an item in the VCN. Upon such a determination, the robotic process automation system of the value chain network digital twin (e.g., via VCN process 10) may extract the invoice information from the emails or other electronic documents and enter the associated data into an accounting management system of VCN process 10, as well as check invoices for accuracy and process payments. This may help streamline the invoicing process and reduce errors.

[3025] Similarly, a robotic process automation system of the value chain network digital twin (e.g., via VCN process 10) may be used for after-sales service as well. For instance, reading data from service request documents, coordinating with other systems to capture and maintain service ticket data, so that if a customer needs to make a return or request a repair, VCN process 10 may use one or more of the UIs discussed throughout to improve visibility on location, time of arrival and duration to complete work, track orders in real-time and send acknowledgement emails to customers automatically.

[3026] In some implementations, the value chain network digital twin (e.g., via VCN process 10) may include an edge computing system integrated with an edge data processing system (such as those discussed throughout). For instance, the combination of edge computing and edge data processing, delivered through networks of human resources, devices, smart machines, sensors and computing systems may allow people to make informed, reliable, secure and agile

decisions at the edges of enterprises. Moreover, the edge computing system and/or the edge data processing of VCN process 10 may find and supply new sources of data, where resources at the edge computing system may be looking for applications that may make use of such data.

[3027] In some implementations, the value chain network digital twin (e.g., via VCN process 10) may include a supply chain security system. For instance, VCN process 10 may the enforcement of security spanning physical levels (e.g., devices, machines, products, operations infrastructure and assets) as well as information and digital data (e.g., customer information, intellectual property, proprietary coding, transactions and personal data).

[3028] In some implementations, the value chain network digital twin (e.g., via VCN process 10) may include a communications system. For instance, as noted above, the value chain network digital twin (e.g., via VCN process 10) may share data across partners without complex integrations into each organization's environment by using the APIs as discussed above.

[3029] In some implementations, the value chain network digital twin (e.g., via VCN process 10) may include a yard management system. For instance, yard management may generally be described as autonomous, and may include enterprise slot booking, predictive ETA, prescriptive analytics, real-time location tracking, gate and loading dock management, task management, driver management and more. Yard management is thus the process of managing the movement of trucks and trailers (or other transportation methods) in and out of a facility or yard. In a supply/demand chain context, this may refer to the management of the area where goods are stored, sorted, and loaded onto transportation vehicles for transportation to their next destination. For instance, there may be a check-in process, where, as trucks arrive at the yard, they might be checked in and assigned to a specific location for unloading or loading. This is typically done through a gate management system that verifies the truck's information, including the driver's name, the carrier, the cargo, and any special requirements As another example, for yard planning, once the trucks are checked in, the yard manager might plan the optimal layout of the yard to ensure efficient use of space and timely delivery of goods. This may involve identifying the optimal location for each truck, based on factors such as cargo type, weight, destination, and required handling equipment. As another example, equipment allocation may be used by the yard manager to ensure that the required handling of equipment, such as forklifts or cranes, are available and allocated to the appropriate trucks. This may help to ensure that loading and unloading can be completed quickly and efficiently. For yard execution, as trucks are assigned to their respective locations, yard personnel might monitor the progress of loading and unloading, and make any necessary adjustments to ensure that the process stays on track. This may involve coordinating with drivers and warehouse staff to resolve any issues that may arise. For the check-out process, once the loading or unloading is complete, the truck may be checked out of the yard, and the gate management system (e.g., via VCN process 10) may update the status of the shipment to reflect its departure. This may allow the next truck to be assigned to the appropriate location and continue the yard management process. In some implementations, IoT enabled tracking and monitoring (sensors and devices) may provide real-time tracking and

monitoring of truck movements, cargo location, equipment status, etc. This may help yard managers optimize truck movements, allocate resources effectively, and reduce waiting times.

[3030] In some implementations, yard management may include VCN process 10 using predictive analytics (such as those discussed throughout), where advanced analytics are used to predict the arrival and departure of trucks, and to identify potential bottlenecks and issues. This may help yard managers plan more effectively and make proactive adjustments to minimize delays. In some implementations, robotics and automation (e.g., autonomous vehicles, drones, and other robotics) may help streamline yard operations and reduce the need for manual labor. For example, autonomous forklifts may move cargo from one location to another, while drones may be used to monitor yard operations from above.

[3031] In some implementations, the value chain network digital twin (e.g., via VCN process 10) may include blockchain-based supply chain visibility, where the use of blockchain technology may provide end-to-end visibility of the supply/demand chain, enabling yard managers to track shipments from origin to destination. This may help to improve transparency, reduce errors, and enhance security.

[3032] In some implementations, the value chain network digital twin (e.g., via VCN process 10) may include the above-noted VR, AR, MR, and DR technologies to enhance training and simulation, enabling yard personnel to learn and practice complex tasks in a safe and controlled environment. This may help to reduce errors and improve overall efficiency. In some implementations, the value chain network digital twin (e.g., via VCN process 10) may use the above-noted AI-based learning models/algorithms
to optimize yard operations, predict the most efficient routes and resource allocation. This may help to reduce costs and improve overall performance.

[3033] It will be appreciated after reading the present disclosure that a value chain network digital twin may be combined for use with any of the implementations/embodiments described throughout. As such, the lack of discussion of a value chain network digital twin should not be taken as precluding the use of the value chain network digital twin.

GENERATIVE AI

[3034] In example embodiments, a generative artificial intelligence engine (GAIE) may be combined with a machine learning system in a transaction environment. Input to the GAIE may include images, video, audio, text, programmatic code, data, and the like. Outputs from a GAIE may include structured and organized prose, images, video, audio content, software / programming source code, formatted data (e.g., arrays), algorithms, definitions, context-specific structures (e.g., smart contacts, transaction platform configuration data sets, and the like), machine language-based data (e.g., API-formatted content), and the like. For GAIE instances in which the models are designed to process text data, the GAIE may interface to other programmatic systems (such as traditional machine learning engines) to process other forms of data into text data. In example embodiments, the other programmatic systems, including systems executing machine learning algorithms, may produce textual based (optionally at volume) that

may be consumed by GAIE. For example, consider such another system building a series of one thousand text-based observations on the other-formatted data; this may be a useful input for a GAIE model to learn and process (e.g., summarize) into text-formatted output information. In example embodiments, an interface between the GAIE and its combined machine learning system may be extended to include a dialogue between the systems, where the GAIE includes and/or accesses a capability to ask the machine learning system specific questions to facilitate the refining of its knowledge. For example, the dialogue capability may include a request of the machine learning system to provide an assessment of current market trading positions. In another example, the dialogue capability may encode numeric outputs from the machine learning engine into text (e.g., words, such as high, medium, low) that may be input for interpretation by the GAIE.

[3035] In example embodiments, the data processed by a GAIE may include one or more types of content. For example, a GAIE may receive, as input, data that represents one or more natural-language expressions, single- or multidimensional shapes or models, real-world and/or virtual scene representations, LIDAR point-cloud representations, sensor inputs and/or outputs, vehicle and/or machine telemetry, geographic maps, authentication credentials, financial transactions, smart contracts, processing directives and/or resources such as shaders, device configurations such as HDL specifications for programming FPGAs, databases and/or database structural definitions, or the like, including metadata associated with any such data types. Input to the GAIE may also include data that represents one or more features of another machine learning model, such as a configuration (e.g., model type, parameters, and/or hyperparameters), input, internal state (e.g., weights and biases of at least a portion of the model), and/or output of the other machine learning model. These and other forms of content may be received as various forms of data. For example, a natural-language expression received as input by a GAIE could be encoded as one or more of: encoded text, an image of a writing, a sound recording of human speech, a video of an individual exhibiting sign language, an encoding according to a machine learning model embedding, or the like, or any combination thereof. In example embodiments, an input received and processed by the GAIE can include an internal state of the GAIE, such as a partial result of a partial processing of an input, or a set of weights and/or biases of the GAIE as a result of prior processing (e.g., an internal state of a recurrent neural network (RNN)).

[3036] In some embodiments, the data and/or content received and processed by a GAIE originates from one or more individuals, such as a person speaking a natural-language expression. In some embodiments, the data and/or content received and processed by a GAIE originates from one or more natural sources, such as patterns formed by nature. In some embodiments, the data and/or content received and processed by a GAIE originates from one or more other devices, such as another machine learning model executing on another device, or from another component of the same device executing the GAIE, such as output of another machine learning model executing on the same device executing the GAIE, or a sensor in an Internet-of Things (IoT) and/or cloud architecture. In some embodiments, the data and/or content received and processed by a GAIE is artificially synthesized, such as synthetic data

generated by an algorithm to augment a training data set. In some embodiments, the data and/or content received and processed by a GAIE is generated by the same GAIE, such as an internal state of the GAIE in response to previous and/or concurrent processing, or a previous output of the GAIE in the manner of a recurrent neural network (RNN).

[3037] In some embodiments, at least some or part of the data and/or content received and processed by a GAIE is also used to train the GAIE. For example, a variational GAIE could be trained on an input and a corresponding acceptable output, and could later receive the same input in order to output one or more variations of the acceptable output. In some embodiments, at least some or part of the data and/or content received and processed by a GAIE is different than data and/or content that was used to train the GAIE. In some such embodiments, the data and/or content received and processed by the GAIE is different than but similar to the data and/or content that was used to train the GAIE, such as new inputs that are exhibit a similar statistical distribution of features as the training data. In some such embodiments, the data and/or content received and processed by the GAIE is different than and dissimilar to the data and/or content that was used to train the GAIE, such as new inputs that exhibit a significantly different statistical distribution of features than the training data. In scenarios that involve dissimilar inputs, one or more first outputs of the GAIE in response to a new input may be compared to one or more second outputs of the GAIE in response to inputs of the training data set to determine whether the first outputs and the second outputs are consistent. The GAIE may request and/or receive additional training based on the new inputs and corresponding acceptable outputs. In scenarios that involve dissimilar inputs, the GAIE may present an alert and/or description that indicates how the new inputs and/or corresponding outputs differ from previously received inputs and/or corresponding outputs.

[3038] In example embodiments, the output of a GAIE may include one or more types of content. For example, a GAIE may generate, as output, data that represents one or more natural-language expressions, single- or multidimensional shapes or models, real-world and/or virtual scene representations, LIDAR point-cloud representations, sensor inputs and/or outputs, vehicle and/or machine telemetry, geographic maps, authentication credentials, financial transactions, smart contracts, processing directives and/or resources such as shaders, device configurations such as HDL specifications for programming FPGAs, databases and/or database structural definitions, or the like, including metadata associated with any such data types. Output of the GAIE may also include data that represents one or more features of another machine learning model, such as a configuration (e.g., model type, parameters, and/or hyperparameters), input, internal state (e.g., weights and biases of at least a portion of the model), and/or output of the other machine learning model. These and other forms of content may be generated by the GAIE as various forms of data. For example, a natural-language expression generated as output by the GAIE could be encoded as one or more of: encoded text, an image of a writing, a sound recording of human speech, a video of an individual exhibiting sign language, an encoding according to a machine learning model embedding, or the like, or any combination thereof. In example embodiments, an output of the GAIE can include an internal state of the GAIE, such as

a partial result of a partial processing of an input, or a set of weights and/or biases of the GAIE as a result of prior processing (e.g., an internal state of a recurrent neural network (RNN)).

[3039] In example embodiments, a language-based dialogue-enabled GAIE may be configured to produce (e.g., write) new machine learning models that may process various types of data to provide new and extended text input for processing by the GAIE. In example embodiments, humans may observe and interact with this ongoing dialogue between the two systems. In example embodiments, the dialogue is initiated by an expression of a conversation partner (e.g., a human or another device), and the GAIE generates one or more expressions that are responsive to the expression of the conversation partner. In example embodiments, the GAIE generates an expression to initiate the dialogue, and further responds to one or more expressions of the conversation partner in response to the initiating expression. In example embodiments, the ongoing dialogue occurs in a turn-taking manner, wherein each of the conversational partner and the GAIE generating an expression based on a previous expression of the other of the conversation partner and the GAIE. In example embodiments, the ongoing dialogue occurs extemporaneously, with each of the conversation partner and the GAIE generating expressions irrespective of a timing and/or sequential ordering of previous and/or concurrent expressions of the conversation partner and/or the GAIE.

[3040] In example embodiments, the dialogue occurs between a GAIE and a plurality of conversation partners, such as two or more humans, two or more other GAIEs, or a combination of one or more humans and one or more other GAIEs. In some such example embodiments, the GAIE and each of the other conversation partners take turns generating expressions in response to prior expressions from the GAIE and the other conversation partners. In some such embodiments, one or more sub-conversations occur among one or more subsets of the GAIE and the plurality of conversation partners. Such sub-conversations may occur concurrently (e.g., the GAIE concurrently engages in a first conversation with a first conversation partner and a second conversation with a second conversation partner) and/or consecutively (e.g., the GAIE concurrently engages in a first conversation with a first conversation partner, followed by a second conversation with a second conversation partner). Such sub-conversations may involve the same or similar topics or expressions (e.g., the GAIE may present the same or similar conversation-initiating expression to each of a plurality of conversation partners, and may concurrently engage each of the plurality of conversation partners in a separate conversation on the same or similar topic). Such sub-conversations may involve different topics or expressions (e.g., the GAIE may present different conversation-initiating expressions to each of a plurality of conversation partners, and may concurrently engage each of the plurality of conversation partners in a separate conversation on different topics). In example embodiments, a first conversation among a first subset of the GAIE and conversation partners may be related to a second conversation among a second subset of the GAIE and conversation partners (e.g., the second subset may engage in a second conversation based on content of the first conversation among a first subgroup).

[3041] In example embodiments, one or more of the GAIE and the conversation partner may embody one or more roles. For example, the GAIE may generate expressions based on a role of a conversation starter, a conversation responder, a teacher, a student, a supervisor, a peer, a subordinate, a team member, an independent observer, a researcher, a particular character in a story, an advisor, a caregiver, a therapist, an ally or enabler of a conversation partner, or a competitor or opponent of a conversation partner (e.g., a "devil's advocate" that presents opposing and/or alternative viewpoints to a belief or argument of a conversation partner). In example embodiments, at least one of the one or more conversation partner embodies one or more aforementioned roles or other rules. In example embodiments, a role of a GAIE is relative to a role of a conversation partner (e.g., the GAIE may embody a superior, peer, or subordinate role with respect to a role of a conversation partner). In example embodiments, a role of a GAIE in a first conversation among a first subset of the GAIE and a plurality of conversation partners may be the same as or similar to a role of a GAIE in a second conversation among a first subset of the GAIE and the plurality of conversation partners. In example embodiments, a role of a GAIE in a first conversation among a first subset of the GAIE and a plurality of conversation partners may differ from a role of a GAIE in a second conversation among a first subset of the GAIE and the plurality of conversation partners (e.g., the GAIE may embody a role of a teacher in a first conversation and a role of a student in a second conversation). In example embodiments, a role of a GAIE in a conversation may change over time (e.g., the GAIE may first embody a role of a student in a conversation, and may later change to a role of a teacher in the same conversation). In example embodiments, a GAIE may embody two or more roles in a conversation (e.g., the GAIE may exhibit two personalities in a conversation that respectively represent one of two characters in a story). In example embodiments, a GAIE generates expressions between two or more roles in a conversation (e.g., the GAIE may generate a dialogue between each of two characters in a story). In example embodiments, a GAIE may engage in each of multiple conversations in a same or similar modality (e.g., engaging in multiple text-based conversations concurrently). In example embodiments, a GAIE may engage in each of multiple conversations in different modalities (e.g., engaging in a first conversation via text and a second conversation via voice).

[3042] In example embodiments, a GAIE participating in a conversation is associated with an avatar (e.g., a name, color, image, two- or three-dimensional model, voice, or the like). Expressions generated by the GAIE may be presented as if originating from the GAIE (e.g., in the voice associated with the GAIE, or in a speech bubble that is displayed near a visual position of a GAIE in a virtual or augmented-reality environment). In example embodiments, an avatar of a GAIE may be based on a role of the GAIE (e.g., a GAIE embodying a role of a teacher may be associated with an avatar depicting a teacher). In example embodiments, an avatar of a GAIE may be included in a real-world actor, such as a robot in a real-world environment such as a stage performance.

[3043] In example embodiments, a GAIE may include generative pretrained transformer elements that may be configured as a language model designed to understand various types of

input and produce chat commands for a chat-type interface system. These commands may include software development tasks, API calls, and the like. In example embodiments, such a language model may include input functions that support receiving images, including video, to build textual output, functions, and additional questions that may be injected into the dialogue between the two systems in the dialogue embodiment described above. In example embodiments, this multimodal support may allow for contextual analysis of images and other media formats. In an example, users/customers may upload images or other media into a GAIE enabled platform. Based on aspects of a corresponding input prompt, a multi-modal GAIE may be configured for use in a valuation workflow to identify both macro and micro attributes and their correlated effects on valuation from a plurality of perspectives. In this example, photographs/images of an old car may be input along with a valuation-related prompt. In response, the GAIE may identify one or more typical values based on detected attributes of the car, such as the make/model, etc. The GAIE may further take into account finer details in the image to suggest potential value-altering metrics. In one example, a finer detail in the image such as damaged body panels may reduce the car value below a typical value. In another example, a finer detail in the image that shows a marking consistent with a limited production run may increase the valuation.

[3044] In example embodiments, such a GAIE may facilitate workflow orchestration for a process that uses a conversational, generative AI agent and another AI-supported process in an orchestrated sequence. In example embodiments, a GAIE may generate, perform, maintain, and/or supervise one or more workflows in a robotic process automation (RPA) environment. For example, a GAIE may be trained to monitor expressions and/or actions of an individual during interaction with other individuals, and may generate similar expressions and/or perform similar actions during similar interactions between the GAIE and other individuals. In some such scenarios, the GAIE passively observes the individual during the interactions with other individuals and self-trains to behave similarly to the individual in similar interactions with other individuals. In some such scenarios, the individual actively trains and/or teaches the GAIE to generate expressions and/or actions (e.g., by creating and/or performing example or pedagogical interactions the GAIE), and based on the training and/or teaching, the GAIE behaves similarly during subsequent interactions between the GAIE and other individuals. In example embodiments, the GAIE is trained and/or taught by an individual to perform a behavior while interacting with individuals, and subsequently performs the behavior while interacting with the same individual who provided the training and/or teaching.

[3045] In example embodiments, a pretrained GAIE system may have a smart contract analysis engine that determines one or more features of a smart contract that is under consideration by a user. The GAIE may further have a conversation engine that explains the features of the smart contract to the user, including summarizing contents of smart contracts.

[3046] In example embodiments, a GAIE may be pre-trained to perform prompt generation based on a data story or a plurality of sources across systems. Example generated prompts may include instructing and/or requesting the pre-trained GAIE to tell a story about a journey of a

product, a business relationship, an event, a service provider, a smart container fleet, a robotic fleet, and the like.

[3047] In example embodiments, the GAIE may receive a plot or outcome of the story, and may generate content that is content with the plot or that produces the outcome. In example embodiments, the GAIE may generate a plot or outcome of the story, and may also generate content that is consistent with the GAIE-generated plot or outcome of the story. In example embodiments, the GAIE may receive a world or environment of a story, and may generate content that occurs within the given world or environment. In example embodiments, the GAIE may generate a world or environment of a story, and may also generate content that occurs within the GAIE-generated world or environment. In example embodiments, the GAIE may receive a character or event to be included in a story, and may generate content that includes the given character or event in the story. In example embodiments, the GAIE may generate a character or event to be included in a story, and may also generate content that includes the GAIE-generated character or event in the story. In example embodiments, the GAIE may generate a world, environment, character, event, or the like "from scratch" (e.g., based on randomized inputs). In example embodiments, the GAIE may generate a world, environment, character, event, or the like based on a given world, environment, character, event, or the like (e.g., a story that is based on a real-world public figure or event).

[3048] In example embodiments, the GAIE may receive a first story and may generate a second story that is related to the first story. For example, the GAIE may generate a second story that is an alternative retelling of the first story (e.g., a second story that includes a retelling of the first story from a perspective of a different character than a narrating character of the first story). The GAIE may generate a second story that occurs in a same or similar world or environment as the first story, or a different world or environment that is related to a world or environment of the first story. The GAIE may generate a second story that features a character or event of the first story, or a different character or event that is related to a character or event of the first story.

[3049] In example embodiments, the GAIE may generate a story from the perspective of a narrator or independent observer of the story (e.g., a third-person story). In example embodiments, the GAIE may generate a story from the perspective of a character or point of view within the story (e.g., a first-person story), including a character generated and/or embodied by the GAIE. In example embodiments, the GAIE may generate a story from the perspective of a listener or audience member to whom the story is presented (e.g., a second-person story). In example embodiments, the GAIE may generate a story from multiple perspectives, such as a first part of a story generated from a perspective of a first character, a second part of the story generated from a perspective of a second character, and a third part of a story generated from a perspective of a narrator. In example embodiments, the GAIE may generate a story involving a sequence of two or more events (e.g., a story that involves two or more events observed by a character). In example embodiments, the GAIE may generate a story involving an event that is portrayed from multiple perspectives (e.g., a story that describes an

event from a perspective of a first character, and that also describes the same event from a perspective of a second character).

[3050] In example embodiments, a GAIE may generate a static story that remains the same upon retelling. In example embodiments, the GAIE may generate a dynamic story that changes upon retelling (e.g., adding more detail to a story upon each retelling). In example embodiments, a GAIE may change a story based on an input of a user (e.g., based on a choice of outcomes selected by one or more receivers of the story). In example embodiments, a GAIE may generate a story based on one or more inputs received from one or more receivers of the story (e.g., based on a prompt of a user, such as a request to create a story that includes a certain event specified by the user). In example embodiments, a GAIE may receive feedback from a receiver about a story (e.g., an expression of pleasure, displeasure, approval, disapproval, delight, dissatisfaction, confusion, or the like regarding a character, event, or property of the story), and the GAIE may update the story based on the feedback (e.g., adding, removing, or clarifying an event in the story, or switching a perspective of an event from a first character in the story to a second character in the story).

[3051] In example embodiments, a GAIE may be pre-trained as a quantum-based GAIE. A quantum-based GAIE may use quantum computing when processing prompts and generating responses.

[3052] In example embodiments, a GAIE may be pre-trained for a value chain network environment, such as optimization of warehouse, port, container, and the like. A multi-modal variant of this GAIE may process text and image prompts. In a text-prompt embodiment, a user may describe to a generative AI assistant a request for how to optimize the layout or packing efficiency of a building, port, storage space, container, and the like. In a non-text (e.g., image-prompt) embodiment, the user may upload an image or other media and ask the generative AI to suggest places where efficiency may be improved. Another application may include providing contextual information for the visually or hearing impaired. In this application example, a multimodal support of GAIE may enable a new way for vision or hearing impaired persons to obtain contextual information about their surroundings by, for example, feeding image or sound into a generative AI-enabled system that provides voice or text dialogue to a speaker and/or on-screen.

[3053] In example embodiments, a GAIE may be pre-trained for making suggestions and/or predictions for robotic automation of value chain activities and the like. Such a GAIE may generate a prediction based on historical data in order to change future actions automatically responsive to a user asking for correlations among any of a plurality of value chain activities for improving costs, efficiency, and the like. The user may ask the GAIE to predict needs custom to each company, from a task level up to and including several tasks within a larger goal (e.g., particular conveyance task of products in a warehouse vs. entire distribution from beginning to end within a warehouse).

[3054] A pre-trained GAIE may be used to predict aspects, such as new technologies, energies, products, materials, etc. to be used with any value chain example based on knowledge of similar

efforts and/or offerings by competitors or those new aspects not used by competitors but underutilized. This GAIE-based predictive activity may be customized to each company but may also be more specifically geared to a particular company division that is most likely being impacted based on knowledge of, for example, preferences of the particular division.

[3055] A pre-trained GAIE may be used to predict the effects on value chains based on existing and/or pending regulations or legislation. This GAIE may be configured to response to a prompt along the lines of: "If this regulation passes in this country what are some effects that might be expected with respect to freight shipping." This GAIE may further respond to prompts regarding assignment of relevancy scores, such as: "What are the five most relevant pieces of legislation in X country within the past year, in order, as it pertains to Y."

[3056] A pretrained GAIE may analyze value chain data in real-time in determining what changes may be made to improve overall goals for a range of value chains. In example embodiments, this GAIE capability may be used at any stage in the value chain, from manufacturing, to packaging, to distributing products. Any and all processes involved may be evaluated in real time for predictive improvements that may be suggested to a user and/or for future automatic execution. In an example, an artificial intelligence (AI) system may include: a value chain data collector for receiving historical data and real time data about a value chain process; and an AI agent for determining one or more improvements for the value chain process based on the historical data and real time data and based on a set of goals provided to the AI agent; wherein the AI agent may be configured to suggest the one or more improvements for future execution. Further, the AI agent may be configured to utilize robotic automation to execute the one or more improvements as a continuous feedback loop with the value chain process based on user permissions.

[3057] In example embodiments, a GAIE may be trained by loading data (such as structured and un-structured data that may be dominated by numerical or non-text values) to the GAIE. Examples of such training data may include one or more database schemas. Techniques for curation and integration of purpose-specific data, including curation of models as inputs to a GAIE may include curating domain-specific data, data and model discovery.

[3058] Candidate areas of innovation enabled by and/or associated with GAIE advances may include user behavior models (optionally with feedback and personalization), group clustering and similarity, personality typing, governance of inputs and process, explaining the basis of GAIE knowledge and proof points, genetic programming with feedback functions, intelligent agents, voice assistants and other user experiences, transactional agents (counterparty discovery and negotiation), agents that deal with other agents, opportunity miners, automated discovery of opportunities for agent generation and application, user interfaces that adapt to the user and context, hybrid content generation, collaboration units of humans and generative AI, purpose-specific data integration, a selected set of data sources, curation of data as models as input to generative AI, and the like.

[3059] In embodiments of a GAIE-enabled system, such as one for robotic process automation, the GAIE system may summarize a set of actions being subjected to robotic

automation and describe context for the actions, such as, "I found these properties as fitting your criteria because of the following features. Which ones are most attractive?" In this way, a process automation system enabled with GAIE may solicit feedback for faster feedback-based training.

[3060] In example embodiments, emerging capabilities of GAIE technology may greatly improve upon earlier versions in terms of, for example, integration of domain-specific knowledge (e.g., math) with a chat interface. Further emerging capabilities may include being better informed about and for processing prompts of complex topics. Yet further, knowledge organization is becoming much improved as GAIE systems evolve. In example embodiments, updated GAIEs may correctly answer a prompt asking about today's date, whereas prior versions may answer that today's date (e.g., the current date) may be the date on which the GAIE was last trained.

[3061] In example embodiments, a context pretrained (e.g., subject matter focused) GAIE may provide better personalization than a base GAIE instance. In general, while a base GAIE, if explicitly informed of details of the user may attempt to personalize its responses, a subject matter focused or other pre-trained GAIE may be configured with and/or with access to structured information about users (e.g., determined based on user identification and/or prompt-based clues, and the like) to provide inherent, latent context for a dialogue that includes user personalized responses.

[3062] In example embodiments, a GAIE is configured to support interpretability and/or explainability of its outputs. In example embodiments, a GAIE provides, along with an output, a description of a basis of the output, such as an explanation of the reason for generating this particular output in response to an input. In example embodiments, a GAIE provides, along with an output, a description of an internal state of the GAIE that resulted in the output, such as a set of variational parameters of a variational encoder that were processed in combination with an input to produce an output, and/or an internal state of the GAIE due to a previous processing of the GAIE that resulted in the output (e.g., similar to a recurrent neural network (RNN)). In example embodiments, a GAIE provides, along with an output, an indication of one or more subsets of features of an input that are particularly associated with the output (e.g., in a GAIE that outputs a caption or summary of an image, the GAIE can also identify the particular portions or elements of the image that are associated with the caption or portions of the summary).

[3063] In example embodiments, an advanced GAIE, such as one pretrained for subject matter specific operation, may be trained for improved epistemology, to help determine evidence of the content that it represents as facts in responses that it provides. One example of improved epistemology may include citing sources of knowledge pertinent to facts in a response as a step toward proof of facts of a response – essentially a way of the GAIE "showing its work," or at least where its work originates. In example embodiments, a GAIE generates output based on information received from one or more external sources (e.g., one or more messages in a message set, or one or more websites on the Internet), and the GAIE indicates one or more

portions of the information that are associated with the output (e.g., one or more websites on the Internet that provided information that is included in the output of the GAIE).

[3064] An advanced GAIE as described and envisioned herein may maintain contextual awareness across chat (user-prompt/GAIE-response) interactions. Maintaining contextual awareness may help avoid the GAIE beginning each chat session from scratch, with no context as to prior chats with the same user. Maintaining contextual awareness may also enable picking up and resuming a conversation from earlier interactions between the GAIE and a user. Yet further maintaining contextual awareness and awareness of passage of time between interaction sessions may facilitate adapting responses to prompts in a later resumed chat session based on trained knowledge of the intervening passage of time and/or changing circumstances. In an example, a GAIE may determine that a deadline described in an earlier chat has expired, a consequential intervening event has occurred (your home-town team lost the big game), and the like. Further, contextual awareness across time-separate chat sessions may be highly valuable when being employed for projects that may have real-world physical constraints on time (e.g., smart contract negotiation may involve human evaluation, discussion, and decision making that may take time based, for example on other priorities seeking involvement of the human). This may determine the difference between treating each conversation as individual/compartmentalized/isolated, and treating ongoing, time-separated conversations as resumable, optionally as if (almost) no time had passed. In example embodiments, a GAIE may be configured with a contextualization module that maintains some notion of conversation sessions and interconnections that may be referred (e.g., a conversation from yesterday) for details and continuity. This contextualization may further enable avoiding repeating responses, making it more efficient to reference a previous conversation. Yet further, a contextualization module may provide context to the GAIE of other conversations between the user and the system, between other users and the system, and the like.

[3065] In such a contextually maintained instance, a context-enabled GAIE may provide a response regarding forecasted weather that references an earlier period of time. In an example, a context-enabled GAIE may provide a weather-related response such as, "On Monday, we discussed the weather, you asked if you would need an umbrella on Wednesday, and I answered 'probably not' based on the forecast at that time. I need to inform you that the updated weather forecast indicates that rain may be more likely on Wednesday, so you probably may need an umbrella."

[3066] Other capabilities of emerging GAIE systems may include adapting a GAIE to the generation and operation of digital avatars. In example embodiments, digital avatars may be programmed with their own visual representations. To accomplish greater similarity between an avatar and its owner based on visual and audio interpretation of users, a GAIE training and/or pre-training data set may require information about body language and nonverbal cues, such as gaze, posture, speech pitch and volume, and the like.

[3067] Emerging GAIE systems may include determining and adapting responses with variations and nuances based on, for example, user activities. A user's physical disposition may

influence content production by a GAIE (e.g., presenting different cues) based on if the user is sitting, walking, driving, exercising, and the like. Further, a GAIE system may adapt responses to prompts based on variations and nuances of real-life interactions versus voice interfaces versus virtual reality. Other aspects that may impact GAIE responding to prompts may include variations and nuances of different cultures, demographics, and the like. Yet further, in example embodiments, methods and systems for advanced GAIE training and operation may include recognition of higher-level communication features of users (humor, sarcasm, dishonesty, double entendre, etc.) and user emotional state, for example.

[3068] In example embodiments, methods and systems for enhancing GAIE platforms, such as those described herein, may include configuring a GAIE to participate in multi-user dialogue, where strict turn-taking interaction with one person might be difficult in a group setting, where the context of who may be speaking to whom matters for each expression. The more fluid multi-user conversational structure vs. turn-taking structure may indicate advances to a GAIE may include developing understanding of: social interactions and cues, such as to whom each expression may be directed; group dynamics (e.g., who may be the group leader?) and interpersonal relationships; the notion of threaded discussions with branches; concurrent discussions between various sub-groups of a group; when to chime in with input so as to avoid interrupting other users; some notion about conversational balance, to avoid dominating the conversation; tact: users' sensitivity about personal information, and when it may and cannot be shared in a group setting based on context, relationships with other users, and the like.

[3069] Independent of whether interactions are one-on-one or multi-user, it is envisioned that a GAIE may be adapted to evolve beyond a turn-taking paradigm. In an example, a GAIE may currently create media (images, music, video, and the like) based on a user prompt (that itself may be one or more types of media), and may refine the created media based on user interactions, such as changing the content in certain ways or extending the boundaries of an image with more content that may be consistent with the existing content (e.g., outpainting). A more sophisticated version of generative AI may flexibly and continuously adapt its generated content to contextual user input and interactions. In an example, generating media may be adapted by the GAIE in response user integration with the generated media content, such as in response to allowing a user to virtually walk around inside the content to interact with and/or react to content items. Such a media-adapting GAIE may generate new content or update the content based on the user input/content virtual interactions. Yet further to facilitate a user to virtually interact immersively with generated content details about the user may be considered part of the criteria for newly generating and/or updating the media.

[3070] In example embodiments, a media-output enabled GAIE without user immersive interaction and feedback may generate media (e.g., a first image) based on a prompt in which a user specifies a theme for a story. The user may then specify a series of scenes that follow, and the GAIE generates an image for each scene, leading to a storyboard series for the story.

[3071] When a media-out enabled GAIE is teamed with user immersive capabilities, the user may control, for example, an avatar that may walk around within the scene and interact with

generated media objects. Based, for example, on an order and manner with which the user traverses the scene and interacts with the objects, the generative algorithm may generate new content (e.g., the user looks at a particular painting on the wall of a gallery and then opens the curtains of a window). Outside the window may be an entire world that may be consistent with the particular painting that the user viewed. If the user chooses to move the avatar into that world, the painting on the wall updates to reflect the user's interactions.

[3072] In another example of immersive user-generated media content engagement, a user may request a science fiction story. In addition to generating a story based on tropes that are generally relevant to science fiction, the GAIE may include tropes that are likely familiar to the user, such as based on the user's age, culture, other interests, etc. (such as science fiction versions of characters that are well-known in the oeuvre of myth and literature to which the user belongs). In some cases, the algorithm may even include individuals in the created story that are analogous to celebrities or public figures in the user's culture or generation, or even the user's own friends and acquaintances.

[3073] In example embodiments, a GAIE may be pretrained for a digital products network (DPN) deployment to facilitate, for example, product lifecycle management, product design, product improvement, product simulation, and the like.

[3074] In an example of a DPN-enabled GAIE generating designs for a new product, a generative AI conversational agent (e.g., GAIE as referenced herein) may be configured to respond to a prompt requesting that it generate a design for a new product by producing one or more new product designs based on the request and contextual clues derived in association with the request (e.g., other product references, product genre, product features, jurisdiction of the request, demographics of the request, and the like). In an example of a DPN-enabled GAIE generating product improvement suggestions, a generative AI conversational or otherwise user-accessible agent may be configured to respond to a prompt to generate product improvement suggestions by generating a set of existing features of the product, contextual evaluations of the features (e.g., based on product-consumer feedback), comparisons to other products with similar features, advances in technology related to the features (e.g., higher resolution imagers), and the like. In an example of a DPN-enabled GAIE generating simulations for a digital twin of a product, a generative AI user-interactive agent may be configured to generate simulations for a digital twin of a product.

[3075] In example embodiments, a superintelligence system may be based on a pre-trained GAIE that facilitates automated discovery of relevant domain-specific knowledge and examples. The superintelligence system may further leverage pre-trained advanced GAIE to leverage domain-specific examples to generate content. Yet further the superintelligence system may include a genetic programming capability to create novel variation. In example embodiments, a superintelligence system may further include feedback systems (e.g., collaborative filtering and automated outcome tracking) to prune variation to favorable outcomes (financial, personalization, group targeting, and the like).

[3076] In example embodiments, a GAIE may be pre-trained for use by and/or in cooperative operation with a digital twin engine, such as an instance of an executive digital twin and the like. In an exemplary deployment, a GAIE may interact with a digital twin to provide a narrative about a topic of the digital twin to give to a viewer. In this example, the digital twin may interact with the GAIE (e.g., through an API and the like) to generate a narrative summary for a CEO and a detailed narrative for a CFO.

[3077] Executive digital twins may be configured for a particular role or user. Therefore, a GAIE system with a digital twin interface may improve executive digital twin capabilities by curating the data for and populating content for consumption by executive digital twins for different roles. In an example a GAIE may receive information about the executive digital twin as well as about the intended human being represented by the executive digital twin (e.g., the role of the user). The GAIE may determine a degree of narrative detail for each executive digital twin. This may be based on generic executive digital twin/user role criteria and/or refined through interaction with a particular user for the executive digital twin. In example embodiments, a CEO with a tech focus may receive more "in-depth" narrative relating to tech or R&D, whereas a CEO with a financial background may end up receiving narratives that are more focused on financial analysis but less granular on tech-related features.

[3078] In example embodiments, a GAIE system that interacts with a digital twin engine (e.g. an executive digital twin instance and/or engine) may determine of the potential universe of content on which it is trained, what may be relevant and what may be noise or unrelated for the specific narrative topic, the target human consumer, and the like. Based on this relevance determination, the GAIE system may generate the output data based on the relevant data and the determined degree of detail.

[3079] Further, the GAIE system may also select real time data sources to connect to a target / requesting executive digital twin. The GAIE may further configure consumption pipelines for those sources on the spot (e.g., data source identification, data requests for identified data sources, API configuration, and the like). Therefore, in this example the GAIE system would be identifying data sources and connecting them to an executive digital twin instance/engine.

[3080] An example use case may include an executive digital twin that has access to full financial data from a previous time-frame (e.g., a previous year/quarter/month, and the like). The executive digital twin may enable access by the GAIE to all of this data. The GAIE may determine a degree of detail of the data for the intended viewer (e.g., target consumer of a narrative regarding a topic captured in the full financial data).

[3081] In the case of a target consumer/view having a role of CEO, the GAIE may determine that the narrative for the CEO will include key insights but not full details. The GAIE may then generate a narrative of the top insights for a target time-frame (e.g., a current quarter) from at least the received data.

[3082] A pre-trained GAIE may be used to generate, manage, and/or manipulate digital twins, such as by describing attributes of a digital twin, describing interactions with other digital twins or environments, describing simulations, using digital twin simulation data to generate content,

enabling context-adaptive executive digital twins, facilitating development of narratives about ongoing, real time operations, tuned to the preferred conversation style of a user represented by a digital twin, and the like. In example embodiments, a context-adaptive executive digital twin integrated with a generative conversational AI system may be configured to generate a set of narratives about operations of an enterprise based on an input data set of real-time sensor data from the operations of the enterprise. The digital twin (or human user) may prompt the GAIE and/or conversational AI system to compare financials with real-time sensor data.

[3083] A GAIE may be adapted (e.g., pre-trained) to facilitate enhancement of AI training data associated with a digital twin application. In example embodiments, a method may include using an AI conversational agent to create synthetic training data.

[3084] Further in association with digital twin technology, a GAIE may be adapted for summarizing highly granular data for consumption by an executive digital twin. In this regard, an executive digital twin system may include an intelligent agent that receives a set of customization features from a user (e.g., an executive represented by the digital twin) that include a role of the user within an organization. The intelligent agent may also determine a respective granularity level of a report based on the customization features. In example embodiments, the set of customization features include granularity designations for different types of reports. Yet further, the intelligent agent determines the granularity level of a report based on the role of the user within an organization. Further, the subject matter of the report may be generated based on the role of the user within the organization.

[3085] In example embodiments, a speech-based user interface for customizing a level of specificity for generating executive digital twin reports may be operatively coupled to a customized GAIE that processes the speech into a set of report instructions (and optionally report content) based on aspects of the user(s). An example of a speech-based request that may be processed as described may include, "I'd like an executive-summary level report on predictive maintenance" or "I'd like a detailed report on competitor analysis." The speech-based user interface may respond to such a request by directing a corresponding executive digital twin system to feed a specificity level for parameters to a generative AI engine (e.g., GAIE) as additional input along with the data. In this example, IoT data from manufacturing facilities may be used in predictive maintenance. A response to a prompt regarding preventive maintenance may be customized with a level of specificity based on target report consumer role(s), such as for an operations-based role. A level of specificity may include what are the costs, when is the maintenance needed by, what may be the predicted downtime, how to offset and/or time the maintenance activity, and the like. For a financial-based role, specificity levels may be adapted to address what may be the disruption going to do for the bottom line in the short term; how does this impact our supply; what may the disruption do to our market-share; will it impact our stock price, and the like.

[3086] When a digital twin may be used to model an individual, a fine-tuned GAIE may be used to coordinate the digital twin with the human for improved fidelity (e.g., when the human behaves or reacts differently than the digital twin predicts, a GAIE may initiate a dialogue with

the user to determine why, and the results may be used to update the digital twin model for the individual). Instead of having a human expert occasionally participate in automated digital twin model training (e.g., to correct errors or provide new examples, and the like), a corresponding GAIE may be occasionally querying the user to solicit more information to update the digital twin model of the individual. As an example, a system may include a digital twin that models an individual, and may further include a conversation engine that facilitates determining an update of the digital twin based on a conversation with the individual that is associated with a difference between an action of the individual and a corresponding action prediction by the digital twin.

[3087] In example embodiments, human-to-robot interfaces may be further enabled and enriched through use of fine-tuned GAIE instances, such as for communicating to the robot fleet and/or receiving information from the robotic fleet. Another robot interface example may include parsing fleet job requests and identifying robotic tasks for establishing a set of fleet configuration parameters. In an example, a fleet management platform may include a job configuration system that interfaces with a GAIE-based intelligent agent, wherein the GAIE-based intelligent agent receives a job request from a client device and determines, for example, a structured set of tasks to be performed by a robotic fleet.

[3088] Subject matter adapted GAIE systems may facilitate providing an interactive framework by which an operator may interact with a robotic element via dialogue to perform a task related to the manufacturing or maintenance of a product. One example may include a voice-enabled control system that may include a collaborative robotic element configured to perform a task, such as lifting, cutting, tightening, and the like. The control system may further include a recommendation engine configured to provide a set of recommendations for performing a task dictated by the user. (e.g. prompt: "What are some ways in which I may reinforce this strut?" response: "Possible reinforcement mechanisms may include...). Responses to such a prompt may further include describing cheaper components that may be used, ways to maximize cost effectiveness, and the like. Further a machine vision enabled combination where the intelligent agent may analyze images of the product being manufactured and then reference similar examples in response to a prompt such as, "show me five similar product component diagrams."

[3089] In example embodiments, a GAIE system may be configured for use in an automated manufacturing environment. In one example, a user may prepare a descriptive prompt of a desired product to have it 3D printed. The GAIE system may generate a 3D printing set of instructions, such as a configuration of an automated 3D printing machine and a rendering indicative of a result of the 3D printing machine following the instructions. In another example, a user may include a photo/video of product as a prompt along with a request for instructions to 3D print an improved version, such as "I want this bike but I want different tires and I want it to be red."

[3090] Another exemplary use of a pre-trained GAIE may include using user behavioral data to generate guiding recommendations for energy conservation, usage shifting, and the like. In

particular, a recommendation system for energy conservation, usage shifting, or optimization may include an integrated generative, conversational AI system that adapts generated output based on user behavior from a user behavior data set.

[3091] In example embodiments, an adapted GAIE may facilitate management of energy resources. An energy resource management system may be enhanced to provide advanced intelligence (e.g., superintelligence) to plan, manage, and/or govern DERs and energy generation, storage, consumption, and transmission facilities. Elements of a superintelligent energy management system may include automated discovery of relevant domain-specific knowledge and examples, generative AI to leverage domain-specific examples to generate content, genetic programming to create novel variation, feedback systems (e.g., collaborative filtering and automated outcome tracking) to prune variation to favorable outcomes (financial, personalization, group targeting, etc., etc.), and the like. In an example, a superintelligent AI-enabled management system may be configured to manage a plurality of systems of an energy edge platform via automated discovery, generative AI, genetic programming, and feedback systems.

[3092] In example embodiments, a GAIE may be adapted (e.g., trained, pre-trained, and the like) for the field of patents to generate patent claims responsive to being provided a patent disclosure. An enabled GAIE may receive patent claims as a prompt and may generate a supportive patent disclosure therefrom. In example embodiments, an enabled GAIE may be trained to understand a patent structure and a claim structure for a plurality of jurisdictions.

[3093] In example embodiments, a GAIE may be pretrained (e.g., finetuned) with a private instance of an enterprise's intellectual property data (e.g., products, business goals, competitive considerations, core inventive ideas, and the like). In example embodiments, a private instance of enterprise data for patent generation may be configured (e.g., as prompt-response pairs) for finetuning the GAIE instance.

[3094] Beyond patent disclosure and figure preparation, a GAIE may be fine-tuned to generate figures, disclosure from figures, claims from figures, office action responses, evidence of use (EOU) for patent monetizing, preparing a matrix of patent claims across a portfolio, high level landscape search strings, enhancement of search strings, and the like. Finetuning may include preparation of prompt-response sets for a range of IP-related actions, such as patent claim assertion, infringement analysis and discovery, claim (term) acceptance and/or rejection, estimate of claim scope broadness, claim quality, and the like. In example embodiments, an IP-tuned GAIE may be pre-trained with information from proceedings related to infringement cases to understand the likelihood of infringement, and the like.

[3095] GAIE training and IP-integration may facilitate elaboration of broadly stated inventive concepts into disclosure that reflects robust enablement and/or support. In an example, an outline may be an input prompt for the purposes of drafting a patent application (e.g., disclosure, figures, summary, abstract, and optionally claims). A generated result may become a portion of a subsequent prompt along with a description of the general theme, category, focus area and/or other categorization or classification of innovation. In an example, one may describe a

transaction environment processing platform and ask for examples of a technical implementation, system, and/or method design, such as: "In the context of a transaction environment processing platform as previously described, what types of hardware and software might be used to implement a governance engine for the transaction environment?"

[3096] Regarding an intellectual property (e.g., patent) monetization-focused development process, a GAIE may facilitate predicting, from a market development view, which domains to select and which categories within domains to emphasize based on the ability to determine where business may be shifting over a longer time (e.g., beyond short-term trends). This may include analyzing historical data and current data for one or more IP domains, optionally in near-real time. An IP-monetization-focused GAIE may tie historical and/or current data to investments and actions having occurred in the IP world for, among other things, patent sales and licensing. An IP-monetizing trained GAIE may also develop particular leads and domain categories with the highest probability of success based on previous sales and/or licensing and/or where the market may be heading. There may be risk in making these decisions but using a trained GAIE may lower this risk so that these decisions become more predictable in the future, especially with company data increasing and likely accessible through various channels..

[3097] A GAIE may be configured, trained, and/or fine-tuned for a range of functions, including, for example, ingestion of proprietary data, determination of a route, determination of an outcome, approval of release/access to data, making a prediction, pattern recognition, and the like. Yet another example application of a fine-tuned GAIE may include layering of voice and visual commands that may be graduated in sound, volume, or spacing similar to flight avionics, thereby generating scripts for voice over of data and/or presentation material. This may enable the development of synthetic speech technology that generates lifelike (AI-generated) voices for podcasts, slideshows, and professional presentations. This may mitigate needs for hiring a voice artist or using any complex recording equipment (e.g., background noise separation, dubbing, and the like).

[3098] In example embodiments, GAIE systems may be configured for facilitating news delivery from NPC-type avatars to adapt current "clickbait" content to conversationally conveyed world news/happenings. In this example, a metaverse environment may include a news-based GAIE conversation agent configured to conversationally inform users of recent events.

[3099] Further in context of metaverse technology, a generative AI conversational agent may be configured to populate the metaverse.

[3100] Yet further within a context of metaverse technology, a GAIE system may be enabled to augment training data for a customized conversational agent with real-time sensor data sets through collecting information from real-world sensors. In an example, a training data augmentation system may be configured for augmenting training of a conversational agent with data from a real-time sensor data set. Further, a metaverse-associated GAIE system may facilitate augmenting training data for a customized conversational agent with process outcome data. A training data augmentation system may be configured for augmenting training of a

conversational agent with process outcome data from a process outcome data set, user behavior data, and the like. In example embodiments, a training data augmentation system based on a GAIE may be enabled (e.g., pre-trained) for augmenting training of a conversational agent with user behavior data from a user behavior data set.

[3101] In example embodiments, application of fine-tuned GAIE systems in the field of governance may facilitate advances in automation of governance, such as governing use of copyrighted material. GAIE-based governance systems may further enhance governing AI training, such as conversational AI training data sets for bias and error, governing conversational AI for contextual appropriateness and other stylistic requirements, and the like. A fine-tuned GAIE system may further improve governing secrecy, such as a progression of what elements of secret, proprietary or confidential information are allowed based on a depth of conversation. Governance may further apply to individuals. Therefore, a governance fine-tuned GAIE system may enhance and/or automate determining a measure of trustworthiness of a user that may be interacting with a generative conversational AI system. Further a governance fine-tuned GAIE system may enrich governance for a generative AI system, such as determining a measure of trustworthiness of a generative conversational AI system. In general, governance use cases may be expanded further in light of GAIE topic-targeting training capabilities.

[3102] A fine-tuned GAIE system may play a role in systematic risk identification, management. and opportunity mining. GAIE-based risk identification systems may respond to risk-related prompts, such as "What may else might we know and should be paying attention to?" by curating data sets and automating the processes of identification of systemic risks, identifying a set of likely scenarios and the risks and opportunities arising from those scenarios, identifying paths for resolution and recommending resolutions.

[3103] Yet another area of risk identification and/or management may involve security concerns with GAIE systems that are configured to generate computer executable code. At the least relying on computers to write computer code raises questions about what security measures are effective and what measures are able to be circumvented by the AI.

[3104] A further area of risk identification, management and/or opportunity harvesting may apply to copyright material. Automated computer code generation may inadvertently introduce copyrighted material, such as algorithms. A risk-finetuned copyright GAIE may assist in detecting candidate copyright violations in any programmatic code, including machine generated code.

[3105] Risk identification of visual training sets (e.g., images, graphs, and the like) may be enhanced by a fine-tuned GAIE that can process these visual training data sets for authenticity indicators that are coded as non-visual data. This may be similar to tail voltage devices providing messages on the end of sine waves. Visual training sets may be coded with non-visual indicators of authenticity that may be detectable by a fine-tuned GAIE.

[3106] Yet another risk-identification related area includes fraud detection. Integrating customer fraud reporting and questioning into pretraining data may enrich holistic scoring, which may comprise a composite score that bridges customer evidence, transactions, and

environmental trends. In an example, an AI based fraud detection system may integrate customer fraud reports and questioning into a training/query data set to produce a holistic scoring system, utilizing a composite score that combines customer evidence, transaction data, and environmental trends to provide a comprehensive approach to fraud detection.

[3107] Imaging applications may benefit from fine-tuned GAIE systems. In example embodiments, optical content (e.g., screen shots and the like) may be processed by machine vision systems so that the GAIE may describe a scene in the optical content using a generative conversational AI agent. In example embodiments, a GAIE may be configured as a first AI/NN sub-system in a Dual Process Artificial Neural Network (DPANN) architecture. Such a DPANN architecture may include, as a second NN sub-system, a formal logic-based and/or fuzzy-based system. Together these DPANN systems may implement learning processes, model management, and the like. In example embodiments, a DPANN architecture may include features that describe building and managing large scale models.

[3108] Referring to Fig. 174, a platform for the application of generative AI 24000 may include a robust task-agnostic next-token prediction artificial intelligence model 24002 that operates to predict a next token given a set of inputs encoded as embedded tokens. A robust task-agnostic next-token prediction AI engine 24002 may include deep learning models, which use multi-layered neural networks to process, analyze, and make predictions with complex data, such as language. An objective of the robust next-token prediction AI engine 24002 may include data science modeling through, among other things, use of topic-specific embeddings, attention mechanisms, and decoder-only transformer models. Capabilities of such an engine 24002 may include a pre-training capability to facilitate configuring next-token prediction for specific subject matter (e.g., marketplace item valuation), a tokenizing capability to facilitate converting complex terms into actionable tokens (e.g., converting compound chemical names into fundamental elements), access to distributed training (e.g., data-parallel training and/or model-parallel training, and the like), few-shot learning to reduce training demand for updates, such as new business intelligence data, and the like. In general the next-token prediction AI engine 24002 may combine large language modeling techniques and decoder-only transformer models to generate powerful foundation models for next-token prediction AI content generation.

[3109] In example embodiments, the next-token prediction AI engine 24002 may be structured with a machine learning (sparse Multi-Layer Perceptron) architecture configured to sparsely activate conditional computation using, for example mixture-of-experts (MoE) techniques. A machine learning architecture may be configured with expert modules that may be used to process inputs and a gating function that may facilitate assigning expert modules to process portion(s) of input tokens. A machine learning architecture may further include a combination of deterministic routing of input tokens to expert modules and learned routing that uses a portion of input tokens to predict the expert modules for a set of input tokens.

[3110] A GAIE 24000 may be trained to operate within a domain, such as written language, computer programming language, subject matter-specific domains (e.g., a software orchestrated marketplace domain), and the like to generate content (constructs) that comply with rules of the

domain. In general, a GAIE may generate content for any topic for which the GAIE is trained. So, for example, a GAIE may be trained on a topic of pig farmers and may therefore generate language-based descriptions, images, contracts, breeding guidance, textual output, and the like for any of a potentially wide range of pig farmer sub-topics.

[3111] Adapting a generative AI engine for subject matter-specific applications may include pretraining a next-token prediction AI model-based system through the use of, for example, in-context (e.g., application, domain, topic-specific) examples that are responsive to a corresponding prompt. While the next-token predictive capabilities of the underlying next-token prediction AI engine may remain unaffected by this pre-training, subject matter-specific pre-trained instances may be developed/deployed.

[3112] In example embodiments, a platform for the application of generative AI 24000 may include a set of subject matter-specific pretrained examples and prompts 24004. This set 24004 may be configured by analyzing (e.g., by a human expert and/or computer-based expert and/or digital twin) information that characterizes various aspects of the domain to generate example prompts and preferred and/or correct responses. Pretraining may also include training the next-token prediction AI engine 24002 by sampling some text (e.g., prompt/response sets) from the set of subject matter-specific pretrained examples and prompts 24004 and training it to predict a next word, object, and/or term. Pretraining may also include sampling some images, contracts, architectures, and the like to predict a next token. These prompt-response sub-sets may facilitate pre-training the prediction AI engine 24002 for predicting a next token (e.g., word, object, image element, and the like) for various aspects.

[3113] When an instance is implemented for textual generation, such a GAIE instance may be referred to as a natural language generation system that constructs words (e.g., from sub-word tokens), sentences, and paragraphs for a target subject and/or domain.

[3114] In example embodiments, real-world instances of the platform 24000 may require ongoing updates to facilitate the platform 24000 being responsive as aspects of a domain (e.g., a business entity in the domain) change, such as business goals change, new products are released, competitors merge, new markets emerge, and the like. In this regard, training the platform 24000 with in-context prompts and examples may be automated and repeated as new data is released for an enterprise to prevent snapshot-in-time data aging-based errors. The platform the application of generative AI 24000 may include an ongoing pre-training module 128 that processes new and updated content into prompt and/or response sets and interactively iterates through rounds of pre-training. New and updated data and/or information may regularly be found in various subject matter specific information sets, such as: a dataset of medical records (e.g., to assist with medical diagnoses), a dataset of legal documents and court decisions (e.g., to provide legal advice), a release of a new product (e.g., images of the product), or a financial dataset such as SEC filings or analyst reports. In example embodiments, uses of the platform 24000 may include applying the pre-training and optimizing techniques to a range of different domains (e.g., medical diagnosis, business operation, marketplace operation, and the like) to

produce a fine-tuned domain specific token-predictive engine including ongoing refinement through (daily) in-context pretraining.

[3115] In example embodiments, an ongoing pre-training module 24028 may work with the next-token prediction AI engine 24002 to update a set of subject matter specific tokens that may be maintained in a subject matter specific instance token storage facility 24008. This subject matter specific instance token storage facility 24008 may be referenced by a subject matter specific instance of the next-token prediction AI engine 24002 during an operational mode (e.g., when processing inputs / prompts). In example embodiments, the platform 24000 may include a plurality of sets of subject matter specific tokens that may be maintained by corresponding ongoing pre-training modules 24028.

[3116] Training, however, may not ensure that the responses to prompts are correct every time. In general, a business entity is likely to be less interested in a tool that provides answers that are probably right and may differ from time to time. A product that can provide accurate responses (e.g., including taking actions) based on what the end-user wants vastly increases the potential use cases and product value. A high level of accuracy and integration with operational systems may enable such a tool to go beyond just generating new content to be more productive; through integration with workflows, it may facilitate automating workflow actions. In this regard, the platform for the application of generative AI 24000 may also include a pre-training optimizing module 24006 that may work cooperatively with the ongoing pre-training module 24028 to further refine accuracy of responses to prompts for a domain. The pre-training optimizing circuit 24006 may facilitate improved accuracy of in-context responses, task-specific fine-tuning, and for sparse model variants of the platform 24000, enrich few-shot learning capabilities. In example embodiments, fine tuning may further benefit the platform by reducing bias that may be present in the training data. This may be essential to ensure subject matter specific jargon is adapted as training data changes (e.g., in the digital marketing/promotional space, ensure that "influencer" is replaced with "creator"). Further, a pre-training optimizing engine 24006 may provide a wider range of prompts and responses based on user preferences (e.g., speaking styles) to enrich the platform's ability to provide user-centric responses. In example embodiments, user-centric responses may include fine tuning the platform 24000 for different roles in an organization. As an example, when a user in a financial planning role inquires about a business development topic, responses may be directed toward the financial planning role (e.g., as compared to a customer/client inquiry about that topic).

[3117] A platform for the application of generative AI 24000 may be used to produce text-based content for a multi-national entity with employees who speak different languages. While the platform 24000 may be trained (and pre-trained) to operate interactively in a plurality of languages, generating automated content may benefit from use of a neural machine translation module 24010. In example embodiments, a portion of the entity in a first jurisdiction may produce content in a first language and resulting recurring generated output (e.g., types of reports and the like) may be generated in the first language. However, employees who speak a second language may benefit from the type of report when translated into the employee's native

language. Therefore, associating the neural machine translation module 24010 with the platform may prove valuable while reducing compute demand for the platform 24000.

[3118] Emerging next-token prediction AI systems feature increasingly adaptable next token prediction capabilities. These capabilities may be further adapted to assist in closed problem set solution prediction, such as allocation of resources, deployment of a robotic fleet and the like. To achieve greater prediction capabilities, a subject matter specific next-token prediction AI-based engine, such as the platform for the application of generative AI 24000, may include a solution-predictive engine 24012 that leverages next-token (e.g., next word) predictive capabilities to predict a most-likely solution to a closed solution-set problem. This may be accomplished optionally through use of sets of problem domain-specific pre-training prompts and examples. Such examples may be adapted for different user preferences. In example embodiments, each user in a closed problem set environment may generate prompts and responses that may enable the platform 24000 to respond to the user based on the user's inquiry style. Alternatively, the solution prediction engine 24012 may adapt a user's prompt and/or configure a prompt based on user preferences to attempt to deliver responses that are consistent with a user's preferences (e.g., engineering-based responses for an engineer role-user and legal-based responses for a lawyer).

[3119] For more complex analysis and decision making/predicting, a formal logic-based AI system 24014 may be incorporated into and/or be referenced by the subject matter specific platform 24000.

[3120] Further, the basic concepts of next-token prediction of a generative AI engine, such as the platform for subject matter based application of generative AI 24000 may be applied to analyzed expressions of images, audio (e.g., encoded text), video (e.g., sequences of related images), programmatic code (domain-specific text with readily understood rules), and the like. Therefore, a next-token prediction AI platform (e.g., platform 24000) may further include an image/video analysis engine 24016 (optionally NN-based) that adds a spatial aspect to the next-token predictive capabilities of a next-token prediction AI system. Images used for training may include 3D CAD images (for a domain that includes physical devices such as vehicles), radiologic images (for a medical analysis domain), business performance graphs, schematics, and the like. In example embodiments, aspects of the underlying task-agnostic next-token prediction AI engine 24002 may be adapted (e.g., different embeddings, neural network structures and the like) for different input formats, such as images, temporal-spatial content, and the like.

[3121] The platform 24000 may further include an expert review and approval portal 24018 through which an expert (e.g., human / digital twin, and the like) can review, edit, and approve content generated. Examples include review and adaptation by a subject matter specific data story expert; a data scientist, and the like. The expert review and approval portal 24018 may operate cooperatively with, for example, the pre-training optimizing module 24006 that may receive and analyze expert feedback (e.g., edits to the content and the like) for opportunities to further optimize the platform 24000.

[3122] The platform 24000 may further include a training data generation facility 24020 that may generate natural language prompts, such as subject matter specific prompts that may be applied by, for example, the pre-training optimizing engine 24006 to increase platform response accuracy and/or efficiency while fine tuning a subject matter specific instance.

[3123] In example embodiments, the platform 24000 may further be configured to access a corpus of domain and/or problem relevant content as a step in responding to a prompt. In example embodiments, the platform may be pre-trained on the content of the corpus. While the content of the corpus may not be directly included in the response, such as if it provides a level of detail beyond what the platform 24000 has been trained to provide in a response, it may be cited in the response to facilitate identifying and expressing sources from which a response is derived. These external source references may be handled via a citation module 24022.

[3124] Business decisions are often context-based. Understanding both the context for a decision and aspects and/or assumptions of the decision process may prove highly valuable for evaluating, for example, competing decisions and/or recommendations. Context may include both tangible and intangible factors. An intangible factor may include historical interactions between parties involved in the evaluation process, for example. A decision process may include not only assumptions on which a decision or recommendation is based, but also criteria by which tangible factors are processed, evaluated, analyzed, and the like. To provide such context for generated output of the platform 24000, an interpretability engine 24024 may be incorporated into and/or be accessible to the platform 24000. An objective of use of the interpretability engine 24024 may be to generate additional content that reflects context for, among other things, how the next-token prediction AI instance operates and/or generates a corresponding output.

[3125] In example embodiments, the next-token predictive capabilities of a next-token prediction AI engine 24002 may be utilized for developing a set of emergent data science predictive and/or interpretive skills. While such a platform may be trained directly on various data sets, context for elements and results in such data sets may be a rich source of complementary training data. By associating data elements with descriptions thereof, the platform 24000 may gain data science capabilities, such as to group by or pivot categorical sums, infer feature importance, derive correlations, predict unseen test cases, and the like. In this regard, a data science emergent skill development system 24026 may be utilized by the platform to enhance further subject matter specific applicability and utility.

[3126] In embodiments, the techniques described herein relate to a generative artificial intelligence system for a value chain network including one or more processors and one or more memories configured to perform operations including: executing, by the generative artificial intelligence system, generative artificial intelligence algorithms trained on value chain network data; receiving input data including at least one of images, video, audio, text, programmatic code, and data; processing the input data using the generative artificial intelligence algorithms to generate output content, wherein the output content includes at least one of structured prose, images, video, audio content, software source code, formatted data, algorithms, definitions, and

context-specific structures; generating an internal state of the generative artificial intelligence system, including a set of weights and/or biases as a result of prior processing; and providing the generated output content to a user interface for presentation to a user.

[3127] In embodiments, the generative artificial intelligence algorithms of the GAIE may be trained on value chain network data. In embodiments, value chain network data may include, but is not limited to, demand data (e.g., historical and forecasted customer demand data, seasonal trend data, purchasing pattern data, market research data, customer behavior analytics, and the like), product data (e.g., specifications, design files, development documentation, lifecycle information, product variations, and the like), product component data (e.g., individual part specifications, sourcing details, costs, and supplier performance metrics), supplier data (e.g., supplier capability information, lead time data, quality metrics, contractual terms, and the like), manufacturing data (e.g., production schedules, process workflows, machine utilization rates, maintenance records, factory floor data, and the like), quality control data (e.g., inspection reports, quality standards, testing results, return or defect rates, and the like), inventory data (e.g., stock levels, storage conditions, turnover rates, reorder points across various locations, and the like), logistics and distribution data (e.g., shipping routes, carrier performance, delivery times, transportation costs, customs clearance details, location data, and the like), customer feedback and service data (e.g., customer reviews, service tickets, warranty claims, post-purchase support interactions, and the like), financial transactions data (e.g., cost of goods sold, operational expenses, pricing strategies, sales revenue, profitability analysis, and the like), regulatory compliance data (e.g., compliance status with local and international regulations, audit trails, certification records, and the like), environmental impact data (e.g., carbon footprint, waste management records, sustainability metrics, and the like), market and competitive analysis data (e.g., competitor strategies, market share information, industry benchmarks, and the like), technology and innovation data (e.g., research and development activities, patent filings, technology adoption rates, and the like), human resources data (e.g., workforce skills, labor costs, productivity levels, employee engagement metrics, and the like), and risk management data (risk assessments, mitigation strategies, incident reports related to supply chain disruptions, and the like).

[3128] For example, generative AI system may be configured for a logistics company that processes real-time GPS data, warehouse inventory images, and shipment tracking text to optimize delivery routes and schedules. The system generates a visual map with the most efficient paths and a structured schedule for drivers, which is then displayed on a dashboard in the logistics control center.

[3129] In some aspects, the techniques described herein relate to a generative artificial intelligence system, wherein the input data further includes natural-language expressions, single- or multidimensional shapes or models, real-world and/or virtual scene representations, LIDAR point-cloud representations, sensor inputs and/or outputs, vehicle and/or machine telemetry, geographic maps, authentication credentials, financial transactions, smart contracts, processing directives, and device configurations. For example, a generative AI system for an automotive

manufacturer may receive CAD models of car parts, audio recordings from quality control checks, and video footage from the assembly line. It may process this data to identify potential manufacturing defects and suggest design modifications, which are then presented in a detailed report to the engineering team.

[3130] In embodiments, the techniques described herein relate to a generative artificial intelligence system, wherein the generative artificial intelligence system is configured to maintain contextual awareness across interactions to facilitate continuity in dialogue with users. For instance, a customer service generative AI system for an e-commerce platform may maintain a conversation history with customers, using this context to provide consistent and personalized support across multiple interactions, such as recommending products based on past purchases and queries.

[3131] In some aspects, the techniques described herein relate to a generative artificial intelligence system, wherein the generative artificial intelligence system is configured to support interpretability and explainability of its outputs by providing a description of the basis of the output. For example, A financial analysis generative AI system may generate a report on market trends and provides explanations for its predictions, such as citing economic indicators or recent news events that influenced its analysis, making the output more transparent for financial analysts.

[3132] In some embodiments, the techniques described herein relate to a generative artificial intelligence system, wherein the output includes a recommendation to improve one or more of the value chain network, an entity within the value chain network, an asset within the value chain network, and the value chain network environment. For instance, a supply chain generative AI system may analyze sales data and inventory levels across a retail network to recommend restocking certain products in specific locations, aiming to improve the overall efficiency of the inventory distribution within the value chain network.

[3133] In some embodiments, the techniques described herein relate to a generative artificial intelligence system, further including a digital twin interface for a digital twin, wherein the digital twin interface is configured to enable access to the generative artificial intelligence system, and wherein the digital twin represents at least one of the value chain network, an entity within the value chain network, an asset within the value chain network, or an environment within the value chain network. In one example, a smart factory generative AI system may be accessed via a digital twin interface that allows operators to interact with a virtual representation of the manufacturing floor, enabling them to test different production scenarios without affecting the actual operations. Continuing with the example, the operators may be able to ask the smart factory generative AI system questions about the different production scenarios.

[3134] In some aspects, the techniques described herein relate to a generative artificial intelligence system, further including a digital twin module configured to generate a digital twin representing at least one of a value chain network, an entity within the value chain network, an asset within the value chain network, and an environment within the value chain network. For instance, a generative AI system for a smart city project may generate a digital twin of the city's

transportation network, simulating traffic flow and public transit operations to propose improvements for reducing congestion and enhancing commuter experience.

[3135] In some aspects, the techniques described herein relate to a generative artificial intelligence system, wherein the processor is further configured to communicate with robotic systems within the value chain network, and the memory stores instructions that enable the generative artificial intelligence system to translate human commands into robotic actions, thereby facilitating human-to-robot interaction. In one example, a warehouse management generative AI system may translate voice commands from workers into actions for robotic forklifts, coordinating the movement of goods and streamlining the loading and unloading process.

[3136] In embodiments, the techniques described herein relate to a generative artificial intelligence system, wherein the output content is further tailored based on the executive role of the user. The GAIE may be configured to tailor the output content based on the executive role of the user within an organization. The system adjusts the level of detail and complexity of the output content to match the user's role, ensuring that the information provided is directly relevant to the user's decision-making needs and responsibilities. For example, an executive dashboard generative AI system may customize financial reports for different roles within a corporation, providing high-level summaries for C-suite executives and detailed breakdowns for department heads.

[3137] In some aspects, the techniques described herein relate to a generative artificial intelligence system, wherein the generated output includes 3D printing instructions for a set of 3D printers based on input data. The system may be configured to analyze product designs and utilize the generative capabilities of the GAIE to create detailed 3D printing instructions, facilitating the physical realization of product concepts. For instance, a design generative AI system for a furniture company may process sketches and material specifications to generate precise 3D printing instructions, enabling rapid prototyping of new furniture designs.

[3138] In some aspects, the techniques described herein relate to a generative artificial intelligence system, wherein the system is part of a Dual Process Artificial Neural Network (DPANN) architecture, combining generative AI capabilities with formal logic-based systems to enhance decision-making and predictive modeling. For example, a healthcare generative AI system may be part of a DPANN architecture, where it works alongside a rule-based diagnostic system to provide both generative insights and logic-driven medical diagnoses to healthcare professionals.

[3139] In embodiments, the techniques described herein relate to a generative artificial intelligence system, further including an augmented reality (AR) interface configured to overlay the generated output content onto a user's real-world view. This AR interface may provide interactive and visual representations of the output content, enhancing user engagement and understanding of complex data. In one example, an augmented reality (AR) interface is integrated with the generative AI system. Continuing the example, as a field technician inspects a piece of heavy machinery using AR glasses, the generative AI system can overlay real-time

data analytics, maintenance history, and performance metrics onto their view of the equipment. This allows the technician to see potential issues highlighted directly on the machinery, receive step-by-step repair instructions, and view predictive maintenance alerts, all superimposed within their field of vision, thereby enhancing the efficiency of on-site diagnostics and repairs.

GRAPH NEURAL NETWORKS AND TRANSFORMER MODELS IN ARTIFICIAL INTELLIGENCE PLATFORMS

[3140] GRAPH NEURAL NETWORKS - INTRODUCTION

[3141] In various embodiments, one or more techniques involve the processing of graph data using one or more machine learning algorithms. In some such embodiments, the one or more machine learning algorithms include one or more graph neural networks (GNNs). The following discussion provides an overview of graph data and graph neural networks.

[3142] In a graph data set, a set of nodes is interconnected by one or more edges that respectively represents a relationship among two or more connected nodes. In many graph data sets, each edge connects two nodes. In other graph data sets that represent hypergraphs, a hyperedge can connect three or more nodes. In various graph data sets, each of the one or more edges is directed or undirected. An undirected edge represents a relationship that relates two or more nodes without any particular ordering of the related nodes. A first undirected relationship that connects a first node N1 and a second node N2 may be equivalent to a second undirected relationship that also connects a first node N1 and a second node N2. In some such graphs, the relationship represents a group to which the two or more related nodes belong. In some such graphs, the relationship represents an undirected and/or omnidirectional connection between two or more nodes. For example, in a graph representing a geographic region, each node may represent a city, and each edge may represent a road that connects two or more cities and that can be traveled in either direction. By contrast, a directed edge includes a direction of the relationship between a first node and a second node. For example, in a graph representing a genealogy or lineage, each node represents a person, and each edge connects a parent to a child. A first directed edge that connects a first node N1 to a second node N2 is not equivalent to a second directed edge that connects the second node N2 to the first node N1. Some graph data sets include one or more unidirectional edges, that is, an edge with one direction among two or more connected nodes. Some graph data sets include one or more multidirectional edges, that is, an edge with two or more directions among the two or more connected nodes. Some graph data sets may include one or more undirected edges, one or more unidirectional edges, and/or one or more multidirectional edges. For example, in a graph representing a geographic region, each node may represent a city; one or more unidirectional edges may represent a one-way road that connects a first city to a second city and can only be traveled from the first city to the second city; and one or more bidirectional or undirected edges that represent a bidirectional road between the first city and the second city that can be traveled in either direction. Some graph data may include, for two or more nodes, a plurality of edges that interconnect the two or more nodes. For example, a graph data set representing a collection of devices may include nodes that

respectively correspond to each device of the collection and edges that respectively correspond to an instance of communication and/or interaction among two or more of the devices. In such a graph data set, a particular subset of two or more devices may engage in a plurality, including a multitude, of instances of communication and/or interaction, and may therefore be connected by a plurality, including a multitude, of edges.

[3143] Some directed and/or undirected graph data sets may include one or more cycles. For example, in a graph representing a social network, a first edge E1 may connect a first node N1 (representing a first person) and a second node N2 (representing a second person) to represent a relationship between the first person and the second person. A second edge E2 may connect the second node N2 and a third node N3 (representing a third person) to represent a relationship between the second person and the third person. A third edge E3 may connect the third node N3 and the first node N1 to represent a relationship between the third person and the first person. Such cycles can occur in undirected graphs (e.g., edges in a social network graph that indicate mutual relationships among two or more individuals), directed graphs (e.g., edges in a social network graph that indicate that a first person is influenced by a second person, a second person is influenced by a third person, and a third person is influenced by the first person), and/or hypergraphs (e.g., cycles of relationships among three or more clusters that respectively include three or more nodes). Some cyclic graphs may include one or more cycles that are interlinked (e.g., one or more nodes and/or edges that are included in two or more cycles). Other directed and/or undirected graph data sets may be acyclic (e.g., graphs in which nodes are strictly arranged according to a top-down hierarchy). Still other directed and/or undirected graph data sets may be partially acyclic (e.g., mostly acyclic) but may include one or more cycles among one or more subsets of nodes and/or edges.

[3144] In some graph data sets, one or more nodes includes one or more node properties. For example, in a graph representing a geographic area, each node may represent a city, and each node may include one or more node properties that correspond to one or more properties of the city, such as a size, a population, or a latitude and/or longitude coordinate. Each node property may be of various types, including (without limitation) a Boolean value, an integer, a floating-point number, a set of numbers such as a vector, a string, or the like. In some graph data sets, one or more nodes does not include a node property. For example, in a graph data set representing a set of particles, each particle may be identical to each other particle, and there may be no specific data that distinguishes any particle from any other particular. Thus, the nodes of the graph data set may not include any node properties.

[3145] In some graph data sets, one or more edges includes one or more edge properties. For example, in a graph representing a geographic area, each edge may represent a road, and each edge may include one or more edge properties that correspond to one or more properties of the road, such as a distance, a number of lanes, a direction, a speed limit, a volume of traffic, a start latitude and/or longitude coordinate, and/or an ending latitude and/or longitude coordinate. In some graph data sets, a direction of an edge may be represented as an edge property. Alternatively or additionally, in some graph data sets, a direction of an edge may be represented

separately from one or more edge properties. In some graph data sets, one or more edges does not include an edge property. For example, in a graph data set representing a line drawing of a set of points, each edge may represent a line connecting two points, and the edges may be significant only due to connecting two points. Thus, the edges of the graph data sets may not include any edge properties.

[3146] In some graph data sets, the graph includes one or more graph properties. Such graph properties may be global graph properties that correspond to one or more properties of the entire graph. For example, in a graph data set representing a geographic region, the graph may include graph properties such as a total number of nodes and/or cities, a two-dimensional or three-dimensional area represented by the graph, and/or a latitude and/or longitude of a center of the graph. Such graph properties may be global graph properties that correspond to one or more properties of all of the nodes of the graph. For example, in a graph data set representing a geographic region, the graph may include graph properties such as an average population size of the cities represented by the nodes and/or an average connectedness of each city to other cities included in the graph.

[3147] Some graph data sets include a single set of data that includes all nodes and all edges. For example, a graph representing a geographic region may include a set of nodes that represent all cities in the geographic region. Some other graph data sets include one or more subgraphs, wherein each subgraph includes a subset of the nodes of the graph and/or a subset of the edges of the graph. For example, a graph representing a geographic region may include a number of subgraphs, each representing a subregion of the geographic region, and the edges that interconnect the cities within each subregion. As another example, a graph representing a geographic region may include a first subgraph representing cities (e.g., groups of people over a threshold population size and/or population density) and a second subgraph representing towns (e.g., groups of people under the threshold population size and/or population density). In some graph data sets, each node and/or each edge belongs exclusively to one subgraph. In some graph data sets, at least one node and/or at least one edge can belong to two or more subgraphs. For example, in a graph representing a geographic region that includes a number of subgraphs respectively representing different geographic subregion, each node representing a city may be exclusively included in one subgraph, while each edge may interconnect two or more cities within one subgraph (i.e., within one subregion) or may interconnect a first city in a first subgraph (i.e., within a first subregion) and a second city in a second subgraph (i.e., within a second subregion).

[3148] Graph neural networks can include features and/or functionality that are the same as or similar to the features and/or functionality of other neural networks. For example, graph neural networks include one or more neurons arranged in various configurations. Each neuron receives one or more inputs from the graph data set or another neuron, evaluates the one or more inputs (e.g., via an activation function), and generates one or more outputs that are delivered to one or more other neurons and/or as an output of the graph neural network. Examples of activation functions that can be included in various neurons of the graph neural network include (without

limitation) a Heaviside or unit step activation function, a linear activation function, a rectified linear unit (ReLU) activation function, a logistic activation function, a tanh activation function, a hyperbolic activation function, or the like.

[3149] As an example, some graph neural networks include only a single neuron, or only a single layer of neurons that is configured to receive graph data as input and to provide graph data as output of the graph neural network. Some graph neural networks are arranged in a series of two or more layers, wherein input is received by neurons included in a first layer. The output of one or more neurons included in the first layer is delivered, as input, to one or more neurons included in a second layer. For example, each neuron in the first layer may include one or more synapses that respectively interconnect the neuron to one or more neurons of the second layer. In many graph neural networks, each neuron N1 of a preceding layer L1 is connected to each neuron N2 of a following layer by a synapse that includes a weight W. Neuron N2 receives, as input, the output of the neuron N1 multiplied by the weight of the synapse connecting neuron N1 and neuron N2. In many neural networks, layer L1 includes a bias B, which is added to the product of the output of neuron N1 and the weight W of the synapse connecting neuron N1 and neuron N2. As a result, the input to neuron N2 includes the sum of the bias B of layer L1 and the product of the output of neuron N1 and the weight W of the synapse connecting neuron N1 and neuron N2. The output of the neurons included in the second layer can be provided as an output of the graph neural network and/or as input to one or more neurons included in a third layer. Each layer of the graph neural network may include a same number of neurons as a preceding and/or following layer of the graph neural network, or a different number of neurons as preceding and/or following layer of the graph neural network.

[3150] As another example, some graph neural networks include one or more layers that perform particular functions on the output of neurons of another layer, such as a pooling layer that performs a pooling operation (e.g., a minimum, a maximum, or an average) of the outputs of one or more neurons, and that generates output that is received by one or more other neurons (e.g., one or more neurons in a following layer of the graph neural network) and/or as an output of the graph neural network. For example, some graph neural networks (e.g., graph convolution networks) include one or more convolutional layers, each of which performs a convolution operation to an output of neurons of a preceding layer of the graph neural network.

[3151] As another example, some graph neural networks include memory based on an internal state, wherein the processing of a first input data set causes the graph neural network to generate and/or alter an internal state, and the internal state resulting from the processing of one or more earlier input data sets affects the processing of second and later input data sets. That is, the internal state retains a memory of some aspects of earlier processing that contribute to later processing of the graph neural network. Examples of graph neural networks that include memory features and/or stateful features include graph neural networks featuring one or more gated recurrence units (GRUs) and/or one or more long-short-term-memory (LSTM) cells.

[3152] As another example, some graph neural networks feature recurrent and/or reentrant properties. For example, at least a portion of output of the graph neural network during a first

processing is included as input to the graph neural network during a second or later processing, and/or at least a portion of an output from a layer is provided as input to the same layer or a preceding layer of the graph neural network. As another example, in some graph neural networks, an output of a neuron is also received as input by the same neuron during a same processing of an input and/or a subsequent processing of an input. The output of the neuron may be evaluated (e.g., weighted, such as decayed) before being provided to the neuron as input. As another example, some graph neural networks may include one or more skip connections, in which at least a portion of an output of a first layer is provided as input to a third layer without being processed by a second layer. That is, the output of the first layer is provided as input both to the second layer (which generates a second layer output) and to the third layer. In some such graph neural networks, the third layer receives, as input, either the output of the first layer or the output of the second layer. That is, the third layer multiplexes between the output of the first layer and the output of the second layer. Alternatively or additionally, in some such graph neural networks, the third layer receives, as input, both the output of the first layer and the output of the second layer (e.g., as a concatenation of the output vectors to generate the input vector for the third layer), and/or an aggregation of the output of the first layer and the output of the second layer (e.g., a sum or average of the output of the first layer and the output of the second layer). Examples of graph neural networks that include one or more skip connections include jump knowledge networks and highway graph neural networks (highway GNNs).

[3153] As another example, some graph neural networks include two or more subnetworks (e.g., two or more graph neural networks that are configured to process graph data concurrently and/or consecutively). Some graph neural networks include, or are included in, an ensemble of two or more neural networks of the same, similar, or different types (e.g., a graph neural network that outputs data that is processed by a non-graph neural network, Gaussian classifier, random forest, or the like). For example, a random graph forest may include a multitude of graph neural networks, each configured to receive at least a portion of an input graph data set and to generate an output based on a different feature set, different architectures, and/or different forms of processing. The outputs of respective graphs of the random graph forest may be combined in various ways (e.g., a selection of an output based on a minimization and/or maximization of an objective function, or a sum and/or averaging of the outputs) to generate an output of the random graph forest.

[3154] In these and other graph neural networks, the number of layers and the configuration of each layer of the graph neural network (e.g., the number of neurons and the activation function used by each neuron of each layer) can be referred to as hyperparameters of the graph neural network that are determined upon generation of the graph neural network. The weights of node synapses and/or the biases of the layers can be referred to as parameters of the graph neural network that are learned through a training or retraining process. Further explanation and/or examples of various concepts of other types of neural networks that can also apply to graph neural networks, and additional concepts that apply to other types of neural networks that can

also be included in graph neural networks, are presented elsewhere in this disclosure and/or will be known to or appreciated by persons of ordinary skill in the art.

[3155] Unlike other types of neural networks, graph neural networks are configured to receive, process, generate, and/or transform one or more graph data sets. Some graph neural networks are configured to receive data representing and/or derived from a graph data set, such as an input vector that includes data representing one or more nodes of the graph (optionally including one or more node properties of one or more nodes), one or more edges of the graph (optionally including one or more edge properties of one or more edges), and/or one or more graph properties of the graph. Some graph neural networks are configured to receive an input vector comprising all of the data of a graph data set (e.g., all of the data representing all nodes, all edges, and the graph). Some graph neural networks are configured to receive an input vector comprising only a portion of the data of a graph data set (e.g., only a subset of the nodes of the graph and/or only a subset of the edges of the graph). For example, some graph data sets include a number of subgraphs, and the input vector to the graph neural network includes the data for all of the nodes and/or all of the edges included in one subgraph of the graph. The entire graph can be processed by processing (e.g., concurrently and/or consecutively) each subgraph and combining the output resulting from the processing of each subgraph. As another example, a graph data set representing a set of users of a social network may be processed by a graph neural network that receives, as input, a subset of nodes that correspond to the most influential users of the social network (e.g., those having more than a threshold number of social network connections) and a subset of edges that interconnect the nodes representing those users. Some graph neural networks are configured to receive, as input, data derived from a graph neural network. For example, a graph data set representing a social network may be processed by a graph neural network that receives, as input, data associated with messages exchanged among users of the social network, and provides, as output, an analysis of the messages. Some graph neural networks are configured to receive, as input, non-graph data (e.g., an input vector including coordinates of roads and/or cities in a geographic region) and generate graph data as output (e.g., a graph including odes that represent the cities, and edges that represent roads interconnecting the nodes representing the cities).

[3156] Some graph neural networks are configured to process input data as graph data. As an example, some graph neural networks are configured to receive, as input, data that represents each of one or more nodes of a graph data set and one or more edges that respectively interconnect two or more nodes of the graph data set. The graph neural network may process a state of each node and/or edge of the input graph data in order to generate an updated state of the node and/or edge. The term "message passing" refers to evaluating and updating the state of a node N or an edge E of a graph based on the states of one or more neighboring nodes N and/or connecting edges E. For example, for each node N1, the graph neural network may evaluate the state of node N1 and/or states of a set of nodes N that are connected to node N1 by at least one edge (e.g., a neighborhood of nodes that includes N1) and may determine an updated state of node N1 based on the state of the node N1 and/or the states of the neighboring nodes N. As

another example, for each node N1, the graph neural network may evaluate the state of the node N1 and/or the states of a set of edges E that connect node N1 to one or more other nodes of the graph, and may determine an updated state of node N1 based on the state of the node N1 and/or the states of the edges E. As yet another example, for each edge E1 of the input graph, the graph neural network may evaluate a state of the edge E1 and/or the states of a set of nodes N of the graph that are connected to the edge E1 and may determine an updated state of edge E1 based on the state of the edge E1 and/or the states of the connected nodes N. As yet another example, for each edge E1 of the input graph that connects a set of nodes N of the graph, the graph neural network may evaluate the state of the edge E1 and the states of the set of edges E that are also connected at least one of the set of nodes N and may determine an updated state of edge E1 based on the state of the edge E1 and/or the states of the other edges. In these and other scenarios, each node N and/or each edge E is evaluated and updated based on a collection of "messages" corresponding to the states of neighboring nodes N and/or connecting edges E.

[3157] In some graph neural networks, each node N1 is updated based a neighborhood of size 1, including only on the states of the edges E that are directly connected to node N1 and/or the states of the other nodes N that are directly connected to node N1 by an edge. In some other graph neural networks, each node N1 is updated based a neighborhood of a size S greater than 1, including the states of other nodes N that are within S edge connections of node N1 and/or edges E that are connected to any such nodes N. In some graph neural networks, each edge E1 is updated based a neighborhood of size 1, including only on the states of the nodes N that edge E1 connects and/or the edges E that are also connected to the nodes N that edge E1 connects. In some other graph neural networks, each edge E1 is updated based a neighborhood of a size S greater than 1, including the states of other nodes N that are within S edge connections of node N1 and/or the set of edges E that are connected to any such nodes N. In some graph neural networks with a neighborhood of size greater than 1, one or more first layers of neurons process each node and/or edge based on the nodes and/or edges within a neighborhood of size 1; a second one or more following layers of neurons further process each node and/or edge based on the nodes and/or edges within a neighborhood of size 2; and so on. That is, the first one or more layers update the state of each node and/or edge based on the states of the directly connected nodes and/or edges, and each following one or more layers further updates the state of each node and/or edge additionally based on the states of indirectly connected nodes and/or edges that are one or more further connections.

[3158] In some graph neural networks, the states of nodes N and/or edges E are evaluated and updated concurrently (e.g., the graph neural network may evaluate the features relevant to each node N and/or each edge E to determine an update, and may do so for all nodes N and/or all edges E, before applying the updates to update the internal states of each node N and/or each edge E). In some graph neural networks, the states of nodes N and/or edges E are evaluated and updated consecutively (e.g., the graph neural network may evaluate the features relevant to a first node N1 and update the state of node N1 before evaluating the features relevant to a second node N2 and updating the state of node N2). In some graph neural networks, the states of the

nodes N and/or the edges E are consecutively evaluated and updated according to a sequential order (e.g., the graph neural network first evaluates and updates a state of a first node N1 that is of a high priority, and then evaluates and updates a state of a first node N2 that is of a lower priority than N1). In some graph neural networks, a state of a node N2 is evaluated after updating a state of a node N1 and, further, based on the updated state of node N1. In some graph neural networks, a state of an edge E2 is evaluated after updating a state of an edge E1 and, further, based on the updated state of an edge E1. In some graph neural networks, the states of nodes N are concurrently evaluated and updated, and then the states of edges E are concurrently evaluated and updated concurrently. In some graph neural networks, the states of edges E are concurrently evaluated and updated, and then the states of nodes N are concurrently evaluated and updated concurrently. These variations in the order of updating the nodes N and/or edges E can be variously combined with the previously discussed variations in the processing of neighborhoods. For example, a graph neural network may include a first one or more layers that are configured to evaluate and concurrently update the states of all nodes and edges within a neighborhood of size 1, followed by a second one or more layers that are configured to evaluate and concurrently update the states of all nodes and edges within a neighborhood of size 2. Another graph neural network may a graph neural network may include a first one or more layers that are configured to evaluate and concurrently update the states of all nodes within a neighborhood of size 1, followed by a second one or more layers that are configured to evaluate and concurrently update the states of all nodes within a neighborhood of size 2, further followed by one or more layers that are configured to update the states of all edges within a neighborhood of size 1 or more.

[3159] Some graph neural networks are configured to evaluate and/or update one or more node properties of one or more nodes of a graph data set. For example, a graph representing a social network may include nodes that represent people, and a graph neural network may evaluate the nodes and/or edges of the graph to predict one or more node properties that correspond to attributes of the person, such as a type of the person, an age of the person, or an opinion of the person. Some graph neural networks are configured to evaluate and/or update one or more edge properties of one or more edges of a graph data set. Some graph neural networks are configured to evaluate and/or update one or more edge properties of one or more edges of a graph data set. For example, a graph representing a social network may include nodes that represent people and edges that represent relationships between people, and a graph neural network may evaluate the nodes and/or edges of the graph to predict one or more edge properties that correspond to attributes of a relationship among two or more people, such as a type of the relationship, a strength of a relationship, or a recency of the relationship. Some graph neural networks are configured to evaluate and/or update one or more graph properties of the graph data set. For example, a graph representing a social network may include nodes that represent people and edges that represent relationships between people, and a graph neural network may evaluate the nodes and/or edges of the graph to predict a feature of a social group to which all of the people

belong, such as a common interest or a common demographic trait that is shared by at least many of the people of the social network.

[3160] Some graph neural networks are configured to generate graph data as output. The generated graph data may include one or more nodes (optionally including one or more node properties), one or more edges (optionally including one or more edge properties), and/or one or more graph properties. The generated graph data may be based on input graph data. Some graph neural networks may be configured to receive at least a portion of a graph data set as input, and may generate, as output, modified graph data. As an example, the input graph data set may include a number of nodes and a number of edges interconnecting the nodes, and in the output graph data set generated by the graph neural network, each of the nodes and/or edges of the graph may have been updated based on one or more nodes and/or one or more edges of the input graph data. For example, an input graph data set may represent a social network including a nodes representing people and edges representing relationships between people. A graph neural network may be configured to receive at least a portion of the input graph data set, and may output an adjusted graph data set, wherein a state at least one of the nodes and/or at least one of the edges is updated based on the processing of the input data set. For example, various edges representing relationships may be updated to include additional data (e.g., edge properties) to represent an updated relationship between two people represented by nodes. Various nodes may be updated to include additional data (e.g., node properties) to represent updated information about corresponding people based on the relationships. Various graph properties of the at least a portion of the graph data set may be updated based on the updated edges and/or nodes, e.g., a new common interest that is shared among many of the people in the social network.

[3161] Some graph neural networks may be configured to output graph data that includes one or more newly discovered nodes based on the input graph data set. For example, an input graph data set representing travel events may include edges that include routes of travelers and nodes that represent locations of interest. A graph neural network may receive the input graph data set, and based on processing of the routes of the travelers, may output an updated graph data set that includes a new node that represents a new location of interest (e.g., a destination of a large number of recent travelers). The output of the graph neural network may include, for one or more new or existing nodes, one or more new or updated node properties (e.g., a classification of the location of interest based on the travel routes). Alternatively or additionally, some graph neural networks may be configured to output graph data that excludes one or more existing nodes of an input graph data set. For example, based on processing the input data set representing routes of travelers, a graph neural network may output an updated graph data set that excludes one of the nodes of the input graph data set representing a location that is no longer a location of interest (e.g., a destination that travelers no longer visit).

[3162] Some graph neural networks may be configured to output graph data that includes one or more newly discovered edges based on the input graph data set. For example, an input graph data set may represent a social network including nodes that represent people and edges that represent connections between people. A graph neural network may receive the input graph data

set, and based on processing of the people and connections, may output an updated graph data set that includes a new connection between two people (e.g., a likely relationship based on shared traits and/or mutual relationships with a number of other people representing a social circle). The output of the graph neural network may include, for one or more new or existing edges, one or more new or updated edge properties (e.g., a classification of a relationship between two or more people). Alternatively or additionally, some graph neural networks may be configured to output graph data that excludes one or more existing edges of an input graph data set. For example, based on processing the input data set representing a social network, a graph neural network may output an updated graph data set that excludes one or more of the edges of the input data set representing a relationship that no longer exists (e.g., a lost connection based on a splitting of a social circle).

[3163] Some graph neural networks may output graph data that is based on data that does not represent an input graph data set. For example, a graph neural network may be configured to receive non-graph data, such as lists of travel routes of drivers, and may generate and output a graph data set including nodes that represent locations of interest and edges that interconnect the locations of interest. Conversely, some graph neural networks may receive input that includes at least a portion of a graph data set and that outputs non-graph data based on the input graph data. For example, a graph neural network may be configured to receive input including graph data, such as a graph of a social network including nodes that represent people and edges that represent connections, and to output non-graph data based on analyses of the input graph data, such as statistics about the people represented in the social network and activity occurring therein.

[3164] GRAPH NEURAL NETWORKS - PROPERTIES

[3165] Graph neural networks, including (without limitation) those described above, may be subject to various properties and/or considerations of design and/or operation. These considerations may affect their architecture, processing, implementation, deployment, efficiency, and/or performance.

[3166] As previously discussed, graph neural networks may include edges with varying directionality, such as undirected edges (e.g., edges that represent distances between pairs of nodes that represent cities in a graph that represents a region), unidirectional edges (e.g., edges that represent parent/child relationships among nodes that represent people in a graph that represents a genealogy or lineage), and/or multidirectional edges (e.g., bidirectional edges that represent bidirectional roads between nodes that represent cities in a graph that represents a region). In some graph data sets, all of the edges have a same directionality (e.g., all edges are undirected). A graph neural network can be configured to receive an input vector corresponding to the input data set and to process the edges according to the uniform directionality of the edges (e.g., processing undirected edges without regard to the order in which the nodes are represented as being connected to the edge). Other graph data sets may include edges with different directionality (e.g., in a graph that represents a region, edges can represent roads between nodes that represent cities, and each edge can be either unidirectional to represent a one-way road or

bidirectional to represent a two-way road). A graph neural network can be configured to receive an input vector corresponding to the input data set and to process the edges according to the distinct directionality of each edge (e.g., processing a unidirectional edge in a different manner than a bidirectional edge). As one such example, the graph neural network can interpret a bidirectional edge connecting two nodes N1, N2 as a first unidirectional edge that connects node N1 to N2 and a second unidirectional edge that connected node N2 to node N1. The pair of unidirectional edges can share various edge properties and/or can be evaluated and/or updated in a same or similar manner (e.g., for a pair of unidirectional edges corresponding to a bidirectional road, the graph neural network can process data representing a weather condition in a same or similar manner to both unidirectional edges associated with the bidirectional road).

[3167] As previously discussed, some graph neural networks are configured to process nodes according to a "message passing" paradigm, in which the evaluation of each node N1 is based on the states and/or evaluations of other nodes within a neighborhood of the node N1 and/or the edges that connect the node N1 to other nodes in the neighborhood of the node N1. That is, the state of each node in the neighborhood of the node N1 and/or the state of each edge that connects N1 to other nodes of the neighborhood serves as a "message" that informs the evaluation and/or updating of the state of node N1 by the graph neural network. Alternatively or additionally, the evaluation of each edge E1 is based on the states and/or evaluations of other edges within a neighborhood of the edge E1. That is, the state of each node connected by edge E1, and, optionally, the states of other nodes connected to those nodes and/or other edges in such connections, serves as a "message" that informs the evaluation and/or updating of the state of edge E1 by the graph neural network. In each case, the size of the neighborhood can vary; for example, the graph neural network can evaluate each node according to a one-hop neighborhood or a multi-hop neighborhood. Graph neural networks that perform multi-hop neighborhood evaluation can include multiple layers, where a first one or more layers are configured to process a first hop between a node N1 and a one-hop neighborhood including its directly connected neighbors and/or directly connected edges, and a second one or more layers following the first one or more layers are configured to process a second hop between the nodes and/or edges of the one-hop neighborhood and additional nodes and/or edges that are directly connected to the nodes and/or edges of the one-hop neighborhood. In this manner, each node N1 is first evaluated and/or updated based on message passing among the one-hop neighborhood, and is then evaluated and/or updated based on additional messages within the two-hop neighborhood, etc. Other architectures of graph neural networks may perform multi-hop neighborhood evaluation in other ways, e.g., by processing individual clusters of nodes and/or edges to perform message passing among the nodes and/or edges of each cluster, and then performing additional message passing between clusters to update nodes and/or edges of each cluster based on the nodes and/or edges of one or more neighboring clusters.

[3168] In some scenarios, a graph may include nodes and/or edges that are stored, represented, and/or provided as input that is not subject to any particular order (e.g., nodes representing points in a line drawing may not have any node properties, and may therefore be represented in

arbitrarily different orders in the input graph data set). In such scenarios, a multitude of semantically equivalent input graph data sets may be logically equivalent to one another. That is, a first representation of a graph may include the nodes and/or edges in a particular order, while a second representation of the same graph may include the same nodes and/or edges in a different order. While both representations of the graph are logically equivalent, the different ordering in which the nodes and/or edges are provided as input to the graph neural network may cause the graph neural network to provide different output. In other scenarios, a graph comprising a set of nodes and a set of interconnecting edges may be organized, stored, and/or represented in a particular order. For example, the nodes may be ordered according to a property of the nodes, and/or edges may be ordered according to a property of the edges (e.g., in a social network, nodes representing people may be ordered according to the alphabetical order of their names, and edges representing relationships may be ordered according to the alphabetical order of the names of the related people). In such scenarios, changes to the order and/or the selected subsets of graph data may result in different input data sets that represent the same or similar (e.g., logically equivalent) graphs. Due to the manner in which a graph neural network processes the input graph data set, logically equivalent input graph data sets may result in different and logically distinct output data.

[3169] In such scenarios, it may be undesirable for the graph neural network to generate different output for different but logically equivalent representations. That is, it may be desirable for the graph neural network to provide the same or equivalent output for different but logically equivalent representations of a graph. Graph neural networks that exhibit this property can be referred to as "permutation invariant," that is, capable of providing output that does not vary across permutations in the representation of the input graph data set. A variety of techniques may be used to achieve, improve, and/or promote permutation invariance. Some such techniques involve changing representations of the input data set. For example, before processing an input graph data set, the graph neural network may reorder the input data set (e.g., by reordering the units of an input vector) such that nodes and edges are represented in a consistent order. As one such example, an input graph data set may include nodes that represent cities, and the input graph data set may include the nodes and/or edges in varying orders. Prior to processing the input graph data set, the graph neural network may reorder the nodes based on latitude and longitude coordinates of the cities, and the edges can similarly be reordered based on the latitude and longitude coordinates of the nodes connected by each edge. Thus, any representation of the graph including nodes that represent the same set of cities is processed in a similar manner. Similar reordering may involve various node properties and/or edge properties, including (without limitation) an alphabetic ordering of names in a graph including nodes that represent people, a chronological ordering of dates in a graph including nodes that represent events, a numeric ordering of content-based hashcodes in a graph including nodes that represent objects, and/or a numeric ordering of identifiers in a graph including nodes that possess unique numeric identifiers. Other techniques for achieving, improving, and/or promoting permutation invariance involve transforming an input graph data set into a different, permutation-invariant

representation that is provided as input to and processed by the graph neural network. For example, a graph data set representing a two-dimensional image or a three-dimensional point cloud may include nodes that represent pixels and edges that represent spatial relationships (e.g., distances and/or orientations) between respective pairs of pixels of the image or respective pairs of points in the point cloud. Different orderings of the pixels and/or points may result in differently ordered, but logically equivalent, graph data sets for a particular image or point cloud. Instead of processing the graph data sets as input, a graph neural network may be configured to convert the input graph data set into a spectral representation, e.g., based on a spectral decomposition of a Laplacian L of the input graph data set. Instead of encoding information about individual pixels and/or points, the spectral representation instead encodes spectral components of the input graph data sets. The spectral components can be ordered in various ways (e.g., by frequency and/or polynomial order) to generate a permutation-invariant input vector, and the processing of the permutation-invariant input vector by a graph neural network may result in invariant (e.g., identical or at least similar) output of the graph neural network for various permutations of the input graph data set.

[3170] Alternatively or additionally, some techniques for achieving, improving, and/or promoting permutation invariance may relate to the structure of the graph neural network. For example, as an alternative or addition to reordering an input graph data set, a graph neural network may include one or more layers of neurons that process an input vector and generate permutation-invariant output. As one such example, a graph neural network may include a pooling layer that receives an input vector (e.g., an input vector corresponding to an input graph data set, and/or an input vector corresponding to an output of one or more previous layers of the graph neural network) and generates output that is pooled over the input, such as a minimum, maximum, or average of the units of the input. Because operations such as a minimum, maximum, and/or average over a data set are permutation-invariant mathematical operations, the graph neural network may therefore exhibit permutation-invariance of output based on the pooling operation for differently ordered but logically equivalent representations of a particular graph data set. As another such example, a graph neural network may include a filtering layer that receives an input vector (e.g., an input vector corresponding to an input graph data set, and/or an input vector corresponding to an output of one or more previous layers of the graph neural network) and generates output that is filtered based on certain permutation-invariant criteria. For example, in a graph representing a social network that includes nodes representing people, a layer of the graph neural network may filter the nodes to limit the input data set based on the top n nodes of the graph neural network that correspond to the most influential people in the social network. Such filtering may be based, e.g., on a count of the edges of each node (i.e., a count of the number of relationships of each person to other people of the social network), or a weighted calculation based on the influence of the nodes to which each node is related and/or the strength of each such relationship. Because such filtering operation are permutation-invariant logical operations, the graph neural network may therefore exhibit permutation-invariance of output based on the filtering operation for differently ordered but logically equivalent

representations of the nodes (i.e., people) and edges (i.e., relationships) of the social network. As yet another example, some graph neural networks include an encoding or "bottleneck" layer, in which an output from N neurons of a preceding layer is received as input and processed by a following layer that includes fewer than N neurons. Due to the smaller number of neurons in the following layer, the volume of data that encodes features of the output of the preceding layer is compressed into a smaller volume of data that encodes features of the output of the following layer. This compression of features, based on learned parameters and training of the graph neural network to produce expected outputs, can cause the graph neural network to encode only more significant features of the processed data, and to discard less significant features of the processed data. The reduced-size output of the neurons of the following layer can be referred to as a latent space encoding of the input feature set. For example, whereas an input graph data set may include nodes that correspond to all pixels of an image of a cat, and an output of a previous layer of the graph neural network may include partially processed information about each node (i.e., each pixel) of the image of the cat, the output of the following layer of the graph neural network may include only features that correspond to visually significant features of the cat (e.g., features that correspond to the pixels that represent the distinctively shaped ears, eyes, nose, and mouth of the cat). Thus, the latent space encoding may reduce the processed input of the graph data set into a smaller encoding of nodes that represent significant visual features of the graph data set, and may exclude data about nodes that do not represent significant visual features of the graph data set. Many such graph neural networks include one or more "bottleneck" layers as one or more autoencoder layers, e.g., layers that automatically learn to generate latent space encodings of input data sets. As one such example, deep generative models may be used to generate output graph data that corresponds to various data types (e.g., images, text, video, scene graphs, or the like) based on an encoding, including an autoencoding, of an input such as a prompt or a random seed, Additional techniques for achieving or promoting permeation-invariance are presented elsewhere in this disclosure and/or will be known to or appreciated by persons of ordinary skill in the art.

[3171] In some scenarios, a graph data set may include a large number of nodes and/or a large number of edges. For example, a graph data set representing a social network may include thousands of nodes that represent people and millions of edges that represent relationships among the people. The size of the graph data set may result in an input vector that is very large (e.g., a very long input vector), and that might require a correspondingly large graph neural network to process (e.g., a graph neural network featuring millions of weights that connect the input graph data set to the nodes of a first layer of the graph neural network). The size of the input data set may result in large and perhaps prohibitive computational resources to receive and/or process the graph data set (e.g., large and costly storage and/or processing to store the input graph data set and/or the parameters and/or hyperparameters of the graph neural network, and/or a protracted delay in completing the processing of an input graph data set by the graph neural network). Further, the graph data set may exhibit properties of sparsity that cause a large portion of the input data set to be inconsequential. For example, a graph data set representing a

social network may be encoded as a vector of N units respectively representing each node (i.e., each person) followed by a vector of NxN units that respectively represent a potential relationship between each node N1 and each node N2. Edges that represent a multidimensional mapping of connections between nodes (such as an NxN mapping of edges that represent possible connections between nodes) can be referred to as an adjacency matrix. However, in the social network, most person may have only a small number of relationships (i.e., far less than N-1 relationships with all other people of the social network). Thus, in the vector encoding of the input graph data set, a large majority of the NxN units that respectively represent potential relationships between each pair of nodes N1, N2 (i.e., the adjacency matrix) may be negative or empty (representing no relationship), and only a very small minority of the NxN units that respectively represent potential relationships between each pair of nodes N1, N2 may be positive or non-empty (representing a relationship). As another example, a graph data set representing a region may include N nodes representing cities and NxN edges representing possible roads between cities. However, if each city is only directly connected to a small number of neighboring cities, then a large majority of the NxN edges representing possible roads between cities (i.e., the adjacency matrix) may be negative or empty (representing no road connection), and only a very small minority of the NxN units that respectively represent potential roads between each pair of nodes N1, N2 may be positive or non-empty (representing an existing road). In such cases, the sparsity of an input vector representing the graph neural network may inefficiently consume computational resources (e.g., inefficiently applying storage and/or computation to large numbers of negative or empty units of the input vector) and/or may unproductively delay the completion of processing of the input graph data set.

[3172] Various techniques can be applied to reduce the sparsity of graph data sets and the processing of such graph data sets by graph neural networks. As a first example, the graph neural network can be pruned to reduce the number of nodes and/or edges included as an input data set (e.g., filtering the nodes of a graph neural network to a small cluster of densely related nodes, such as a small number of highly interrelated nodes that represent the members of a social circle in a social network). As a second example, the graph neural network can be encoded in a way that reduces sparsity. For example, rather than encoding the input graph data set as an adjacency matrix, the graph neural network may be configured to receive an encoding of the input graph data set as an adjacency list, i.e., as a list of edges that respectively connect two or more nodes of the graph. Due to encoding only information about existing edges, an adjacency list can eliminate or at least reduce the encoding of nonexistent edges. As a result, the size of the adjacency list may therefore be much smaller than a size of a corresponding adjacency matrix., and can therefore eliminate or at least reduce the sparsity of the input graph data set. The adjacency list can include edge properties of the edges of the graph data set. The adjacency list can be limited to a particular size (e.g., the top N most influential connections in a social network). The nodes of the input graph data set can be limited based on the edges included in the adjacency list (e.g., excluding any nodes that are not connected to at least one of the edges included in the adjacency list). As yet another example, rather than encoding an entire

set of nodes and edges, a graph neural network can be represented as an encoding of the nodes and edges. For example, a graph data set may include nodes that represent pixels of an image and edges that represent spatial representations of the pixels. However, if large areas of the image are inconsequential (e.g., dark, empty, or not associated with any notable objects in a segmented image), then large portions of the nodes and/or edges would be inconsequential. Instead, the image can be reencoded as a frequency-domain representation as coefficients associated with respective frequencies of visual features within the image. The frequency-domain representation may present greater information density than the adjacency matrix of pixels, and therefore may present an input to the graph neural network that encodes the visual features of the input graph data set with reduced sparsity.

[3173] Other techniques for eliminating or reducing sparsity, and therefore increasing efficiency, involve the architecture of the graph neural network. For example, the input graph data set may encode edges as an adjacency matrix, and a first layer of the graph neural network may reencode the edges of the input graph data set as an adjacency list for further processing by the graph neural network. As another example, the graph neural network may include a first one or more layers that is configured to process an entirety or at least a large portion of the nodes and/or edges of an input graph data set, followed by a filtering layer that is configured to limit an output of the first one or more layers of the graph neural network. For example, in a graph data set that includes nodes that represent people and edges that represent connections, a first one or more layers may process all of the nodes and/or edges, and a filtering layer can limit the further processing of the output of the first one or more layers to the nodes and/or edges for which the outputs of the first one or more layers are above a threshold (e.g., an influence and/or relationship significance threshold). As still another example, the graph neural network may receive a sparse graph input data set but may only process a portion of the input graph data set (e.g., one or more random sampling of subsets of nodes and/or edges). In some cases, the graph neural network may compare results of the processing of subsets of the input graph data set (e.g., randomly sampled subsets of the nodes and/or edges) and may aggregate such results until the results appear to converge within a confidence threshold. In this manner, the graph neural network may generate an acceptable output within the confidence threshold while avoiding processing an entirety of the sparse input graph data set. Many such techniques for eliminating and/or reducing sparsity are presented elsewhere in this disclosure and/or will be known to or appreciated by persons of ordinary skill in the art.

[3174] GRAPH NEURAL NETWORKS – INPUT, PROCESSING, AND OUTPUT

[3175] Graph data sets may represent a variety of data types, including (without limitation) maps of geographic regions, including nodes representing cities and edges representing roads that connect two or more cities; social networks, including nodes representing people and edges representing relationships between two or more people; communication networks, including nodes representing people or devices and edges representing communication connections between the nodes or edges; economies, including nodes representing companies and edges representing transactions between two or more companies; molecules, including nodes

representing atoms and edges representing bonds between two or more atoms; collections of events, including nodes representing individual events and edges representing causal relationships among two or more events; and periods of time, including nodes representing events and edges representing chronological periods among two or more events. Graph data sets may also be represent data types, such as passages of text, including nodes representing words and edges representing relationships among two or more words; images, including nodes representing pixels and edges representing spatial relationships among two or more pixels; object graphs, including nodes representing objects and edges representing dependencies among two or more objects; and three-dimensional spatial maps, including nodes representing three-dimensional objects and edges representing spatial relationships among two or more of the three-dimensional objects. Some graph data sets may include two or more subgraphs. In some such graph data sets, each node and/or each edge is exclusively included in one subgraph. In some other graph data sets, at least one node and/or at least one edge may be included in two or more subgraphs, or in zero subgraphs. Some graph data sets are associated with non-graph data that is also included as input to a graph neural network. For example, a graph neural network that evaluates traffic patterns within a geographic region may receive, as input, both an input graph data set that includes nodes that represent cities and edges that represent roads interconnecting the cities, and also non-graph data representing traffic and/or weather features within the geographic region (e.g., traffic volume estimates and current or forecasted weather conditions that affect the traffic patterns).

[3176] As another example, some graph data sets may include an indication of zero or more cycles occurring among the nodes and/or edges of the graph data set. For example, a directed and/or undirected graph data set may include an indication that a particular cycle exists within the graph and includes a particular subset of nodes and/or edges. Alternatively, a directed and/or undirected graph data set may include an indication that the graph is acyclic and does not include any cycles. A graph neural network may be configured to receive, as input, and process a graph data set that includes an indication of zero or more cycles.

[3177] As another example, some graph data sets may include nodes for which the edges provide spatial dimensions. As a first example, in a graph representing a geographic region, nodes that represent cities are related by edges that represent distances, wherein the nodes and interrelated edges can form a spatial map of the geographic region. As a second example, in a graph representing a molecule, nodes that represent atoms are related by edges that represent chemical bonds between the atoms, and the arrangement of atoms by the bonds forms a three-dimensional molecular structure. In some such scenarios, the spatial relationships are well-defined by the nodes and edges. In other such scenarios, the spatial relationships can be inferred based on semantic relationships among the nodes and/or edges of the graph data set. For example, in a graph representing a language, nodes that represent words are related by edges that represent semantic relatedness of the words within a high-dimensional language space. A language model can generate an embedding of the words of the language in a multidimensional embedding space, wherein nodes that are close together within the embedding space represent

synonyms, closely related concepts, or words that frequently appear together in certain contexts, whereas nodes that are not close together within the embedding space represent unrelated concepts or words that do not commonly appear together in various contexts. A variety of graph embedding models may be applied to this task, including (without limitation) DeepWalk, node2vec, line, and/or GraphSAGE. A graph neural network can be configured to receive, as input, an embedding of a graph data set instead of representations of the nodes and/or edges of the graph data set. Alternatively, a graph neural network can be configured to receive an input graph data set including representations of the nodes and/or edges of the graph data set, generate an embedding based on the input graph data set, and apply further processing to the embedding instead of to the input graph data set. A graph neural network that is configured to process an embedding instead of an input graph data set may exhibit greater permutation invariance (e.g., due to the semantic associations represented by the embedding) and/or increased efficiency due to reduced sparsity of the input.

[3178] Some graph data sets include representations of each of one or more nodes and each of one or more edges. Some graph neural networks are configured to receive and process such representations of graph neural networks. For example, the graph neural network may be configured to receive an input vector including an array of data representing each of the one or more nodes followed by an array of data representing each of the one or more edges, either as an adjacency matrix of possible edges between pairs of nodes or an adjacency list of existing edges. The input vector may encode the nodes and/or edges in a particular order (e.g., a priority order of nodes and/or a weight order of edges) or in an unordered manner. Alternatively or additionally, the graph data set may include and/or encode other types of information about each of one or more nodes and/or each of one or more edges of the graph data set. For example, the graph may include a hierarchical organization of nodes and/or edges relative to one another and/or to a fixed reference point. The graph neural network may be configured to receive and process an input graph data set that includes an indication of the arrangement of one or more nodes and/or one or more edges in the hierarchical organization.

[3179] As another example, a graph may include an indication of a centrality of one or more nodes and/or edges within the graph (e.g., a graph of a social network including nodes that are ranked based on a centrality of each node to a cluster). The graph neural network may be configured to receive and process an input graph data set that includes an indication of a centrality of one or more nodes and/or one or more edges in the graph.

[3180] As another example, a graph may include an indication of a degree of connectivity of one or more nodes and/or edges within the graph (e.g., a graph of a social network including nodes that are ranked according to a count of other nodes to which each node is connected by one or more edges, and/or a degree of significance of a relationship represented by an edge based on the nature of the relationship and/or the degrees of the nodes connected by the edge). The graph neural network may be configured to receive and process an input graph data set that includes an indication of a degree of one or more nodes and/or one or more edges in the graph.

[3181] As another example, a graph may include an indication of one or more clusters occurring within the graph. For example, a graph may include a result of a clustering analysis of the graph, e.g., a determination of k clusters within the graph and an identification of the nodes and/or edges that are included in each cluster. The clusters may be determined by a k-means clustering analysis, a Gaussian mixture model of with variable numbers of clusters and variable Gaussian orders, or the like. A graph may include a clustering coefficient of one or more nodes and/or one or more edges (e.g., a measurement of a degree to which at least some of the nodes and/or edges of a subgraph of the graph are clustered based on similarity and/or activity). The graph neural network may be configured to receive and process an input graph data set that includes an indication of a clustering coefficient of one or more nodes and/or one or more edges in the graph or a subgraph thereof.

[3182] As another example, a graph may include an indication of a graphlet degree vector that indicates a graphlet that is represented one or more times in the graph. For example, in a graph representing atoms in a regular structure such as a crystal, the graph may include a graphlet degree vector that indicates and/or describes a graphlet representing a recurring atomic structure, and an encoding of the regular structure that indicates each of one or more occurrences of a graphlet, including a location and/or orientation, and/or a count of occurrences of the graphlet. The graph neural network may be configured to receive and process an input graph data set that includes a graphlet degree vector, and, optionally, features of one or more occurrences of a graphlet in the graph and/or a count of the occurrences of the graphlet in the graph.

[3183] As another example, a graph may include an indication of one or more paths and/or traversals of one or more nodes and/or one or more edges of the graph, optionally including additional details associated with a path or traversal such as a popularity, frequency, length, difficulty, cost, or the like. For example, in a graph representing a spatial arrangement of nodes, the graph may include a path or traversal of edges that connect a first node to a second node through zero or more other nodes, as well as properties of the path or traversal such as a total length, distance, time, and/or cost. The graph neural network may be configured to receive and process an input graph data set that includes additional details associated with one or more paths or traversals, including an indication (e.g., a list) of the associated nodes and/or edges and a list of one or more properties of the path and/or traversal.

[3184] As another example, a graph may include an indication of metrics or properties that relate one or more nodes and/or one or more edges. For example, in a graph including a spatial arrangement of nodes, the graph may include an indication of a shortest distance between two nodes and/or an indication of a set of nodes and/or edges that are common to two nodes. As another example, a graph representing a network of communicating devices may include a routing table of one or more routes that respectively indicate, for a particular node and a particular edge connected to the node, a list of other nodes and/or edges that can be efficiently reached by traversing based on the particular edge. As yet another example, in a graph representing a social network including nodes that represent people, the graph may indicate, for at least one pair of nodes, a measurement of similarity of the nodes based on their node

properties, edges, locations in the social network, connections to other nodes, or the like (e.g., a Katz index of node similarity) and/or, for at least one pair of edges, a measurement of similarity of the edges based on their edge properties, connected nodes, locations in the social network, or the like (e.g., a Katz index of edge similarity). The graph neural network may be configured to receive and process an input graph data set that includes one or more metrics or properties that relate one or more nodes and/or one or more edges (e.g., a routing table of routes within the graph, and/or a Katz index that indicates a measurement of similarity among at least two nodes and/or at least two edges).

[3185] As another example, a graph may include an indication of various graph properties of the graph (e.g., a graph size, graph density, graph interconnectivity, graph chronological period, graph classification, a count of subgraphs within the graph, or the like). For example, in a graph including two or more subgraphs (e.g., a social network including two or more social circles), the graph data set may include a measurement of a similarity of each subset of at least two subgraphs of the graph. The measurement of the similarity may be determined based on one or more graph kernel methods (e.g., a Gaussian radial basis function that can be applied to the graph to identify one or more clusters of similar nodes that comprise a subgraph). As another example, a graph may include a measurement of similarity with respect to another graph (e.g., an indication of whether a particular social network graph resembles other social network graphs that have been classified as representing a genealogy or lineage, a set of friendships, and/or a set of professional relationships). The graph neural network may be configured to receive and process an input graph data set that includes measurements determined by one or more graph properties (e.g., one or more measurements of similarity of one or more nodes, edges, and/or subgraphs, and/or a measurement of similarity of the graph to other graphs). Further explanation and/or examples of various graph data sets that may be provided as input to graph neural networks are presented elsewhere in this disclosure and/or will be known to or appreciated by persons of ordinary skill in the art.

[3186] Graph neural networks may be configured to perform various types of processing over such graph data sets. As previously discussed, a graph neural network can be organized as a series of layers, each of which can include one or more nodes that receive input, apply an activation function, and generate output. The output of each node of a first layer can be multiplied by a weight of a connection between the node and a node of a second layer, and then added to a bias associated with the first layer, to generate an input to the node of the second layer. The graph neural network can include various additional layers that perform other types of processing, including (without limitation) pooling, filtering, and/or latent space encoding operations, memory or stateful features, and recurrent and/or reentrant processing.

[3187] Some graph neural networks may perform label propagation among the nodes and/or edges of a graph data set. For example, in an input graph data set, one or more nodes and/or one or more edges may be associated with one or more labels of a label set, while one or more other nodes and/or one or more other edges may not be associated with any labels. A graph neural network may apply a label propagation algorithm (LPA) to assign labels to one or more

unlabeled nodes and/or one or more unlabeled edges. For example, the graph neural network may assign a label to an unlabeled node based on labels associated with one or more edges connected to the node, and/or with one or more other nodes that are connected to the node by the one or more edges. The graph neural network may assign a label to an unlabeled edge based on labels associated with one or more nodes connected by the edge, and/or with one or more other edges that are also connected to the nodes connected by the edge. Some graph neural networks may perform label propagation based on a voting, consensus, weighting, and/or scoring determination. For example, a graph neural network may be unable to perform a classification of an unlabeled node and/or unlabeled edge based solely on the node properties and/or edge properties, but may be able to perform the classification based on a further consideration of the labels associated with other nodes and/or edges within a neighborhood of the unlabeled node and/or unlabeled edge.

[3188] Some graph neural sets may perform a scoring and/or ranking of nodes and/or edges of a graph data set. As an example, in a graph data set that represents the World Wide Web and that includes nodes that represent web pages and directed edges that represent hyperlinks of linking web pages to linked web pages, a graph neural network may determine one or more scores of each node (i.e., each web page) based on the scores of other nodes that hyperlink to the node. Each score may further be based on the scores of the other nodes that include a directed edge to this node (e.g., the scores of other web pages that hyperlink to this page). Additionally, each score associated with a node may represent a weight of an association between the web page and a particular topic (e.g., a particular topic or keyword that is associated with the web page, hyperlinks, and/or other pages that hyperlink to this web page). In some cases, the scores may be personalized based on the activities of a particular user (e.g., based on the hyperlinks from pages that the user frequently visits). A search engine may use the scores as rankings in order to generate search results for web searches including various topics or keywords (e.g., in response to a web search for a particular search term, present search results that correspond to the nodes with the highest scores associated with the search term, and present the search results in ranked order based on the scores). As another example, for a graph data set representing a social network, a graph neural network may generate a reputation score for each node based on other nodes that are associated with the node and the reputation scores of such other nodes. The scores of the nodes may be used to recommend new connections in the social network (e.g., recommending a first person connect with a second person, based on a high reputation score of the second person by people who are closely associated with the first person).

[3189] Some graph neural networks may perform a clustering analysis of the nodes and/or edges of a graph data set. As a first example, in a graph data set representing a social network, a graph neural network may perform a clustering analysis of the nodes representing the people of the social network, based on edges representing relationships among two or more nodes, in order to identify one or more clusters that represent social circles of highly interconnected people within the social network. Based on this clustering analysis, the graph neural network may partition the social network into subgraphs that respectively represent social circles, and may

perform further, finer-grained evaluation of each social circle and the people represented by the nodes in each subgraph. As a second example, in a graph data set representing a social network, a graph neural network may perform a clustering analysis of the edges representing the relationships among people of the social network, in order to identify one or more clusters that represent different types of relationships, such as familial relationships, friendships, and professional relationships. Based on this clustering analysis, the graph neural network may partition the social network into subgraphs that respectively represent different types of social networks, and may perform further analysis of relationships among two or more individuals based on the type of relationship associated with the subgraph to which the relationship belongs. In these and other scenarios, in order to perform clustering analysis, a graph neural network may utilize a variety of clustering algorithms. As one such example, a graph neural network may apply spectral clustering techniques, wherein a similarity matrix that represents similarities among nodes and/or edges is evaluated to identify eigenvalues that indicate significant similarity relationships. Based on the similarity matrix, the graph neural network may perform a dimensionality reduction of the graph data set (e.g., reducing the features of the nodes and/or edges that are evaluated to determine clusters in order to focus on features that are highly correlated with and/or indicative of significant similarities). Dimensionality reduction of the graph data set based on the similarity matrix may enable the graph neural network to determine clusters more efficiently and/or rapidly, e.g., by reducing a high-dimensionality graph data set (wherein each node and/or edge is characterized by a multitude of node properties and/or edge properties) into a lower-dimensionality graph data set of a subset of features that are highly correlated with and/or indicative of similarity and clustering.

[3190] Some graph neural networks may perform a centrality determination among nodes and/or edges of a graph data set. For example, for a graph data set representing a social network, a graph neural network may evaluate the graph data set to identify a subset of nodes based on a centrality among the edges representing the connections of the social network, e.g., people who are at the center of each of one or more social circles within the social network. Alternatively or additionally, some graph neural networks may perform a "betweenness" determination among the nodes and/or edges of the graph data set. For example, a node may be considered to be "between" two clusters of nodes, such as a member of two or more clusters representing two or more social circles. Such "between" nodes may represent a communication bridge that conducts information between clusters (e.g., a person who can convey ideas and/or influence from a first social circle to a second social circle and vice versa). Some such graph neural networks may perform "betweenness" determinations based on a betweenness centrality measurement, e.g., based on a measurement of a shortest path between all pairs of nodes in the graph data set. As another example, a graph data set may represent a collection of text documents, wherein each node represents a document and each edge represents a relationship between documents (e.g., a unidirectional or bidirectional citation between a first document and a second document). A graph neural network can perform a centrality determination and/or a betweenness determination to determine significant documents within the collection (e.g., a document that is heavily cited

by one or more clusters of other documents, and/or a document that includes ideas or associations between the documents of a first cluster and the documents of a second cluster).

[3191] Some graph neural networks may perform analyses of structures occurring within a graph neural network. As an example, for a graph data set that represents a social network, a graph neural network may determine a notable sequence of relationships, such as a first relationship between node N1 and node N2 based on a shared interest, a second relationship between node N2 and node N3 based on the same shared interest, and a third relationship between node N3 and node N4 based on the same shared interest. Based on this sequence or chain of relationships, the graph neural network may recommend to a person represented by node N1 some further relationships with the people represented by nodes N3 and N4, due to the combination of shared interests and mutual relationships. In some such cases, a graph neural network may perform such structural analysis based on a traversal algorithm that traverses a sequence of nodes connected by one or more edges, and/or that traverses a sequence of edges connected by one or more nodes. As an example, a graph neural network may perform a random walk within the graph data set, such as starting with a first node (e.g., a first person of a social network) and following a limited set of edges that connect the first node to other nodes. In some cases, the traversal may be random (e.g., traversing from a node based on a random selection among the edges that connect the node to other nodes). In some other cases, the traversal may be weighted (e.g., each edge may include an edge property including a weight that represents a strength of a relationship among two or more nodes, and the traversal may be based on a weighted random selection that preferentially selects higher-weighted connections over lower-weighted connections). In some cases, the traversal can include a restart probability, e.g., a probability of retrying the traversal beginning with the original node or another node, based on a score such as a distance of the traversal with respect to the original node. In these and other cases, the results of a random walk can be used in further analyses and/or activities of the graph neural network (e.g., presenting recommendations for new social connections among the nodes of a social network).

[3192] Some graph neural networks may perform an analysis of a graph data set based on an attention model. For example, in a social network, the influence of a particular person P1 may not be determined by the connectedness of person P1 to other people in the social network, but based on a perception of person P1 by other people of the social network as being knowledgeable, skilled, influential, or the like. Thus, a graph neural network may be configured to evaluate a graph data set representing a social network in which nodes represent people and edges represent relationships, but may be unable to determine influence based only on graph concepts such as connectedness of the nodes based on the edges. Rather, the graph neural network might model influence as an attention of each node (i.e., a second person P2 of the social network) upon each other node (e.g., person P1 of the social network). Thus, a particular opinion of person P2 of the social network may depend not only on the connections of person P2 to other people of the social network (including person P1), but also upon the attention that person P2 accords to such other people of the social network (including person P1). That is,

even though person P2 is closely connected to certain people of the social network by various edges, the opinion of person P2 may be heavily shaped by person P1 and other people to whom person P2 is only indirectly connected in the social network. As a second such example, in a graph data set that represents traffic flow within a region, an edge E1 (e.g., a first road) may be directly connected to other edges of the graph data set, but an edge property of the edge E1 (e.g., a traffic volume and/or congestion of the road) may be impacted more heavily by edge properties of other edges to which edge E1 is not directly connected (e.g., roads in other parts of the geographic region for which traffic volume and/or congestion is highly determinative of the traffic volume and/or congestion of this road). Thus, in order to predict and/or estimate a traffic volume and/or congestion of a particular road, a graph neural network may evaluate not only the traffic volume and/or congestion of other roads that are directly connected to the particular road, but also other roads for which traffic volume and/or congestion is highly determinative of corresponding conditions of this road. In these and other scenarios, a graph neural network may evaluate a graph data set based on an attention model, in which analyses and updates of the state of nodes and/or edges of the graph data set are based, at least in part, on an attention of each node and/or edge upon other nodes and/or edges of the graph data set. For example, the graph neural network may include an attention layer that determines, for a particular node and/or edge of an input graph data set, which other nodes and/or edges of the input graph data set are likely to be relevant to determining an updated state of the particular node and/or edge. Various attention models may be used by such graph neural networks, including multi-head attention models in which each node and/or edge is related to a plurality of other nodes and/or other edges with varying weighted attention values (e.g., by each of a plurality of attention layers). Multi-head attention models can allow a graph neural network to consider the influences upon a particular node and/or edge of a plurality of other nodes and/or edges, which may (or may not) be further related to one another by the graph structure and/or attention. Based on the attention model and the attention layers included in the graph neural network, the graph neural network can perform a more sophisticated graph analysis that is based on more than the structural relationships of the graph.

[3193] Some graph neural networks may be configured to process a graph data set in order to determine, and optionally output, various types of data (e.g., measurements, calculations, inferences, explanations, or the like) that relate to one or more nodes, one or more edges, and/or one or more subgraphs of the input graph data set and/or to the input data graph set as a whole. Some graph neural networks are configured to generate, and optionally output, various types of representations of graph neural networks. For example, the graph neural network may be configured to determine, and optionally output, an output vector including an array of data representing each of the one or more nodes followed by an array of data representing each of the one or more edges, either as an adjacency matrix of possible edges between pairs of nodes or an adjacency list of existing edges. The output vector may encode the nodes and/or edges in a particular order (e.g., a priority order of nodes and/or a weight order of edges, or corresponding to a corresponding order of the nodes and/or edges in the input graph data set) or in an

unordered manner. Alternatively or additionally, the graph neural network may be configured to determine, and optionally output, other types of information about each of one or more nodes and/or each of one or more edges of the graph data set. For example, the graph neural network may be configured to determine, and optionally output, a hierarchical organization of nodes and/or edges relative to one another and/or to a fixed reference point. Alternatively or additionally, the graph neural network may be configured to determine, and optionally output, an output graph data set that includes an indication of the arrangement of one or more nodes and/or one or more edges in the hierarchical organization.

[3194] As another example, a graph neural network may be configured to determine, and optionally output, an indication of a centrality of one or more nodes and/or edges within the input graph data set (e.g., a graph of a social network including nodes that are ranked based on a centrality of each node to a cluster). Alternatively or additionally, the graph neural network may be configured to determine, and optionally output, an output graph data set that includes an indication of a centrality of one or more nodes and/or one or more edges in the graph.

[3195] As another example, a graph neural network may be configured to determine, and optionally output, an indication of a degree of connectivity of one or more nodes and/or edges of an input graph data set (e.g., a graph of a social network including nodes that are ranked according to a count of other nodes to which each node is connected by one or more edges, and/or a degree of significance of a relationship represented by an edge based on the nature of the relationship and/or the degrees of the nodes connected by the edge). Alternatively or additionally, the graph neural network may be configured to determine, and optionally output, an output graph data set that includes an indication of a degree of one or more nodes and/or one or more edges in the output graph data set.

[3196] As another example, a graph neural network may be configured to detect, identify, and/or analyze one or more clusters occurring within an input graph data set. For example, a graph neural network may be configured to perform a clustering analysis of an input graph data set to determine, and optionally output, a determination of k clusters within the input graph data set and an identification of the nodes and/or edges that are included in each cluster. The graph neural network may be configured to determine clusters based on a k-means clustering analysis, a Gaussian mixture model of with variable numbers of clusters and variable Gaussian orders, or the like. The graph neural network may be configured to determine, and optionally output, an indication of a clustering coefficient of one or more nodes and/or one or more edges of an input graph data set (e.g., a measurement of a degree to which at least some of the nodes and/or edges of a subgraph of the graph are clustered based on similarity and/or activity). Alternatively or additionally, the graph neural network may be configured to determine, and optionally output, an output graph data set that includes an indication of one or more clusters including one or more nodes and/or one or more edges in the output graph data set or a subgraph thereof (e.g., a result of a k¬-means clustering analysis of an output graph data set, a Gaussian mixture model of an output graph data set, and/or one or more clustering coefficients of an output graph data set).

[3197] As another example, a graph neural network may be configured to determine, and optionally output, an indication of a graphlet degree vector that indicates a graphlet that is represented one or more times in an input graph data set. For example, for a graph representing atoms in a regular structure such as a crystal, the graph neural network may be configured to determine, and optionally output, a graphlet degree vector that indicates and/or describes a graphlet representing a recurring atomic structure, and an encoding of the regular structure that indicates each of one or more occurrences of a graphlet, including a location and/or orientation, and/or a count of occurrences of the graphlet in the input graph data set. Alternatively or additionally, the graph neural network may be configured to determine, and optionally output, an output graph data set that includes a graphlet degree vector, and, optionally, features of one or more occurrences of a graphlet in the output graph data set and/or a count of the occurrences of the graphlet in the output graph data set.

[3198] As another example, a graph neural network may be configured to determine, and optionally output, an indication of one or more paths and/or traversals of one or more nodes and/or one or more edges of the input graph data set, optionally including additional details associated with a path or traversal such as a popularity, frequency, length, difficulty, cost, or the like. For example, for an input graph data set representing a spatial arrangement of nodes, the graph neural network may be configured to determine, and optionally output, a path or traversal of edges that connect a first node to a second node through zero or more other nodes of the input graph data set, as well as properties of the path or traversal such as a total length, distance, time, and/or cost. Alternatively or additionally, the graph neural network may be configured to determine, and optionally output, an output graph data set that includes additional details associated with one or more paths or traversals, including an indication (e.g., a list) of the associated nodes and/or edges of the output graph data set and a list of one or more properties of each such path and/or traversal.

[3199] As another example, a graph neural network may be configured to determine, and optionally output, an indication of metrics or properties that relate one or more nodes and/or one or more edges of an input graph data set. For example, for an input graph data set including a spatial arrangement of nodes, the graph neural network may be configured to determine, and optionally output, an indication of a shortest distance between two nodes and/or an indication of a set of nodes and/or edges that are common to two nodes of the input graph data set. As another example, for an input graph data set representing a network of communicating devices, the graph neural network may be configured to determine, and optionally output, a routing table of one or more routes that respectively indicate, for a particular node of the input graph data set and a particular edge connected to the node, a list of other nodes and/or edges of the input graph data set that can be efficiently reached by traversing based on the particular edge. As yet another example, for an input graph data set representing a social network including nodes that represent people, the graph neural network may be configured to determine, and optionally output, an indication for at least one pair of nodes of a measurement of similarity of the nodes of the input graph data set based on their node properties, edges, locations in the social network, connections

to other nodes, or the like (e.g., a Katz index of node similarity) and/or, for at least one pair of edges of the input graph data set, a measurement of similarity of the edges based on their edge properties, connected nodes, locations in the social network, or the like (e.g., a Katz index of edge similarity). Alternatively or additionally, the graph neural network may be configured to determine, and optionally output, an output graph data set that includes one or more metrics or properties that relate one or more nodes and/or one or more edges (e.g., a routing table of routes within the graph, and/or a Katz index that indicates a measurement of similarity among at least two nodes and/or at least two edges).

[3200] As another example, a graph neural network may be configured to determine, and optionally output, an indication of various graph properties of an input graph data set (e.g., a graph size, graph density, graph interconnectivity, graph chronological period, graph classification, a count of subgraphs within the graph, or the like). For example, for an input graph data set including two or more subgraphs (e.g., a social network including two or more social circles), the graph neural network may be configured to determine, and optionally output, a measurement of a similarity of each subset of at least two subgraphs of the input graph data set. The measurement of the similarity may be determined based on one or more graph kernel methods (e.g., a Gaussian radial basis function that can be applied to the input graph data set to identify one or more clusters of similar nodes that comprise a subgraph). As another example, a graph neural network may be configured to determine, and optionally output, a measurement of similarity of an input graph data set with respect to another graph data set (e.g., an indication of whether a particular social network graph resembles other social network graphs that have been classified as representing a genealogy or lineage, a set of friendships, and/or a set of professional relationships). Alternatively or additionally, the graph neural network may be configured to determine, and optionally output, an output graph data set that includes measurements determined by one or more graph properties of an output graph data set (e.g., one or more measurements of similarity of one or more nodes, edges, and/or subgraphs, and/or a measurement of similarity of the output graph data set to the input graph data set and/or other graph data sets). Further explanation and/or examples of various types of processing that graph neural networks can determine, and optionally output, for various input graph data sets and/or output graph data sets are presented elsewhere in this disclosure and/or will be known to or appreciated by persons of ordinary skill in the art.

[3201] Graph neural networks may be configured to generate various forms of output that correspond to various tasks. For example, graph neural networks can generate output that represents node-level predictions that relate to one or more nodes of an input graph data set. The node-level predictions can include a discovery of a new node that was not included in the input graph data set. For example, in a graph data set including edges that represent travel of individuals in a region, the nodes can represent points of interest, and the graph neural network can discover a new node that corresponds to a new point of interest. The node-level predictions can include an exclusion of a node that is included in the input graph data set. For example, in a graph data set including edges that represent travel of individuals in a region, the nodes can

represent points of interest, and the graph neural network can exclude an existing node that no longer represents a point of interest. The node-level predictions can include a classification of a node that is included in the input graph data set, or of a newly discovered node that was not included in the input graph data set (e.g., a classification of the node as being of a node type selected from a set of node types, as being associated with one or more labels of a classification label set, and/or as belonging to zero or more subgraphs of the graph data set). For example, in a graph data set representing locations within a geographic region, the graph neural network can generate a prediction of a classification of a location of interest as one or more particular types of locations of interest (e.g., a source of food, a source of fuel, a lodging location, and/or a tourist destination). The node-level predictions can include an identification of a node from among the nodes of the input graph data set based on various features, or of a newly discovered node. For example, in a graph data set representing a social network and including nodes that represent people, the graph neural network can identify a particular node that corresponds to a particular person, such as an influential person of the social network. The node-level predictions can include a determination and/or updating of one or more node properties of one or more existing and/or newly discovered nodes, such as a prediction of a demographic feature, opinion, or interest of a node representing a person in a social network.

[3202] As another example, graph neural networks can generate output that represents edge-level predictions that relate to one or more edges of an input graph data set. The edge-level predictions can include a discovery of a new edge that was not included in the input graph data set. For example, in a graph data set representing a social network that includes nodes that represent people, a graph neural network can output a prediction (e.g., a recommendation) of a relationship between two nodes that correspond to two people in a small social circle of highly interconnected people. The node-level predictions can include an exclusion of a node that is included in the input graph data set. For example, in a graph data set representing a social network that includes nodes that represent people, a graph neural network can output a prediction of a no-longer-existing edge that corresponds to a relationship that no longer exists (e.g., a lost connection based on a splitting of a social circle). The edge-level predictions can include a classification of an edge that is included in the input graph data set, or of a newly discovered edge that was not included in the input graph data set (e.g., a classification of an edge as being a of an edge type selected from a set of edge types, as being associated with one or more labels of a classification label set, and/or as belonging to zero or more subgraphs of the graph data set). For example, in a graph data set representing a social network, a graph neural network can generate a predicted classification of an edge as representing a relationship between two people as of one or more relationship types (e.g., a familial relationship, a friendship, or a professional relationship). The edge-level predictions can include an identification of an edge from among the edges of the input graph data set based on various features, or of a newly discovered edge. For example, in a graph data set representing a social network and including edges that represent relationships, the graph neural network can identify a particular edge that corresponds to a potential relationship to be recommended to the associated people, such as two

people of the social network who are not yet connected but who share common personal or professional interests. The edge-level predictions can include a determination and/or updating of one or more edge properties of one or more existing and/or newly discovered edges, such as a prediction of a demographic feature, opinion, or interest that serves as the basis for a relationship between two people of the social network.

[3203] As another example, graph neural networks can generate output that represents graph-level predictions that relate to one or more graph properties of the input graph data set. The graph-level predictions can include a discovery of a new graph property that was not associated with the input graph data set. For example, in a graph data set representing a social network that includes nodes that represent people and edges that represent relationships, a graph neural network can output a prediction of a demographic trait, opinion, or interest that is common or popular among the people of the social network, or a relationship behavior that is exhibited in the relationships among the people of the social network. The graph-level predictions can include an exclusion of a graph property that was associated with the input graph data set. For example, in a graph data set representing a social network that includes a graph property based on a shared interest, a graph neural network can output a prediction that the interest no longer appears to be common and/or popular among the people of the social network, or of a relationship behavior that is no longer exhibited among the relationships of the people of the social network. The graph-level predictions can include a classification of the input graph data set (e.g., a classification of the graph data set, or at least a portion thereof, as being associated with one or more labels of a classification label set). For example, in a graph data set representing a social network, a graph neural network can generate a predicted classification of the graph as representing a familial social network, a friendship social network, and/or a professional social network. The graph-level predictions can include an identification of one or more subgraphs of the graph based on common features of the nodes and/or edges included in the subgraph. For example, in a graph data set representing a social network, the graph neural network can subgraphs that correspond to various social circles of highly interconnected people. The graph-level predictions can include a determination and/or updating of one or more graph properties of the graph, such as an updating of a frequency of communication and/or a strength of relationships among the people of a social network.

[3204] As another example, graph neural networks can perform graph-to-graph translation by receiving an input graph data set and generating output that represents a different graph data set. For example, a graph neural network can receive an input graph data set and can generate an output graph data set that includes one or more newly discovered nodes and/or edges; an exclusion of one or more nodes and/or edges; a classification of one or more nodes and/or edges; an identification of one or more nodes and/or edges; and/or an update of one or more node properties, edge properties, and/or graph properties. A graph neural network can receive an input graph data set and can generate an output graph data set that shares various similarities with the input graph data set. For example, a graph neural network can receive, as input, a first graph representing a first geographic region (e.g., a real geographic region) and can generate, as

output, a first graph representing a different geographic region (e.g., a fictitious geographic region) that shares similarities with the first graph and that has some dissimilarities with respect to the first graph. A graph neural network can receive, as input, an input graph data set and can generate, as output, a subgraph of the input graph data set. A graph neural network can receive, as input, an input graph data set and can generate, as output, an expanded graph including a first subgraph corresponding to the input graph data set and a second subgraph that is newly generated. A graph neural network can receive, as input, a first graph that corresponds to a first time and can generate, as output, a second graph that corresponds to a different time than the first time. For example, the graph neural network can receive, as input, a graph data set that corresponds to a state of a geographic region at a current time, and can generate, as output, a graph data set that predicts the state of the geographic region at a past time or a future time.

[3205] As another example, graph neural networks can generate graphs from non-graph input data. For example, a graph neural network can receive, as input, locations of travelers within a geographic region over a period of time, and can generate, as output, graph data that includes one or more nodes that represent points of interest among the travelers and edges that represent paths between the points of interest (e.g., roads that connect the points of interest). As another example, a graph neural network can receive, as input, a description of a graph (e.g., a natural-language description of a geographic location) and can generate, as output, graph data that corresponds to the description of the graph (e.g., a graph of a region that includes one or more nodes representing locations and one or more edges representing roads that interconnect the locations). The graph neural network may receive both graph data and non-graph data (e.g., a graph representing a social network and an indication of a particular person in the social network) and can generate, as output, graph data based on the input (e.g., a subgraph of the people who consider the identified person to be influential).

[3206] As another example, graph neural networks can receive an input graph data set and can generate, as output, non-graph data. For example, a graph neural network can receive, as input, a graph representing a social network including nodes that represent people and edges that represent relationships, and can generate, as output, one or more metrics of the social network (e.g., an average number of connections among the people of the social network, an identification of a person of high influence within the social network, or a description of a relationship behavior that commonly occurs within the social network). As another example, a graph neural network can receive, as input, a graph representing a geographic region including nodes that represent locations and edges that represent roads connecting the locations, and can generate, as output, one or more predictions and/or measurements of traffic within the geographic region. The graph neural network may receive both graph data and non-graph data (e.g., a graph representing a social network and an indication of a particular person in the social network) and can generate, as output, non-graph data based on the input (e.g., a summary and/or prediction of the social behaviors of the identified person). For example, a graph neural network that evaluates traffic patterns within a geographic region may process, and optionally output, both an output graph data set that includes nodes that represent cities and edges that represent

roads interconnecting the cities, and also non-graph output data representing predictions and/or inferences of traffic and/or weather features within the geographic region (e.g., traffic volume estimates and current or forecasted weather conditions that affect the traffic patterns).

[3207] As another example, some graph neural networks may be configured to determine, and optionally output, an indication of zero or more cycles occurring among the nodes and/or edges of an input graph data set. For example, for a directed and/or undirected input graph data set, a graph neural network may determine, and optionally output, an indication that a particular cycle exists within the input graph data set and includes a particular subset of nodes and/or edges. Alternatively, for a directed and/or undirected graph data set, a graph neural network may determine, and optionally output, an indication that the graph is acyclic and does not include any cycles. A graph neural network may be configured to determine, and optionally output, an output graph data set that includes an indication of zero or more cycles.

[3208] As another example, graph neural networks can receive an input graph data set and can generate, as output, an interpretation and/or explanation of the input graph data set. For example, a graph neural network can receive, as input, a graph representing a collection of devices, including nodes that respectively represent a device and edges that respectively represent an instance of communication and/or interaction among two or more devices. The graph neural network can generate, as output, an interpretation and/or explanation of the communications and/or interactions represented in the graph, such as an explanation of a set of interactions as being part of a collective and/or collaborative effort among the two or more devices and/or a related series of interactions that are associated with a particular activity. The explanation and/or interpretation may include, for example, a classification of one or more nodes, edges, patterns of activity, and/or the graph; a natural-language summary or narrative explanation of one or more nodes, edges, patterns of activity, and/or the graph; a data set that characterizes one or more nodes, edges, patterns of activity, and/or the graph; and/or a presentation (e.g., a static or motion visualization) of one or more nodes, edges, patterns of activity, and/or the graph. As one such example, a graph neural network may identify, within an input graph data set, one or more subgraphs (e.g., one or more clusters of related nodes and/or edges), and may output an interpretation and/or explanation of the subgraph (e.g., a description of the set of features that characterize the subgraph or cluster). As another example, a graph neural network may generate a visualization of a subgraph of an input graph data set, wherein the visualization depicts, highlights, and/or illustrates a structure and/or an anomalous feature of the subgraph. Some such graph neural networks may be configured to generate interpretations and/or explanations of any input graph data set, e.g., based on an identification of features of an input data set that inform such interpretations and/or explanations, such as clusters, outliers, or determinations of apparent structure and/or data relationships. Other such graph neural networks may be configured to generate domain-specific interpretations and/or explanations of domain-specific graph data sets. For example, a graph neural network may be configured to analyze a graph data set representing a social network identify both a subset of the social network corresponding to an influential cluster of people of the social network and also an interpretation and/or explanation of why this

cluster of people appears to be influential within the social network. Graph neural networks can generate interpretations and/or explanations using a variety of techniques, including "white-box" analysis techniques that can be applied to various properties of graph data sets and components thereof. Examples of graph neural networks that include instance-level explanations based on gradients and/or features include, without limitation, Guided BP, class activation mapping (CAM), and GradCAM. Examples of graph neural networks that include instance-level explanations based on perturbations include, without limitation, GNNExplainer, PGExplainer, ZORRO, and Graphmask. Examples of graph neural networks that include instance-level explanations based on decomposition include, without limitation, layer-wise relevance propagation (LRP), Excitation BP, and GNN LRP. Examples of graph neural networks that include instance-level explanations based on surrogate analysis include, without limitation, GraphLIME, RelEX, and PGMExplainer. Examples of graph neural networks that include model-level explanations include XGNN. Further explanation and/or examples of various interpretable and/or explainable features of graph data sets or components thereof that may be generated by graph neural networks are presented elsewhere in this disclosure and/or will be known to or appreciated by persons of ordinary skill in the art.

[3209] GRAPH NEURAL NETWORKS – ARCHITECTURES AND FRAMEWORKS

[3210] Graph neural networks may be designed and/or organized according to various architectures. For example, a multilayer graph neural network may include a number of layers, each layer including a number of neurons. In each layer of the graph neural network, the neurons may be configured to receive, as input, at least a portion of an input data set (e.g., an input graph data set) and/or at least a portion of an output of at least one neuron of one or more layers of the graph neural network. Additionally, in each layer of the graph neural network, the neurons may be configured to generate, as output, at least a portion of an output data set of the graph neural network (e.g., an output graph data set of graph neural network) and/or at least a portion of an input to at least one neuron of one or more layers of the graph neural network.

[3211] In some graph neural networks, an architecture of the graph neural network is based on the input to the graph neural network. For example, a fixed-size graph of N nodes and E edges interconnecting the nodes may be received and processed by a graph neural network that includes an input layer featuring N neurons respectively configured to receive input from one of the N nodes and/or E neurons respectively configured to receive input from one of the E edges. A graph including an adjacency list having a maximum of E edges may be received and processed by a graph neural network that includes an input layer featuring E neurons respectively configured to receive and process one of the E edges represented in the adjacency list. A graph including two subgraphs may be received and processed by a graph neural network that includes an input layer featuring a first set of neurons that are configured to process the nodes and/or edges of the first subgraph and a second set of neurons that are configured to process the nodes and/or edges of the second subgraph. In some graph neural networks, an architecture of the graph neural network may be based on non-graph input data that is received and processed by the graph neural network. For example, a graph neural network may be

configured to receive, as input, a description of a graph (e.g., a number of nodes and/or edges and one or more properties of the graph). The graph neural network may be further configured to generate a graph corresponding to the description, and to process and optionally output the graph according to various graph neural network processing techniques.

[3212] In some graph neural networks, an architecture of the graph neural network is based on an output of the graph neural network. For example, a graph neural network may be configured to determine, and optionally output, a fixed-size output graph data set including N nodes and E edges. The graph neural network may therefore include an output layer featuring N neurons respectively configured to generate output corresponding to one of the N nodes and/or E neurons respectively configured to generate output corresponding to one of the E edges. A graph neural network may be configured to determine, and optionally output, an adjacency list having a maximum of E edges. The graph neural network may therefore include an output layer featuring E neurons that respectively generate output corresponding to one of the E edges represented in the adjacency list. A graph neural network may be configured to determine, and optionally output, an output graph data set including two subgraphs. The graph neural network may therefore include an output layer featuring a first set of neurons that are configured to generate output corresponding to the nodes and/or edges of the first subgraph and a second set of neurons that are configured to process the nodes and/or edges of the second subgraph. In some graph neural networks, an architecture of the graph neural network may be based on non-graph output data that is determined, and optionally output, by the graph neural network. For example, a graph neural network may be configured to determine, and optionally output, a description of an input graph data set and/or an output graph data set (e.g., a number of nodes and/or edges and one or more properties of the input graph data set and/or the output graph data set), according to various graph neural network processing techniques.

[3213] In some graph neural networks, an architecture of the graph neural network may be based on a directionality of one or more edges included in an input data set and/or an output data set. For example, an input graph data set including a undirected edge that connects a first node N1 and a second node N2 may be received and processed by a graph neural network including a first neuron NN1 and a second neuron NN2 that are bidirectionally connected to one another, such that message passing can occur from the first node NN1 to the second node NN 2 and, concurrently or consecutively, from the second node NN2 to the first node NN1. An input graph data set including a unidirectional edge that connects a first node N1 to a second node N2 may be received and processed by a graph neural network including a first neuron NN1 (e.g., a neuron in a first layer of a feed-forward graph neural network) that is unidirectionally connected to a second neuron NN2 (e.g., a neuron in a second layer of a feed-forward graph neural network), such that message passing can occur from the first node NN1 to the second node NN 2 but not from the second node NN2 to the first node NN1. An input graph data set including an edge that connects three or more nodes may be received and processed by a graph neural network in which three or more nodes are correspondingly connected.

[3214] Some graph neural networks may be configured to receive and process an input graph data set including a homogeneous set of nodes and/or a homogeneous set of edges. For example, a first neuron of the graph neural network that corresponds to a first node and/or edge of the input graph data set may include a same or similar number of inputs, a same or similar activation function, and/or a same or similar number of outputs as a second neuron of the graph neural network that corresponds to a second node and/or edge of the input graph data set.

[3215] Some graph neural networks may be configured to receive and process an input graph data set including a heterogeneous set of nodes and/or a heterogeneous set of edges. For example, different nodes of an input graph data set may be associated with different labels that respectively indicate different classifications of the nodes, and/or different edges of the input graph data set may be associated with different labels that respectively indicate different classifications of the edges. An architecture of the graph neural network may exhibit variations corresponding to the heterogeneity of the nodes and/or edges. For example, a first neuron of the graph neural network that corresponds to a first node and/or edge of the input graph data set that is associated with a first label or classification may include a different number of inputs, a different activation function, and/or a different number of outputs as a second neuron of the graph neural network that corresponds to a second node and/or edge of the input graph data set that is associated with a second label or classification. As another example, a graph neural network may include a first layer that receives and processes, as input, a first portion of an input data set that includes a first subset of neurons and/or edges that are associated with a first label or classification, and a second layer that receives and processes, as input, a second portion of an input data set that includes a second subset of neurons and/or edges that are associated with a second label or classification. The first layer and the second layer may be processed concurrently or consecutively. The first layer and the second layer may be processed independently (e.g., each layer providing a different portion of an output graph data set). Alternatively, the first layer and the second layer may be processed together (e.g., an output of the first layer may be additionally provided as input to the second layer, and/or an output of the second layer may be additionally provided as input to the first layer).

[3216] Some graph neural networks may include an architecture that is based on one or more node properties of one or more nodes of an input graph data set, one or more edge properties of one or more edges of the input graph data set, and/or one or more graph properties of the input graph data set. As an example, in some input graph data sets, one or more nodes may include a node property indicating a weight of the node (e.g., an indication of a centrality and/or betweenness of a node among at least a portion of the nodes of the input graph data set). The graph neural network may include a neuron that corresponds to the node, wherein one or more weights of synapses that connect the neuron to other neurons of the graph neural network is based on the weight of the node. As another example, in some input graph data sets, one or more edges may include an edge property indicating a weight of the edge (e.g., an indication of a significance and/or priority of a relationship among two or more nodes of the input graph data set). The graph neural network may include two or more nodes that are connected by a synapse,

wherein a weight of the synapse connecting the two or more nodes is based on a weight of an edge of the input graph data set. Examples of node-based graph neural networks include, without limitation, GraphSAGE, PinSAGE, and VR-GCN. Examples of layer-based graph neural networks include, without limitation, FastGCN and LADIES. Examples of subgraph-based graph neural networks include, without limitation, ClusterGCN and GraphSAINT.

[3217] Some graph neural networks may be configured to receive and process fixed input graph data sets, wherein a number and arrangement of nodes and edges of an input data set that is received and processed by the graph neural network does not vary for different instances of processing the input data set. The architecture of such graph neural networks may be configured based on the invariance of the input graph data set. For example, the graph neural network may feature a fixed number and/or arrangement of neurons and/or layers, wherein the fixed architecture of the graph neural network corresponds to the fixed nature of the input graph data set.

[3218] Some graph neural networks may be configured to receive and process dynamic input graph data sets, wherein a number and arrangement of nodes and edges of an input data set that is received and processed by the graph neural network during a first instance of processing can differ from a number and arrangement of nodes and edges of an input data set that is received and processed by the graph neural network during a second instance of processing. As an example, a graph neural network may be configured to perform node and/or edge discovery of an input graph data set and to generate, as output, an output graph data set that includes at least one more node and/or at least one more edge than the input graph data set. Further, the graph neural network may be configured to receive the output graph data set from a first processing as input for a second processing, wherein a number of nodes and/or edges received as input during the second processing is greater than a corresponding number of nodes and/or edges received as input during the first processing. In such cases, an architecture of such graph neural networks may be fixed, but may be configured to receive and process a variety of different input graph data sets (e.g., input graph data sets with a variable number of nodes and/or connections). For example, the graph neural network may include an input layer featuring N input neurons, each corresponding to a node of an input graph data set. Such a graph neural network may be configured to use the fixed architecture to receive and process input graph data sets featuring a variable number of nodes up to, but not exceeding, N. For example, in order to receive and process an input graph data set featuring fewer than N nodes, the graph neural network may activate only a number of input neurons of the input layer that correspond to the number of nodes in the input graph data set, and to deactivate remaining neurons of the input layer that do not correspond to a node of the input graph data set (e.g., refraining from processing the remaining neurons, and/or processing the neurons but zeroing the weights of the synapses that connect the neurons to other neurons of the graph neural network). As another example, the graph neural network may perform a first processing of a first input graph data set including N nodes, and, accordingly, may deactivate one or more neurons of the input layer. The graph neural network may then perform a second processing of a second input graph data set including

more than N nodes (e.g., an output of the first processing may include an output graph data set that includes one or more newly discovered nodes). During the second processing, the graph neural network may activate one or more of the previously deactivated neurons of the input layer in order to receive and process input from the additional nodes of the second input graph data set. For example, the graph neural network may enable or reenable the processing of one or more neurons of the input layer, and/or may reset (e.g., restore and/or initialize) the weights of one or more synapses that connect one or more neurons of the input layer to other neurons of the graph neural network. In some cases, an architecture of such graph neural networks may dynamic, and may change in correspondence with a dynamic nature of the input graph data set. For example, a graph neural network may include an input layer with a variable number of neurons, and may select, adapt, and/or change the number of neurons in the input layer based on a dynamic property of an input graph data set (e.g., a number of nodes and/or edges in the input graph data set). Such graph neural networks may generate new neurons of the input layer (e.g., initializing and/or selecting weights of the synapses of the new neurons, such as copying the weights from the synapses of other neurons of the input layer) based on a larger number of nodes and/or edges of an input graph data set to be received and processed as input. Alternatively or additionally, such graph neural networks may be configured to eliminate and/or merge neurons of the input layer (e.g., initializing and/or selecting weights of the new neurons) based on a smaller number of nodes and/or edges of an input graph data set to be received and processed as input.

[3219] In some graph neural networks, an architecture of the neural network may be selected and/or adapted based on a topology of one or more input graph data sets and/or output graph data sets. For example, a bipartite input graph data set may include two more subgraphs, and a graph neural network may include two or more distinct subsets of neurons that are respectively configured to receive and process data associated with the nodes and/or edges included in one of the subgraphs. As another example, a multigraph input graph data set may include a plurality of edges connecting two or more nodes. For example, a graph representing a social network may include various types of edges that represent various types of relationships (e.g., familial relationships, friendships, and/or professional relationships), and two or more nodes may be connected by a plurality of edges (e.g., a first edge indicating a friendship among the two or more nodes and a second edge indicating a professional relationship among the two or more nodes). An architecture of the graph neural network may correspond to the multigraph nature of the input graph data set. For example, a graph neural network may include two or more distinct subsets of neurons that are respectively configured to receive and process data associated with a subset of edges of the input graph data set that are of a particular edge type (e.g., a first subset of neurons that is configured to receive and process nodes connected by edges that represent friendships, and a second subset of neurons that is configured to receive and process nodes connected by edges representing professional relationships). As yet another example, an input hypergraph data set may include one or more hyperedges that interconnect three or more nodes. An architecture of a graph neural network that is configured to receive and process the input

hypergraph data set may include one or more neurons with synapses that interconnect to two or more other neurons in correspondence with one or more hyperedges of the input hypergraph data set.

[3220] As another example, an architecture of some graph neural networks include one or more layers that perform particular functions on the output of neurons of another layer, such as a pooling layer that performs a pooling operation (e.g., a minimum, a maximum, or an average) of the outputs of one or more neurons, and that generates output that is received by one or more other neurons (e.g., one or more neurons in a following layer of the graph neural network) and/or as an output of the graph neural network. Examples of graph neural networks that include one or more direct pooling layers include, without limitation, SimplePooling, Set2Set, and SortPooling. Examples of graph neural networks that include one or more hierarchical pooling layers include, without limitation, Coarsening, ECC, DiffPool, TopK, gPool, Eigenpooling, and SAGPool.

[3221] As another example, some graph neural networks (e.g., graph convolution networks) include one or more convolutional layers, each of which performs a convolution operation to an output of neurons of a preceding layer of the graph neural network.

[3222] As another example, an architecture of some graph neural networks include memory based on an internal state, wherein the processing of a first input data set causes the graph neural network to generate and/or alter an internal state, and the internal state resulting from the processing of one or more earlier input data sets affects the processing of second and later input data sets. That is, the internal state retains a memory of some aspects of earlier processing that contribute to later processing of the graph neural network. Examples of graph neural networks that include memory features and/or stateful features include graph neural networks featuring one or more gated recurrence units (GRUs) and/or one or more long-short-term-memory (LSTM) cells. In some graph neural networks, these features may be further adapted to accommodate graph processing, such as gated graph neural networks (GGRUs), tree LSTM networks, graph LSTM networks, and/or sentence LSTM networks.

[3223] As another example, an architecture of some graph neural networks includes one or more recurrent and/or reentrant properties. For example, at least a portion of output of the graph neural network during a first processing is included as input to the graph neural network during a second or later processing, and/or at least a portion of an output from a layer is provided as input to the same layer or a preceding layer of the graph neural network. As another example, in some graph neural networks, an output of a neuron is also received as input by the same neuron during a same processing of an input and/or a subsequent processing of an input. The output of the neuron may be evaluated (e.g., weighted, such as decayed) before being provided to the neuron as input.

[3224] As another example, an architecture of some graph neural networks includes two or more subnetworks (e.g., two or more graph neural networks that are configured to process graph data concurrently and/or consecutively). Some graph neural networks include, or are included in, an ensemble of two or more neural networks of the same, similar, or different types (e.g., a

graph neural network that outputs data that is processed by a non-graph neural network, Gaussian classifier, random forest, or the like). For example, a random graph forest may include a multitude of graph neural networks, each configured to receive at least a portion of an input graph data set and to generate an output based on a different feature set, different architectures, and/or different forms of processing. The outputs of respective graphs of the random graph forest may be combined in various ways (e.g., a selection of an output based on a minimization and/or maximization of an objective function, or a sum and/or averaging of the outputs) to generate an output of the random graph forest.

[3225] In some cases, an architecture of a graph neural network may be designed by a user. For example, a user may choose one or more hyperparameters of a graph neural network (e.g., a number of layers, a number of neurons in each layer, an activation function used by at least some neurons, and the like) in order to process an input graph data set. In some cases, the selected one or more hyperparameters may be based on domain-specific knowledge, e.g., a specific data type, internal organization or structure, and/or task associated with an input graph data set.

[3226] Alternatively or additionally, in some cases, an architecture of a graph neural network may be selected by an automated process. For example, a hyperparameter search process may determine one or more hyperparameters of a graph neural network based on an analysis of an input graph data set to be received and processed by the graph neural network and/or an analysis of an output graph data set to be generated and provided as output by the graph neural network. The hyperparameter search process may determine various combinations of hyperparameters for variations of the graph neural network (e.g., graph neural networks with different numbers of layers, different numbers of neurons within each layer, graph neural networks including neurons with different activation functions, and/or graph neural networks with different sets of synapses interconnecting the neurons of various layers). The hyperparameter search process may process an input graph data set (e.g., a training input graph data set) using different graph neural networks that correspond to different sets of hyperparameters. The hyperparameter search process may compare the output of the different graph neural networks (e.g., determining a performance measurement for the output of each graph neural network, and comparing the performance measurements of the different graph neural networks) in order to determine and select a graph neural network that generates desirable output (e.g., output that most closely corresponds to a target output associated with the training input graph data set). The hyperparameter search process may discard the other graph neural networks and may use the selected graph neural network to process input graph data sets. In some cases, the hyperparameter search process may iteratively generate and test refined combinations of hyperparameters. For example, after selecting a graph neural network in a first hyperparameter search processing the hyperparameter search process may perform a second hyperparameter search processing by generating additional graph neural networks based on combinations of hyperparameters that are closer to the hyperparameters of the selected graph neural network, and evaluating the output of the additional graph neural networks. In some cases, the hyperparameter

search process may perform a grid search over the set of valid hyperparameter combinations. Iterative refinement of the hyperparameters may enable the hyperparameter search process to determine an architecture of a graph neural network that is well-tuned to a particular task (e.g., an architecture of a graph neural network that demonstrates consistently high performance on input graph data sets within a particular domain of data and/or a particular task). In some cases, a hyperparameter search process may communicate with a user to determine combinations of hyperparameters to evaluate and/or to select for the graph neural network. For example, the hyperparameter search process may present, to a user, a result of a first hyperparameter evaluation (e.g., an output of a graph neural network that was selected through a first hyperparameter search processing). Based on an evaluation of the output by the user, the hyperparameter search process may perform a second or further hyperparameter search processing (e.g., choosing a small refinement of the hyperparameters based on a positive response of the user to the output of a selected graph neural network, and/or choosing a larger refinement of the hyperparameters based on a negative response of the user to the output of the selected graph neural network).

[3227] As another example, some graph neural networks include architectures based on graph convolutional networks (GCNs), wherein a convolutional layer applies a convolution operation to outputs of one or more filters of a previous filter layer of the graph convolutional network. Graph convolutional networks may include spectral convolutional networks that are configured to receive, as input, a spectral representation of an input graph data set, and to apply processing (including one or more convolutional operations) to various spectral components of the spectral representation of the input graph data set. Examples of spectral convolutional networks include, without limitation ChebNet and diversified graph convolutional networks (DGCNs). As another example, some graph convolutional networks include architectures based on spatial convolutional networks (SCNs) that are configured to receive, as input, spatial representations of an input graph data set (e.g., spatial information that represents one or more neighborhoods of nodes and/or edges of the input graph data set), and to apply processing (including one or more convolutional operations) to various spatial components of the spatial representation of the input graph data set. Examples of spatial convolutional networks include, without limitation, spatial convolutional neural networks (SCNNs), spatial and/or spatial-temporal GraphSAGE networks, and some deep convolutional neural networks (DCNNs).

[3228] Graph neural networks can be generated by a variety of machine learning platforms, frameworks, and/or tools, including, without limitation, PyTorch Geometroc, Deep Graph Library, TensorFlow GNN, Graph Nets, Spektral, and Jraph. Frameworks for graph convolutional networks include, without limitation, message passing neural networks (MPNNs), non-local neural networks (NLNNs), mixture model neural networks (MoNet), and Graph Networks (GN).

[3229] Further explanation and/or examples of various architectures of graph neural networks, including the design and implementation of designs and architectures of such graph neural

networks, are presented elsewhere in this disclosure and/or will be known to or appreciated by persons of ordinary skill in the art.

[3230] GRAPH NEURAL NETWORKS – TRAINING AND PERFORMANCE EVALUATION

[3231] Like other types of neural networks, graph neural networks are typically generated with arbitrarily selected parameters (e.g., synaptic weights that are initially set to randomized values). Also, like other types of neural networks, an initialized graph neural network to evaluate input graph data sets through training, in which the parameters of the graph neural network are adjusted to promote desirable processing that produces expected and/or desirable outputs.

[3232] The training of graph neural networks may involve one or more training data sets. For graph neural networks that receive and process input graph data sets, the training data may include one or more training input graph data sets. Alternatively or additionally, for graph neural networks that receive and process input non-graph data, the training data may include one or more sets of training non-graph data.

[3233] The training data for a graph neural network may be based on authentic input data that was previously collected and/or analyzed, or that was collected and analyzed for the purpose of training the graph neural network. For example, in order to process graphs that represent an industrial environment, the training data may include sensor data that was previously and/or is currently received from one or more sensors associated with the industrial environment. Alternatively or additionally, the training data may include partially and/or fully synthetic data. For example, a first portion of training data may include data derived from an analysis of authentic data; authentic data that has been supplemented with synthetic data (e.g., an image of a real-world scene including an inserted artificial object); authentic data that has been modified by a suer (e.g., an image of a real-world scene that has been modified by a user); and/or data generated by one or more algorithms (e.g., other machine learning models and/or simulations of real-world processes). In some cases, the training data set may include both authentic training data and synthetic training data that is based on the authentic training data (e.g., both a real-world image and a modified version of the real-world image that has been adjusted in brightness, contrast, size, resolution, scale, shape, aspect ratio, color depth, or the like).

[3234] The training data for a graph neural network may be limited to a selected data domain. For example, training data for a graph neural network that analyzes social networks may include one or more samples of individuals from within one or more selected social networks. In other cases, the training data for a graph neural network may be generated from a variety of data domains. For example, training data for a graph neural network that analyzes geographic data may include one or more samples of locations of interest and interconnecting pathways from natural outdoor geographic regions (e.g., forests), artificial outdoor geographic regions (e.g., road networks), indoor geographic regions (e.g., caves or shopping malls), historic geographic regions (e.g., maps from ancestral eras and/or civilizations), and/or synthetic geographic regions (e.g., geographic maps from videogames).

[3235] The training data for a graph neural network may be wholly or partially unlabeled. For example, the training data set for an industrial environment may include sensor measurements collected from the industrial environment, but may not include any data indicating an analysis, classification, metadata, interpolations, extrapolations, interpretation, explanation, and/or user reaction associated with the sensor measurements. Alternatively or additionally, the training data for a graph neural network may be wholly or partially labeled. For example, the training data set for an industrial environment may include sensor measurements collected from the industrial environment, and one or more subsets of sensor measurements may be associated with one or more analyses, classification labels, metadata, interpolations, extrapolations, determinations, interpretations, explanations, and/or user reactions associated with the subset of sensor measurements. Training data may associate labels, metadata, or the like with one or more nodes and/or node properties of a training input graph data set; one or more edges and/or edge properties of a training input graph data set; one or more graph properties of the training input graph data set; and/or one or more portions of non-graph data of a training input data set. In some cases, the labels, data, metadata, or the like associated with at least a portion of a training input data set are selected by one or more users (e.g., a human classification of at least a portion of the training data set). In some cases, the labels, data, metadata, or the like associated with at least a portion of a training input data set are selected by another algorithm (e.g., a simulation or another machine learning model). In some cases, the labels, data, metadata, or the like associated with at least a portion of a training input data set are selected by a cooperation of a human and an algorithm (e.g., a determination by a simulation or another machine learning model that is verified by a reviewing human user).

[3236] Graph neural networks can be trained based on one or more training data sets and one or more learning techniques. As an example, some graph neural networks are trained through an unsupervised learning technique. For example, a training input data set may not include any labels, data, metadata, or the like associated with various portions of the training input data set. The graph neural network may be trained to identify patterns arising within the training input data sets. For example, a training input data set may include data that indicates one or more anomalies (e.g., nodes and/or edges that appear to represent outliers in a data distribution of the nodes and/or edges of the graph) and/or distinctive patterns or structures arising in the data (e.g., cycles arising in a directed and/or undirected graph). The graph neural network may be trained to detect such anomalies, patterns, and/or structure in the training input data sets. The results of unsupervised learning of a graph neural network may be evaluated based on an evaluation of the output of the graph neural network (e.g., a confusion matrix that includes determinations of true positive determinations, true negative determinations, false positive determinations, and/or false negative determinations) and/or performance scores (e.g., an F1 performance score based on ratios of true positives, false positives, true negatives, and false negatives). The weights of various parameters of the graph neural network can be automatically adjusted, corrected, refined, or the like, such that subsequent processing of the same input training data set and/or other input training data sets generates improved evaluations and/or performance scores.

[3237] As another example, some graph neural networks are trained through a supervised learning technique. For example, a training input data set may associate respective portions (e.g., respective training data samples, such as different training input graph data sets) with one or more labeled outputs that are expected and/or desirable of the trained graph neural network. As an example, a graph neural network may be trained to output a classification of a training input graph data set and/or one or more nodes and/or edges thereof. During a supervised learning process, the training input graph data set may be provided as input to the graph neural network and processed by the graph neural network to generate a predicted classification of a training input graph data set and/or one or more nodes and/or edges thereof. The predicted classifications may be compared with one or more labeled outputs associated with the training input graph data set (e.g., one or more labels associated with an expected and/or desirable classification of the training input graph data set and/or one or more nodes and/or edges thereof). Based on the comparison, the weights of various parameters of the graph neural network can be automatically adjusted, corrected, refined, or the like, such that subsequent processing of the same input training data set and/or other input training data sets generates improved evaluations and/or performance scores (e.g., more accurate predictions of one or more labels associated with an expected and/or desirable classification of the training input graph data set and/or one or more nodes and/or edges thereof).. As another example, a graph neural network may be trained to generate, as output, an output graph data set that is based on a processing of a training input graph data set. During a supervised learning process, the training input graph data set may be provided as input to the graph neural network and processed by the graph neural network to generate an output graph data set. The output graph data set generated by the graph neural network may be compared with one or more expected and/or desirable output graph data sets corresponding to the training input graph data set (e.g., one or more output graph data sets that are expected and/or desired as output when the graph neural network processes the training input graph data set). Based on the comparison, the weights of various parameters of the graph neural network can be automatically adjusted, corrected, refined, or the like, such that subsequent processing of the same input training data set and/or other input training data sets generates improved evaluations and/or performance scores (e.g., more desirable and/or expected output graph data sets).

[3238] As another example, some graph neural networks are trained through a blended training process that includes both supervised and unsupervised learning. For example, a blended training process may evaluate the performance of a graph neural network in training based on both a comparison of predicted outputs of the graph neural network to expected and/or desirable outputs corresponding to an input training data set, and based on one or more automatically determined performance metrics, such as a confusion matrix and/or F1 scores. Some blended training processes may include a round of supervised learning following by a round of unsupervised learning, or may perform rounds of training that include both supervised and unsupervised learning techniques (e.g., optionally with different weights and/or performance

thresholds associated with the evaluation of the graph neural network and the updating of the parameters).

[3239] As another example, some graph neural networks are trained through a semi-supervised learning process. For example, a training data set may include a large number of samples, of which only a small number of samples are labeled (e.g., associated with expected and/or desirable outputs) and a large remainder of the samples are unlabeled (e.g., not associated with expected and/or desirable outputs). The graph neural network may be trained based on the labeled and/or unlabeled training data, and a performance of the graph neural network may be evaluated based on the labels and/or other metrics. In particular, some unlabeled portions of the input training data may be identified as being incorrectly evaluated by the graph neural network (e.g., the graph neural network may generate incorrect outputs such as predictions or classifications, incorrect and/or malformed output graph data sets, or the like). At least a portion of such unlabeled portions of the input training data (e.g., training data samples that appear to be difficult to classify correctly and/or with high confidence) may be submitted to a human reviewer, and the semi-supervised learning process may receive, from the human reviewer, one or more labels that correspond to an expected and/or desirable output of the graph neural network for such portions of the input training data. Training or retraining of the graph neural network may involve the newly labeled portions of the input training data, as well as other portions of the input training data. Semi-supervised learning may enable graph neural networks to be trained based on a smaller degree of human involvement (e.g., a smaller number of labels associated with portions of the input training data set by human reviewers), and may therefore improve a speed, cost, and/or performance of training the graph neural network.

[3240] A training of a graph neural network may occur in one or more epochs. For example, for each epoch, the graph neural network may be provided with input comprising each portion of a training data set, a performance of the graph neural network may be determined based on the output of the graph neural network for each portion of the training data set. Based on the determined performance, and one or more parameters of the graph neural network may be updated. For example, weights of the synapses between neurons of the graph neural network may be adjusted such that a performance of the graph neural network over each portion of the training data set. During the training of a graph neural network, various techniques may be used to evaluate the performance of the graph neural network. As a first example, outputs of the graph neural network (e.g., output graph data sets and/or predictions, such as classifications of the graph, one or more nodes, and/or one or more edges) may be compared with expected and/or desirable outputs. Differences between the outputs and the expected and/or desirable outputs may be used to determine an entropy and/or loss of the output of the graph neural network as compared with corresponding expected and/or desirable outputs. In some variations, the entropy or loss of the graph neural network determined during or after a current epoch may be compared with an entropy or loss of the graph neural network determined during or after a previous epoch to determine a differential and/or marginal entropy or loss. A negative differential and/or marginal entropy or loss may indicate that the training of the graph neural network is productive

(e.g., the performance of the graph neural network improved in the current epoch as compared with a previous epoch). A zero or positive differential and/or marginal entropy or loss may indicate that the training of the graph neural network is unproductive (e.g., the performance of the graph neural network did not improve, or diminished, in the current epoch as compared with a previous epoch). Training of the graph neural network may therefore continue as long as the differential and/or marginal entropy or loss remains negative and, optionally, exceeds a threshold magnitude that indicates significant training progress.

[3241] As another example, outputs of the graph neural network (e.g., output graph data sets and/or predictions, such as classifications of the graph, one or more nodes, and/or one or more edges) may be classified as one of a true positive, a false positive, a true negative, or a false negative. The performance of the graph neural network may be evaluated as a confusion matrix, e.g., based on a calculation of the performance over the incidence of true positive, false positive, true negative and false negative outputs. In some cases, the calculation may be weighted based on a risk matrix that applies different weights to each classification of the output. For example, in a graph neural network that generates classifications of graphs that correspond to diagnoses of medical conditions, it may be determined false negatives (e.g., missed diagnoses) are very harmful or costly, while false positives (e.g., misdiagnoses that can be corrected by further evaluation) may be determined to be comparatively harmless. Accordingly, the performance of the graph neural network may be determined based on a weighted calculation over the confusion matrix that more severely penalizes the performance based on false negatives than false positives.

[3242] As another example, the training of a graph neural network may involve an improvement of an objective function that serves as a basis for measuring the performance of the graph neural network. For example, the objective function may include (without limitation) a loss minimization, an entropy minimization, a precision maximization, a recall maximization, an error minimization, or a consistency maximization. The objective function may include a comparison of the performance of the graph neural network over various distributions of the input data set (e.g., a minimax optimization, such as minimizing a maximum loss over any portion of the input data set, or a maximin optimization, such as maximizing a minimum loss over any portion of the input data set). In some training scenarios that involve reinforcement learning, the output of a graph neural network may include and/or may be interpreted as a policy, e.g., a set of responses of an agent based on respective conditions. The performance of the graph neural network may be based on various objective functions that evaluate various properties of the generated and/or interpreted policy. For example, in a q-learning reinforcement learning process, the objective function applied to the policy may include a maximization of an action value of each behavior that may be performed in response to various conditions.

[3243] As another example, the training of graph neural networks may occur concurrently with the hyperparameter search and/or selection. For example, a hyperparameter search process may initially identify a first set of combinations of hyperparameters of graph neural networks to be evaluated using a training data set. Based on each such combination of hyperparameters, a graph

neural network may be generated and at least partially trained to determine its performance. Based on the evaluation of the outputs of the graph neural networks corresponding to respective combinations of hyperparameters, the hyperparameter search process may identify a candidate graph neural network with the highest performance. The hyperparameter search process may then generate a second set of combinations of hyperparameters based on the hyperparameters of the candidate graph neural network, and may further (at least partially) train and evaluate the performance of additional graph neural networks based on the second set of combinations of hyperparameters. A comparison of the performance of the additional graph neural networks may cause the hyperparameter search process to retain the candidate graph neural network or to choose a new candidate graph neural network from among the additional graph neural networks. The hyperparameter search process may continue until additional improvements in the performance of candidate graph neural networks are not achievable and/or are below a threshold performance improvement. In this selection process, a variety of performance metrics may be used. As previously discussed, the performance metrics may include an evaluation of the outputs of the graph neural networks (e.g., a loss or entropy, a differential or marginal loss or entropy, a confusion matrix, an F1 score, or the like). Alternatively or additionally, the performance metrics may include other features of the output, such as a consistency of the output of the graph neural network over the distribution of data in the training data set and/or a bias in the performance the output of the graph neural network for selected data distributions of the training data set, and/or a smoothness or oversmoothness of the graph nodes represented in the graph neural network. Alternatively or additionally, the performance metrics may include one or more measurements of computational resource expenditures to perform training and/or inference of input data sets with the graph neural network (e.g., CPU and/or GPU utilization, memory usage, training time and/or complexity, processing latency between receiving input and generating output, or the like). Aggregate performance measurements may be based on a variety of such considerations, and may enable a human designer and/or a hyperparameter search process to perform a selection of a graph neural network based on various performance tradeoffs (e.g., a preference for a first graph neural network that produces high-accuracy, high-consistency, and/or high-confidence results but that requires a large amount of computational resources, time, and/or cost, vs. a preference for a second graph neural network that produces reasonable-accuracy, reasonable-consistency, and/or reasonable-confidence results using a smaller amount of computational resources, time, and/or cost). For example, a measurement of computational resource utilization by a particular graph neural network may correspond to a numeric penalty in various measurement of the performance of the graph neural network (e.g., a loss, entropy, and/or objective function output).

[3244] In various forms of graph neural network training based on these and other learning techniques, various training methods can be used to update the parameters of a graph neural network in training and/or to evaluate the performance of a graph neural network in training. For example, optimizers that may be used during the training of graph neural networks may include (without limitation) linear regression; root mean squared propagation (RMSprop); stochastic

gradient descent; adaptive stochastic gradient descent (Adagrad); adaptive stochastic gradient descent with adaptive learning (Adadelta); adaptive moment estimation (Adam); Nesterov accelerated adaptive moment estimation (Nadam); Nesterov accelerated gradient and momentum (NAG); Monte Carlo simulations involving various variance reduction techniques, such as control variates; or the like, including variations and/or combinations thereof. Training techniques for particular types of graph neural networks may include optimizers that are specialized for such particular types of graph neural networks (e.g., graph convolutional networks may be trained using a FastGCN optimizer and/or receptive field control (RFC) optimizers).

[3245] As further examples, graph neural network training may include a variety of techniques that are also applicable to non-graph machine learning models, including non-graph neural networks. As a first such example, training may occur in batches and/or mini-batches of the training data set, wherein the graph neural network evaluates a batch (e.g., plurality of input data sets) of an input training data set, and the parameters of the graph neural network are updated based on an aggregation of the evaluation of the outputs of the graph neural network for the batch of input data sets. In various training techniques, batches may be selected at random from the training input data set or may be selected in an organized manner, e.g., as various subsets that are representative of one or more data distributions of the training input data set. For example, if the graph neural network in training exhibits good performance over some data distributions of the training input data and poor performance over other data distributions of the training input data, the continued training of the graph neural network may focus on, prioritize, and/or overweight the training based on batches of training input data that reflect the data distributions associated with poor performance. In various training techniques, a batch size of batches of training input data sets may be fixed, or the batch size may vary based on a progress of the training of the graph neural network.

[3246] As another example, in various training techniques for graph neural networks, an entire set of training input data may be partitioned into a training data set that is used only to train the graph neural network and update its parameters; a validation data set that is used only to evaluate a prospective and/or in-training graph neural network; and/or a test data set that is used to only evaluate a final performance of the fully trained graph neural network. The partitioning of the training input data may be based on one or more ratios (e.g., a 90/5/5 partitioning of the training input data into a training data set, a validation data set, and a test data set, or a 98/1/1 partitioning of the training input data into a training data set, a validation data set, and a test data set). For example, during an epoch, the performance of the graph neural network may be evaluated based on various portions of the training data set, and the parameters of the graph neural network may be adjusted based on the determined performance. However, continued training and updating of the graph neural network based on the training data set may result in overfitting, e.g., "memoization" of correct outputs that correspond to various portions of the training data set. Due to such overfitting, the performance of the graph neural network in evaluating previously evaluated input data sets may improve, but performance of the graph

neural network on previously unevaluated input data sets may decline. Instead, at the conclusion of an epoch, the performance of the graph neural network may instead be evaluated based on various portions of the validation data set, which is not otherwise used to update the parameters of the graph neural network. Evaluation of the performance of the graph neural network on previously unseen data can indicate that the performance of the graph neural network is genuinely improving (e.g., based on learned principles of data evaluation that apply consistently to both previously seen and previously unseen input data sets), resulting in a continuation of training. Alternatively, Evaluation of the performance of the graph neural network on previously unseen data can indicate that the performance of the graph neural network is resulting in overfitting to the training data set (e.g., based on "memoization" of correct outputs for previously seen input data sets that do not inform the correct evaluation of previously unseen input data sets), resulting in a conclusion of training. Such conclusion may be referred to as "early stopping" of training to reduce overfitting of the graph neural network to the training data set and to preserve the performance of the graph neural network on previously unsee input data sets.

[3247] As another example, various training techniques for graph neural networks may include one or more regularization techniques, in which the inputs to the graph neural network and/or the processing of the input are adjusted to reduce overfitting. As a first example, the training of a graph neural network may include a dropout regularization technique, in which some neurons of the graph neural network are disabled for some instances of processing input data sets. In various regularization techniques, neurons to be disabled are selected randomly (e.g., 5% of the neurons during each epoch) and/or can be selected in a sequence (e.g., a round-robin selection of deactivated neurons). The selected neurons may be disabled by refraining from processing the inputs of the neurons and setting the outputs of the selected neurons to zero, and/or by processing the selected neurons but temporarily setting the weights of the synapses of the neurons to zero. As a second example, the training of a graph neural network may include a dropnode and/or dropedge regularization technique, in which portions of an input graph data set that include some nodes and/or some edges of the input graph data set are disabled. In various regularization techniques, nodes and/or edges to be disabled for an instance of processing are selected randomly (e.g., 5% of the nodes and/or edges during each epoch) and/or can be selected in a sequence (e.g., a round-robin selection of deactivated nodes and/or edges). The selected nodes and/or edges may be disabled by refraining from processing portions of the input data set that correspond to the selected nodes and/or edges, and/or by deactivating neurons of an input layer of the graph neural network that are configured to receive input data from the selected nodes and/or edges. As a third example, the performance of a graph neural network may be subjected to various forms of regularization, including L1 ("lasso") regularization and/or L2 ("ridge") regularization. These and other forms of regularization may be used, alone or in combination, to reduce overfitting of a graph neural network to an input training data set. For example, regularization may reduce an overweighting of a subset of nodes, edges, and/or neurons in the processing of various input data sets (e.g., by reducing and/or penalizing neurons

having synaptic weights with magnitudes that are disproportionately large compared to the synaptic weights of other neurons of the graph neural network).

[3248] As another example, various training techniques for graph neural networks may combine a graph neural network with one or more other machine learning models, including one or more other graph neural networks and/or one or more non-graph neural networks. For example, a bootstrap aggregation ("bagging") training technique involves a determination of a decision tree as an ensemble of machine learning models based on different bootstrap samples of the training input data set. Each machine learning model, including one or more graph neural networks, may be trained based on a random subsample of the training input data set. For a particular input data set, many of the trained machine learning models of the ensemble, including one or more graph neural networks, may present poor or only adequate performance. However, one or a few of the trained machine learning models may generate high-performance output for the particular input data set and others like it (e.g., for input data sets that share one or more properties, such as a select graph property, a select node property, and/or a select edge property). Thus, for any particular input data set, an evaluation of the specific properties of the particular input data set may enable a selection among the available models of the ensemble that may be used to evaluate the particular input data set. That is, a machine learning model (e.g., a graph neural network) that is generally a poorly performing model on most input data sets may exhibit good performance over a small neighborhood of input data sets that includes the particular data set, and may therefore be selected to evaluate the particular data set. Alternatively or additionally, the bootstrap aggregation may involve an evaluation of an input data set by a plurality of machine learning models (optionally including one or more graph neural networks of the ensemble) and a combination of the outputs of the selected machine learning models. In such scenarios, it is possible the individual outputs of the individual machine learning models exhibit poor performance (e.g., incorrect and/or low-confidence classifications of an input data set), but a determination of a consensus over the outputs of the multiple machine learning models may exhibit high performance (e.g., accurate and/or high-confidence classifications of the input data set).

[3249] As another example, various training techniques for graph neural networks may include a boosting ensemble technique, in which an output of a first trained machine learning model (e.g., a first graph neural network) is evaluated by a second trained machine learning model (e.g., a second graph neural network) to predict an accuracy and/or confidence of the prediction of the first trained machine learning model. For example, a first trained graph neural network may be evaluated to determine that it generates accurate and/or high-confidence output for a first group of input data sets (e.g., input graph data sets that include a first graph property, a first node property, and/or a first edge property), but inaccurate and/or low-confidence output for a second group of input data sets (e.g., input graph data sets that include a second graph property, a second node property, and/or a second edge property). A particular input data set may initially be processed by the first trained graph neural network to determine a first output (e.g., an output graph neural network or a prediction, such as a classification). A second trained graph neural

network may evaluate the input data set and/or the output of the first graph neural network to predict an accuracy and/or confidence of the first graph neural network over input data sets that resemble the particular input data set. If the second trained graph neural network predicts that the output of the first graph neural network is likely to be of high accuracy and/or confidence, then the second trained graph neural network may provide the output of the first trained graph neural network as its output. However, if the second trained graph neural network predicts that the output of the first graph neural network is likely to be of low accuracy and/or confidence, then the second trained graph neural network may adjust, correct, and/or discard the output of the first trained graph neural network, or preferentially select an output of a different machine learning model (e.g., a third trained graph neural network) to be provided as output instead of the output of the first trained graph neural network. In such scenarios, it is possible that the individual outputs of the individual machine learning models exhibit poor performance (e.g., incorrect and/or low-confidence classifications of an input data set), but the review and validation of the output of some machine learning models by other machine learning models may enable a determination of a consensus over the outputs of the multiple machine learning models that exhibits high performance (e.g., accurate and/or high-confidence classifications of the input data set).

[3250] As another example, following conclusion of training a graph neural network, the graph neural network may be deployed for use (e.g., transferred to one or more devices, deployed into a production environment, and/or connected to a source of production input data). The performance of the graph neural network over input data sets may continue to be evaluated and monitored to verify that the graph neural network continues to perform well over various inputs. In some cases, the performance of the graph neural network may change between training and deployment. For example, a distribution of production input data processed by the graph neural network may differ from the distribution of training input data that was used to train the graph neural network. Alternatively or additionally, a distribution of production input data may change over time, e.g., between a time of deploying the graph neural network and a later time after such deployment. Such instances of changes in the performance of a fully trained and deployed graph neural network may be referred to as "drift." In some such cases, "drift" may be reduced or eliminated by retraining or continuing training of the graph neural network, e.g., using additional training input data that corresponds to an actual or current distribution of the production input data. Alternatively or additionally, "drift" may be reduced or eliminated by training a substitute graph neural network to replace the initially deployed graph neural network. For example, the substitute graph neural network may include a different set of hyperparameters than the initially deployed graph neural network (e.g., additional layers and/or neurons to provide greater learning capacity; additional regularization techniques to reduce overfitting to the training data set; and/or the inclusion of specialized layers, such as pooling, filtering, memory, and/or attention layers). As another example, the initially deployed graph neural network may be added to an ensemble of other machine learning models, optionally including other graph neural networks,

to generate improved outputs (e.g., higher-accuracy predictions) based on a consensus determined over the outputs of a number of machine learning models.

[3251] As another example, the training and/or use of graph neural networks may be susceptible to various forms of adversarial attack. For example, in an adversarial attack scenario, a particularly designed and/or selected input to a graph neural network (an "adversarial input," such as an unusual, malformed, and/or anomalous) may cause the graph neural network to generate output that is incorrect, inconsistent with other outputs, and/or surprising. As an example, in a form of graph modification adversarial attack that may be referred to as node injection poisoning adversarial attack (NIPA), one or more nodes of an input graph data set are selected and/or altered to shift an output of the graph neural network based on the adversarial input (e.g., altering a classification and/or prediction of the input graph data set, or altering an output graph data set based on the adversarial input graph data set). As another example, in a form of graph modification adversarial attack that may be referred to as an edge perturbing adversarial attack (NIPA), one or more edges of an input graph data set are selected and/or altered to shift an output of the graph neural network based on the adversarial input (e.g., altering a classification and/or prediction of the input graph data set, or altering an output graph data set based on the adversarial input graph data set). As another example, in a training data injection attack, one or more portions of training input data on which a graph neural network is trained are designed and/or altered to alter the training of the graph neural network (e.g., a mislabeling of a particular training data input that causes the graph neural network to misclassify other inputs that correspond to the mislabeled training data input, and/or an injection of data samples into a training data set that alter a data distribution of the training data set upon which the graph neural network is trained). As another example, in a membership inference adversarial attack, properties and/or outputs of a graph data set are evaluated to identify properties of one or more training data inputs on which the graph data set was trained (e.g., an influential property of an input data set that causes the graph data set to select a particular classification for the any input data sets that include the property). As another example, in a property inference adversarial attack, properties and/or outputs of a graph data set are evaluated to identify general properties of training data inputs on which the graph data set was trained (e.g., a distribution of data included in the training data set, which may indicate particular distributions of input data over which the graph neural network was not trained, or over which the graph neural network was incompletely and/or incorrectly trained). As another example, in a model inversion adversarial attack, outputs of a graph neural network are examined to identify properties of corresponding input data sets that cause the graph neural network to generate such outputs.

[3252] Based on these and other forms of adversarial attack, the training and/or evaluation of a graph neural network may be adjusted to protect the graph neural network from such adversarial attack. For example, before an input to a graph neural network is processed, the input may be evaluated and/or classified (e.g., by another machine learning model, including another graph neural network) in order to determine whether the input is adversarial. If so, the graph neural network may refrain from processing the adversarial input, may process the adversarial input in

more limited conditions (e.g., processing only a portion of the adversarial input, and/or replacing a malformed or anomalous portion of the adversarial input with a corresponding non-malformed and/or non-anomalous portion). As another example, during processing of an input data set, the internal behavior of the graph neural network may be evaluated and/or classified (e.g., by another machine learning model, including another graph neural network) to determine whether the behavior indicates a processing of adversarial input (e.g., unusual neuron activations, unusual outputs of one or more neurons, and/or updates of internal states of memory units). If so, the processing of the adversarial input may be halted and/or an internal state of the graph neural network may be restored to a time before the adversarial input was processed. As another example, before output of a graph neural network is provided in response to an input data set, the output may be examined and/or classified (e.g., by another machine learning model, including another graph neural network) to determine whether it is incorrect, inconsistent with other inputs, and/or surprising. If so, the output of the graph neural network may be discarded and/or altered before being provided in response to the input data set. Further explanation and/or examples of various techniques for training and performance evaluation of graph neural networks are presented elsewhere in this disclosure and/or will be known to or appreciated by persons of ordinary skill in the art.

[3253] GRAPH NEURAL NETWORKS – APPLICATIONS

[3254] Graph neural networks can be applied to input data sets (including input graph data sets and/or input non-graph data sets) in various applications, and can be configured and/or trained to generate outputs (including output graph data sets and/or output predictions, such as classifications) that are relevant to various tasks within such applications.

[3255] For example, in the field of social networking, a graph data set may represent at least a portion of a social network, including nodes that represent people and that are connected by edges that represent relationships among two or more people. The graph data set representing a social network may be provided, as input, to a graph neural network that is configured to receive and process the input graph data set. The graph neural network may generate, as output, an output graph data set. For example, the output graph data set may include one or more new nodes that correspond to one or more newly discovered people within the social network, and/or one or more new edges that correspond to one or more newly discovered relationships that connect two or more people of the social network. The output graph data set may include one or more subgraphs and/or clusters that represent highly interconnected people of the social network, e.g., a social circle. The output graph data set may include a prediction of a recommendation of a relationship among two or more nodes corresponding to two or more people of the social network who share common personal traits, interests, and/or connections to other people. The output graph data set may include a prediction of a classification of a node corresponding to a person of the social network, e.g., a prediction of a personal interest of the person or a demographic trait of the person. The output graph data set may include a prediction of a classification of an edge that connects nodes representing two or more people of the social network, e.g., a prediction of a criminal association among two or more people of the social

network. The output graph data set may include a determination of a relationship within the social network based on an attention model, e.g., an identification of a first node corresponding to a first person of the social network that appears to be influential to a second person of the social network represented by a second node of the graph. The output graph data set may include a prediction of a graph property of the graph, e.g., a classification of the social network as one or more types (e.g., a genealogy or familial social network, a friendship social network, and/or a professional relationship social network).

[3256] As another example, in the field of pharmaceuticals, a graph data set may represent at least a portion of a molecule (e.g., a protein or a DNA sequence), including nodes that represent atoms of the molecule and that are connected by edges that represent bonds and/or spatial relationships among two or more atoms. The graph data set representing a molecule may be provided, as input, to a graph neural network that is configured to receive and process the input graph data set. The graph neural network may generate, as output, an output graph data set. For example, the output graph data set may include one or more new nodes that correspond to one or more newly discovered atoms that may be added to the molecule, and/or one or more new edges that correspond to one or more newly discovered atoms of the molecule. The output graph data set may include one or more subgraphs and/or clusters that represent highly interconnected subregions of the molecule, such as carbon atoms that form a benzene ring or a binding site for a protein. The output graph data set may include a prediction of a classification of one or more nodes corresponding to one or more atoms of the molecule, e.g., a prediction that a subset of atoms of the molecule include a binding site for an enzyme that may active and/or deactivate a protein. The output graph data set may include a prediction of a classification of an edge that connects nodes representing atoms of the molecule, e.g., a prediction of a chemically reactive bond that can be altered to alter a property of the molecule. The output graph data set may include a prediction of a graph property of the graph, e.g., a prediction of a shape or organization of the molecule, a classification of the molecule as an enzyme, and/or a prediction of a potential side-effect of a drug due to an undesirable interaction with another drug.

[3257] As another example, in the field of software, a graph data set may represent at least a portion of a marketplace, including nodes that represent products and that are connected by edges that represent relationships between products. The graph data set representing a marketplace may be provided, as input, to a graph neural network that is configured to receive and process the input graph data set. The graph neural network may generate, as output, an output graph data set. For example, the output graph data set may include one or more new nodes that correspond to one or more newly discovered product, and/or one or more new edges that correspond to one or more newly discovered products. The output graph data set may include one or more subgraphs and/or clusters that represent highly interconnected products (e.g., two or more products that are often purchased and/or used together, or that compete in a particular market sector). The output graph data set may include a prediction of a recommendation of a relationship among two or more nodes corresponding to two or more products. The output graph data set may include a prediction of a classification of a node

corresponding to a product, e.g., a prediction of an appeal, value, and/or demand of a product in a particular market segment, such as a particular subset of users. The output graph data set may include a prediction of a classification of an edge that connects nodes representing products, e.g., a prediction of a functional relationship between two or more products. The output graph data set may include a prediction of a graph property of the graph, e.g., a classification of the marketplace as increasing and/or decreasing in terms of supply, demand, size, prognosis, and/or public interest.

[3258] As another example, in the field of logistics, a graph data set may represent at least a portion of a supply chain, including nodes that represent locations where resources are generated, manufactured, stored, exchanged, and/or consumed and that are connected by edges that represent means of transport of resources between two or more locations. The graph data set representing a supply chain may be provided, as input, to a graph neural network that is configured to receive and process the input graph data set. The graph neural network may generate, as output, an output graph data set. For example, the output graph data set may include one or more new nodes that correspond to one or more newly discovered location of interest, and/or one or more new edges that correspond to one or more newly discovered locations of interest. The output graph data set may include one or more subgraphs and/or clusters that represent highly interconnected locations of interest, such as locations between which certain resources are frequently transported. The output graph data set may include a prediction of a recommendation of a relationship among two or more nodes corresponding to two or more locations of interest. The output graph data set may include a prediction of a classification of a node corresponding to a location of interest, e.g., a prediction of an availability, supply, demand, value, and/or appeal of a resource in the location of interest. The output graph data set may include a prediction of a classification of an edge that connects nodes representing locations of interest, e.g., a prediction of a volume of utilization of a mode of transport between two locations of interest. The output graph data set may include a prediction of a graph property of the graph, e.g., a classification of a stability of the supply chain based on social, economic, political, and/or environmental changes.

[3259] As another example, in the field of energy, a graph data set may represent at least a portion of an energy grid, including nodes that represent energy generators, stores, distributors, and/or consumers, and that are connected by edges that represent relationships among energy generators, stores, distributors, and/or consumers. The graph data set representing an energy grid may be provided, as input, to a graph neural network that is configured to receive and process the input graph data set. The graph neural network may generate, as output, an output graph data set. For example, the output graph data set may include one or more new nodes that correspond to one or more newly discovered energy generators, stores, distributors, and/or consumers, and/or one or more new edges that correspond to one or more newly discovered energy generators, stores, distributors, and/or consumers. The output graph data set may include one or more subgraphs and/or clusters that represent highly interconnected energy generators, stores, distributors, and/or consumers. The output graph data set may include a prediction of a

recommendation of a relationship among two or more nodes corresponding to two or more energy generators, stores, distributors, and/or consumers. The output graph data set may include a prediction of a classification of a node corresponding to energy generators, stores, distributors, and/or consumers, e.g., a prediction of a current or future state or property of the energy generator, store, distributor, and/or consumer. The output graph data set may include a prediction of a classification of an edge that connects nodes representing energy generators, stores, distributors, and/or consumers, e.g., a prediction of a transaction between two or more energy generators, stores, distributors, and/or consumers. The output graph data set may include a prediction of a graph property of the graph, e.g., a classification of a stability of the energy grid to sustain energy generation and to support energy demands based on social, economic, political, and/or environmental changes.

[3260] As another example, in the field of civil engineering, a graph data set may represent at least a portion of a geographic region, including nodes that represent locations of interest and that are connected by edges that represent roads. The graph data set representing a geographic region may be provided, as input, to a graph neural network that is configured to receive and process the input graph data set. The graph neural network may generate, as output, an output graph data set. For example, the output graph data set may include one or more new nodes that correspond to one or more newly discovered locations of interest, and/or one or more new edges that correspond to one or more newly discovered locations of interest. The output graph data set may include one or more subgraphs and/or clusters that represent highly interconnected locations of interest. The output graph data set may include a prediction of a recommendation of a relationship among two or more nodes corresponding to two or more locations of interest. The output graph data set may include a prediction of a classification of a node corresponding to location of interest, e.g., a prediction of a current or future volume of visitors to a location of interest and/or a volume of traffic at or through the location of interest. The output graph data set may include a prediction of a classification of an edge that connects nodes representing locations of interest, e.g., a prediction of a volume of traffic on a road that connects two or more locations of interest. The output graph data set may include a prediction of a graph property of the graph, e.g., a classification of a sufficiency of a road network of the geographic region to support a current or future volume of traffic.

[3261] As another example, in the field of industrial systems, a graph data set may represent at least a portion of an industrial plant, including nodes that represent machines of the industrial plant and that are connected by edges that represent functional relationships among the machines. The graph data set representing the industrial plant may be provided, as input, to a graph neural network that is configured to receive and process the input graph data set. The graph neural network may generate, as output, an output graph data set. For example, the output graph data set may include one or more new nodes that correspond to one or more newly discovered machines, and/or one or more new edges that correspond to one or more newly discovered machines. The output graph data set may include one or more subgraphs and/or clusters that represent highly interconnected machines. The output graph data set may include a

prediction of a recommendation of a relationship among two or more nodes corresponding to two or more machines. The output graph data set may include a prediction of a classification of a node corresponding to a machine, e.g., a prediction of a current or future maintenance state of a machine. The output graph data set may include a prediction of a classification of an edge that connects nodes representing machines, e.g., a prediction of a functional relationship between a first machine and a second machine that may significantly impact an efficiency, output, cost, or the like of the industrial plant. The output graph data set may include a prediction of a graph property of the graph, e.g., a classification of the industrial plant as belonging to a particular industry, such as raw material processing, semiconductor fabrication, tool manufacturing, vehicle manufacturing, textile manufacturing, and/or pharmaceuticals manufacturing. The output graph data set may include a prediction of a future and/or optimized state of the industrial plant, e.g., a reorganization of the machines of the industrial plant to optimize machine placement and/or floor planning.

[3262] As another example, in the field of cybersecurity, a graph data set may represent at least a portion of a device network, including nodes that represent devices and that are connected by edges that represent communication and/or interactions among two or more devices. The graph data set representing the device network may be provided, as input, to a graph neural network that is configured to receive and process the input graph data set. The graph neural network may generate, as output, an output graph data set. For example, the output graph data set may include one or more new nodes that correspond to one or more newly discovered devices, and/or one or more new edges that correspond to one or more newly discovered devices. The output graph data set may include one or more subgraphs and/or clusters that represent highly interconnected devices. The output graph data set may include a prediction of a recommendation of a relationship among two or more nodes corresponding to two or more devices. The output graph data set may include a prediction of a classification of a node corresponding to a device, e.g., a prediction of a security status of the device as being safe, vulnerable, or corrupted. The output graph data set may include a prediction of an activity occurring among the nodes of the graph data set, e.g., an occurrence of an intrusion or an attack based on anomalous activities represented by the edges of the graph data set. The output graph data set may include a prediction of a classification of an edge that connects nodes representing devices, e.g., a prediction that a particular interaction between two or more devices is associated with a security vulnerability or attack. The output graph data set may include a prediction of a graph property of the graph, e.g., a classification of the set of devices as safe from security flaws or vulnerable to one or more attack mechanisms, such as denial-of-service (DoS) attacks, distributed-denial-of-service (DDoS) attacks, social engineering attacks such as phishing, eavesdropping attacks such as man-in-the-middle attacks, or the like. The output graph data set may include a prediction of a theoretical state of the graph data set, e.g., a security state of the device network in response to a particular type of attack, and/or a security state of the device network based on the inclusion of additional devices in the future. The output graph data set may include a recommendation to modify the graph neural network based on one or more security

considerations, e.g., a recommendation to reorganize the device network to reduce susceptibilities to one or more security risks. The output graph data set may include a technique to defend the graph neural network from various types of adversarial attack, e.g., training-time attacks that affect the manner in which the graph neural network learns to evaluate and/or classify the graph data set, one or more nodes, and/or one or more edges. For example, the message passing operations of the graph neural network may be modified to reduce a susceptibility of the graph neural network to adversarial perturbation during training, while preserving the learning capabilities of the graph neural network.

[3263] Examples of additional applications of various graph neural networks to various graph data sets include, without limitation: graph mining applications (e.g., graph matching and/or clustering); physics (e.g., physical systems modeling and/or evolution over time); chemistry (e.g., molecular fingerprints and/or chemical reaction predictions); biology (e.g., protein interface predictions, side effects predictions, and/or disease classification); knowledge graphs (e.g., knowledge graph completion and/or knowledge graph alignment); generation (e.g., output graph data set generation that corresponds to an expression, an image, a video, a music sample, or a scene graph); combinatorial optimization; traffic networks (e.g., traffic state prediction); recommendation systems (e.g., user-item interaction predictions and/or social recommendations); economic networks (e.g., stock markets); software and information technology (e.g., software defined networks, AMR graph-to-text tasks, and program verification); text processing (e.g., text classification, sequence labeling, machine translation, relation extraction, event extraction, fact verification, question answering, and/or relational reasoning); and image processing (e.g., social relationship understanding, image classification, visual question answering, object detection, interaction detection, region classification, and/or semantic segmentation). Further examples of applications for processing various graph data sets by various graph neural networks are presented elsewhere in this disclosure and/or will be known to or appreciated by persons of ordinary skill in the art.

[3264] ATTENTION

[3265] In embodiments, an artificial intelligence system, machine learning model, or the like, of any of the types disclosed herein, may comprise, integrate, link to, or include an attention feature. Attention may be generally described as a determination, among a set of inputs, of the relatedness of each input to the other inputs in the set of inputs. In "self-attention," the input includes a sequence of elements, and attention is determined between each pair of elements in the sequence. As a first example, the set of inputs includes a sequence of words in a language, and attention is applied to determine, for each word in the sequence, the relatedness of the word to each other word in the sequence. As a second example, an input includes an image comprising a set of pixels, and attention is applied to determine, for each group of pixels in the image, the relatedness of the group of pixels to each other group of pixels in the image. Attention can also be applied between sets of input, wherein attention is determined between each element of a first set of input and each element of a second set of input. For example, the set of inputs can include a first sequence of words in a first language and a second sequence of

words in a second language, and attention can be determined to indicate how each word in the first sequence is related to each word in the second sequence.

[3266] FIG. 175 presents an example of a determination of attention by a machine learning model. In the example of FIG. 175, an input sequence includes a set of tokens, each representing a word ("The", "Furry", "Dog", "Chased", "The", "Cat"). Each token includes an indicator of a position of the token in the sequence. In various embodiments, the tokens of the input sequence may include complete words, portions of words (e.g., a first token indicating a word root and a second token indicating a modifier of the word root), punctuation, or the like. Some tokens may indicate metadata, such as a start-of-sequence token, an end-of-sequence token, or a null token indicating a padding of the sequence or a mask that hides a token of the sequence.

[3267] The input sequence is processed by a position encoder that determines, for each token, an encoding of the position. In some embodiments, the position encoding may include an ordinal numerical value that indices the ordinal position of each token in the sequence, such as an index beginning at zero or one. In some embodiments, the position encoding may include a relative numerical value that indicates a position of each token in the sequence relative to a fixed position, such as a current word (encoded position 0), an immediately preceding word (encoded position -1), or an immediately following word (encoded position 1). In some embodiments, the position encoding may include non-integer values and/or multiple values, such as a first index indicating a sine calculation (with a given frequency) of the position of each token and a second index indicating a cosine calculation (with a same or different frequency) of the position of each token.

[3268] The input sequence is also processed by an embedding model. The embedding model determines, for each token in the input sequence, a mapping of the token into a latent space representation of the input (e.g., a latent space representation of a language). The latent space may position each token along a plurality of n dimensions, wherein each dimension represents a distinct type of relationship among the elements of the language. The embedding model clusters the tokens such that related tokens are positioned closer to each other within the latent space. For example, along one dimension of the latent space, the words "Cat" and "Dog" may be positioned close together as being words that describe animals, while also being positioned apart from words that do not describe animals, such as "Baseball" and "School." Along another dimension of the latent space, the words "Dog" and "Furry" may be positioned close together as words that commonly occur in the context of dogs, while also being positioned apart from words that do not describe dogs, including "Cat." For each token of the input sequence, the embedding model generates one or more values that indicate the position of the token within the latent space. In some embodiments, the values are encoded as a vector, and the proximity of two tokens within the latent space may be determined based on vector proximity calculations, such as cosine similarity.

[3269] Based on the positions encoded by the position encoder and the embeddings determined by the embedding model, a model input can be generated for the input sequence. As shown in FIG. 175, the model input includes a query, a set of keys, and a set of values. As an

example, the query may include an indicator of a particular token in the input sequence, such as the sixth token ("Cat"). The keys may include the position encodings of respective tokens of the input sequence, as determined by the position encoder, and a corresponding embedding of the respective token as determined by the embedding model. The values may indicate additional data features of the tokens. As an example, the values may indicate, for each token of the input sequence, a determined sentiment (e.g., a ranking between -1, indicating very negative words, and +1, indicating very positive words). In some embodiments, no additional data features are available, and the values are identical to the keys.

[3270] The model input is received and processed by an attention layer. In FIG. 175, the attention layer first includes a set of fully-connected layers: a first fully-connected layer processes the query of the model input; a second fully-connected layer processes the keys of the model input; and a third fully-connected layer processes the values of the model input. Each fully-connected layer includes a bias and a set of weights that adjust the values of the query, key, or value, respectively. The bias and weights of each fully-connected layer are model parameters that are initialized (e.g., to random values) and then incrementally adjusted during training.

[3271] Optionally, in some embodiments, the outputs of the fully-connected layers are further processed by a masking layer. The masking layer removes one or more values from the model input adjusted by the fully-connected layers. As a first example, the masking layer can reduce to zero the values of the key and/or value at a given position, such as a token at a current position to be predicted, or a token at a position following the current position that is to be hidden from the model. As a second example, the masking layer can reduce to zero the values of particular keys and/or values, such as padding values that are provided to adapt the size of the model input to a size of input that the attention layer is configured to receive and process. The masking layer can produce output for certain tokens (e.g., reduced to zero) for the indicated tokens (e.g., the current token, future tokens, and/or padding tokens) and that is the same as the input for the remaining tokens.

[3272] Optionally, in some embodiments, the outputs of the masking layer are further processed by a multi-head reshaping layer. The multi-head reshaping layer can reshape an input vector comprising the weighted and/or masked model input such that subsets of the input can be processed in parallel by different attention heads. As an example, an attention layer may include two attention heads, and the input can be reshaped such that each attention head is applied to only half of the inputs. The multi-head attention model can enable attention determinations over different subsets of the input (e.g., a first attention head can determine the relatedness of a first token to a first subset of tokens of the input sequence, and a second attention head can determine the relatedness of the same first token to a second subset of tokens of the input sequence). Alternatively or additionally, the multi-head attention model can enable different types of attention determinations among the tokens of the input sequence (e.g., a first attention head can determine a first type of relatedness of a first token to a subset of tokens of the input sequence, and a second attention head can determine a second type of relatedness of the same first token to the same or different subset of tokens of the input sequence). The multi-head attention model

may enable parallel processing of the input sequence (e.g., the input for each attention head can be processed by a different processing core).

[3273] The attention layer includes an attention calculation that determines, based on the model input, the attention of a token of the input sequence with respect to other tokens of the input sequence. In some embodiments, the attention calculation includes an additive attention ("Bahdanau Attention") calculation, in which attention is determined as a sum of weighted calculations of the distances of the tokens along each dimension of the latent space. In some embodiments, the attention calculation includes a dot product determination, as a comparison of the distances between the vectors of the tokens within the latent space. In some embodiments, the attention calculation is performed over the query, keys, and values of the model input, optionally after processing with a masking layer. In some embodiments, the attention calculation is performed for each of a plurality of attention heads, each of which processes a particular subset of the tokens of the input sequence.

[3274] In embodiments that include multi-head reshaping, the output of the attention calculation is further processed by a merge operation that merges the attention calculations for the respective attention heads. In some embodiments, the merge operation includes a concatenation and/or interleaving of the attention calculations of the attention heads. In some embodiments, the merge operation includes an arithmetic operation applied to the attention calculations of the attention heads, such as an arithmetic mean, median, min, and/or max calculation.

[3275] The attention layer outputs, for at least one token of the input sequence, a determination of attention between the token and at least one other token of the input sequence. The output of the attention calculation may include a vector that indicates, for at least one token of the input sequence, the determinations of attention between the token and a set of other tokens of the input sequence. The output of the attention calculation may include a set of vectors that indicate, for respective tokens of the input sequence, the determinations of attention between the respective token and at least one other token of the input sequence. The output of the attention calculation may indicate, for a token of a first sequence, the attention of the token to one or more tokens of a second sequence. As shown in FIG. 175, the output of the attention layer includes pairwise determinations of relatedness between pairs of tokens (e.g., each pair including a current token in an input sequence and each preceding token in the input sequence). In some embodiments, the pairwise determinations may be further processed. For example, a softmax calculation can be applied to normalize the pairwise attention determinations based on a desired range of output values (e.g., probability values between 0.0 and 1.0, with a 1.0 sum over all output values).

[3276] The attention layer may be trained by providing sets of training input sequences and comparing the outputs of the attention layer with expected outputs. Alternatively or additionally, the attention layer may be trained by incorporating the attention layer into a larger model (e.g., a transformer model) and adjusting the parameters of the attention layer (e.g., the parameters of the fully-connected layers) for a given training input sequence in order to adjust the output of the attention layer toward a desired output for the training input sequence. As an example, in a

backpropagation training process, the output of the attention layer is provided as input to a succeeding layer. The output of the model including the attention layer and the succeeding layer may be compared with a desired output for the training input sequence. Based on this comparison, adjustments of the output of the succeeding layer (e.g., based on an error calculation) may inform a determination of desired adjustments of the input of the succeeding layer, which correspond to adjustments of the output of the attention layer. The adjustments of the output may be achieved by internally adjusting the parameters of the attention layer (e.g., the weights and/or biases of the fully-connected layers shown in FIG. 175) such that the attention layer subsequently generates output for the training input sequence that more closely corresponds to the desired input for the succeeding layer. Incremental training over a set of training input sequences can cause the attention layer to generate output that corresponds to the desired output for the training input sequences. As an example, if the input sequences are sentences in a language and the desired output of the model includes the probabilities of words in the language that could follow a given set of input words, the attention layer can be incrementally adjusted to indicate the attention (e.g., relatedness) between the next word in the input sequence and the preceding words in the input sequence.

[3277] It is to be appreciated that the attention layer shown in FIG. 175 presents only one example, and that attention layers may include a variety of variations with respect to the example of FIG. 175. For example, attention layers may include, without exception, additional layers or sub-layers that perform one or more of: normalization; randomization; regularization (e.g., dropout); one or more sparsely-connected layers; one or more additional fully-connected layers; additional masking; additional reshaping and/or merging; pooling; sampling; recurrent or reentrant features, such as gated recurrence units (GRUs), long short-term memory (LSTM) units, or the like; and/or alternative layers, such as skip layers. Alternatively or additionally, the architecture of the attention layer shown in FIG. 175 may vary in numerous respects. For example, masking may be applied to the model input instead of to the outputs of the fully-connected layers. One or more fully-connected layers may be omitted, replaced with a sparsely-connected layer, and/or provided as multiple fully-connected layers, including a sequence of two or more fully-connected layers; or the like. Model parameters (e.g., weights and biases) and/or hyperparameters (e.g., layer counts, sizes, and/or embedded calculations) may be modified and/or replaced with variant parameters and/or hyperparameters. Many such variations may be included in attention layers that are incorporated in a variety of machine learning models to process a variety of types of input sequences.

[3278] In some aspects, the techniques described herein relate to a system for improving a value chain networks using graph neural networks, the system including one or more processors and one or more memories configured to perform operations including: receiving an input graph data set representing a value chain network, including nodes representing entities within the value chain and edges representing transactions or relationships between entities; generating an embedding based on the input graph data set specific to the value chain context; applying a plurality of graph neural network layers to the embedding to produce an output graph data set,

wherein the output graph data set includes updates to nodes and edges reflecting changes in the value chain network; performing a clustering analysis on the nodes or edges of the output graph data set to identify clusters representing highly interconnected segments of the value chain; and outputting the optimized value chain network graph data set including updated node properties, edge properties, or graph properties based on the clustering analysis and value chain optimization criteria.

[3279] In embodiments, the value chain network entities may include, but are not limited to, products, suppliers, producers, manufacturers, retailers, businesses, owners, operators, operating facilities, customers, consumers, workers, mobile devices, wearable devices, distributors, resellers, supply chain infrastructure facilities, supply chain processes, logistics processes, reverse logistics processes, demand prediction processes, demand management processes, demand aggregation processes, machines, ships, barges, warehouses, maritime ports, airports, airways, waterways, roadways, railways, bridges, tunnels, online retailers, ecommerce sites, demand factors, supply factors, delivery systems, floating assets, points of origin, points of destination, points of storage, points of use, networks, information technology systems, software platforms, distribution centers, fulfillment centers, containers, container handling facilities, customs, export control, border control, drones, robots, robotic handling systems, 3D printers, vehicles, autonomous vehicles, hauling facilities, waterways, and port infrastructure facilities.

[3280] In embodiments, changes in the value chain network may include, but are not limited to, new entities, discontinued entities, new relationships (e.g., supplier relationships), discontinued relationships, altered transactional dynamics, improved distribution routes, shifts in manufacturing sites, new storage facilities, inventory redistribution, and the like.

[3281] Input graph data for a graph neural network system, as described, can take various forms depending on the context of the value chain network being analyzed. In one example, the input graph data set could represent the entire supply chain of a manufacturing company. Nodes could represent suppliers, manufacturing plants, distribution centers, and retailers. Edges could represent the flow of materials, products, and information between these entities. In a logistics context, the input graph data could include nodes representing warehouses, ports, shipping routes, and transportation hubs. Edges could represent logistical connections such as shipping lanes, trucking routes, and rail lines, as well as the frequency and volume of shipments. For a retail business, the input graph data set could represent a network of retail stores, distribution centers, and suppliers. Nodes could represent individual stores and their inventory levels, while edges could represent supply lines and the movement of goods. For a telecommunications company, the input graph data set could represent the network infrastructure with nodes for cell towers, routing centers, and customer endpoints. Edges could represent communication links and data transfer paths. In project management, the input graph data could represent the tasks, milestones, and dependencies within a project. Nodes could represent individual tasks or work packages, and edges could represent dependencies or sequences in which tasks must be completed. For the agricultural sector, the input graph data set could include nodes representing farms, processing facilities, distributors, and retail outlets. Edges could represent the flow of

agricultural products and information about demand and supply between these nodes. In a smart city context, the input graph data could represent the transportation network with nodes for intersections, public transport stops, and parking facilities. Edges could represent roads, public transport routes, and pedestrian pathways. Each of these examples of input graph data sets provides a structured representation of complex relationships and interactions within a particular value chain network, which the graph neural network system can analyze and optimize. For example, in a value chain network of a manufacturing company, nodes could represent suppliers, manufacturers, distributors, and retailers, while edges could represent the supply contracts or delivery schedules between them.

[3282] In one example, a company that manufactures electronics wants to optimize its value chain network. Using a graph neural network system, the company inputs data representing all entities in its supply chain, including raw material suppliers, component factories, assembly plants, distribution centers, retailers, and end consumers. Each entity is a node in the network, and the edges represent the flow of materials, components, and finished products, as well as information and financial transactions between these entities. The graph neural network analyzes this complex web of interactions to identify inefficiencies. For instance, it might find that certain suppliers are consistently late in delivering materials, causing bottlenecks in production. Or it might discover that some distribution routes are longer than necessary, leading to delays and increased costs. Based on these insights, the system generates recommendations such as diversifying the supplier base, opening a new distribution center to serve a high-demand region more efficiently, or reallocating inventory to different retailers based on predictive sales data. These recommendations are then presented to the company's decision-makers, who can take strategic actions to streamline operations, reduce costs, and improve the overall efficiency of the value chain network.

[3283] In embodiments, the system may perform dimensionality reduction on the graph data set based on a similarity matrix to facilitate the clustering analysis. This process simplifies the graph data set by focusing on the most relevant features that contribute to similarities between nodes or edges, which can enhance the efficiency and accuracy of the clustering analysis. In the context of a value chain network, dimensionality reduction might reveal that certain suppliers are interchangeable in terms of the materials they provide, allowing the system to simplify the network by treating these suppliers as a single entity for optimization purposes.

[3284] In embodiments, the system may be configured to apply spectral clustering techniques during the clustering analysis. Spectral clustering uses eigenvalues of a similarity matrix to identify significant relationships within the data, which can be particularly effective for complex value chain networks where traditional clustering methods may fall short. For example, spectral clustering could be used to detect communities of businesses within a value chain that frequently collaborate on joint ventures or share logistics resources.

[3285] In embodiments, the system may be configured to generate an output graph data set that includes graphlet degree vectors indicating recurring structures within the input graph data set. This feature allows the system to recognize and represent patterns that occur repeatedly within

the value chain, such as common configurations of suppliers, manufacturers, and distributors that form a standard supply chain module. An example of this could be a recurring structure where a particular set of suppliers always feeds into a specific manufacturing process, which could be optimized as a unit.

[3286] In some implementations, the system may be configured to perform graph-to-graph translation to generate an output graph data set that represents a different graph data set from the input graph data set. This capability enables the system to transform the structure of the value chain network to represent different scenarios or optimizations. For instance, the system could translate a current value chain graph into a future state graph that represents the network after a planned expansion of distribution centers.

[3287] In embodiments, the system is configured to utilize instance-level explanations based on gradients, features, perturbations, or decomposition to provide interpretability of the output graph data set such that the system can explain the reasoning behind the updates made to the value chain network, such as why certain nodes were added or removed, or why specific edges were strengthened or weakened. In a value chain network example, this could help stakeholders understand why the system recommends increasing the frequency of deliveries between certain entities.

[3288] In embodiments, the system is configured to perform hyperparameter search processing to refine the graph neural network based on user feedback regarding the output graph data set. This process involves adjusting the settings of the graph neural network to improve its performance based on the outcomes observed and feedback received. For example, if users indicate that the system's recommendations for a value chain network do not adequately account for seasonal demand fluctuations, the hyperparameter search could adjust the network to better factor in these variations.

[3289]

[3290] TRANSFORMER MODELS

[3291] In embodiments, an artificial intelligence system, machine learning model, or the like, of any of the types disclosed herein, may comprise, integrate, link to, or include a transformer model, that is, a neural network that learns context and meaning by tracking relationships in a set of sequential data inputs. Transformer models may include one or more attention layers, including (but not limited to) the attention layer shown in FIG. 175.

[3292] FIG. 176 presents an example of a transformer model. The transformer model of FIG. 176 is based on an encoder-decoder architecture in which an encoder processes an input sequence and a decoder processes an output sequence to generate output probabilities. As a first example, the input sequence may include a sequence of words in a first language; the output sequence may include a sequence of words in a second language corresponding to a translation of the input sequence; and the output probabilities may include the probabilities of words in the second language for a particular position in the translation. As a second example, the input sequence may include a sequence of words in a language that represent a query or prompt; the output sequence may include a sequence of words in the same language that represent a response

to the query or prompt; and the output probabilities may include the probabilities of words in the second language for a particular position in the response. In some cases, the output sequence includes only the tokens up to a particular position (e.g., the first n-1 tokens of the output sequence), and the output probabilities represent the probabilities of tokens in the language of the output sequence that could follow the output sequence (e.g., the nth token in the output sequence). In some cases, the output sequence includes all of the tokens except the token a particular position (e.g., all of the tokens except the nth token of the output sequence), and the output probabilities represent the probabilities of tokens in the language of the output sequence that could represent the missing token in the output sequence (e.g., the nth token in the output sequence).

[3293] The encoder receives an input sequence comprising a set of tokens. The input sequence may be padded to a given length corresponding to a configured input size for the encoder. The input sequence is processed by a position encoder to encode the positions of the respective tokens of the input sequence. The input sequence is also processed by an embedding model to determine the embeddings of the tokens of the input sequence. The encoded positions and embeddings are used to generate an encoder model input, including a query (e.g., a position of one or more tokens in the input sequence), a set of keys (e.g., the encoded positions and embeddings for each token of the input sequence), and a set of values (e.g., additional language features of the tokens such as outputs of sentiment analysis). The set of values may be a copy of the set of keys if no additional data features are available. The encoder model input is processed by a multi-head attention layer, such as an instance of the attention layer shown in FIG. 175. The multi-head attention layer determines self-attention within the input sequence (e.g., the relatedness of a respective token of the input sequence to each other token of the input sequence). The output of the multi-head attention layer is received and processed by a layer normalization component. Additionally, a skip layer is provided that passes the encoder model input through to the layer normalization component. The layer normalization component combines the output of the multi-head attention layer with the encoder model input (e.g., via arithmetic mean, median, min, max, addition, multiplication, or the like) and normalizes the combined output to within a desired range. In some embodiments, the encoder includes a sequence of two or more instances of this combination of multi-head attention layers, skip layer, and layer normalization components. The encoder also includes a feed-forward layer (e.g., a fully-connected layer and/or a sparsely-connected layer) including a set of trainable parameters. The output of the feed-forward layer is provided to another layer normalization component, along with the output of the preceding layer normalization component via a skip layer. The encoder outputs an input sequence attention, which indicates, for each of one or more tokens of the input sequence, the relatedness of each other token of the input sequence.

[3294] The decoder features an architecture that is similar to the encoder, but that includes additional components to incorporate the input sequence attention generated by the encoder. The decoder receives an output sequence comprising a set of tokens. The output sequence may be padded to a given length corresponding to a configured input size for the decoder. The output

sequence is processed by a position encoder to encode the positions of the respective tokens of the output sequence. The output sequence is also processed by an embedding model to determine the embeddings of the tokens of the output sequence. The encoded positions and embeddings are used to generate a decoder model input, including a query (e.g., a position of one or more tokens in the output sequence), a set of keys (e.g., the encoded positions and embeddings for each token of the output sequence), and a set of values (e.g., additional language features of the tokens such as outputs of sentiment analysis). The set of values may be a copy of the set of keys if no additional data features are available. The decoder model input is processed by a masked multi-head attention layer, such as an instance of the attention layer shown in FIG. 175. In addition to determining attention, the masked multi-head attention layer masks the input values of a current token of the output sequence and any tokens of the output sequence that follow the current token. The masked multi-head attention layer determines self-attention within the output sequence (e.g., the relatedness of a respective token of the output sequence to each preceding token of the output sequence). The output of the multi-head attention layer is received and processed by a layer normalization component. Additionally, a skip layer is provided that passes the encoder model input through to the layer normalization component. The layer normalization component combines the output of the multi-head attention layer with the encoder model input (e.g., via arithmetic mean, median, min, max, addition, multiplication, or the like) and normalizes the combined output to within a desired range. In some embodiments, the encoder includes a sequence of two or more instances of this combination of multi-head attention layers, skip layer, and layer normalization components. The decoder further includes an encoder-decoder multi-head attention layer that receives both the output of the preceding layer normalization component and the input sequence attention generated by the encoder. The encoder-decoder multi-head attention layer does not determine self-attention within the output sequence, but, rather, determines the attention between the tokens of the output sequence and the corresponding tokens of the input sequence. The output of the encoder-decoder multi-head attention unit is also received and processed by a second layer normalization component. Additionally, a skip layer is provided that passes the input to the encoder-decoder multi-head attention layer through to the second layer normalization component. The second layer normalization component combines the output of the multi-head attention layer with the input to the encoder-decoder multi-head attention unit (e.g., via arithmetic mean, median, min, max, addition, multiplication, or the like) and normalizes the combined output to within a desired range. The decoder also includes a feed-forward layer (e.g., a fully-connected layer and/or a sparsely-connected layer) including a set of trainable parameters. The output of the feed-forward layer is provided to a third layer normalization component, along with the output of the preceding layer normalization component via a skip layer. The output of the decoder is processed by a fully-connected layer and a softmax normalization layer based on a cross-entropy determination.

[3295] The output of the softmax normalization layer includes a set of probabilities for each possible token of a language of the output sequence for the current token. As a first example, the

input sequence may include a sequence of words in a first language; the output sequence may include a sequence of words in a second language corresponding to a translation of the input sequence, up to a current (nth) word in the translation; the output probabilities may include the probabilities of words in the second language for the nth word in the translation. As a second example, the input sequence may include a sequence of words in a language that represent a query or prompt; the output sequence may include a sequence of words in the same language that represent a response to the query or prompt, up to a current (nth) word in the response; and the output probabilities may include the probabilities of words in the language for the nth word in the response.

[3296] During training, the transformer model may be provided with a set of input sequences and complete corresponding output sequences. As a first example involving language translation, the transformer model may be provided with a training data set including a first corpus of sentences in a first language and a second corpus of sentences in a second language that respectively correspond to the sentences in the first language. As a second example involving a generative model, the transformer model may be provided with a training data set including a first corpus of queries or prompts in a language and a second corpus of responses in the language that correspond to the respective queries or prompts. For each training data input, a pair of sentences of the first corpus and second corpus are selected. The encoder is provided with the first (input) sentence, and the model is processed to determine the first word in the second (output) sentence. In this case, the output sequence provided to the decoder is completely masked so that the decoder cannot make predictions based on the expected words in the second sentence. The word probabilities determined by the decoder are compared with the actual first word in the output sequence, and backpropagation is applied through the decoder and encoder to increase the likelihood of outputting the expected word. The backpropagation includes adjusting the parameters of the attention layers to increase the attention between the first word and related words of the input sequence. The encoder is then provided again with the first (input) sentence, and the model is processed to determine the second word in the second (output) sentence. In this case, the output sequence provided to the decoder includes the unmasked first word, but masks all words after the first word. The word probabilities determined by the decoder are compared with the actual second word in the output sequence, and backpropagation is applied through the decoder and encoder to increase the likelihood of outputting the expected word. The backpropagation includes adjusting the parameters of the attention layers to increase the attention between the second word, the known first word of the output sequence, and related words of the input sequence. In this manner, the transformer model performs an autoregressive prediction, wherein the output probability of each nth token of the output sequence is based on the input sequence, the previously predicted tokens of the output sequence, and the encoder-decoder attention therebetween. Training continues over the entirety of the first and second corpora to improve the output predictions.

[3297] In many cases, the training of the transformer model occurs in batches. For example, the previous (simplified) training example described an incremental training of the transformer

model over each corresponding pair of sentences of the first and second corpora, wherein the parameters of the transformer model are adjusted via backpropagation after each instance of processing. In batch training, the input and output sequences are vectorized, as are the layers of the transformer model, such that predictions over each word of the output sequence are predicted in parallel. Backpropagation parameter adjustment is performed for each batch of the training data set, based on the outputs for all of the pairwise inputs of each batch of the training data set.

[3298] After training, the transformer model can be used to predict an output sequence based on an input sequence. First, the input sequence is processed by the encoder, while the decoder processes a null output sequence (e.g., an output sequence in which all outputs are initially nulled and/or masked by the masked multi-head attention layer). The output probability of the decoder is used to determine a first token of the output sequence. In some embodiments, the first token is chosen as the token having the highest probability. In other embodiments, the first token is chosen based on a random sampling over the output probabilities. In either case, the transformer is then applied to the same input sequence and an output sequence including only the determined first token of the output sequence, and the output of the decoder determines the second token of the output sequence. This process continues until reaching an output token cap and/or upon determining, as the output of the decoder, an end-of-sequence token. In this manner, the transformer model is applied over the input sequence to determine, in serial and autoregressive manner, the tokens of the output sequence.

[3299] It is to be appreciated that the transformer model shown in FIG. 176 presents only one example, and that transformer models may include a variety of variations with respect to the example of FIG. 176. For example, the architecture of the encoder and/or decoder may include, without exception, additional layers or sub-layers that perform one or more of: normalization; randomization; regularization (e.g., dropout); one or more sparsely-connected layers; one or more additional fully-connected layers; additional masking; additional reshaping and/or merging; pooling; sampling; recurrent or reentrant features, such as gated recurrence units (GRUs), long short-term memory (LSTM) units, or the like; and/or alternative layers, such as skip layers. Alternatively or additionally, the architecture of the encoder and/or decoder shown in FIG. 176 may vary in numerous respects. For example, masking may be applied directly to the output sequence instead of within the multi-head attention models. One or more fully-connected layers may be omitted, replaced with a sparsely-connected layer, and/or provided as multiple fully-connected layers, including a sequence of two or more fully-connected layers; or the like. Model parameters (e.g., weights and biases) and/or hyperparameters (e.g., layer counts, sizes, and/or embedded calculations) may be modified and/or replaced with variant parameters and/or hyperparameters. Many such variations may be included in transformer models to process a variety of types of input and output sequences.

[3300] Transformer models, including the example shown in FIG. 176, may be applied in a variety of circumstances. As an example, transformer models may be trained on and/or configured to process a variety of types of input sequences and/or output sequences. Sequential data inputs and/or outputs can include a wide variety of types described herein, such as strings of

text, sequences of sensor data from or about an entity, sequences of steps in a process (e.g., chemical, physical, biological, and many others) or flow (e.g., a human workflow, information technology traffic flow, physical traffic flow, sequences of user behavior (e.g., attention to content, clickstream behavior, shopping behavior (digital and real world), and many others. Any of these, and others can be provided as inputs to train a transformer model, which may be alternatively described herein as a self-attention model, a foundation model, or the like. A range of mathematical self-attention techniques can be applied to detect how data elements in sequential data mutually affect each other (such as in feed forward, feedback, and other forms of influence and dependency). In various embodiments described herein and in the documents incorporated by reference herein, a set of transformer models may be deployed for a wide range of use cases, including for predictive text applications (e.g., generating a next token of text based on a previous set of tokens, such as for intelligent agent dialog, responses to queries, and the like); for extraction of information (such as extraction of meaningful elements from sensor data, signal data, and the like, such as analog signal data from sensors on machines, wearable devices, infrastructure sensors, edge and IoT devices, and many others); for analysis of human factors, such as emotional response, sentiment, satisfaction, opinion, and the like; for summarizing data (such as providing summaries of text, images, video, sensor data, and many other streams of data of the type collected and processed as described herein); for trend detection, prediction and forecasting (and hence also for anomaly detection, such as fraud in financial transactions), including for a wide range of trends, including health (human, animal, mental, financial, machine condition, and others), performance (wellness, financial, physical, and many others), and many others; for recognition of entities and behaviors (such as objects appearing in video or image data, objects captured in LIDAR and other point-cloud rendering systems, objects located by SLAM systems, and many others); for generation and execution of instructions (e.g., recipes, control instructions, rules, regulations, governance instructions, and many others); and for many other uses.

[3301] In embodiments, an input data set, such as an analog or digital sensor data stream, a body of text, a set of images, a set of structured data (such as data from a graph database or other form of database noted herein, a sequence of blockchain or distributed ledger entries (or other ledger data, such as accounting, financial, health or other data), a set of signals (of the various types noted herein), is provided in order to train a transformer model. In embodiments, initial training may include a step of facilitating compression of the input data, such as by constraining the size of the transformer neural network and/or its outputs, to dimensionality that is significantly smaller (or less granular, etc.) than that of the input data. By requiring the output of the constrained transformer model to match, within a required metric of fidelity, the input data, the transformer model is caused to generate an "embedding" of the input data into a more compressed, efficient format. A decoding neural network may then be trained to operate on the output of the constrained, embedding transformer model, such that it can reproduce the input data from the output of the constrained model within the required metric, thereby assuring that the data is compressed without losing critical meaning.

[3302] Once the embedding transformer model is so trained, the decoding neural network can be removed and replaced by one or more of a set of use-case driven decoding models, each of which is trained to operate on the output of the embedding model to produce a target outcome, such as performing any of the use cases noted above to a satisfactory degree. These use-case decoding models can be fine-tuned iteratively over time with feedback from users, outcomes, or the like. Thus, a trained embedding foundation/transformer model, once created, can be used across many different use cases that may benefit from understanding the meaning of the input data set.

[3303] In embodiments, one type of use-case decoder can be trained to allow the embedding transformer model to operate on lower quality data than was originally supplied to train the model. To accomplish this, both low quality and high quality data (such as high granularity sensor data and low granularity sensor data, or high dimensionality signal data and low dimensionality signal data, or noisy acoustic data and filtered acoustic data, or the like) can be simultaneously fed to a pair or more of instances of the trained, embedding transformer model, and a decoder for the instance of low quality data can be trained to generate an output that matches, within a metric of fidelity, the output of the instance of the embedding transformer model that is fed the high quality data. As an example, gap-free analog waveform data from a three-axis vibration sensor on a machine component can be captured simultaneously with less granular data from a single- or two-axis accelerometer on the same component, and a decoder, operating on the output of the instance of the embedding transformer model that takes the single- or two-axis input, can be trained to match (within a tolerance) the output of the instance of the embedding transformer model that takes the more granular data as an input. Once created, the resulting decoder, coupled with the embedding transformer model, serves as a projection transformer model, effectively projecting lower quality data into higher quality data, which can then be used by other decoders to enable use cases. This class of projecting transformer models can be applied to a wide range of use cases where high quality data can be obtained during a training phase (often at higher expense), but lower quality data can be used as an input during a deployment phase (such as where lower quality data is more widely or cheaply available, such as in the case of vibration data noted above). Among other things, these projecting transformer models allow powerful, real-time, low latency use cases for AI even when input data is sparse, noisy, of low dimensionality, or the like.

[3304] In embodiments, feedback from various decoder models can be used to improve instances of an embedding foundational or transformer model. In embodiments, a set of transformer models, a set of decoders, or both, can be arranged in a workflow, which may be directed/acyclical or with processing loops, to create higher-level use cases that benefit from multiple applications of AI. For example, one model may be used to classify a condition, another used to generate a recommendation, and another used to generate a control instruction, among a huge range of possible embodiments. This may include serial, parallel, iterative, feed forward, feedback and other configurations.

[3305] In embodiments, a set of models may be trained to generate instructions for configuration of other models.

[3306] In embodiments, transformer models may be deep learning, self-learning, self-organizing, or the like, and may be used for any of the embodiments of self-learning, self-organization, or other self-referential capabilities noted throughout this disclosure or the documents incorporated by reference herein. They may also be supervised, semi-supervised, or the like. Transformer models may be coupled with, integrated with, linked to, or the like, in series, parallel or other more complex workflows, with other AI types, such as other neural network types (e.g., CNNs, RNNs, and others). For example, in embodiments, a transformer model operating on sequential data may be coupled with a model suited to operate on non-sequential data (e.g., for pattern recognition) to achieve a use case.

[3307] In embodiments, transformer models discover patterns in large bodies of data by application of a set of mathematical functions, optionally operating in parallel processing configurations, thereby eliminating or reducing the need for human labeling (and thereby greatly expanding the set of available data that can be used to train a model).

[3308] Self-attention may be accomplished in a transformer model by introducing a set of positional encoders that tag data elements entering and exiting a neural network and inserting a set of attention units at appropriate places in the encoding and decoding framework of an AI system. The attention units generate a mathematical map of interrelationships among data elements. In embodiments multi-headed attention units are deployed, executing a matrix of equations in parallel to determine the interrelationships. Transformer models, using self-attention, have displayed strong capabilities to provide outputs that are consistent with how humans find patterns and meaning in data.

[3309] In embodiments, transformer models may be embodied with very large numbers of parameters (e.g., hundreds of millions, billions, trillions, or more) operating on very large sets of parallel processors. For example, the Megatron-Turing Natural Language Generation Model by NVIDIA and Microsoft is reported to have 530 billion parameters. As noted above, from a foundational model, various use-case specific models (decoders, projections, and the like) can be purpose-built for specific applications. Accordingly, in embodiments a set of transformer models may be deployed using advanced computational techniques and/or processing architectures, such as ones that simplify or converge processors, simplify I/O, and the like. For example, 3D chipset or chiplet architectures may facilitate much higher density, faster computation, making transformer models more cost-effective. Quantum computation may also facilitate massively parallel processing in form factors that are faster, more energy efficient, or the like. Similarly, embodiments may use a tensor-engine GPU chip with a specific transformer engine, such as the NVIDIA H100 Tensor Core GPU. Another example of a transformer model is Google's switch transformer model, a trillion-parameter model that uses sparsity and a mixture-of-experts architecture to enable gains in performance and reductions in training speed.

[3310] As noted above, in embodiments smaller or more constrained transformer models may be trained to generate embeddings, particularly for very complex data sets, such as granular analog data.

[3311] In embodiments a set of transformer models may be configured to operate on structured data processing systems, such as on results from queries that are directed to a database, results of inputs directed to a set of APIs, or the like. This may facilitate better understanding of what meaning a transformer model is recognizing in a data pattern, which can be critical to ensuring quality (e.g., where a model may, due to flaws in underlying data, generate poor conclusion, such as replicating historical racial bias, missing critical balancing information, failing to understand formal logical constructs, or the like). As noted elsewhere in this disclosure and the documents incorporated herein, governance of AI in general, is a need, and the scale and complexity of transformer models likely compounds problems recognized with other neural networks, including their "black box" nature, uncertainty about input quality, and the like. Thus, governance concepts disclosed herein and in documents incorporated by reference should be understood to apply to various embodiments that use transformer models, as with other types of AI. One example is in the training of models, where models may be trained, in embodiments, in various disciplines, optionally similar to the educational frameworks by which humans are trained not just to sense pattern meaning, but also how to test and govern those abilities with formal reasoning and logic, mathematics, probability, and frameworks of ethics and morality.

[3312] In some aspects, the techniques described herein relate to a system for optimizing and/or improving a value chain network (VCN) using transformer models including one or more memories and one or more processors configured to perform operations including: receiving an input data set representing a VCN including nodes and edges; encoding the input data set using an encoder of a transformer model to generate a contextual representation; decoding the contextual representation using a decoder of the transformer model to generate an output data set indicative of VCN improvements; and output the improved VCN data set for facilitating decision-making in the VCN.

[3313] The system for improving a value chain network (VCN) utilizes the transformer model architecture to process complex and multi-dimensional input data sets. The input data set may include a variety of data types such as production volumes, inventory levels, lead times, supplier performance metrics, transportation costs, market demand signals, customer order histories, and the like. Each data type may be represented as nodes (e.g., factories, warehouses, products) and edges (e.g., supply lines, distribution routes) within the VCN.

[3314] The system, equipped with the transformer model's encoder, is configured to transform this raw data into a high-dimensional space where relationships and patterns can be discerned through self-attention mechanisms. The encoder may use positional encodings to retain the sequential nature of the data, such as the order of events in a supply chain timeline. It may then apply multiple layers of self-attention where each layer computes attention scores that signify the importance or influence of different nodes and edges on each other. This process allows the

model to contextualize each element within the entire network, taking into account both direct and indirect dependencies.

[3315] An example embodiment of this system could involve a multinational manufacturing company seeking to optimize its global supply chain. The input data set for the transformer model could include real-time data streams from IoT sensors on factory equipment, historical production data, current inventory levels across global warehouses, in-transit shipment statuses, supplier delivery records, and predictive demand forecasts generated by market analysis tools, among many others. By processing this data, the system could identify bottlenecks, predict potential disruptions, and suggest reallocations of resources such as rerouting shipments to avoid delays caused by a natural disaster or reallocating production to underutilized plants to meet a surge in demand in a specific region. The output of the system would be an optimized VCN data set that provides actionable insights, such as adjusting order quantities, reconfiguring distribution networks, or changing supplier selection criteria to improve overall network resilience and efficiency.

[3316] In some aspects, the techniques described herein relate to a system, wherein the system is further configured to apply multi-head attention mechanisms to determine relationships between nodes and edges within the VCN. The system employs multi-head attention mechanisms within the transformer model to analyze and interpret the relationships between various entities in the VCN. This approach allows the system to concurrently process different types of relationships, such as supply chain dependencies and production bottlenecks, by projecting these relationships into different representation subspaces and then integrating the information. For example, in a VCN that includes a complex logistics network, the system could use multi-head attention to simultaneously evaluate the impact of transportation delays, supplier reliability, and demand variability on overall network efficiency.

[3317] In implementations, the techniques described herein relate to a system, wherein the system is further configured to perform autoregressive prediction of VCN configurations using the output data set. The system's autoregressive prediction feature enables it to sequentially generate future states of the VCN by considering each node and edge in the context of the previously generated outputs. This is achieved through the decoder component of the transformer model, which builds the output sequence one element at a time, conditioned on the accumulated sequence thus far. In practice, this could manifest in a VCN that anticipates and adjusts to potential disruptions in the supply chain, such as a sudden increase in raw material costs or unexpected changes in consumer demand.

[3318] In some embodiments, the techniques described herein relate to a system, wherein the system is further configured to utilize positional encoding to maintain the sequence order of the VCN data within the transformer model. Positional encoding is a critical feature of the transformer model that allows the system to maintain the order of events within the VCN. This is particularly important for time-series data where the sequence of transactions or logistical events carries significant meaning. The positional encoding adds information to each node in the sequence, enabling the model to differentiate between elements based on their position in the

sequence. An example embodiment could involve a VCN where the system uses positional encoding to optimize the timing of product launches across different markets.

[3319] In some aspects, the techniques described herein relate to a system, wherein the system is further configured to implement layer normalization within the transformer model to stabilize the learning process. Layer normalization is implemented within the transformer model to ensure consistent training dynamics and to help the model generalize across different inputs. By normalizing the inputs to each sub-layer within the encoder and decoder, the system can train more effectively, leading to faster convergence and improved performance. For instance, a VCN that experiences seasonal demand spikes could benefit from a system that adapts quickly to these changes, ensuring that the network remains responsive and efficient.

[3320] In embodiments, the techniques described herein relate to a system, wherein the system is further configured to adjust the transformer model parameters based on a set of training data representing historical VCN performance. The system's parameter adjustment is informed by historical VCN performance data, allowing for the refinement of the transformer model over time. This iterative training process involves adjusting weights and biases within the model to minimize loss functions that measure the discrepancy between the model's predictions and actual historical outcomes. An example embodiment might involve a VCN that refines its predictive maintenance schedules for machinery by learning from past maintenance records and operational data.

[3321] In some aspects, the techniques described herein relate to a system, wherein the system is further configured to generate predictions for VCN resource allocation based on the output data set. The system generates resource allocation predictions for the VCN based on the output data set, which may include optimized configurations and operational recommendations. These predictions may be derived from the transformer model's ability to synthesize large amounts of data and identify patterns that may not be immediately apparent to human analysts. For example, a VCN could use the system to dynamically allocate production capacity across different factories in response to shifting market trends, thereby maximizing efficiency and reducing lead times.

VCN CONVERGING TECHNOLOGY STACK

[3322] Referring to FIG. 177, a value chain network (VCN) converging technology stack 23000 is illustrated in accordance with some embodiments. A plurality of VCN modules 23006 is increasingly enabled at various layers by the convergence of AI capabilities 23002 with other technologies, impacting existing VCN operations, and some cases, enabling entirely new VCN operations. This technology convergence enables various VCN operations, which support various use cases and/or converging technology stack examples 23004 for a multitude of VCN scenarios.

[3323] In embodiments, the VCN modules 23006 may include automated governance of VCN modules at the governance layer 23008, VCN control towers and VCN system of systems modules at the enterprise layer 23010, an AI-driven product management platform modules at

the offering layer 23012, automated orchestration of demand shaping and value chain network transactions modules at the transaction layer 23014, converged AI-based demand shaping and value chain shipping and logistics orchestration modules at the operations layer 23016, digital product networks and adaptive edge infrastructure networks modules at the network layer 23018, context-aware sensor fusion to inform VCN analytics and AI modules at the data layer 23020, and demand-aware value chain component and resource optimization modules at the resource layer 23022.

[3324] At the governance layer 23008, artificial intelligence (AI) capabilities 23002 for embedded policy and governance may enable an automated governance of VCNs modules. Converging technology stack examples 23004 at the governance layer 23008 may include policy automation, regulatory compliance automation, reporting automation, executive digital twins, safety automation, and the like. The automated governance of VCNs module may address how increasingly digitized and networked product networks and infrastructure operations can be governed by policy automation that keeps in step with ever-shifting regulatory frameworks that apply to operations.

[3325] In embodiments, the automated governance of VCN modules are supported by advanced embedded policy and governance AI capabilities. The automated governance of VCN modules may be configured to autonomously enforce compliance and governance standards across VCN activities, transactions, and operations by leveraging a sophisticated AI framework. The automated governance of VCN modules may be configured to interpret and apply a comprehensive array of regulatory requirements, internal control policies, and industry standards to real-time VCN data flows. In embodiments, the automated governance of VCN modules utilize AI algorithms to continuously monitor, analyze, and make determinations on the compliance status of each transaction, activity, and/or operation, thereby ensuring adherence to the pertinent legal and regulatory frameworks. The AI-driven modules may dynamically adapt to regulatory changes, thereby maintaining up-to-date compliance. Furthermore, the modules may automate the generation of detailed compliance reports and maintain an immutable audit trail for each transaction, activity, and/or operation, thereby facilitating transparency and accountability. By embedding these AI capabilities directly within the VCN infrastructure, the modules significantly enhance the efficiency, accuracy, and reliability of the governance process, while simultaneously mitigating risk and reducing the operational burden associated with manual governance and compliance checks.

[3326] At the enterprise layer 23010, AI capabilities 23002 for contextual simulation and forecasting enable VCN control tower and VCN system of systems modules. Converging technology stack examples 23004 at the enterprise layer 23010 may include the VCN control tower, VCN mini control towers, big data and analytics, executive digital twins, supply chain and demand shaping integration, VCN system of systems, and the like. The VCN control tower and VCN system of systems modules may provide centralized and decentralized control frameworks for managing disparate product, infrastructure, transportation and other intelligent and networked entities involved in supply chain and demand planning activities.

[3327] In embodiments, an AI-based VCN control tower and VCN system of systems modules are empowered by contextual simulation and forecasting capabilities. These modules may integrate a sophisticated artificial intelligence framework that utilizes contextual data analysis to simulate various VCN scenarios and forecast potential outcomes. By processing vast datasets, including historical data, demand data, supplier data, current market trends, and predictive indicators, among many others, the modules can use comprehensive models that provide deep insights into the potential ramifications of different VCN strategies, operations, transactions, activities, and the like. The forecasting engine may employ advanced algorithms to predict future demand conditions, financial performance, risk exposure, and the like, thereby enabling enterprises to make informed decisions. The contextual simulation aspect may allow for the creation of virtual environments where hypothetical VCN decisions can be tested, providing a sandbox for strategic planning without the risk of actual commitment. The AI-driven modules may be configured to assist enterprises in optimizing their workflows for VCN, aligning strategies with business objectives, and proactively managing risks, thereby enhancing the overall efficacy and strategic agility of the enterprise's VCN operations, activities, and transactions.

[3328] At the offering layer 23012, AI capabilities 23002 for expert systems and generative AI enable AI-driven product management platform modules. Converging technology stack examples 23004 at the offering layer 23012 may include, but are not limited to, a VCN management platform, networked digital product families, product lifecycle management, recommendation systems, smart products, extended reality systems (e.g., AR, VR, MR), targeted advertising, expert systems, generative AI, and the like. The AI-Driven product management platform modules may be configured to enable AI optimization of features across digital networks and families of products at all phases of the product life cycle, including design, R&D, planning and simulation, shipping and logistics, storage, retailing and customer use.

[3329] In embodiments, the AI-driven product management platform modules may leverage the combined strengths of expert systems and generative artificial intelligence (AI) to deliver product management capabilities, including product development, inventory management, marketing and sales, quality assurance, lifecycle management, and many others. Expert systems within the module may utilize various approaches to analyze customer behaviors and transaction histories, enabling the identification of customer needs, preferences, and future demand. Generative AI algorithms may synthesize this data to create and propose targeted marketing campaigns. This AI approach ensures that products are in demand by consumers and that such demand is met by available inventory in preferred distribution channels. The modules seamlessly support digitally connected products, providing vast amounts of data around product usage, product performance, product environments, and the like. Customer interactions with the digitally connected products are continuously fed back into the modules, refining the AI models to enhance future product designs and improve customer satisfaction. These sophisticated modules thus represent a significant advancement in the customization and delivery of products, driving engagement and value for both the enterprise and its customers.

[3330] At the transaction layer 23014, AI capabilities 23002 for discovery, generation, and optimization enable automated orchestration of demand shaping and VCN transactions modules. Converging technology stack examples 23004 at the transaction layer 23014 may include multiparty value chain orchestration, predictive demand and supply orchestration, automated transaction orchestration, and the like. The automated orchestration of demand shaping and VCN transactions modules may enable automated adjustment of pricing, promotion, and other transaction parameters based on marketplace conditions and sensor data from products and infrastructure.

[3331] In embodiments, automated orchestration of demand shaping and VCN transactions modules are fundamentally enabled by AI specialization in discovery, generation, and optimization. These modules may employ AI to intelligently shape demand by adjusting pricing, marketing, providing distribution channel incentives, and the like. The modules may analyze market behaviors, customer behaviors, demand factors, transactional histories, sensor data from products, and many others to recommend optimal strategies to shift demand. The automated VCN transaction orchestration use cases may be implemented through a combination of machine learning algorithms that recommend transaction partners (e.g., suppliers, retailers, logistics partners, and the like), predict transactional outcomes, natural language processing for contract generation, and neural networks that adaptively learn from each transaction to enhance future performance. Technical solutions for the implementation may include blockchain technology for secure and transparent smart contract execution, distributed ledgers for maintaining a consistent and immutable record of transactions, and the like.

[3332] At the operations layer 23016, AI capabilities 23002 for routing, control, optimization, and generation enable converged, AI-based demand shaping and value chain shipping and logistics and orchestration modules. Converging technology stack examples 23004 at the operations layer 23016 may include smart containers and transportation infrastructure; automated routing and location of VCN entities; and robotics, UAVs and process automation. Additional converging technology stack examples may include autonomous control; supervised control; digital product networks; supply chain networks; value chain networks; smart product operations; smart asset operations; smart infrastructure operations; smart machine operations; shipping operations; human-machine cooperative operations; and the like. Converged, AI-based demand shaping and value chain shipping and logistics orchestration modules may automate demand management activities and optimize transportation routing and use of storage and warehousing infrastructure, each based on marketplace conditions and sensor data from products and infrastructure.

[3333] In embodiments, converged, AI-based demand shaping and value chain shipping and logistics and orchestration modules are enabled by sophisticated artificial intelligence (AI) capabilities in routing, control, optimization, and generation. These modules may utilize AI to automate demand management activities such as demand forecasting, demand planning, product portfolio management, customer relationship management, order management, pricing management, marketing and promotion, demand shaping, channel management, supply chain

coordination, and risk management. Such automation may be driven by many types of data, including sensor data, marketplace data, customer behavior data, historical sales data, and the like. In embodiments, these modules may manage the routing and control of smart containers, trucks, ships, ports, transportation infrastructure, robotics, UAVs, and the like to enable an optimized and automated VCN. Robotic process automation (RPA) may be leveraged by this module to automatically schedule shipments, process invoices, and the like.

[3334] At the network layer 23018, AI capabilities 23002 for adaptive networking enable digital product networks and adaptive edge infrastructure networks modules. Converging technology stack examples 23004 at the network layer 23018 may include networked infrastructure (edge, IoT, and cloud), networked products (cellular, WiFi, and Bluetooth), and networked workers (wearables and AR/VR). Digital product networks and adaptive edge infrastructure networks modules may support peer-to-peer interactions among smart products or product families for data collection and automated coordination of supply chain and demand shaping activities.

[3335] In embodiments, digital product networks and adaptive edge infrastructure networks modules are enabled by adaptive networking AI capabilities. These modules may be configured to facilitate communications among smart products, their users, their manufacturers, and the like for data collection and automated supply chain optimization while also leveraging AI to dynamically adapt network configurations and optimize data flow. The integration of edge computing with cloud services ensures that data processing and operation orchestration can occur closer to the data source, reducing latency and enhancing real-time decision-making capabilities. The AI algorithms associated with these modules may be capable of intelligently routing VCN data through the most efficient network paths, whether they be cellular, WiFi, Open Radio Access Network (ORAN), Bluetooth, or other IoT communication protocols. For implementation, the modules may utilize technical features such as machine learning for predictive network traffic management, ensuring bandwidth is allocated where needed most, and cryptographic techniques for securing data at the edge. Additionally, the module may employ AI-driven anomaly detection systems to monitor network health and preemptively address potential disruptions. By integrating these technical features, the digital product networks and adaptive edge infrastructure networks modules are capable of supporting the complex requirements of modern distributed digital product networks and operations.

[3336] At the data layer 23020, AI capabilities 23002 for sensor and data fusion enable context-aware sensor fusion to inform VCN analytics and AI modules. Converging technology stack examples 23004 at the data layer 23020 may include product networks sensor data; market, environmental, social, and web data; and infrastructure sensor data; and the like. Context-aware sensor fusion to inform VCN analytics and AI modules fuse data from disparate sensor and other data sources to facilitate AI classification, prediction, and optimization for a wide range of demand shaping and supply chain operations.

[3337] In embodiments, context-aware sensor fusion to inform analytics and AI modules are facilitated by the integration of data and/or sensor fusion technology. These modules may be

configured for synthesizing diverse data streams, including real-time sensor data, social media analytics, and web data, to provide a comprehensive view of VCN transactional and operational environments. By employing sensor fusion, the modules may aggregate and process data from various sources, such as IoT devices, digitally connected products, and online behavior patterns, among many others, to generate a multidimensional context for each VCN activity and operation. The use of APIs and Service-Oriented Architecture (SOA) facilitates the seamless integration and exchange of data across distributed systems, ensuring that the modules have access to the most relevant and up-to-date information. Technical features for implementation may include advanced data normalization techniques to harmonize disparate data formats, machine learning algorithms for pattern recognition and predictive analytics within the fused data sets, and robust data security protocols to protect sensitive information. The AI component of the modules may utilize the enriched data to enhance VCN analytics, providing insights into customer behavior, market trends, supply chain risks, and the like. By leveraging these technical features, the context-aware sensor fusion to inform analytics and AI modules may significantly improve the accuracy and reliability of VCN analytics, enabling businesses to make data-driven decisions with greater confidence and strategic foresight.

[3338] At the resource layer 23022, AI capabilities 23002 for resource optimization enable demand-aware value chain component and resource optimization modules. Converging technology stack examples 23004 at the resource layer 23022 include components and materials, energy, and infrastructure. Demand-aware value chain component and resource optimization modules enable automated provisioning of resources used in product production, shipping, warehousing, and retailing to improve efficiency and other outcomes at all stages of a value chain network.

[3339] In embodiments, the demand-aware value chain component and resource optimization modules are enriched by resource optimization AI. The modules may be designed to optimize the allocation and utilization of infrastructure for product production, shipping, warehousing, and retailing; components and materials resources; energy resources; advanced computation resources; and other VCN resources through the application of advanced AI algorithms. In the context of advanced computation, the module may employ AI to dynamically allocate processing power and memory resources across various VCN applications, ensuring optimal performance and cost-efficiency. For energy optimization, the AI may analyze energy efficiency ratios and metrics in real-time. Technical features enabling these implementations may include deep learning networks for complex modeling, real-time analytics engines for monitoring resource utilization, and evolutionary algorithms that adapt strategies to changing market conditions. Additionally, the module may incorporate distributed ledger technology for transparent tracking of resource allocation decisions and smart contracts for the automated execution of optimization strategies. By integrating these technical features, the resource optimization modules provide a sophisticated framework for maximizing the efficiency and effectiveness of VCN resources.

SPECIALIZED CHIPS FOR ROBOTIC INTELLIGENCE LAYER

[3340] In embodiments, the various robots and associated systems described herein may leverage one or more specialized chipsets to carry out one or more functions for the robot and/or robotic fleet. These specialized chipsets may include one or more physical orientation determination chips 9100, one or more network enhancement chips 9200, one or more diagnostic chips 9300, one or more governance chips 9400, one or more prediction, classification, and recommendation chips 9500, and/or one or more of any of the other specialized chips described herein. For example, as shown at Fig. 178, the chips may include one or more specialized integrated chipsets 20800 and/or one or more chiplets 20802 (as described in additional detail below). The specialized chipsets may use various specialized techniques and architectures to provide optimized performance on tasks performed by the robot and/or robotic fleet, as described in detail throughout this disclosure. In embodiments, although many functions are described as being performed by specialized chips, general-purpose processing chips such as CPUs/GPUs/TPUs and/or other general processing units (whether on their own and/or as part of the specialized chips) may also be used for some tasks and/or in some cases. In other words, although the specialized chips described herein may be more performant, efficient, or otherwise beneficial in many cases, they may not be necessary for performing each and every task for the robot and/or robotic fleet.

[3341] In embodiments, the specialized chips may be used to execute any of the tasks ascribed to the robot control system 12150, robot-level intelligence layer 12140, fleet operations system 12002, and/or fleet intelligence layer 12004 (e.g., any tasks at the robot or fleet level). In embodiments, tasks performed by the intelligence layer may include, but are not limited to, data gathering, achieving goals assigned by various clients (e.g., including robot-level goals and/or fleet-level goals), training and/or executing various artificial intelligence models (e.g., neural networks, machine vision models, natural language processing models, rules-based systems, models designed for robotic process automation, generative AI models, etc.), performing action recommendations, updating digital twins, executing simulations using digital twins, carrying out governance tasks, performing decision analysis, or any other tasks assigned to these components as described herein.

[3342] In embodiments, as shown at Fig. 178, the robot control system 12150 may incorporate various specialized chips into a data processing system 12142, described elsewhere herein. Thus, a special-purpose robot 12160 and/or multi-purpose robot 12100 may leverage the specialized chips described herein to perform various tasks that are delegated to the robot control system 12150 and/or generated by the robot intelligence layer 12140. As described elsewhere herein, the robot control system 12150 may coordinate and communicate with a baseline system 12102 of robots 12160, 12100 for various tasks.

[3343] In embodiments, as shown at Fig. 179, the fleet data processing system 12030 (e.g., of a robotic fleet operations platform) may also incorporate various specialized chips and use them to carry out tasks assigned to the data processing system 12030 (e.g., as requested by intelligence system clients 12260) and/or generated by the fleet-level intelligence layer 12004.

In these embodiments, the data processing system 12030 and/or the intelligence layer 12004 may be in communication and coordination with fleet security 12006 and/or a fleet operations system 12002 for various tasks, as described elsewhere herein. In embodiments, although the same specialized chips may be used at the robot level (e.g., by the robot control system 12150) and at the fleet level, the specialized chips may also be further tuned and/or customized based on factors such as power capabilities of a robot versus a stationary platform. For example, the specialized chips onboard the robots 12160, 12100 may be tuned for better power efficiency, may omit particular components to reduce power usage, and/or the like, whereas fleet-level versions that are deployed into platform components with better power sources may be tuned for performance at the expense of power.

[3344] In embodiments, the intelligence layer (e.g., either the robot-level intelligence layer 12140 and/or the fleet-level intelligence layer 12004) may use one or more physical orientation chips 9100 (which may be deployed on a robot or remote from a robot) for any of the capabilities of the chip 9100 as described herein. The physical orientation chip 9100 may perform tasks including determination of a location of a robot or component of the robot, determination of relative motion of the robot or component of the robot, object detection and classification, scene understanding (e.g., simultaneous localization and mapping (SLAM), scene classification, etc.) and/or any other machine vision tasks described elsewhere herein using images/video captured by the robot, orientation within an environment of the robot or component of the robot, updating of a digital twin based on sensor data captured by the robot, and/or the like. For example, if the intelligence layer is carrying out a task requiring physical orientation, machine vision, object detection and/or classification, and/or the like, the intelligence layer 12140 may assign the task to the one or more physical orientation chips 9100.

[3345] In embodiments, the intelligence layer may use one or more network enhancement chips 9200 (which may be deployed on a robot or remote from a robot) for any of the network enhancement features described herein. The network enhancement chip(s) 9200 may perform network analysis, network and/or data optimization, data/traffic configuration, and network configuration tasks, among other such tasks, for the fleet of robots. In embodiments, the intelligence layer 12004 may leverage the network enhancement chip to optimize communications among individual robots and/or fleet-level communications involving some or all of a robotic fleet. Additionally or alternatively, the network enhancement chip 9200 may optimize communications with any centralized non-robotic systems in communication with the robots and/or fleet such as server devices, sensor devices, IOT devices, devices that implement platform-level intelligence layers, or any other relevant devices described herein.

[3346] In example embodiments, the intelligence layer may use one or more network enhancement chips 9200 for various tasks, such as dynamically adjusting network factors (e.g., bandwidth allocation) to optimize network communications among the robots in a fleet based on current conditions. In these embodiments, the intelligence layer may instruct the network enhancement chipset to continuously monitor network conditions such as traffic levels and/or current conditions of the robotic fleet (e.g., changing positions of the robots within the fleet,

robots coming online or offline as they charge/finish charging, etc.) and optimize the network accordingly. To implement this or other similar tasks, the network enhancement chip 9200 may identify congested routes and/or detect changing communications availability (e.g., as robots move into and out of communication range with each other), then redistribute network resources accordingly to ensure efficient data exchange, as described in detail above for the network enhancement chip 9200. As another example, the intelligence layer may use the network enhancement chip 9200 to monitor signal strength and re-route communications (e.g., to reduce latency, improve packet loss, etc.) involving robots and/or other devices (e.g., servers, sensors, IOT devices, etc.). For example, the chipset may perform real-time signal strength analysis, adjusting the transmission power or selecting alternative communication channels to improve signal quality and/or reduce latency.

[3347] In example embodiments, the intelligence layer may use one or more network enhancement chips 9200 to facilitate the establishment of secure communication channels among the robots within the fleet and/or any other devices such as servers, base stations, and the like. For example, the data encryption circuit 9234 of the network enhancement chip 9200 may automatically recognize and encrypt certain types of inter-robot communications that may involve sensitive data. In embodiments, the optimization module 9220 of a network enhancement chip 9200 may determine that encryption is required and/or that additional encryption is required based on one or more context factors for the robotic fleet, such as location, data being transmitted, suspected jamming or other attacks (e.g., which may be detected based on robotic devices suddenly disappearing from the network and/or based on detection of wireless noise levels increasing and/or being above a certain threshold).

[3348] In embodiments, the intelligence layer may receive assigned tasks (e.g., from one or more intelligence system clients 12260, which may maintain a task queue and assign a next task from the queue) and use one or more network enhancement chips 9200 within a robotic fleet to carry out the tasks. For example, another specialized chipset being used by or implementing the intelligence layer 12004 may detect a potential network issue, such as a data transmission delay, loss of signal strength, loss of transmission data, data corruption, and/or the like. The other specialized chipset may then send a job/task request to the intelligence layer 12004, which may then assign a task for network diagnostics and repair to the network enhancement chipset 9200. The network enhancement chipset 9200 may then carry out a network analysis to identify a potential source of the problem and subsequently apply corrective measures. Additionally or alternatively, the intelligence layer may assign routine maintenance or "housekeeping" activities to the network enhancement chipset 9200, such as performing ongoing and/or periodic network optimization tasks, which may include any of the specialized capabilities of the network enhancement chip 9200 as described herein.

[3349] In embodiments, the intelligence layer may use one or more diagnostic chips 9300 (which may be deployed on a robot or on a platform in communication with a robot) for any of the capabilities of the chip 9300 as described herein. The diagnostic chip 9300 may perform tasks including gathering biological, chemical, electromechanical, and/or environmental sensor

data, analysis of the sensor data, and/or generation of combined analyses and reports based on data captured by a robot. For example, if the intelligence layer is carrying out a task requiring data collection and/or analysis, the intelligence layer 12140 may leverage one or more diagnostic chips 9300 to perform the data collection and/or analysis.

[3350] In embodiments, the intelligence layer may implement and/or leverage a governance chip 9400 to monitor and/or apply governance for individual robots and/or a robotic fleet. In embodiments, the governance chip 9400 may perform one or more analyses of whether governance applies, selection of one or more governance frameworks or policies, and application of the governance frameworks/policies to actions or operations that are assigned to the intelligence layer 12004. In embodiments, the governance chip 9400 may automatically determine and apply governance frameworks or policies based on one or more of the robot's operational parameters.

[3351] As an example, if an intelligence layer managing a fleet of autonomous delivery robots is operating within an urban setting, the governance chip 9400 may monitor actions related to navigation within the specific urban setting and/or the use of personal data for various individual users of the service. Thus, for example, the intelligence layer may leverage the governance chip 9400 to analyze real-time data from the robot's sensors to determine whether the robot's proposed actions (e.g., entering private property, operating at certain speeds after detecting a school zone sign, etc.) are compliant with existing regulations and the selected governance framework. Additionally or alternatively, the governance chip 9400 may detect certain uses of customer data and apply frameworks for securing and/or limiting the use of the customer data (e.g., encrypting the data, immediately deleting the customer data after its use, preventing the use of customer data for certain tasks, etc.). In embodiments, the governance chip 9400 may reject or modify any action scheduled or proposed by the intelligence layer 12004 based on the frameworks stored or generated by the governance chip 9400.

[3352] In embodiments, the governance chip 9400 may leverage other chipsets to perform AI-assisted techniques, such as predictive modeling, to aid its decision-making process. For instance, it may use digital twins to simulate potential future states of an individual robot and/or fleet in order to determine whether any particular governance frameworks may be applicable. For example, a digital twin may reveal a potential need for maintenance for a robot, potential traffic issues that may interfere with delivery commitments, and/or other such predicted issues.

[3353] In embodiments, the intelligence layer may leverage a prediction, classification, and recommendation (PCR) chip 9500 to perform a variety of tasks. These tasks may include generating and optimizing predictions, carrying out classification tasks, recommending actions, analyzing decision criteria, executing recommended actions, and/or providing feedback on the effectiveness of these actions, as well as any other tasks that may be carried out by the PCR chip 9500 as described elsewhere herein.

[3354] As an example, the intelligence layer may be carrying out a task for conducting environmental or hazard monitoring and may leverage one or more PCR chips 9500 to generate environmental forecasts, predict occurrences of hazardous conditions, and/or the like using

collected data. In embodiments, the PCR chips 9500 may perform on-device training and/or optimization to continually improve prediction models, as described in more detail elsewhere herein. As another example, the PCR chips 9500 may use model optimization to continually optimize AI models that predict robot maintenance based on real-time operational parameters and/or historical data of each robot in a fleet. In other words, the PCR chips 9500 may continually receive ground truth data and compare it to predictions generated by models to retrain and optimize any prediction models used by the PCR chips 9500 and/or other specialized chipsets. In embodiments, the models may be optimized on-device based on on-device data to generate specialized prediction models that may be tuned to a single robot or set of robots, a specific fleet of robots, and/or the like.

[3355] In embodiments, the intelligence layer may leverage one or more PCR chips 9500 to perform classification tasks such as identifying and categorizing items within sensor range of the robots during surveillance routes. In embodiments, the PCR chips 9500 may be configured to perform classifications when specialized machine vision chips (or other detection and classification chipsets) fail to generate a classification or identification of an item. For example, if a robot encounters an abnormal item within captured image data and a machine vision chipset is unable to classify it, the intelligence layer may leverage a PCR chip 9500 to analyze the captured image data, obtain a model or database for identifying the item, and assign a classification based on the obtained model or database.

[3356] In embodiments, the intelligence layer may leverage one or more PCR chips 9500 to recommend certain tasks or sub-tasks. For example, the PCR chips 9500 may evaluate multiple operational strategies for accomplishing an assigned goal, such as different navigation routes or task prioritizations, and recommend the task that best satisfies a set of ranked decision criteria (e.g., most efficient, fastest, least power, etc.). For instance, the PCR chips 9500 may recommend specific sequences of task execution for individual robots to maximize throughput of the entire fleet.

[3357] In some embodiments, the PCR chip 9500 may delegate tasks to other specialized chips present in the robotic system and/or managed by the intelligence layer 12004. For example, if the PCR chip 9500 predicts that the robot's battery level will fall below the optimal range during its planned route, it may delegate the task of optimizing power consumption to a specialized power management chip, which may adjust the robot's movement speed, reduce the usage of non-essential sensors, reroute the robot to a charging station, etc. As another example, the PCR chip 9500 may delegate specific sensor-related detection tasks to a dedicated processing chip for the sensor and/or to one or more diagnostic chips 9300.

[3358] In embodiments, the intelligence layer may implement fleet-level intelligence for a robotic fleet using any combination of specialized chips, including (without limitation) one or more physical orientation determination chips 9100, one or more network enhancement chips 9200, one or more diagnostic chips 9300, one or more governance chips 9400, one or more prediction, classification, and recommendation chips 9500, and/or one or more of any of the other specialized chips described herein. In these embodiments, the one or more chips may

reside on one or more dedicated robots within a fleet (e.g., fleet management robots), a remote platform or server, or another device that maintains communication with the robotic fleet, or any combination thereof.

[3359] In the following illustrative embodiments, a fleet-level intelligence layer may implement fleet-level intelligence using specialized chipsets that may be distributed throughout a fleet to efficiently optimize operations. The combination and interaction of the example chips described herein thus beneficially provides for comprehensive, adaptive, and efficient decision-making at a fleet level, enhancing the overall operational effectiveness of the robotic fleet.

[3360] In example embodiments, the fleet-level intelligence layer may be assigned to monitor and optimize the operational efficiency of a robotic fleet involved in warehouse logistics. The fleet-level intelligence layer (which may be within a fleet manager robot) may leverage one or more physical orientation chips 9100 (which may be located within the individual robots of the fleet or elsewhere) to accurately detect the location and orientation of all the robots in the fleet within an environment. Concurrently, the fleet-level intelligence layer may leverage one or more prediction, classification, and recommendation chips 9500 to generate predictions about the optimal paths for the robots to follow, classify tasks based on their priority, and/or recommend a sequence of actions to each robot. Additionally or alternatively, the fleet-level intelligence layer may leverage one or more network enhancement chips 9200 to improve communication between the robots and/or other devices (e.g., IoT sensors) by optimizing the network configuration. Additionally or alternatively, the fleet-level intelligence layer may leverage one or more governance chips 9400 to apply appropriate governance frameworks to ensure the fleet adheres to operational and safety parameters/regulations.

[3361] In example embodiments, the fleet-level intelligence layer may be assigned to coordinate a fleet of search and rescue robots navigating in a hazardous and/or disaster-stricken area. The fleet-level intelligence layer may leverage one or more physical orientation chips 9100 to determine whether any of the robots are disabled or damaged, and may leverage one or more diagnostic chips 9300 and/or prediction, classification, and recommendation chips 9500 to preemptively gather and analyze various sensor data, anticipate hazardous/destructive conditions, classify areas of interest for search operations, and/or recommend optimal paths to navigate through obstacles. Additionally or alternatively, the fleet-level intelligence layer may leverage one or more network enhancement chips 9200 to route around communication losses as robots may be damaged or destroyed. Additionally or alternatively, the fleet-level intelligence layer may leverage one or more governance chips 9400 to apply governance frameworks to prioritize search operations, triage victim response (e.g., based on sensor data and/or analyses performed by the diagnostic chips 9300), and/or the like.

[3362] In example embodiments, the fleet-level intelligence layer may be assigned to manage a fleet of autonomous agricultural robots tasked with crop monitoring and maintenance (e.g., or other fleets engaged in monitoring and maintenance tasks). The fleet-level intelligence layer may leverage one or more physical orientation chips 9100 to ensure efficient coverage of a field and that no areas are passed over during monitoring. The fleet-level intelligence layer may

leverage one or more diagnostic chips 9300 and/or prediction, classification, and recommendation chips 9500 to gather sensor data and to analyze soil and crop data to predict crop health, classify areas requiring attention, and/or recommend appropriate actions such as watering, fertilizing, or pest control. In embodiments, the fleet-level intelligence layer may leverage one or more network enhancement chips 9200 to optimize network traffic for efficient data collection and processing and may leverage one or more governance chips 9400 to apply governance frameworks that ensure the robots follow agricultural regulations and/or best practices.

[3363] In embodiments, the intelligence layer may facilitate the generation of digital twins for individual robots, components of individual robots, environments comprising one or more robots, and/or a fleet of robots by leveraging the specialized chips in combination with each other and/or the digital twin system 1700 (described elsewhere herein). The intelligence layer may leverage any of the specialized chips described herein, either individually or in combination, to generate and/or update different aspects of a digital twin representation. For example, the intelligence layer may leverage one or more environment digital twins 9154 generated by one or more physical orientation and determination chips 9100, one or more network digital twins 9254 generated by one or more network enhancement chips 9200, and/or one or more digital twins of a digital twin library 9454 of a governance chip 9400 or a digital twin library 9554 of a prediction, classification, and recommendation chip 9500. In these embodiments, the intelligence layer 12004 may combine the various digital twins (e.g., one or more environment digital twins 9154 and/or one or more network digital twins 9254) to obtain a digital twin that may represent environmental aspects, network aspects, and other aspects for some or all of the robots of a fleet and their surrounding environments, networks, etc. In embodiments, the intelligence layer may generate various digital twins by updating a digital twin generated by the digital twin system 1700 using digital twin information received from the specialized chips and/or other devices (e.g., IoT sensors). Additionally or alternatively, the intelligence layer may manage various digital twins separately but provide communications between the various digital twins, where a communication from a sender digital twin to a receiver digital twin may be used to update the receiver digital twin.

[3364] In example embodiments, the intelligence layer may leverage a unified digital twin to optimize the performance of a robotic fleet. The intelligence layer may leverage one or more network enhancement chips 9200 to receive network digital twins 9254 and combine the various network digital twins 9254 to create a unified network digital twin for simulating the communication architecture of the entire fleet. Additionally or alternatively, the intelligence layer may leverage one or more physical orientation chips 9100 to receive environment digital twins 9154 and combine the various environment digital twins 9154 into a unified environment digital twin (which may separate from or combined with the unified network digital twin) that may provide precise spatial data for each robot and its environment, thus allowing the simulation of fleet-level operations. Additionally or alternatively, the intelligence layer may use digital twins obtained from the digital twin system 1700 to generate a unified digital twin. Using a

unified environment digital twin, the system may analyze various operational scenarios, test new strategies and/or protocols, and/or optimize the fleet's performance without disrupting actual operations.

[3365] In example embodiments, the intelligence layer may leverage separate digital twins in communication with each other to optimize the performance of a fleet of robots. For example, if each robot in a fleet has a local environment digital twin 9154 and/or network digital twin 9254, the intelligence layer may coordinate communications between the various digital twins to carry out simulations. For example, the intelligence layer may cause various physical orientation chips 9100 to exchange environment data as necessary to optimize fleet-wide navigations, ensure complete and/or consistent coverage of a surveillance/monitoring area, etc. In embodiments, the intelligence layer 12004 may leverage one or more network enhancement chips 9200 to optimize the exchange of digital twin data between devices. Similarly, the intelligence layer may cause various network enhancement chips 9200 to exchange network digital twin data in order to generate better estimates of network conditions in an area, better optimizations for various sub-networks, and/or the like. Thus, the intelligence layer may manage communications between digital twins to perform coordinated tasks and/or simulations of tasks and to improve fleet-wide performance.

[3366] In some embodiments, the intelligence layer may implement robotic process automation (RPA) for individual robots and/or at the fleet level. In these embodiments, the intelligence layer may leverage various specialized chips to facilitate the various RPA operations described above. In these embodiments, an RPA system may act as an intelligence system client 12260. In example embodiments, the intelligence layer may receive various RPA tasks and may carry them out using the prediction, classification, and recommendation chip 9500. For example, the intelligence layer may automate tasks such as observing humans, classifying activities performed by humans, predicting human activity, retraining RPA models based on loss functions that measure deviations between predicted human actions and actual human actions, and/or the like by leveraging one or more prediction, classification, and recommendation chips 9500. In a warehouse scenario, for example, the intelligence layer may use the PCR chips 9500 to observe pick-and-pack tasks and train RPA models that enable robots to perform the same tasks. In embodiments, the intelligence layer 12004 may implement RPA by collaboratively leveraging multiple specialized chips. For instance, the intelligence layer 12004 may leverage a governance chip 9400 to ensure the automated processes adhere to operational and safety regulations, leverage one or more physical orientation chips 9100 to provide spatial data to assist in robot coordination, and/or the like.

[3367] Fig. 180 illustrates a set of components of a specialized integrated chipset 20800 and/or a collection of chiplets. In embodiments, some or all of the illustrated components may be integrated into a single specialized chipset 20800 and/or may be separated into one or more chiplets in communication with each other. Thus, when the term specialized chip is used herein, it should be understood to encompass an integrated chipset such as specialized integrated chipset 20800 and/or a set of separate chiplets, which may use a modular architecture.

[3368] In embodiments, the specialized integrated chipset 20800 and/or set of chiplets may be located on board a robot and/or a platform that governs multiple robots. When the specialized integrated chipset 20800 and/or set of chiplets are on board a robot, they may control the robot itself and/or other robots in communication with the robot. Thus, the robotic control circuit 20902 can manage a single robot and/or a set of multiple robots and control various for the robot(s), as described elsewhere herein.

[3369] In embodiments, the specialized integrated chipset 20800 and/or set of chiplets may include a robotic control circuit 20902. The robotic control circuit 20902 may be configured to manage and/or control various functions and/or operations for a robot or robots. The robotic control circuit 20902 may be an application-specific integrated circuit (ASIC) or some other custom circuit that is pre-configured to manage a variety of functions for one or more robots. Additionally or alternatively, the robotic control circuit 20902 may be implemented as a more general-purpose circuit (e.g., one or more CPUs, GPUs, TPUs, etc.) that may execute a set of instructions to manage various robotic control functions, execute operations for one or more AI models that manage various robotic control functions, and/or otherwise execute an algorithm for managing various robotic control functions.

[3370] In embodiments, the specialized integrated chipset 20800 and/or set of chiplets may include a data collection circuit 20904. The data collection circuit 20904 may be configured to manage data from one or more data generating/capturing devices, which may include sensor devices and various other Internet of Things (IoT) devices, or any of the other data generating/gathering devices disclosed herein. In embodiments, the data collection circuit 20904 may receive data from devices (e.g., sensors) located onboard the robot, external IoT devices, and/or devices (e.g., sensors) onboard other robots. Like the robotic control circuit 20902, the data collection circuit 20904 may be an ASIC, some other custom circuit, and/or a general-purpose processor that employs software, AI models, or other algorithms to perform any data-related functions. Additionally or alternatively, the data collection circuit 20904 may be a physical orientation chip 9100 and/or diagnostic chip 9300.

[3371] In embodiments, the specialized integrated chipset 20800 and/or set of chiplets may include an AI control circuit 20906. The AI control circuit 20906 may operate on the output of an AI model and may deliver operational control parameter(s) to the robotic control circuit 20902 using any of the control techniques described herein. In embodiments, the AI control circuit 20906 may be a neural network control circuit (e.g., when it operates on the output of a neural network classifier or another neural network model). Additionally or alternatively, the AI control circuit 20906 may operate on the output of any other AI models.

[3372] In embodiments, the specialized integrated chipset 20800 and/or set of chiplets may include one or more processing units, which may include one or more CPUs 20908, one or more GPUs and/or TPUs 20910, one or more FPGAs 20912, and/or one or more other processing units 20914. In embodiments, the processing units (e.g., processing units 20914) may include one or more physical orientation chips 9100, one or more network enhancement chips 9200, one or more diagnostic chips 9300, one or more governance chips 9400, and/or one or more

prediction, classification, and recommendation chips 9500. In other words, the various architectures described herein may be applied to any or all of the chips 9100-9500.

[3373] The various processing units may be capable of implementing various software instructions and/or operations for various AI models 20920, including one or more neural networks 20922 and/or one or more other AI models 20924. For example, any of the processing units may serve as a neural network classifier by executing inference using a neural network 20922 to process data received from various devices, (e.g., sensors, IoT devices, etc.) and classify the state of an environment where the robot or other robots operate. In embodiments, AI models may be executed in part via one or more CPU(s) 20908, and in part by one or more GPUs/TPUs 20910 or other processing units. For example, the CPU 20908 may offload complex matrix multiplications to one or more GPUs/TPUs 20910 for fastest operation.

[3374] Additionally or alternatively, any of the processing units may execute inference using other AI models 20924 to implement different types of neural networks or various types of other AI models (e.g., generative AI models), which are described elsewhere herein. Furthermore, any of the processing units may utilize training data 20930 to train and/or fine-tune any of the AI models 20920, including the neural networks 20922 or the other AI models 20924.

[3375] In embodiments, the specialized integrated chipset 20800 and/or the set of chiplets may comprise one or more integrated memories 20950. These memories 20950 may store the AI models 20920 and/or training data 20930, as well as any other data described herein (not shown in Fig. 180).

[3376] In embodiments, some or all of the various components of the integrated chipset 20800 and/or the set of chiplets may share a set of I/O capabilities. For example, the various components of the integrated chipset 20800 and/or the set of chiplets may share I/O ports, data, sensors, actuators, and/or a set of functions for controlling one or more robots (e.g., a robot that includes the integrated chipset 20800 and/or robots in communication with a device that includes the integrated chipset).

[3377] In embodiments, any or all of the components of the specialized integrated chipset 20800 and/or any other chips disclosed herein may be integrated on a common substrate. In these embodiments, the integrated chipset may use a monolithic architecture (e.g., a system on chip), whereas a set of chiplets may use a modular architecture. For example, the various components of the integrated chipset may be manufactured on a single silicon wafer, may be part of a single chip, may be separately manufactured chips that are bonded to the common substrate, may be enclosed in a single package, and/or may be enclosed in a package of packages, where the enclosed packages may each include one or more of the components of the integrated chipset 20800 and/or may be interconnected with other enclosed packages via common interface. In embodiments, any type of circuit may be integrated on the single substrate (e.g., a robotic control circuit, a governance analysis circuit, a governance model circuit, a predictive modeling circuit, a predictive model optimization circuit, a network interface circuit, a network analysis circuit, a network optimization circuit, a data collection circuit, a neural

network classifier, a neural network control circuit, and many others). In some embodiments, the components and/or chiplets may communicate using a UCIe™ standard.

[3378] The specialized integrated chipset 20800 and/or the set of chiplets may use some or all of a variety of architecture technologies. Some of the architecture technologies may be particularly suitable in various configurations and/or applications.

[3379] For example, in embodiments, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use neuromorphic architectures, which may beneficially mimic the structure and functioning of the human brain. In embodiments, neuromorphic architectures may be particularly suitable for AI-based tasks due to their low power consumption (e.g., energy efficiency), high speed, robustness against execution failures, and ability to learn.

[3380] Additionally or alternatively, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use a spintronic architecture. Spintronic (spin transport electronics) technology uses the spin of electrons to store, process, and communicate information, which may enable high-density data storage and improved processing speed.

[3381] Additionally or alternatively, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use a 2.5D architecture and/or 3D architecture, which allow for vertical integration of components, which may beneficially reduce the distance data needs to travel, thus increasing speed and efficiency. Thus, a 2.5D/3D architecture may allow for a high-density integration of the various processing units, memories, and/or other circuits in the specialized integrated chipset 20800 and/or set of chiplets. In these embodiments, the components of the integrated chipset may be connected vertically using through-silicon vias. Additionally or alternatively, the integrated chipset may be enclosed within a package that itself encloses a plurality of vertically stacked packages, where each of the plurality of vertically stacked packages are connected via a common interface.

[3382] Additionally or alternatively, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use a perimeter I/O architecture, where the components are laid out such that I/O circuitry (e.g., a shared set of I/O capabilities) is located at the periphery of the chipset or chiplet. This architecture may optimize space for circuits, processing units, and memories within a central area, thus improving connectivity and data transfer rates among the central area components. For example, the permitter I/O circuitry may comprise shared I/O ports disposed on the perimeter of the chipset, which may be configured to send/receive data to/from shared sensors and/or actuators. Additionally or alternatively, the shared set of perimeter I/O capabilities may comprise the robotic control circuit 20902, which may include functions for controlling one or more robots.

[3383] Additionally or alternatively, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use a clustered architecture, where similar or related components are grouped together, which may increase operational efficiency and power consumption. A clustered architecture may be particularly beneficial when

specialized integrated chipset 20800 and/or the set of chiplets includes large numbers of various processing units and memories. In these embodiments, for example, the various components of the chipset (e.g., processing cores) may be concentrated in the middle portion of the chip and served by a set of I/O capabilities located on the perimeter of the chip. In some cases, an off-chip interconnection capability may be located substantially at the center of the integrated chipset. In embodiments, the shared set of I/O capabilities include shared I/O ports disposed on the perimeter of the chipset, where the shared I/O ports may be configured to send/receive data to/from shared sensors and/or actuators. Additionally or alternatively, Additionally or alternatively, the shared set of perimeter I/O capabilities may comprise the robotic control circuit 20902, which may include functions for controlling one or more robots. Additionally or alternatively, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use a modular architecture with embedded multi-chip interconnect bridges, which may facilitate inter-chip communication with greater bandwidth and lower latency, thus optimizing data exchange among different circuits, processing units, and/or memories. In these embodiments, the integrated chipset 20800 may have a set of modular processing clusters connected by a set of embedded multi-chip interconnect bridges to a set of high bandwidth memory modules. For example, a first module processing cluster may comprise a first subset of components (e.g., AI components such as a neural network classifier and/or neural network control circuit) and a second module processing cluster may comprise a second subset of components (e.g., robotic components such as a robotic control circuit and/or a data collection circuit). Each of the high bandwidth memory modules may use various high bandwidth memory standards, such as HBM, HBM2, HBM2E, HBM3, etc. In embodiments, the embedded multi-chip interconnect bridge may be a network on chip (NoC) bridge, an advanced extensible interface (AXI) bridge, a PCI express (PCIe) bridge, a high-speed inter-chip (HSIC) bridge, and/or a hypertransport bridge.

[3384] Additionally or alternatively, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use a bidirectional NoC (Network-on-Chip) architecture, such as a bidirectional torus NoC, which may increase communication efficiency between various components of the chipset or set of chiplets by increasing the capacity and/or management of bidirectional traffic.

[3385] Additionally or alternatively, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use a modular architecture with die-to-die connectivity to allow each individual chip or chiplet to function independently while also communicating effectively with others, thus enhancing scalability and/or flexibility of the system. In these embodiments, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may be modular elements that are arranged in a 2.5D or 3D stacked configuration. In embodiments, the die-to-die connectivity may use silicon interposers. Additionally or alternatively, the die-to-die connectivity may conform to one or more standards such as Embedded Multi-Die Interconnect Bridge (EMIB), Advanced Interconnect Bus (AIB), and/or Chip-to-Chip Direct Connect (C2C). Additionally or

alternatively, the integrated chipset 20800 may be enclosed within a package using Wafer-Level Fan-Out (WLFO) and/or Fan-Out Wafer-Level Packaging (FOWLP).

[3386] Additionally or alternatively, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use dynamic voltage and frequency scaling (DVFS), which may manage power usage by adjusting the voltage and frequency of a component based on its workload (e.g., to increase energy efficiency).

[3387] Additionally or alternatively, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use partitioned optical communications, which may leverage electrical signals and/or optical signals as appropriate to enable high-speed data transmission among various components of the chipset or set of chiplets. In these embodiments, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may be integrated on an optical chipset where optical communication is partitioned by wavelength to allow selective prioritization by wavelength.

[3388] Additionally or alternatively, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use high-NA EUV (High Numerical Aperture Extreme Ultraviolet) technology, which may enable smaller feature sizes in the semiconductor fabrication process, (e.g., to enhance the performance of the processing units, memories, and other components).

[3389] Additionally or alternatively, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use gate all-around FETs (Field-Effect Transistors), Nanowire FETs, gate-all-around nanosheet FETs, Gate FETs, and/or CFETs (Complementary FETs), which may improve performance in terms of speed, power efficiency, and/or integration density.

[3390] Additionally or alternatively, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use carbon nanotubes (e.g., for transistors that may be much smaller, faster, and/or energy-efficient than traditional silicon-based transistors).

[3391] Additionally or alternatively, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use high bandwidth memory (HBM) SRAM to provide high-speed access to data (e.g., for the circuits and/or processing units in the specialized integrated chipset 20800 and the set of chiplets).

[3392] Additionally or alternatively, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use 3D NAND flash for high-density, non-volatile memory, which may increase storage capacity.

[3393] Additionally or alternatively, some or all of the components of the specialized integrated chipset 20800 and/or the set of chiplets may use hybrid bonding to integrate the various components or chiplets at a very fine pitch (e.g., to enhance the performance and/or density of the integrated chipset).

[3394] In many cases, especially in the context of robotic tasks, AI models may use a considerable amount of data for training, fine-tuning, and/or optimization. Depending on the

model, the training data may include data from a myriad of sources such as video or image feeds, sensor readings (e.g., from robotic sensors, IoT sensors, etc.), text sources, digital twin data, and/or other data sources described herein. For example, a fleet of autonomous vehicles may use models trained and/or fine-tuned using data on traffic patterns, pedestrian movement, road conditions, and/or other environmental factors, which may be sourced from sensors and/or camera feeds in real time. Similarly, a robotic fleet involved in warehouse operations may be trained and/or fine-tuned using data on inventory levels, object locations, human worker movements, etc.

[3395] In embodiments, a robot may leverage one or more specialized chips to generate synthetic training data and use the synthetic training data to enhance the training of AI models. For example, as shown in Fig. 181, a robot 30002A may feature, as part of its data processing system 12142A, one or more specialized chips 30008A (which may include any of the chips shown in Figs. 178-180) for leveraging training data 30004A and/or synthetic training data 30006A to accelerate the training/optimization process for various onboard AI models 30010A stored by the robot, thus improving the operation of the robot and/or the robotic fleet. Additionally, the robot 30002A may use one or more specialized chips 30008A to generate synthetic training data. Synthetic training data may allow the robot 30002A to obtain larger amounts of training data, which may enable the robot to improve the performance of various AI models 30010A, fine-tune them for specific tasks or contexts, and/or otherwise improve their quality.

[3396] In embodiments, as shown at Fig. 181, a synthetic data generation service 30012A of the intelligence layer 12140A may configure the specialized chips 30008A to generate the synthetic training data 30006A. Then, a machine learning service 12632A of the intelligence layer 12140A may use the synthetic training data 30006A (alone or together with other training data 30004A) to train the various AI models 30010A. In some cases, as shown at Fig. 181 and as described in more detail below, training data and/or synthetic training data may additionally or alternatively be received from other robots within a fleet.

[3397] In embodiments, an intelligence layer 12140A on board the robot 30002A may control the data processing system 12142A to leverage various types of AI models, including Generative Adversarial Networks (GANs), variational autoencoders (VAEs), long short-term memory networks (LSTMs), transformer models, and/or condition generative models, as well as other types of AI models 30010A to generate synthetic training data 30006A for training purposes. In these embodiments, the intelligence layer 12140 may leverage various generative models as described elsewhere herein. In embodiments, the one or more specialized chips 30008A may be configured to quickly and/or efficiently execute generative models for the generation of synthetic training data. For example, a specialized chip 30008A may have onboard hardware specialized for processing a specific type of generative model, such as a transformer, LSTM, GAN, and/or the like. In these embodiments, the specialized chip 30008A may have dedicated hardware for efficiently implementing different types of neural network layers, various operations used by different architectures (e.g., multi-head attention layers for

transformers), and/or the like. In embodiments, any of the specialized chipsets and/or architectures described herein may be employed to more efficiently implement various generative AI models.

[3398] In embodiments, chips that are specialized for synthetic data generation may include various dedicated modules to expedite synthetic data generation and/or training. In other words, the dedicated modules may be specifically designed to accelerate the generation of synthetic data and/or enhance the speed or efficiency of AI model training using this synthetic data. For example, the specialized chips 30008A may include dedicated circuits for random number generation, noise injection, feature extraction, and/or other features and functionalities that may contribute to the production of synthetic data. Additionally or alternatively, the specialized chips may include dedicated processing units for parallel computations, which may enable more efficient simultaneous processing of multiple data streams for training complex AI models that require handling of large matrices and/or tensors.

[3399] In embodiments, the specialized chips 30008A may include various circuits that are dedicated to training and/or fine-tuning models using large training data sets, such as the massive training data sets that may be generated using synthetic data. For example, the specialized chips 30008A may include advanced memory management systems to facilitate rapid data retrieval and storage, ensuring efficient data flow during training. Additionally or alternatively, the specialized chips 30008A may include low-power operation modes to maintain energy efficiency during periods of less intensive computation (e.g., to contribute to overall system efficiency and power usage, especially in the context of mobile robotic systems where power consumption may be a limitation). Additionally or alternatively, the specialized chips 30008A may include hardware-accelerated algorithms for specific AI training techniques, such as backpropagation or optimization algorithms like Stochastic Gradient Descent (SGD) and its variants. By implementing these algorithms directly in hardware, the specialized chips 30008A may be able to achieve performance improvements in model training and inference. Additionally or alternatively, the specialized chips 30008A may include error detection and correction capabilities to ensure the integrity of the data and computations (e.g., to ensure accurate transmission and/or reception of large volumes of synthetic data from other chips).

[3400] In embodiments, the intelligence layer 12140A may include a digital twin system and/or service 12630A that controls the generation of a digital twin environment and/or one or more digital twin simulations, as described elsewhere herein. In these embodiments, the digital twin service 12630A may leverage one or more specialized chips, which may include dedicated circuits configured to generate a digital twin environment and/or execute a simulation via a digital twin environment. In embodiments, the specialized chips 30008A may use a digital twin simulation to generate and capture synthetic training data 30006A. For example, by executing large numbers of simulated scenarios via digital twins (e.g., where each scenario may include random variations on interactions between the robot 30002A and other objects within the simulated environment, including other robots, machines, items, etc.), the specialized chips 30008A may be able to generate large amounts of synthetic training data 30006A to supplement

existing training data sets. In some examples, a specialized chip 30008A may be configured to simulate a particular environment and sensors within the environment, and may capture the simulated sensor data. The intelligence layer 12140A may capture the synthetic sensor data together with simulated outcome/state data as synthetic training data 30006A, thus enabling generation of a larger training data set to train one or more AI models 30010A to enhance the performance of the AI models 30010A.

[3401] In embodiments, a fleet-level intelligence layer 12004 may leverage one or more specialized chip(s) 30008 (which may include any of the chips shown at Figs. 179-180 and/or any other specialized chips described herein) to generate synthetic training data 30006A that may be used for training AI models 30010A that control individual robots and/or fleets of robots. In these examples, because the fleet-level intelligence layer 12004 controls the generation of the synthetic training data 30006, the fleet-level intelligence layer 12004 may create specific types of data (e.g., specific scenarios) that may be the most useful for training and/or optimizing the various AI models used throughout the fleet to increase robot and/or fleet performance on particularly relevant tasks and/or to for relevant operational scenarios. In these embodiments, the fleet-level intelligence layer 12004 may distribute the trained/optimized AI models throughout the fleet as appropriate (e.g., based on task history, performance history, upcoming/assigned tasks, predicted future tasks, etc.) to some or all of the robots of the fleet in order to increase fleet performance.

[3402] In embodiments, the intelligence layer (e.g., the fleet-level intelligence layer) may leverage and/or deploy various digital twin environments for the generation of synthetic data for different robots or tasks. In these embodiments, the intelligence layer (e.g., a synthetic data generation service 30012A of the intelligence layer) may instruct a digital twin service 12630A to generate synthetic data using digital twin simulations. In this example, the digital twin service 12630A may generate synthetic training data 30006 for specific operational scenarios, contexts, and/or sub-tasks in which a particular robot is expected to operate. Additionally or alternatively, the intelligence layer may leverage digital twin environments to generate synthetic training data 30006 that is tailored to the designated role of a particular robot within a fleet. For example, if a robot is assigned to operate within a specific area, such as a building in a warehouse environment, the intelligence layer may use the digital twin environment to simulate specific sets of operations and/or tasks that are likely to occur within that building. Thus, the intelligence layer can leverage the specialized chipsets to generate synthetic data to train the models on scenarios, contextual factors, and/or tasks that a particular robot is most likely to encounter.

[3403] In examples, the intelligence layer may determine (e.g., using historical data and/or various prediction models as described elsewhere herein) that a particular robot is likely to be assigned a specific task, and then leverage specialized chips 30008 to generate synthetic data pertinent to that task in high volumes. In embodiments, the intelligence layer may generate synthetic data 30006 with a focus on scenarios and/or contexts in which an AI model has been known to underperform (e.g., based on historical data or other analysis methods), such as edge cases or specific context factors (e.g., bad weather, interactions with humans, etc.). Accordingly,

the intelligence layer may generate synthetic data that may be used to improve specific aspects of a model's performance with a focus on the aspects that are most relevant to a given robot. This robot-specific customization of synthetic data may lower development times (e.g., by focusing optimization on the most critical aspects of model training and/or fine-tuning) and improve fine-tuning of individual robots for specific tasks. Applying this tactic across a fleet (e.g., generating custom synthetic training data set for some or all of the individual robots within a fleet), the intelligence layer may generate a highly customized fleet of robots where each robot is optimized to operate within a specific scenario or context.

[3404] As an example, in the context of an autonomous vehicle fleet, an intelligence layer may generate synthetic data that simulates local road conditions, traffic scenarios, and environmental factors that a particular vehicle in the fleet is most likely to encounter based on a set of context factors. These factors may include the capabilities of the vehicle (e.g., size or type of vehicle, maneuverability, sensor range, processing power), areas or times in which the vehicle is typically used, role or tasks assigned to the vehicle, etc. For example, a single fleet may include delivery vehicles, passenger vehicles, vehicles optimized for operation at specific times or during specific weather conditions, etc., and the intelligence layer may leverage specialized chips for the generation of customized synthetic data for each vehicle accordingly. The intelligence layer may then use the customized synthetic data to train and/or fine-tune the vehicle's driving AI for its specific operational context.

[3405] In embodiments, a similar approach can be applied at the role or fleet level. The intelligence layer may leverage specialized chips 30008 to generate synthetic training data sets that are highly tailored to a location and/or set of tasks that a fleet (or class/role of robot within the fleet) is expected to perform. These training data sets may be used to train and optimize the AI models used throughout the fleet (or class/role within the fleet). For example, in the context of a robotic fleet used for warehouse operations, the intelligence layer may generate synthetic data based on simulations of various scenarios related to specific roles such as inventory management, object handling, and/or interaction with human workers. The intelligence layer may then use the generated synthetic data to train and/or fine-tune various AI models for optimal performance in a designated role.

[3406] Accordingly, the intelligence layer may leverage specialized chips 30008 to generate synthetic training data sets for individual robots, for entire fleets, and/or at intermediate levels such as at the role level or task level. Thus, the intelligence layer may leverage specialized chipsets to finely customize the training of various AI models used in different capacities throughout a robotic fleet, thereby enhancing the fleet's efficiency and effectiveness in its operational context.

[3407] In embodiments, an intelligence layer (e.g., either a fleet-level intelligence layer and/or a robot intelligence layer 12140A) may train AI models for a specific robot based on real and/or synthetic training data received from surrounding robots of a fleet (and/or other related devices). For example, if the intelligence layer detects that a first robot is underperforming in certain tasks and/or with respect to certain context factors (e.g., locations, conditions, etc.), the intelligence

layer may request/instruct other robots to transfer training data 104 and/or generate synthetic data 106 for use by the first robot. Additionally or alternatively, if the first robot is assigned a new role or task (e.g., a task that the first robot has not previously performed or has not performed within a certain context), the intelligence layer may request/instruct other robots to transfer training data 104 and/or generate synthetic data 106 model so that the first robot may more rapidly train/optimize its AI models 30010A prior to beginning the new role or task.

[3408] For example, as shown at Fig. 181, a first robot 30002A may receive training data 30004B and/or synthetic training data 30006B from a second robot 30002B, may receive training data 30004C from a third robot 30002C, and/or may receive synthetic training data 30006D from a fourth robot. The received data may be stored as part of the training data 104A and/or synthetic training 30006A stored within the robot 30002A and may be used to retrain/optimize any of the AI models 30010A.

[3409] In these embodiments, a robot-level intelligence layer 12140 running on the first robot and/or a fleet-level intelligence layer 12004 running on an overseeing robot or platform may determine that the first robot requires optimization using additional training data. For example, the first robot may report a failure to perform an assigned task and/or the intelligence layer may analyze historical data for the first robot to detect certain contexts or tasks that require optimization. Following this determination, the intelligence layer (e.g., at the robot and/or platform level) may dispatch a request to other robots within the fleet (e.g., all robots, robots with spare computational capacity, etc.) to generate synthetic training data 30006B for the first robot and/or transfer relevant training data 30004.

[3410] In some embodiments, each of the other robots may generate synthetic training data 30006 and transfer the synthetic training data 30006 together with any relevant training data 30004 already stored by the corresponding robot (if any). Each individual robot may generate synthetic training data 30006 having a diversity of data characteristics. For example, each individual robot may generate synthetic training data 30006 that is based on stored data currently held by the assisting robots. Thus, the synthetic training data 30006 generated by the various other robots may reflect the diverse data stored by each robot, which may vary by distinct sensor capabilities of each robot, varying historical data that may reflect location or other contextual differences in each robot's operation, the varying tasks each robot has performed, etc.

[3411] In embodiments, each of the robots may use onboard specialized chips 30008 to generate synthetic training data. Accordingly, by transmitting instructions to multiple other robots, an intelligence layer may cause more rapid parallel generation of synthetic data without being limited by the power and/or computational capacity of a single robot. Accordingly, the intelligence layer may leverage a fleet of robots to generate diverse synthetic datasets reflecting varied perspectives for optimizing a single robot (or class/role of robots) within the fleet.

[3412] In embodiments, the intelligence layer may further use the fleet of robots to optimize/retrain one or more AI models for a first robot in parallel based on a large synthetic training data set (e.g., a training data set generated by one or more of the fleet robots). For

example, the intelligence layer may distribute the task of retraining or optimizing a first robot's model(s) among different robots (each of which may leverage various specialized chipsets for the retraining/optimizing), and then cause the different robots to deliver the resultant optimized model to the first robot.

[3413] In embodiments, the intelligence layer may leverage specialized chips that are tailored to operate using one or more Generative Adversarial Networks (GANs) or other generative models to generate synthetic training data for robots and/or fleets of robots. For example, in the context of a robotic fleet operating in a warehouse, the intelligence layer may use generative models to generate synthetic data depicting a variety of operating scenarios encompassing a diverse range of operational situations, such as navigating through crowded aisles, handling different types of goods, responding to potential hazards, and/or the like. The intelligence layer may the leverage chips that are specialized in various ways to train various AI models for the robots (e.g., navigation and object manipulation modules of the robots), thereby enhancing their ability to operate according to desired parameters (e.g., safety, efficiency) in varied conditions.

[3414] In embodiments, the specialized chips 30008 may execute one or more generative models to generate synthetic sensor data for training robotic perception systems. In these examples, the specialized chips 30008 may use the generative models in an inference mode to generate outputs based on various operational parameter inputs, where the generative models may be configured to output synthetic training data 30006 that simulates signals from lidar, radar, or other sensors typically used by robots. In embodiments, the specialized chips 30008 may generate synthetic sensor data representing various scenarios, such as object detection, obstacle avoidance, and terrain recognition, in order to create synthetic training data for training and/or optimizing appropriate AI models (e.g., for autonomous navigation or the like).

[3415] In embodiments, the specialized chips 30008 may execute one or more generative models to create synthetic communication data, for example to train models that improve communications and/or coordination within a fleet of robots. In these examples, the intelligence layer may leverage the specialized chips 30008 to create synthetic data that simulates varied communication patterns and scenarios, which the intelligence layer may later use for training/optimizing models responsible for inter-robot communication and collaboration.

[3416] In embodiments, the specialized chips 30008 may execute one or more Large Language Models (LLMs), including multimodal LLMs, for synthetic data generation for a robot or a fleet of robots. For example, the intelligence layer may use an LLM to generate synthetic training data simulating various conversational dialogues (e.g., customer queries, complaints, etc.). The intelligence layer may then use the synthetic training data 30006 to train and/or optimize a conversational model in order to improve a robot's ability to respond effectively.

[3417] In embodiments, the specialized chips 30008 may execute multimodal generative AI models (e.g., multimodal LLMs) to generate synthetic data integrating text and sensory information (e.g., visual information, audio/sound information, etc.). In example embodiments, the intelligence layer may cause a specialized chip 30008 to execute a multimodal LLM to generate synthetic data sets comprising specific sounds and/or tactile feedback with textual

descriptions of particular mechanical malfunctions in a robot. In this example, the intelligence layer may then use the synthetic data to train and/or optimize a predictive maintenance model, thereby allowing robots to anticipate and communicate potential issues before they cause a failure.

[3418] In embodiments, a fleet of robots may coordinate to use multiple digital twins for simulation and testing, training/learning, predictive maintenance, and/or the like. In these embodiments, the intelligence layer (e.g., a fleet-level intelligence layer) may communicate with one or more specialized chips that are distributed throughout a fleet of robots, where each of the specialized chips may be optimized for training tasks associated with a specific functional role of a robot and/or fleet. In these embodiments, the intelligence layer may leverage each specialized chip to generate different synthetic data that is adapted to a particular task or role. For example, a first specialized chip (e.g., on a first robot) may use a navigation role-based digital twin to generate data for training a navigational model, a second specialized chip (e.g., on the first robot or on a second robot) may use a communication role-based digital twin to generate data for enhancing an inter-robot communication model, and/or the like.

[3419] In embodiments, the intelligence layer may instruct a plurality of individual chips to each execute one of a plurality of digital twins in parallel (e.g., at the same time and/or at overlapping times) for training different aspects of a model. Additionally or alternatively, the intelligence layer may instruct a specialized chip to execute multiple digital twins in parallel. As an example, for a complex task such as autonomous navigation in a dynamic environment, the intelligence layer may instruct a first chip to train/optimize a navigation model based on output from a sensory processing digital twin, instruct a second chip to train/optimize the same model based on output from a path planning digital twin, and instruct a third chip to train/optimize the same model based on output from a dynamic obstacle avoidance digital twin. Additionally or alternatively, the intelligence layer may instruct a single chipset to retrain/optimize the model based on outputs from the plurality of example digital twins. In these embodiments, the intelligence layer may coordinate communications between the various digital twins to perform coordinated simulations of tasks and to train/optimize performance of various models that may be used by individual robots and/or the fleet based on outputs of the digital twins.

[3420] In embodiments, the intelligence layer may initiate and adapt the training of models for controlling robots based on specific characteristics of assigned tasks. The intelligence layer may assess the requirements, objectives, methods, and/or other context factors associated with a task that is assigned to a robot and/or fleet (e.g., where the task may be generated by the intelligence layer or a component managed by the intelligence layer) and then execute training to improve the performance of one or more AI models with respect to some or all of the context factors. For example, if a task requires precision manipulation in tight spaces that will be carried out by a specific robot arm, the intelligence layer may identify this requirement and initiate training of an AI model corresponding to the robot arm to optimize/improve its capabilities for accurate control in compact environments. This optimization/training may involve modifying parameters of control algorithms, adjusting feedback loops, adapting sensor inputs, generating synthetic

data (e.g., using digital twins) and optimizing models using the synthetic data, and/or other techniques. In embodiments, the intelligence layer may use machine learning techniques to optimize performance of AI models over time, potentially even during the execution of the task itself.

[3421] In some embodiments, the intelligence layer may begin a task-specific optimization process with a task requirement determination, which may comprise analyzing demands and/or constraints of an assigned task and then generation of a training regimen comprising one or more steps for improving the performance of any robotic control algorithms with respect to the demands and/or constraints. For example, if a fleet of robots is assigned to perform inventory management in a large warehouse, the task requirements may include efficient navigation within the given warehouse (e.g., including operations near and/or interactions with any humans and/or robots that may be simultaneously operation with the large warehouse), accurate barcode and/or RFID scanning, accurate detection and/or analysis of certain types of items that are within the warehouse, effective communication with a centralized inventory system, and/or the like. Based on the identified demands and/or constraints, the intelligence layer may then generate a training regimen for optimizing one or more control algorithms to improve performance with respect to these specific demands, thus ensuring optimal task performance. For example, the intelligence system may generate synthetic data sets to optimize AI models using one or more digital twins of the warehouse, as described above.

[3422] In embodiments, the intelligence system may incorporate nested training methods to handle complex scenarios that may consist of multiple tasks, each with potentially numerous subtasks. In these embodiments, the intelligence layer may analyze each individual task and/or subtask to determine various sets of demands and/or constraints on a task or sub-task basis. In some embodiments, the intelligence system may then perform task-specific training to optimize various models to perform different sub-tasks, even on a temporary basis. For example, for an assembly line inspection robot that has to navigate a specific area of a cluttered warehouse, inspect various items using different sensors on a specific portion of an assembly line, and potentially move certain items to a specific designated area, the intelligence system may identify several subtasks, each requiring different skills and operating within different contexts. The intelligence layer may then initiate specific training for each sub-task, like obstacle avoidance for navigation that is optimized for the specific area, object recognition optimized for the specific sets of items that occur at the specific portion of the assembly line, and precise control within the context of the specific designated area, using any or all of the techniques described herein.

[3423] In embodiments, the intelligence layer (e.g., using the machine learning service 12632A) may leverage specialized chips 30008A designed to facilitate training and/or optimization. In embodiments, the specialized chips may possess unique features and/or combinations of features to enhance the efficiency and effectiveness of model training. These features may include, for example, optimized processing units for specific machine learning algorithms, high-bandwidth memory for rapid data access during training, architectures

optimized for digital twin generation, advanced cooling systems to handle thermal loads during intensive computations, and/or any of the other architectural and/or structural features described herein. In embodiments, the specialized chips may be designed for energy efficiency, ensuring they are suitable for use in mobile robotic systems where power consumption may be a critical consideration.

[3424] In embodiments, the specialized chips 30008A may be optimized to support loop-based training or learning. Loop-based learning may involve repetitive cycles of performance, feedback, and adjustment that may allow models to progressively refine their capabilities. These repetitive cycles may involve rapid iterations of forward and backward propagations in neural networks, which demand intensive computation and/or memory access. The specialized chips may therefore feature optimized architectures for the forward and backward propagation operations, allowing the models to iterate faster and more efficiently through via the learning loops.

[3425] In embodiments, the specialized chips 30008A may be optimized for on-device model retraining, which may allow a robot to refine its own models based on real-world feedback and/or synthetic data generated on-device or on other devices. For example, the robot-level intelligence layer 12140 may leverage these chips to improve the object recognition capabilities of an AI model by continuously updating training data sets based on encountered objects during operations of the robot and/or generating synthetic data. The robot-level intelligence layer 12140 may then retrain the AI models using the updated training data set (including any synthetic training data). Specialized chips 30008A may facilitate this process by providing optimized computational resources, which may reduce or eliminate the need for communication with a remote platform (e.g., a platform running a fleet-level intelligence system). On-device retraining features of the specialized chipsets may comprise features such as energy-efficient processing units, adaptable memory management systems, and/or dedicated neural network accelerators, and may include any of the other architectural and/or structural features described herein. These features may help the robot-level intelligence layer 12140 to balance the demands of on-device retraining with the power and thermal limitations of the corresponding robot.

[3426] In embodiments, the fleet-level intelligence layer 12004 may manage training tasks and coordinate operations taking into account the current and/or historical communication patterns of the fleet of robots. In these embodiments, the intelligence layer may leverage the network enhancement chip 9200 for training and/or optimization purposes. For example, the intelligence layer 12004 may leverage the network analysis module of the network enhancement chip 9200 to detect patterns based on the current and/or historical network status, such as communication bottlenecks, and use them to determine a specific training and/or optimization process. Additionally or alternatively, the intelligence layer 12004 may analyze communication patterns to determine locations associated with the most frequently used network routes for a fleet-optimized mesh networking protocol and then generate an optimization process that causes additional communication robots to occupy those areas.

[3427] In embodiments, the fleet-level intelligence layer may leverage a network optimization module of the network enhancement chip 9200 to generate synthetic data for training more efficient communication protocols for the fleet. For example, the intelligence layer 12004 may generate various networking scenarios (e.g., in a digital twin) and then generate optimizations for the various scenarios, thus yielding synthetic training data that may be used to improve communication models/algorithms used by the robots that handle network configuration. Similarly, the fleet-level intelligence layer 12004 may leverage the data/traffic configuration module of a network enhancement chip 9200 to generate synthetic data for various networking scenarios (e.g., in a digital twin) and provide various data/traffic optimizations for each scenario. Additionally or alternatively, the fleet-level intelligence layer 12004 may leverage the network configuration module of the network enhancement chip 9200 to generate synthetic data for training a model to adjust network settings in certain contexts (e.g., to prioritize certain types of data transfer during high usage times, thus improving latency and throughput). The intelligence layer 12004 may then use this synthetic data to improve models that handle data/traffic/network optimizations for the fleet.

[3428] In embodiments, an intelligence layer may be configured to train a governance chip 9400 to handle permissioned access to data within and/or throughout a fleet of robots. For example, different robots within a fleet may collect diverse sets of data, where different sets may have different privacy considerations (e.g., the data may contain different types of Personally Identifiable Information (PII)). For example, in a scenario where robots as a service are deployed within a customer's environment (e.g., a warehouse, a private residence, etc.), individual robots may collect confidential and/or personal data related to routines, employees, customers, items, and/or the like. This data may potentially include sensitive PII, which may require governance frameworks to be correctly trained and applied (e.g., using the governance chip 9400 as described earlier in the disclosure).

[3429] In these embodiments, the intelligence layer may train one or more models used by the governance analysis module of the governance chip 9400 to identify and categorize PII in the data collected by the robot. In these embodiments, the intelligence layer may generate large synthetic datasets of anonymized personal information and train/optimize the models using the synthetic data set, as described elsewhere herein.

[3430] Additionally or alternatively, the intelligence layer may train one or more models used by the governance framework module of the governance chip 9400 to apply suitable privacy frameworks to the identified PII. For example, the intelligence layer may optimize the models using training examples that indicate that certain types of sensitive data must be encrypted and only stored locally, that certain data should be anonymized before being shared, and/or the like. In embodiments, the intelligence layer may generate these training data sets based on historical privacy incidents and/or best practices in the field of data privacy.

[3431] In embodiments, the intelligence layer may train robot-level models to provide additional layers of data security in some situations. For instance, the intelligence layer may train/optimize the robot-level models to identify and encrypt certain types of data collected by

the robot itself before sharing it, thus ensuring that only authorized entities can access the data. For example, a robot operating in a warehouse may collect sensitive inventory data or proprietary operational procedures. In this example, the intelligence layer may train models operating on the robot to prohibit or redact the transmission of certain types of data to certain other devices prior to any transmission occurring.

[3432] In embodiments, the intelligence layer may perform on-demand training of AI models based on ephemeral knowledge. In these embodiments, ephemeral data may refer to data that may be specific to a given context that is unlikely to re-occur for the robot or fleet of robots. Accordingly, the intelligence layer may gather and use the ephemeral data to temporarily optimize/train models on a short-term basis (e.g., until the given context ends/changes).

[3433] In some embodiments, the ephemeral data may be temporary due to time, geography, weather, and/or environmental factors. Additionally or alternatively, the ephemeral data may be unlike to reoccur because a robot or fleet of robots is performing a task involving a large number of contextual factors (e.g., interacting with a particular item at a particular location within a particular building, and/or other such contextual factors). In these embodiments, the intelligence layer may initially obtain as much data as possible concerning one or more of the various contextual factors (e.g., real or synthetic data from another robot that pertains to a first contextual factors, real or synthetic data from another robot that pertains to a second contextual factor, etc.) and generate an ephemeral training data set for retraining/optimizing one or more AI models for the unique context. The intelligence layer may then initiate retraining/optimization of the AI models using one or more of the specialized chipsets and/or techniques disclosed herein.

[3434] In embodiments, ephemeral training may be suitable for robotic fleets where individual robots move between very different and complex contexts, such that it would not make sense to pre-generate and/or pre-store optimized models for each of the different combinations of context factors (which, if combined multiplicatively, may generate hundreds, thousands, or more combinations). In these scenarios, the intelligence layer may perform on-demand ephemeral training/optimization for the unique combinations of contextual factors as they arise.

[3435] In some cases, the intelligence layer may store certain optimized models if the combination of contextual factors is likely to re-occur and/or may delete certain optimized models after the context has passed if the combination of contextual factors is unlikely to re-occur. For example, for one-off events such as musical performances occurring at specific sites, the intelligence layer may generate temporary optimized models based on location data, predicted weather parameters for the event, a map of the temporary event setup, a scheduled set of times during which the event will occur, estimates of attendance, a schedule of the event, and/or the like. In these embodiments, the intelligence layer may gather real data (e.g., scanning the event location before and/or after event setup completes and/or receiving historical data from other events that occur in similar contexts) and/or generate synthetic data based on a digital twin that simulates the event to generate a training data set. Then, the intelligence layer may train/optimize models for use during the event using any of the specialized chips and/or

techniques described herein. After the event ends, the intelligence layer may delete the models and/or synthetic training data.

[3436] In embodiments, the intelligence layer may evaluate the continued relevance and/or performance of a specialized model over time. In these embodiments, the intelligence layer may determine whether a context has ended (e.g., and the specialized model is therefore no longer relevant based on a determination that the specialized model is performing sub-optimally, that a performance drop has occurred, and/or the like. In these embodiments, based on the detection that the context for a specialized model has ended, the system may delete specialized model and/or data used to train the specialized model and roll back to a more general model. In some cases, after generating a specialized/optimized model, the intelligence system may continue to use the specialized model and a generalist model in parallel. The intelligence system may then evaluate which model is performing better (e.g., if one model fails at a task but the other model does not). Based on the evaluation, the intelligence layer may discard the specialized model and revert to the generalist model if the specialized model performs worse, performs only marginally better while using more resources, and/or the like.

[3437] In embodiments, as described above, a job configuration system 12018 of a fleet platform 100 and/or robot 30002A may generate and assign tasks and workflows to the robots within a fleet based on a variety of factors. In embodiments, these factors may include (in addition to or as an alternative to the factors mentioned above) one or more roles assigned to a robot and/or to individual chipsets onboard a robot. In these embodiments, the fleet operations system 12020 may assign roles to different robots and/or chipsets based on the unique capabilities of the chipset(s) on the robots. For example, the system may assign a role to a robot with a chipset that contains dedicated hardware for more efficiently performing common tasks for the role, such as image signal processors (ISPs) and/or hardware optimized to executed machine vision algorithms/models for an exemplary enhanced vision role. When the robot/chipset is assigned a specific role, the job configuration system 12018 may prioritize certain tasks and/or workflows associated with the role for assignment to that robot.

[3438] The job configuration system 12018 may maintain a task queue comprising a plurality of tasks, including a next task and/or one or more future tasks. The job configuration may process the queue (e.g., determining a next task from the queue) and issues task and/or role assignments in order to perform the next task. Additionally or alternatively, the job configuration system 12018 may look ahead into the queue (e.g., for upcoming/future tasks) and proactively issue task and/or role assignments to prepare a fleet of robots to handle the upcoming/future tasks. Example task/role assignments are described in more detail below.

[3439] Fig. 182 illustrates an example environment including a fleet management platform 100 and/or robot 30002A that may implement the job configuration system 12018. In embodiments, the job configuration system 12018 may be part of the intelligence layer (e.g., intelligence layer 12140A / fleet-level intelligence layer 12004). In embodiments, the platform 100 / robot 30002A may include a library 12314 as described above, which may contain data that may be used for task and/or role assignment. In embodiments, the library may include data about one or more

robots of the fleet and/or specialized chip data for the specialized chips onboard each robot. For example, the fleet may include a robot 30002B having specialized chips 30008B1-3 (in the illustrated example, one of the specialized chips is an FPGA 30008B3). The library 12313 may include corresponding robot data 30002B describing various aspects of the robot 30002B, including specialized chip data 30104B describing, for each of the specialized chips 30008B, one or more modules, circuits, architectures, capabilities, etc. of the specialized chip. As described above, the job configuration system 12018 may use any of the data in the library 12314 to assign tasks and/or roles, including the robot data 30102 and/or specialized chip data 30104 as described according to the various examples below. Furthermore, in embodiments, the job configuration system 12018 may assign tasks and/or roles to individual chips onboard a robot. To assign a task and/or role, the job configuration system may communicate a task/role assignment 30110 to a particular robot. Each robot may provide status updates 30112B to the job configuration system 12018 on a regular basis, in response to receiving a command or assignment, and/or in response to changing status and/or context factors. The job configuration system 12018 may dynamically reassign tasks and/or roles based on the changing statuses of the robots.

[3440] In embodiments, an exemplary role that may be assigned to a robot and/or chip is a data crunching expert role, which may involve prioritization for tasks requiring the processing of large volumes of data efficiently (e.g., for training purposes), processing involving large data pipelines (e.g., video streams), and/or the like. For example, in the context of a surveillance fleet, a data crunching robot/chip may be tasked with analyzing large amounts of video data collected by cameras onboard other robots to produce real-time analytics and/or predictions. In embodiments, the job configuration system 12018 may assign this role to a robot/chip based on specialized chip data 30104B indicating that the robot has one or more specialized chipsets with a high computational capability (e.g., speed and/or number of CPUs, GPUs, TPUs, etc.) to handle the heavy data-processing load.

[3441] In embodiments, the job configuration system 12018 may assign an exemplary decision-making expert role to certain robots/chips that are optimized for performing tasks such as decomposing goals into tasks or subtasks, formulating strategic plans, and assisting other robots in decision-making. For example, in supply chain scenarios, an intelligence layer may leverage decision-making expert robots/chips to generate optimal routes for delivering items to designated areas or locations. In embodiments, the job configuration system 12018 may assign this role to robots/chips having specialized chipsets with capabilities such as a powerful CPU, an ASIC specifically configured for decision-making algorithms, and/or an FPGA that can be reprogrammed on the fly to adapt to varying decision-making scenarios.

[3442] The job configuration system 12018 may assign additional roles depending on the context and requirements of a particular robot fleet as well as the capabilities of specialized chips throughout the robotic fleet. Accordingly, it should be understood that the roles described herein are merely exemplary. For example, roles may be specifically tailored for applications such as inventory management in a warehouse fleet, tracking and capturing target objects in a

surveillance fleet, efficient resource distribution in a supply chain management scenario, and/or the like.

[3443] In embodiments, the job configuration system 12018 may assign one or more robots/chips to a controller role that is responsible for managing individual robots and/or the entire fleet. For example, as shown at Fig. 182, a controller robot 30002A may implement the job configuration system 12018 itself and be responsible for task/role assignments to other robots. In embodiments, this role may shift from robot to robot as the needs of the fleet and/or usage of individual robot resources changes. Thus, for example, the robot 30002A may reassign the controller role to the robot 30002B. In this example, a corresponding task/role assignment 30110B may further include data (e.g., executables, state information, etc.) for transferring the job configuration system 12018, library 12314, etc. to the robot 30002B.

[3444] In the controller role, a platform/robot may be responsible for dynamically assigning and reassigning roles based on real-time conditions, robot capabilities, chipset workloads, power levels, proximity to task objectives, and/or the like. In embodiments, the controller robot may dynamically reassign tasks to other robots if/when a particular fleet robots loses power, malfunctions, etc., as indicated by status updates 30112 received from the various robots.

[3445] In embodiments, a task management system 12144 on a robot (e.g., robot 30002B) may assign tasks, sub-tasks, and/or roles to specialized chips on the robot. For instance, when a task is assigned to robot 30002B by the job configuration system 12018, the task management system 12144 may add the task to a task queue. Then, depending on the roles assigned to the specialized chips 30008B within the robot 30002B, the task management system 12144 may process the task queue by determining the next task from the queue and then assigning/distributing one or more parts of the task (e.g. one or more sub-tasks) across one or multiple specialized chips 30008B.

[3446] For example, for a robotic fleet operating within a warehouse environment, an assigned next task may involve object identification, manipulation, and/or transportation. Individual specialized chips 30008B may be assigned to roles associated with one or more of these sub-tasks, such as a machine vision role and/or a navigation role (e.g., in accordance with a task/role assignment 30110B received from the job configuration system 12018). Accordingly, the task management system 12144 may assign various sub-tasks to various specialized chips to optimize the efficiency and performance of the task. In this example, a first specialized chip 30008B1 may be optimized for executing an AI model specializing in a particular type of image recognition, and a second specialized chip 30008B2 may be optimized for executing an AI model specializing in vision-based navigation. Correspondingly, the first specialized chip 30008B1 may be assigned an object recognition role and the second specialized chip may be assigned a navigation role. Thus, the task management system 12144 may distribute the task across multiple specialized chips based on the capabilities and assigned roles for each chip.

[3447] In some embodiments, the task management system 12144 may reprogram one or more Field-Programmable Gate Arrays (FPGAs), such as FPGA 30008B3 onboard robot 30002B. In these embodiments, the task management system 12144 may reprogram an FPGA to more

efficiently implement a specific task or role for a temporary and/or ongoing task/role assignment. The task management system 12144 may reprogram the FPGA to optimize it for execution of a frequently occurring task, a task that is predicted to occur multiple times in the near future, an upcoming task with stringent performance requirements, and/or to otherwise optimize performance of a task and/or role.

[3448] In embodiments, the task management system 12144 may instruct an intelligence layer 12140 onboard the robot 30002B to determine how to reprogram the FPGA 30008B3. For instance, if the task management system 12144 instructs the intelligence layer 12140 to reprogram the FPGA 30008B3 to optimize performance of a particular task and/or role, the intelligence layer 12140 may determine that the particular task and/or role requires execution of a particular AI model. Thus, the intelligence layer 12140 may reprogram the FPGA 30008B3 to efficiently run inference using the AI model. In another example, if the intelligence layer 12140 determines that a designated task and/or role requires frequent retraining of a model that will be executed by another specialized chip (e.g., specialized chip 30008B2), the intelligence layer 12140 may reprogram the FPGA to efficiently retrain the model. Accordingly, without limitation to these examples, the task management system 12144 and/or the intelligence layer 12140 may reprogram the FPGA to optimize the performance based on various assigned tasks and/or roles (e.g., including robot roles and/or chip-specific roles), predicted tasks and/or role assignments, frequent task and/or role assignments, and/or various permutations thereof.

[3449] In embodiments, a job configuration system 12018 may assign various roles to robots and/or chips within robots using a hierarchy of roles, where each robot and chipset may be assigned a specific role or sub-role, and certain robots and/or chips may manage the assignment of tasks to other robots and/or chips that perform roles and/or sub-roles lower in the hierarchy. For instance, the job configuration system 12018 may assign a high-level role to a first robot (e.g., robot 30002B) and assign various sub-roles to other robots (e.g., robot 30002C) and/or chips (e.g., specialized chips 30008B1-3 that fall under the higher-level role of robot 30002B. In these embodiments, the higher-level robots/chips may assign tasks and/or sub-tasks to the lower-level robots/chips and/or otherwise manage operations for the lower-level robots/chips.

[3450] For example, robot 30002B may be assigned a governance role that may involve governance of task performance, data storage, data communication, etc. among one or more robots/chips that are assigned to various worker roles (e.g., roles that are primarily concerned with executing specific tasks). Additionally or alternatively, the job configuration system 12018 may assign more specialized tasks/roles or sub-tasks/roles to robots with more specialized chipsets aligned with the given specialized roles. Additionally or alternatively, the job configuration system 12018 may assign higher positions within the hierarchy to robots equipped with more advanced AI models and/or chips. For example, robots with more advanced AI models and/or chips may have access to more sources of information and/or be better connected within the network (e.g., such that they may be responsible for network configuration for lower-level robots). Additionally or alternatively, the job configuration system 12018 may assign higher-level roles to robots that possess more computational power (e.g., enabling them to

process more data) such as assigning or prioritizing tasks and/or roles to other robots within a fleet.

[3451] In some embodiments, the job configuration system 12018 and/or task management system 12144 may assign models associated with various tasks and/or roles to various distinct module(s)/component(s) within a specialized chip and/or to an individual chiplet. For example, as shown in Fig. 182, a specialized chip 30008B1 may comprise multiple CPUs, one or more GPUs, and/or one or more TPUs (Tensor Processing Units), among any other type of module such as FPGA modules, neuromorphic modules, or modules designed according to various other hardware architectures or chip architectures described herein (not shown in Fig. 182). Additionally or alternatively, any or all of the modules may be separate chiplets. For instance, numerous individual CPU chiplets, GPU chiplets, TPU chiplets, and/or other chiplet variations may be in communication with each other and with other systems onboard the robot.

[3452] As generally described herein, a robot may undertake a wide array of general purpose and specialist AI tasks, which may involve general purpose or specialized AI models/algorithms. These tasks may include object recognition employing various general purpose or specialized recognition models/algorithms (e.g., machine vision models), navigation using generalist models or specialized models/algorithms (e.g., models that are fine-tuned based on local environments), speech recognition/generation that may be general or specialized to various languages and/or types of communication, various large language models that may be fine-tuned for various purposes, etc. In embodiments, the job configuration system and/or task management system may dynamically assign the models/algorithms to individual modules or chiplets in order to optimize task and/or robot performance.

[3453] The task management system and/or the job configuration system may dynamically allocate different models/algorithms to distinct chip modules and/or chiplets based on various tasks and/or roles assigned to a robot and/or specialized chip. For example, the task management system and/or the job configuration system may initially determine a set of models/algorithms that are required for performance of one or more tasks assigned to a robot and/or chip, associated with a role assigned to the robot and/or chip, etc. The task management system and/or the job configuration system may then select the most frequently used and/or computationally intensive models/algorithms and assign them to faster and more specialized chip modules/chiplets, while assigning more occasional or less computationally intensive models/algorithms to more generalist and/or slower modules. In some examples, the more generalist or slower modules may include CPUs, while the more specialized modules may include GPUs and/or TPUs. In embodiments, the task management system may dynamically reprogram one or more FPGA modules and/or chiplets to generate the most specialized modules that may execute certain critical models/algorithms quickly, efficiently, or otherwise optimally (e.g., where latency and/or other factors are of prime importance).

[3454] In embodiments, the job configuration system and/or the task management system may designate one or more of the chip modules/chiplets for executing a prediction model (e.g., a reinforcement learning model with a performance measurement function) to predict which

models/algorithms are likely to be used at which times. Based on the predicted model usage, the job configuration system and/or the task management system may dynamically assign or reassign the models/algorithms among the chip modules/chiplets (e.g., based on the predicted usage amount of each model and/or the computational requirements of each model).

[3455] In embodiments, the task management system may dynamically obtain specialist AI models/algorithms and/or switch between generalist AI models/algorithms and specialized AI models/algorithms to optimize performance of a particular task. For example, a specialist AI model may be specific to a sensor/task combination, optimized for a specific context, more complex (e.g., requiring more computation to run inference), and/or the like. In specific examples, a robot may usually use a general machine vision model to recognize objects, but for performance of a task requiring accurate identification/classification of a specific type of object, the task management system 12144 may obtain and execute a more specialist image recognition model.

[3456] In these embodiments, the task management system 12144 may automatically and dynamically assign the generalist and/or specialist AI models/algorithms to various chip modules and/or chiplets based on the requirements of the various models/algorithms. For example, although a generalist image recognition model may normally be executed by a certain number of GPUs/TPUs, a more specialized model may require a different number of GPUs/TPUs and/or may only be compatible with a CPU. Accordingly, the task management system 12144 may assign the specialized model/algorithm to a different set of resources, reassign any other models that were previously assigned to the different set of resources, and/or otherwise dynamically balance the models/algorithms among the various processing resources.

[3457] In embodiments, the task management system 12144 may assign models/algorithms to modules/chiplets based on numerous factors, such as the compatibility of the models with the module/chiplet in question, power efficiency of the modules/chiplets, parallelizability of the models, latency requirements, cross-model communication requirements, as well as various context factors like location, the task being performed, prioritized lists of tasks to be completed, an assigned role, recent model usage, and/or the like.

[3458] In embodiments, the task management system 12144 may temporarily execute a specialist AI model/algorithm for carrying out a specific task within a specific temporary context in which the specialist AI model/algorithm may be more efficient, more accurate, and/or otherwise improve performance. In these embodiments, if resources allow (e.g., if sufficient power and/or processing resources are available), the task management system 12144 may continue running a generalist AI model for the same task. For example, the generalist model and the specialist model may check each other's results, generate hybrid outputs that combine the generalist and/or specialist outputs, and/or the like. In these cases, the task management system 12144 and/or intelligence layer 12140 may temporarily re-route and/or fuse sensor data to optimize performance and/or minimize resource usage. For example, the task management system 12144 and/or intelligence layer 12140 may temporarily stop sending some or all received

image data to a multi-modal generalist model when a specialist image recognition model is running to reduce battery usage and/or improve performance.

[3459] In embodiments, as shown at Fig. 183, the fleet management platform 100 may communicate with an AI data/model marketplace 30170 to obtain various AI models and/or training data that may be stored in a library 12314, requested by one or more of the robots 30002, and/or assigned to the various robots 30002. For example, the AI data/model marketplace 30170 may store various AI models that may be adapted and/or specialized for various AI tasks, where each model may have been trained from scratch to perform one or more tasks, may have been fine-tuned based on other models (e.g., using public training data, proprietary training data, synthetic training data, etc.) to better perform certain specialized tasks, and/or the like. Additionally or alternatively, the AI data/model marketplace 30170 may store various training data sets that may be obtained for retraining and/or fine-tuning a model. In these embodiments, marketplace 30170 may provide a mechanism for monetizing the valuable efforts that various entities spend on obtaining new training data and/or training models using the training data, thereby opening up new commercial revenue streams, encouraging adoption of the best models, and avoiding wasted effort by sharing training data and models trained using the training data.

[3460] In embodiments, the library 12314 may store a plurality of AI models 30150, some of which may have been obtained (e.g., purchase) from the marketplace 30170 and/or some of which may have been trained and/or fine-tuned by various entities, including the platform 100 and/or the robots 30002. In embodiments, AI models may be distributed to the various robots as necessary based on requests and/or task/role assignments. For example, according to a first exemplary data flow, a job configuration system 12018 may transmit a task/role assignment 30110B to a robot 30002B. The task management system 12144 of the robot 30002B may, in the process of carrying out the role and/or task assignment, store one or more assigned tasks, which may require a new model (and/or may be made more efficient using a new model) and/or additional training data. In these embodiments, although the intelligence layer 12140 may already be using one or more AI models 30160B, it may determine that a newer and/or better AI model may improve performance in carrying out the assigned role and/or task. For example, if the intelligence layer 12140 determines that the robot 30002B is continually failing to perform (and/or optimally perform) a certain type of task, it may determine that a new AI model may improve performance for the assigned task.

[3461] Based on the determination that a new AI model and/or training data may improve performance, the robot 30002B may transmit a data/model request 30114B to the platform 100 / robot 30002A. For example, the request 30114B may specify the task and/or role assigned to the robot 30002B and provide indicators (e.g., a list) of AI models 30160B already stored by the robot 30002B. Then, in response to the data/model request 30114B, the platform 100 / robot 30002A may determine whether better models and/or retraining data 30152 that may be used to retrain the model are already stored in the library 12314 and/or if better models and/or retraining data 30152 are available from a marketplace 30170. If better models and/or retraining data

30152 are available in a marketplace 30170, the platform 100 / robot 30002A may obtain the models and/or retraining data from the marketplace 30170.

[3462] In response to determining that a better AI model and/or retraining data is available (and optionally obtaining the model/data), the platform 100 / robot 30002A may send the better model/data to the robot 30002B as a data/model response 30116B. The robot 30002B may then the new AI model to the AI models 30160B stored at the robot 30002B, such that the AI model may be assigned to various specialized chips, chip modules, and/or chaplets, used to reprogram an FPGA, and/or otherwise used as described herein. Additionally or alternatively, the robot 30002B may use any retraining data 30152 received from the platform 100 / robot 30002A to retrain (e.g., fine-tune) any AI models 30160B. These embodiments may be combined with embodiments that obtained and/or use training data, including synthetic training data, from other robots in a fleet. Accordingly, training data (including synthetic training data) used to train and/or retrain models may be obtained from other robots within a fleet (including from digital twin environments), from a library 12314, and/or a marketplace 30170.

[3463] In embodiments, instead of the robot 30002B performing the retraining using the retraining data 30152 and/or other training data, the job configuration system 12018 and/or task management system 12144 may assign retraining tasks to other robots in the fleet and/or to a platform 100 or other component. For example, if the robot 30002B is at computational capacity but other processing resources are available for retraining, a retraining task may be distributed to one or more other components in communication with the fleet.

[3464] Fig. 183 illustrates another example data flow in which a task/role assignment (e.g., a next task from a task queue and/or a role for performing a next or upcoming task) is sent to a robot 30002C. In this data flow, as part of assigning a task and/or role 30110C to the robot 30002C, the job configuration system 12018 may determine that a particular AI model should also be assigned to the robot 30002C (e.g., because the AI model will make performance of the task and/or role more efficient, effective, etc.). Each robot may provide status updates 30112C to the job configuration system 12018 on a regular basis, in response to receiving a command or assignment, and/or in response to changing status and/or context factors. Thus, in this example, the platform 100 / robot 30002A may proactively transmit the AI model (which may be retrieved from the library 12314 and/or obtained from a marketplace 30170) to the robot 30002C a part of an AI model assignment 30116C without requiring any request from the robot 30002C. The robot 30002C may then receive and store the model, which the robot 30002C may then execute as required using one or more specialized chips, chip modules, chiplets, etc.

[3465] Fig. 183 illustrates a third example data flow in which a task/role assignment 30110D (e.g., a next task from a task queue and/or a role for performing a next or upcoming task) is sent to a robot 30002D, which may cause the robot 30002D to send a retraining data request 30114D for optimizing performance of the task and/or role. Each robot may provide status updates 30112D to the job configuration system 12018 on a regular basis, in response to receiving a command or assignment, and/or in response to changing status and/or context factors. The platform 100 / robot 30002A may then obtain additional retraining data 30152 (e.g., from the

library 12314, from the marketplace 30170, from other robots of the fleet, etc.), and transmit a retraining data response 30116D to the robot 30002D. The robot 30002D may then proceed to retrain (e.g., fine-tune) open or more AI models using the retraining data 30152.

[3466] In embodiments, after a robot receives a task/role assignment 30110, the task management system 12144 and/or intelligence layer 12140 of the robot may generate and assign one or more subtasks for carrying out the task. The robot may then assign the subtasks to various specialized chips, chip modules, and/or chiplets, each of which may carry out the subtask to accomplish the assigned task. For example, the job configuration system 12018 may transmit a task/role assignment 30110B to robot 30002B. Upon receiving the assignment, the task management system 12144 and/or intelligence layer 12140 within robot 30002B may generate one or more subtasks, assigning them to specialized chips 30008B1-3 and/or to various chip modules (e.g., one or more CPUs/GPUs/TPUs of the specialized chips) or chiplets (not shown in Fig. 183).

[3467] In embodiments, although a centralized platform 100 or controller robot 30002A may be well positioned to generate high-level tasks based on a fleet's overarching objectives, the robots located at the "edge" of the fleet (e.g., robot 30002B) may have the most detailed, real-time data related to a task being performed by that robot or a nearby robot. For example, the centralized platform 100 and/or controller robot 30002A may obtain digest or summary data that provides a high-level overview of the edge data at some or all of the edge robots, and each edge robot may obtain more detailed data from its own sensors and/or from other fleet robots (e.g., using an edge query language, described elsewhere herein). The edge robots may use the detailed edge data for subtask generation, including real-time updating of a subtask plan and/or to determine progress towards accomplishment of the task. As an illustrative example, a robot assigned a high-level navigation task may use real-time vision data to determine its progress, to determine when to use various AI models for navigation (e.g., depending on location and/or context), and/or to determine situations/contexts in which specialized AI models should be used. Thus, the task management system 12144 and/or intelligence layer 12140 of a robot 30002 may be best positioned to dynamically generate subtasks and assign them among the various specialized chips, chiplets, or chip modules onboard the robot.

[3468] The task management system 12144 and/or intelligence layer 12140 may use several exemplary AI approaches to generate subtasks in pursuit of an assigned task. In some embodiments, the intelligence layer 12140 may implement reinforcement learning using trial and error. For example, the intelligence layer 12140 may simulate (e.g., using a digital twin environment) and/or try various actions in pursuit of a goal, receive feedback (either positive or negative), and adjust future decisions based on the feedback. For example, the intelligence layer 12140 may execute a navigation model to continually generate various routes for navigating its environment. The intelligence layer 12140 may then simulate the use of the routes within a digital twin environment. Based on the simulated performance and results (e.g., success or failure to navigate a route), the intelligence layer 12140 may continually retrain the navigation model.

[3469] Additionally or alternatively, the intelligence layer 12140 may use goal decomposition algorithms for generating subtasks. In these embodiments, the intelligence layer 12140 may execute goal decomposition algorithms to decompose a high-level task into a sequence of smaller subtasks. For example, if the high-level task is to clean a room, a goal decomposition algorithm may decompose the goal into subtasks such as picking up trash, vacuuming the floor, or dusting furniture. The intelligence layer 12140 may then pass the various subtasks back to the task management system 12144 for assignment.

[3470] Additionally or alternatively, the intelligence layer 12140 may use hierarchical task networks (HTNs) for subtask generation. In these embodiments, the intelligence layer 12140 may execute HTNs to decompose assigned tasks into subtasks in a hierarchical manner. For example, a task to check inventory in a warehouse might involve subtasks like scanning a first section, scanning a second section, etc. Each of these subtasks can further be broken down into smaller tasks such as scanning a first shelf within the first section, scanning a second shelf within the first section, etc. The intelligence layer 12140 may then pass the various subtasks, sub-subtasks, etc. back to the task management system 12144 for assignment.

[3471] Additionally or alternatively, the intelligence layer 12140 may leverage a multi-agent system approach for subtask generation. In these embodiments, the intelligence layer 12140 may coordinate with the intelligence layers of other robots to generate various subtasks that may be executed by different agents (e.g., different robots) that can work collectively to perform a larger task (e.g., a task that may be complex for a single agent, take too long for a single agent). For instance, a group of robots might work together to quickly scan a large area, with each robot assigned a specific subarea. The intelligence layer 12140 may then assign the various subtasks to the different robots, with each robot's task management system 12144 managing execution of the subtask.

[3472] Additionally or alternatively, the intelligence layer 12140 may leverage case-based reasoning (CBR) for subtask generation. In these embodiments, the intelligence layer 12140 may execute CBR algorithms to generation subtasks for carrying out assigned tasks based on previous subtask strategies for similar past tasks. For example, the intelligence layer 12140 may retrieve a previous subtask plan for a task such as navigating an environment (e.g., the plan may be retrieved from the robot's own storage and/or from other robots using an edge query language). The intelligence layer 12140 may then generate subtasks based on the past subtask plans and any data indicating the success and/or failure of various tasks that were executed to accomplish the past navigation task. The intelligence layer 12140 may then pass the various subtasks back to the task management system 12144 for assignment.

[3473] Additionally or alternatively, the intelligence layer 12140 may leverage genetic algorithms for subtask generation. For example, the intelligence layer 12140 may execute algorithms to generate a population of potential subtask solutions, select the best solutions (e.g., based on a fitness function and/or by evaluating the solution using a digital twin simulation), and then iteratively refine these solutions through crossover and/or mutation operations. The

intelligence layer 12140 may then pass the various subtasks of the refined solution back to the task management system 12144 for assignment.

[3474] In embodiments, the role assignment 30110 received by a robot 30002 may be a controller role (e.g., a role for implementing the functions of the fleet management platform 100 / robot 30002A). In these embodiments, the robot 30002 may use subtask generation to generate the various subtasks assigned to the fleet management platform 100 / robot 30002A. For example, the robot 30002 may generate subtasks for dynamically assigning tasks/roles to the various robots within the fleet, obtaining robot data, AI models, and/or retraining data, and otherwise performing any of the various tasks/subtasks ascribed to the platform 100 / robot 30002A.

[3475] In embodiments, the task assignment 30110 received by a robot 30002 may be a training/retraining task for an AI model. In these embodiments, the robot 30002 may generate and perform various subtasks such as obtaining training data, generation synthetic training data, requesting and receiving training data and/or synthetic training data from other systems, training/retraining one or more AI models, and/or otherwise performing any of the training tasks/subtasks described herein.

[3476] In some embodiments, the intelligence layer 12140 may leverage multiple AI models for subtask generation. For example, the intelligence layer 12140 may execute various subtask generation algorithms (e.g., including some or all of the approaches described above) in parallel to generate multiple subtask plans. Then, the intelligence layer 12140 may compare which subtasks generated by different AI approaches are part of most or all of the subtask plans.

[3477] Additionally or alternatively, the intelligence layer 12140 may initially employ a fast algorithm to begin executing a task by creating the first subtask. Later, as additional resources become available (e.g., when processing resources free up), when more contextual data has been collected, and/or when more specialized models are accessible, the robot may switch to a slower but more accurate subtasks generation algorithm. The intelligence layer 12140 may then reassign the subtasks generated by the second algorithm to the task management system 12144.

[3478] In embodiments, the task management system 12144 may leverage the intelligence layer 12140 to execute an AI model to analyze and/or classify a task assigned to the robot. Based on this classification, the intelligence layer 12140 may then determine which subtask generation algorithm or model is most suitable for decomposing the task into subtasks. For example, if the assigned task involves navigating a cluttered environment, the intelligence layer 12140 may select a subtask generation algorithm adept at dynamically adjusting the robot's path based on real-time sensor data.

[3479] In embodiments, robotic systems integrate a robotic control circuit, a plurality of sensors, a governance analysis circuit, and a governance model circuit, all on a single substrate, facilitating rapid data processing and execution of robotic functions. This integration ensures that the robotic control circuit can effectively control the robot's functions and/or operations in accordance with governance actions determined by the governance model circuit.

[3480] The plurality of sensors may be configured to collect a diverse range of data from the robot's operational environment. The governance analysis circuit may analyze the collected data to select appropriate governance frameworks. These frameworks may include safety standards, security standards, quality standards, regulatory standards, financial standards, health standards, legal standards, environmental standards, ethical standards, and industry-specific standards, among others, ensuring comprehensive compliance. In embodiments, the analyzed data indicates the state of an environment containing the robotic system. Environmental states may include operational states (e.g., active production, maintenance, idle or standby), physical conditions (e.g., spatial layout, obstructions, cleanliness and order), environmental factors (e.g., lighting conditions, temperature, noise levels), safety and security states (e.g., emergency situation, security breach), inventory state (e.g., stock levels, damaged goods), human interaction (e.g., worker presence, human-robot collaboration), technological state (e.g., network connectivity, system updates), logistical dynamics (e.g., supply influx, shipping and receiving activities), regulatory compliance states, and many others.

[3481] In embodiments, the governance model circuit is configured to generate a model that applies the selected set of governance frameworks to determine specific governance actions. This model may be dynamic, allowing the robotic control circuit to adjust the robot's functions in real-time based on the governance actions derived from the model, enabling the robot to maintain operational integrity and compliance under varying environmental conditions.

[3482] In embodiments, the governance analysis circuit employs machine learning algorithms to analyze sensor data and environmental context, enabling it to select the most appropriate governance frameworks for the current situation. The governance model circuit can utilize a dynamic neural network architecture that continuously updates and refines its model based on real-time feedback, ensuring that the applied governance actions remain optimal as the robot's environment and tasks evolve. The robotic control circuit can be configured to integrate with the governance actions determined by the governance model circuit, adjusting the robot's functions in real-time to maintain compliance with the selected governance frameworks. When conflicts arise between different governance frameworks, the governance model circuit can employ a prioritization algorithm that considers factors such as safety criticality, regulatory requirements, and operational efficiency to resolve these conflicts and determine the most appropriate course of action. The governance chip system may be implemented using specialized AI chips integrated on a single substrate, allowing for high-speed communication between the robotic control circuit, governance analysis circuit, and governance model circuit, thus enabling rapid decision-making and action implementation in complex, dynamic environments.

[3483] Furthermore, the governance model circuit is capable of prioritizing among a plurality of governance frameworks. When conflicts arise between different frameworks, such as safety versus efficiency, the governance model circuit resolves these conflicts by evaluating the priorities of each framework, ensuring that the most critical standards are upheld in the robot's operations.

[3484] The governance model circuit may be configured to apply the generated model to a second set of data captured after the model's generation. This feature enables continual refinement and validation of governance actions, ensuring they remain effective as new data is collected. Additionally, the governance model circuit can be configured to continually adjust the model based on real-time data from the sensors, enhancing the robot's adaptability to sudden changes in its operational environment.

[3485] In scenarios involving multiple robots or systems, the robotic control circuit can extend its functionality to control one or more functions of a secondary robotic system based on the determined governance actions. This capability is crucial for coordinated operations in complex environments, such as manufacturing facilities or logistics operations, where multiple robots work in tandem.

[3486] The robotic system can also transmit instructions to the secondary robotic system to control its functions, further enhancing operational coordination and efficiency. The governance actions determined by the system can include changing the state of the robotic system, changing tasks assigned to the robot, transmitting warnings or alarms, and transforming data to comply with various governance frameworks.

[3487] Moreover, the governance model circuit can simulate the governance actions within a digital twin environment. This simulation allows for risk-free testing and optimization of governance strategies, providing a robust platform for refining actions before they are executed in the real world.

[3488] In implementations, the circuits, including the robotic control circuit, the governance analysis circuit, and the governance model circuit, are implemented using specialized AI chips, which offer enhanced processing capabilities and efficiency. Alternatively, these circuits can also be implemented using a combination of CPUs and GPUs, providing flexibility in design and deployment.

[3489] The system's architecture can employ dynamic voltage and frequency scaling to optimize power consumption and performance. The robotic control circuit, governance analysis circuit, and governance model circuit may be integrated on a single substrate that may include a 2.5D or 3D stack of chips, enhancing inter-circuit connectivity and data throughput. High-speed bridges and high bandwidth memory are used to support rapid data exchange and storage, crucial for real-time robotic operations. Additionally, the modular elements of the system can be connected using die-to-die connectivity, allowing for scalable and flexible system configurations.

[3490] In embodiments, the robotic system may integrate a robotic control circuit, a plurality of sensors, a predictive modeling circuit, and a predictive model optimization circuit, all on a single substrate. This configuration can help to ensure seamless data processing and rapid execution of robotic functions, enhancing the robot's operational efficiency and adaptability. The integration on a single substrate, potentially using advanced technologies such as 2.5D or 3D stacking, facilitates efficient communication and data processing between these components.

[3491] In embodiments, the plurality of sensors is configured to collect a diverse range of data from the robot's operational environment. The predictive modeling circuit can utilize one or more artificial intelligence models to generate predictions based on this collected data. These predictions can support proactive decision-making in dynamic environments. The predictive model optimization circuit enhances this functionality by re-training the predictive model based on conditions detected after the initial prediction, ensuring the model remains accurate and relevant over time.

[3492] Further enhancing its capabilities, the predictive model optimization circuit may be configured to train the predictive model based on training data generated by the robotic system itself. This self-sufficiency in generating and utilizing training data accelerates the learning process and reduces dependency on external data sources. The training data may include classification data generated based on the data captured by the sensors, providing detailed insights into data categories and characteristics, which enhances the model's predictive accuracy. Additionally, the predictive model optimization circuit can utilize training data generated by an environment digital twin, allowing for sophisticated scenario analysis and simulation.

[3493] The predictive model optimization circuit may also be configured to re-train the predictive model based on the accuracy of the predictions generated by the predictive modeling circuit, facilitating continuous improvement and refinement of the model, and maintaining high reliability and performance of the robotic system.

[3494] A recommendation circuit may be included to provide recommended actions for the robotic system based on the predictions. This circuit can enhance the system's ability to act on the predictive insights effectively. The robotic control circuit can be configured to control the robotic functions based on these recommended actions, translating predictive insights into tangible actions. The recommended actions can specify not only the action itself but also the entity on which the action will be taken and any modifiers for the action, allowing for nuanced and precise operational control.

[3495] For example, in a warehouse environment, a robotic system's neural network classifier processes data from various IoT sensors and cameras, predicting an increase in human traffic in a particular aisle within the next fifteen minutes due to a scheduled inventory check. Based on this prediction, the recommendation circuit generates a specific action plan. It suggests reducing the speed and increasing the proximity sensors' sensitivity for a particular forklift robot. The recommended action includes precise modifiers: reducing the robot's speed by 30%, increasing its sensor range by two meters, and activating its audio warning system. The robotic control circuit then implements these recommendations, adjusting the forklift robot's operations to ensure safe and efficient coexistence with the predicted increase in human presence.

[3496] The robotic system can be further configured to simulate the recommended actions using an environment digital twin, providing a virtual environment to evaluate the potential impacts and effectiveness of different actions. Additionally, the recommendation circuit can provide a second recommended action for controlling functions of a second robotic system, enhancing coordinated multi-robot operations. The robotic system can transmit this second

recommended action to the second robotic system, ensuring effective communication and synchronization between systems.

[3497] Moreover, the robotic system may be configured to generate a report indicating the outcome of the recommended action, providing feedback for assessing the effectiveness of the actions and the accuracy of the predictions and facilitating continuous improvement.

[3498] In embodiments, the circuits, including the robotic control circuit, the predictive modeling circuit, and the predictive model optimization circuit, can be implemented using specialized AI chips or a combination of CPUs and GPUs. The circuits may be configured to use dynamic voltage and frequency scaling to optimize power consumption and performance. High-speed bridges and high bandwidth memory support rapid data exchange and storage, which is crucial for real-time robotic operations. Additionally, the modular elements of the system can be connected using die-to-die connectivity, allowing for scalable and flexible system configurations.

[3499] In implementations, the robotic system integrates a robotic control circuit, a plurality of sensors, a network interface circuit, a network analysis circuit, and a network optimization circuit, all on a single substrate.

[3500] The plurality of sensors can be configured to collect a diverse range of data, including physical signal measurements, network traffic, network device information, and network configuration data. The network analysis circuit may be configured to utilize one or more artificial intelligence models to analyze both the collected data and the communication with other robotic systems. This analysis supports the understanding of network conditions and interactions between robotic systems.

[3501] The network analysis circuit can be configured to predict future network conditions based on current data and trends. This predictive capability allows the robotic system to anticipate and prepare for potential network issues (e.g., network congestion, security vulnerabilities, bandwidth saturation, data quality issues, inefficient data routing, scheduling conflicts, or latency problems) before they occur.

[3502] In embodiments, the network optimization circuit uses the analysis provided by the network analysis circuit to optimize various aspects of network communication. This may include optimizing traffic flows between robotic systems on the network, prioritizing data on the network, and adjusting the protocols used by the robotic systems on the network. Such optimizations can help ensure efficient and reliable network performance, enabling the coordinated operation of multiple robotic systems. The network analysis circuit may be configured to generate or update a network digital twin based on its analysis. This digital twin provides a virtual representation of the network, allowing for detailed simulation and testing of network strategies and configurations. The network optimization circuit can use this digital twin to simulate network optimizations, providing a risk-free environment to evaluate the potential impacts and effectiveness of different optimization strategies before they are implemented in the real network.

[3503] The network analysis circuit may leverage artificial intelligence models to analyze real-time data from sensors and network traffic, enabling it to predict future network conditions and identify potential bottlenecks or security vulnerabilities. The network optimization circuit can use these insights to dynamically adjust traffic flows, prioritize data transmission, and modify network protocols in real-time, ensuring optimal performance of the robotic fleet's communication infrastructure. This optimization process may include advanced techniques such as adaptive routing, dynamic bandwidth allocation, and intelligent load balancing across multiple communication channels. The network interface circuit may integrate with both the network analysis circuit and network optimization circuit, providing a high-speed, low-latency connection that allows for rapid implementation of network adjustments and ensures minimal disruption to ongoing robotic operations. The network interface circuit, the network analysis circuit, and the network optimization circuit may all be integrated on a single substrate.

[3504] In embodiments, the optimizations performed by the network optimization circuit may include optimizing the schedule of the network, the quality of data transmitted, and/or the security of data transmissions. In embodiments, the optimizations performed by the network optimization circuit may include compressing, decompressing, up-sampling, down-sampling, reformatting, delaying, buffering, or rescheduling traffic transmitted to or from the robotic system via the network interface circuit. Additionally, the circuit can instruct robotic systems to adjust their operational parameters, such as powering up or down, switching networks, adjusting transmission schedules, re-routing traffic, or compressing data. These actions help in maintaining optimal network performance and security.

[3505] In one example, in a large manufacturing facility, the network analysis circuit of a robotic system continuously monitors the network infrastructure that connects various robotic units, IoT devices, and control systems. Based on its analysis of network traffic patterns, device performance, and potential bottlenecks, the circuit generates a network digital twin, which models the entire network topology, including data flows, latency issues, and security vulnerabilities. Using this digital twin, the network optimization circuit simulates various optimization strategies. For instance, it tests a new data routing algorithm that reduces network congestion during peak production hours. The simulation reveals that while the algorithm improves overall throughput, it could potentially create security vulnerabilities in certain network segments. Based on these insights, the optimization circuit refines the algorithm to address the security concerns before implementation. Subsequently, the network optimization circuit implements a series of optimizations. It adjusts the network schedule to prioritize critical control data during specific production phases, enhances data compression for non-time-sensitive information to improve transmission quality, and strengthens encryption protocols for sensitive operational data. Additionally, the circuit instructs several robotic systems to modify their behavior. For example, it directs autonomous forklifts to switch to a secondary network during inventory counts to prevent bandwidth saturation, orders stationary robotic arms to compress their status update data during off-peak hours, and instructs mobile inspection robots to adjust their transmission schedules to avoid network congestion.

[3506] The network optimization circuit may also be capable of modifying instructions being routed to robotic systems, changing the topology of the network, and altering the headers of data packets.

[3507] In embodiments, the robotic system also can include a governance circuit configured to monitor and apply governance actions to traffic transmitted between robotic systems via the network, ensuring that all network communications comply with established policies and standards and enhancing the overall governance of the robotic system's network interactions.

[3508] The circuits, including the robotic control circuit, network interface circuit, network analysis circuit, and network optimization circuit, may be implemented using specialized AI chips or a combination of CPUs and GPUs. In embodiments, the circuits are configured to use dynamic voltage and frequency scaling to optimize power consumption and performance. High-speed bridges and high bandwidth memory support rapid data exchange and storage, which enable real-time network operations. Additionally, the modular elements of the system can be connected using die-to-die connectivity, allowing for scalable and flexible system configurations.

[3509] In embodiments, the integrated chipset may comprise a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit, all sharing a set of I/O capabilities, facilitating communication and data handling between the circuits and enhancing the operational efficiency and adaptability of the robotic system in dynamic environments.

[3510] In embodiments, the robotic control circuit can be configured to control a set of functions for a set of robots, ensuring coordinated and efficient robotic operations. In embodiments, the data collection circuit handles data from a set of IoT devices, collecting diverse environmental and operational data and the neural network classifier processes this collected data to output a classification of the state of the environment in which the robots operate, providing critical insights into environmental conditions and potential obstacles or requirements.

[3511] The neural network control circuit can operate on the output of the neural network classifier to output operational control parameters to the robotic control circuit. This operation allows the system to adapt the robots' functions based on real-time environmental data.

[3512] In embodiments, the shared set of I/O capabilities of the integrated chipset may include shared I/O ports, shared data, shared sensors, shared actuators, and the like. These shared I/O capabilities ensure that data and control signals are efficiently distributed among the circuits, minimizing latency and maximizing the responsiveness of the system.

[3513] The neural network classifier within the chipset can be implemented using various technologies, including an application-specific integrated circuit (ASIC), a graphics processing unit (GPU), a tensor processing unit (TPU), or a field-programmable gate array (FPGA). Each of these implementations offers specific advantages, such as enhanced processing speed or flexibility in programming, which can be selected based on the specific requirements of the robotic system.

[3514] The integrated chipset, and any other integrated chipsets described throughout this disclosure, may be onboard a robot that manages multiple robots or a platform that manages a plurality of robots, providing centralized control and data processing capabilities.

[3515] The neural network classifier's capabilities can extend to recognizing objects within the environment, performing scene understanding, determining human activities, recognizing sounds, determining the pose of robots, mapping the environment, and the like. These functionalities enable the robotic system to understand and interact with its environment, supporting advanced applications such as navigation, interaction with objects, and interaction with humans within the environment.

[3516] The neural network control circuit can further enhance the system's capabilities by controlling navigation within the environment, interactions with objects, and interactions with humans. These control functions support applications where robots must operate in environments shared with humans and other objects, requiring careful navigation and interaction strategies to avoid collisions and ensure cooperative operation.

[3517] For example, in a warehouse environment, a robotic system equipped with advanced neural network capabilities operates alongside human workers. The neural network classifier continuously scans the surroundings, identifying various objects such as pallets, forklifts, and inventory items with high accuracy. It performs real-time scene understanding, distinguishing between different areas like storage zones, loading docks, and pedestrian walkways. The classifier also determines human activities, recognizing when workers are picking items, operating machinery, or engaging in team discussions. Simultaneously, the system's audio processing capabilities allow it to recognize important sounds, such as the beeping of reversing vehicles or the distinct noise of a package being dropped. The neural network classifier also maintains awareness of the poses of other robots in the vicinity, ensuring coordinated movements and preventing collisions. As it operates, the system continuously updates its internal map of the environment, noting any changes in layout or the position of mobile obstacles. The neural network control circuit guides the robot's actions based on this comprehensive environmental understanding, planning efficient navigation paths through the warehouse, dynamically adjusting routes to avoid congested areas or newly detected obstacles. When interacting with objects, the control circuit calculates precise movements for tasks such as picking up boxes or operating controls on machinery. When human workers are present, the control circuit modulates the robot's behavior to ensure safe and cooperative interactions. This might involve slowing down in shared spaces, maintaining a respectful distance, or using visual and auditory cues to communicate its intentions to nearby humans.

[3518] In some implementations, the integrated chipset comprises a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit, all integrated on a common substrate. The integration of these circuits on a common substrate, which can be a single silicon wafer, a single chip, or a package that encloses multiple smaller packages connected via a common interface, facilitates efficient communication and data processing between these components.

[3519] In embodiments, the integrated chipset comprises a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit, all configured as layers in a 3D chipset architecture. This configuration can enhance the integration density and operational efficiency by utilizing vertical space, which is crucial for complex processing tasks in robotic systems.

[3520] The integration of these circuits in a 3D chipset architecture, connected vertically using through-silicon vias, facilitates efficient communication and data processing between these components. This configuration minimizes latency and maximizes the responsiveness of the system, supporting real-time operations. The integrated chipset may be enclosed within a package that contains multiple vertically stacked packages connected via a common interface, further enhancing the compactness and integration density of the system.

[3521] In embodiments, the integrated chipset may comprise a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit, all sharing a set of I/O capabilities that are disposed on the perimeter of the chipset. This configuration enhances the efficiency of data handling and signal processing, facilitating integration and communication between the components.

[3522] The shared set of I/O capabilities, including shared I/O ports located on the perimeter of the chipset, facilitate efficient communication between the chipset's components and external devices such as sensors and actuators. This arrangement not only optimizes the physical layout for signal integrity but also supports high-speed data transfer and reduces electromagnetic interference, which is crucial for maintaining the reliability and accuracy of the robotic system's operations.

[3523] In embodiments, the integrated chipset comprises a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit, all integrated on a chipset with a design that features a set of processing cores concentrated in the middle portion of the chip, which are served by a set of I/O capabilities located on the perimeter of the chip. An off-chip interconnection capability is substantially positioned at the center of the chip, enhancing the connectivity and efficiency of data handling between the chip's internal components and external devices.

[3524] In embodiments, the integrated chipset uses an advanced perimeter I/O architecture, where shared I/O capabilities are strategically positioned around the outer edge of the chip. This configuration optimizes signal integrity and minimizes electromagnetic interference by concentrating I/O functions at the chip's periphery. The shared I/O capabilities include a set of ports that facilitate high-speed data transfer between the chipset's internal components and external devices such as sensors and actuators. This arrangement reserves the central areas of the chip for critical processing units and memory components. The perimeter I/O architecture enhances the overall performance of the robotic system by reducing latency in data transmission and improving power efficiency. Furthermore, this design supports the integration of various functional units within the chipset, including the robotic control circuit, data collection circuit,

neural network classifier, and neural network control circuit, enabling them to share common I/O resources effectively.

[3525] In embodiments, the integrated chipset comprises a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit, all integrated on a chipset featuring a modular architecture that includes a set of modular processing clusters connected by a set of embedded multi-chip interconnect bridges to a set of high bandwidth memory modules. This configuration enhances the efficiency and scalability of the chipset, allowing for high-speed data processing and communication between the modules.

[3526] The modular processing clusters may be strategically organized, with a first module processing cluster comprising the neural network classifier and the neural network control circuit, and a second module processing cluster comprising the robotic control circuit and the data collection circuit. This separation optimizes the processing capabilities of each cluster, focusing on specific tasks to enhance overall system performance.

[3527] In implementations, the high bandwidth memory modules connected to these clusters are advanced, including options such as HBM, HBM2, HBM2E, or HBM3 modules. These memory modules provide the necessary speed and capacity to handle large volumes of data processed and generated by the chipset, supporting complex computational tasks required by modern robotic systems.

[3528] The embedded multi-chip interconnect bridges, which may include technologies such as network on chip (NoC), advanced extensible interface (AXI), PCI express (PCIe), high-speed inter-chip (HSIC), or hypertransport bridges, facilitate high-speed data transfer between the clusters and memory modules. This connectivity ensures that data flows efficiently across the chipset, minimizing latency and maximizing the responsiveness of the robotic system.

[3529] In embodiments, the integrated chipset described comprises a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit, all integrated on a chipset featuring a bi-directional torus network on chip (NoC) architecture. This architecture enhances the efficiency of data routing and processing, enabling high-speed communication between the chipset's components and supporting complex computational tasks required by modern robotic systems.

[3530] The bi-directional torus NoC architecture facilitates efficient and flexible data flow across the chipset. This architecture supports multiple pathways for data transmission, reducing bottlenecks and improving data handling capabilities, which is crucial for maintaining the reliability and accuracy of the robotic system's operations.

[3531] In embodiments, the integrated chipset comprises a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit. These components can be integrated on the chipset as a set of modular elements utilizing die-to-die connectivity. This configuration facilitates enhanced communication and operational efficiency between the components, supporting complex computational tasks required by modern robotic systems.

[3532] The modular elements of the chipset can be arranged in a 2.5D or 3D stacked configuration, which is facilitated by the use of silicon interposers or other advanced interconnect technologies such as Embedded Multi-Die Interconnect Bridge (EMIB), Advanced Interconnect Bus (AIB), or Chip-to-Chip Direct Connect (C2C). These technologies enable efficient and flexible data flow across the chipset, minimizing latency and maximizing the responsiveness of the robotic system.

[3533] Furthermore, the chipset may be integrated within a package using advanced packaging technologies such as Wafer-Level Fan-Out (WLFO) or Fan-Out Wafer-Level Packaging (FOWLP). These packaging technologies support the high-density integration of the modular elements and enhance the overall robustness and performance of the chipset.

[3534] In embodiments, the integrated chipset comprises a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit. These components are uniquely integrated on the chipset and utilize dynamic voltage and frequency scaling (DVFS) to enhance power efficiency and performance adaptability under varying operational demands.

[3535] The neural network classifier processes the data collected from the IoT devices to classify the state of the environment in which the robots operate. This classification provides critical insights into environmental conditions, enabling the identification of potential obstacles or requirements. Subsequently, the neural network control circuit operates on the output of the neural network classifier to generate operational control parameters, which are then communicated to the robotic control circuit. This operation allows the system to adapt the robots' functions based on real-time environmental data, thereby enhancing the robots' ability to interact effectively with their surroundings.

[3536] Dynamic voltage and frequency scaling is employed within the chipset to optimize power consumption and processing speed in response to the workload demands of the robotic system. By adjusting the voltage and frequency of the chipset components, DVFS enables the system to reduce power consumption during lower activity periods and enhance performance during peak operational demands, thereby maintaining an optimal balance between power efficiency and computational performance.

[3537] The integrated chipset may be deployed onboard a robot that manages multiple robots or a platform that manages a plurality of robots, providing centralized control and data processing capabilities. This configuration allows for sophisticated management and coordination of large groups of robots, enhancing the overall efficiency of operations.

[3538] In implementations, the integrated chipset comprises a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit, all integrated on an optical chipset. This optical chipset utilizes optical communication that is partitioned by wavelength, allowing for selective prioritization by wavelength. This approach enhances the efficiency and precision of data transmission within the chipset, supporting high-speed communication and reducing latency in processing complex computational tasks required by modern robotic systems. The optical communication within the chipset, partitioned by

wavelength, allows for the prioritization of certain data types or signals, ensuring that critical information is processed with higher priority and faster throughput. This capability is useful in scenarios where real-time decision-making and responsiveness are essential, such as in dynamic and unpredictable environments.

[3539] In embodiments, the integrated chipset includes a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit. These components are uniquely integrated on the chipset using integrated fan-out (IFO) packaging. This advanced packaging technology enhances the chipset's performance by allowing for a more efficient layout and improved thermal management, which is important for maintaining the reliability and functionality of the system under various operational conditions.

[3540] Integrated fan-out packaging used in the chipset facilitates a higher degree of integration and a smaller form factor compared to traditional packaging methods. This packaging technology supports the inclusion of a higher number of I/O ports and improves the electrical performance by reducing the interconnect lengths between the components. Additionally, IFO packaging allows for the incorporation of additional passive components and possibly even other active components within the same package, further enhancing the chipset's functionality and performance.

[3541] The integrated chipset may include a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit, all integrated on a chipset utilizing high numerical aperture, extreme ultraviolet (high-NA EUV) optical technology. This advanced optical technology enhances the chipset's performance by enabling smaller feature sizes in the semiconductor fabrication process, which significantly improves the density, speed, and energy efficiency of the integrated circuits.

[3542] The use of high-NA EUV technology in the chipset's fabrication allows for the integration of more transistors into a smaller area, increasing the processing power and reducing power consumption. This technology is particularly beneficial in applications requiring high-performance computing capabilities and low energy usage, such as in advanced robotic systems.

[3543] In embodiments, the integrated chipset includes a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit, all integrated on a chipset utilizing gate-all-around field-effect transistors (GAAFETs). This advanced transistor technology enhances the chipset's performance by providing superior control over the current flow, significantly reducing leakage, and improving energy efficiency, which is crucial for maintaining the reliability and functionality of the system under various operational conditions.

[3544] The use of GAAFETs in the chipset's fabrication allows for the integration of more transistors into a smaller area, increasing the processing power and reducing power consumption. This technology is particularly beneficial in applications requiring high-performance computing capabilities and low energy usage, such as in advanced robotic systems.

[3545] The integrated chipset may comprise a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit, all integrated on a chipset

utilizing a set of gate-all-around nanowire field-effect transistors (GAA-NWFETs). This advanced transistor technology enhances the chipset's performance by providing superior electrostatic control over the channel, significantly reducing leakage, and improving energy efficiency, which is crucial for maintaining the reliability and functionality of the system under various operational conditions.

[3546] The use of GAA-NWFETs in the chipset's fabrication allows for the integration of more transistors into a smaller area, increasing the processing power and reducing power consumption. This technology is particularly beneficial in applications requiring high-performance computing capabilities and low energy usage, such as in advanced robotic systems.

[3547] In embodiments, the integrated chipset comprises a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit, all integrated on a chipset utilizing a set of gate-all-around nanosheet field-effect transistors (GAA-NWFETs). This advanced transistor technology enhances the chipset's performance by providing superior electrostatic control over the channel, significantly reducing leakage, and improving energy efficiency. The use of GAA-NWFETs in the chipset's fabrication allows for the integration of more transistors into a smaller area, increasing the processing power and reducing power consumption.

[3548] The integrated chipset may include a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit. These components are integrated on a chipset utilizing a set of gate-all-around complementary field-effect transistors (GAA-CFETs). This advanced transistor technology enhances the chipset's performance by providing superior electrostatic control over the channel, significantly reducing leakage, and improving energy efficiency.

[3549] In embodiments, the integrated chipset described herein comprises a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit, all integrated on a chipset utilizing carbon nanotube technology, which enhances the chipset's performance by providing superior electrical conductivity and thermal properties, significantly reducing power consumption, and improving the speed and reliability of the system under various operational conditions. The use of carbon nanotube technology in the chipset's fabrication allows for the integration of highly conductive and durable components into a smaller area, increasing the processing power and reducing power consumption.

[3550] The integrated chipset may include a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit. These components are integrated on a chipset that includes high-bandwidth SRAM memory, enhancing the chipset's performance by providing rapid access to data for the real-time processing and responsiveness required in robotic control systems. The integration of these circuits on a chipset with high-bandwidth SRAM memory supports the intensive data processing demands of machine learning algorithms and real-time control tasks.

[3551] In embodiments, the integrated chipset comprises a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit, all integrated

on a chipset that incorporates 3D-NAND flash memory. This memory technology enhances the chipset's capacity for data storage and speed, facilitating efficient handling and processing of large volumes of data from IoT devices.

[3552] In some embodiments, the integrated chipset comprises a robotic control circuit, a data collection circuit, a neural network classifier, and a neural network control circuit, all integrated on a hybrid-bonded chipset. This advanced integration technique enhances the chipset's performance by enabling higher interconnect density and improved thermal management.

[3553] In embodiments, a robotic fleet includes a plurality of robotic systems, each equipped with an integrated chipset and a set of sensors. Each integrated chipset within these robotic systems can be configured to generate synthetic training data, enabling the robotic systems to simulate various operational scenarios and enhance their AI models based on synthesized experiences. Additionally, the fleet includes a robotic system that is in communication with at least a subset of the plurality of robotic systems. This particular robotic system also contains an integrated chipset that performs several critical functions to optimize the performance of an AI model it executes.

[3554] The integrated chipset in this central robotic system can measure the performance of the AI model and determine when additional training data is needed to enhance the model's effectiveness. Upon identifying the need for more data, it may transmit a request for training data to the subset of robotic systems. This request can specify one or more context factors relevant to the robotic system's current operational environment or tasks. In response, the subset of robotic systems generates synthetic training data, which is then sent back to the central robotic system. This synthetic training data can be utilized to fine-tune the AI model, optimizing its performance for the specified context factors.

[3555] In some embodiments, the subset of robotic systems generates the synthetic training data using an environment digital twin and the specified context factors, allowing for a highly accurate simulation of environmental conditions. Alternatively, the synthetic training data may be generated using a plurality of role-based digital twins. Additionally, the synthetic training data can be generated using generative AI models, such as generative adversarial networks (GANs) or large language models (LLMs).

[3556] The generation of synthetic training data can be further diversified by different robotic systems within the fleet using different sets of sensors or different AI models. For instance, a first robotic system might generate a portion of the synthetic training data based on its unique set of sensors, while a second robotic system may generate another portion using a different set of sensors. Similarly, different AI models may be employed by different robotic systems to generate varied data.

[3557] The synthetic training data may include data captured by the set of sensors on the robotic systems, ensuring that the data is grounded in the physical realities experienced by the robots. The context factors guiding the generation of synthetic training data include specific tasks being performed by the robotic system, the local environment of the robotic system, the presence of nearby humans or devices, and the like.

[3558] The AI models optimized using this synthetic training data may include navigation models; object manipulation models; language models; network optimization models; and multimodal models that process audio, image, or video data; among many others. The robotic system that coordinates the training data requests and AI model optimization may also include a network enhancement chipset to facilitate efficient communication with the subset of robotic systems, and its integrated chipset may comprise multiple processing units integrated on a single substrate, enhancing processing power and efficiency.

[3559] The robotic system may comprise an integrated chipset and an intelligence layer. The integrated chipset can include a plurality of processing units, enhancing the system's capability to handle complex computational tasks efficiently. The intelligence layer may be configured to manage various operations crucial for the autonomous functioning of the robotic system.

[3560] In some embodiments, the intelligence layer first determines a task that needs to be performed by the robotic system. Following this, it selects an appropriate AI model from a range of models that are best suited for executing the determined task. To optimize the selected AI model's performance on the task, the intelligence layer obtains training data. This training data can be retrieved from storage onboard the robotic system or generated anew as synthetic training data.

[3561] In scenarios where synthetic training data is required, the integrated chipset can generate this data using an environment digital twin, incorporating one or more context factors relevant to the robotic system's operational environment. These context factors may include specific requirements, objectives, or methods of performing the task, or they may describe nearby humans or devices that could influence the task's execution. Once the training data is obtained, the intelligence layer causes the integrated chipset to retrain the AI model using this data, ensuring that the model is finely tuned to perform the task effectively. After retraining, the intelligence layer then directs the integrated chipset to execute the retrained AI model to carry out the task.

[3562] In some embodiments, the generation of synthetic training data involves simulating the performance of the task directly or interacting with other robotic systems. The robotic system may transmit a request for training data to other robotic systems in communication with it and receive synthetic training data generated by these systems. This data might include information captured by sensors of the other robotic systems or be based on simulations they perform.

[3563] In embodiments, the selection of the most optimal processing unit within the integrated chipset for retraining the AI model is based on factors such as the processing capability or power efficiency of each processing unit. In cases where an FPGA is the most optimal processing unit, the intelligence layer can reprogram the FPGA specifically for executing the retraining of the AI model.

[3564] Additional functionalities of the intelligence layer may include monitoring the performance of the task and updating the training data in real-time based on this performance. This allows for continuous improvement of the AI model as it adapts to real-world conditions and changes in the task environment. If the context for performing the task ends, the intelligence

layer may also delete the retrained AI model to free up resources and maintain system efficiency.

[3565] The AI model used by the robotic system may include navigation models; object manipulation models; language models; network optimization models; multimodal models that handle various types of data such as audio, image, or video data; and the like. The plurality of processing units within the integrated chipset can integrated on a single substrate, and in some configurations, they may be manufactured on a single silicon wafer, enhancing the integration and coordination of computational resources within the robotic system.

[3566] The robotic fleet may include a fleet management platform and a robotic system in communication with this platform. The fleet management platform may be configured to assign a plurality of roles to a plurality of robotic systems within the robotic fleet, facilitating specialized and efficient task management across the fleet. The robotic system, equipped with an integrated chipset comprising a plurality of processing units, may be configured to perform several key operations to enhance its functionality and responsiveness to fleet dynamics.

[3567] Upon receiving a role assignment from the fleet management platform, the robotic system may configure its processing units to perform tasks associated with the assigned role, which may involve enhanced vision, data analysis, decision-making, and/or other specialized functions. The robotic system can then determine the next task from a task queue and can assign this task to a suitably configured processing unit, taking into account one or more context factors that may affect task execution. These context factors can include the AI model used to perform the task, the power efficiency of the processing unit, the parallelizability of the task, timing requirements, or the communication speed of the processing unit. The task can then be executed using the configured processing unit, ensuring that the robotic system performs optimally within the parameters set by its role and current operational needs.

[3568] In embodiments, the fleet management platform is capable of dynamically re-assigning roles among the robotic systems based on the current state of the robotic fleet. This state may include the status of each robotic system, characterized by factors such as power levels, availability for additional tasks, and processing capabilities. It may also consider the broader operational environment of each robotic system or the set of tasks currently assigned to the fleet. This dynamic re-assignment allows the fleet to adapt to changing conditions and operational demands.

[3569] In some configurations, the fleet management platform is onboard a controller robotic system, which may itself assign a fleet management role to another robotic system within the fleet, further decentralizing control and enhancing operational flexibility. The robotic system, upon receiving a role assignment, may request an AI model associated with the role from another device within the fleet, ensuring it has the necessary computational tools to perform its role effectively.

[3570] Configuring the plurality of processing units to perform tasks associated with the role often involves assigning specific AI models to specific processing units. This may include reprogramming an FPGA to execute an assigned AI model, allowing for flexible and efficient

use of hardware resources. The AI models involved can vary widely, including navigation models, object manipulation models, language models, or network optimization models, depending on the needs of the specific role and tasks.

[3571] The plurality of processing units within the robotic system's integrated chipset may be integrated on a single substrate, and in some configurations, they are manufactured on a single silicon wafer.

[3572] In embodiments, the robotic system comprises an integrated chipset with a plurality of processing units and an intelligence layer. Upon receiving a role assignment from a fleet management platform, the intelligence layer configures the plurality of processing units within the integrated chipset to perform tasks associated with the assigned role. The intelligence layer then determines the next task from a task queue designated for performance by the robotic system. To effectively decompose this task into manageable sub-tasks, the intelligence layer selects an appropriate algorithm for sub-task generation. This algorithm could be based on various methodologies, including reinforcement learning, which might utilize simulations within a digital twin environment, goal decomposition algorithms, hierarchical task networks, genetic algorithms, among many others. The choice of algorithm can be made based on its suitability for generating sub-tasks for the specific next task at hand. Once the algorithm is selected, the intelligence layer can cause the integrated chipset to execute this algorithm, resulting in the generation of one or more sub-tasks. These sub-tasks are then assigned to the appropriate processing units within the chipset, ensuring that each unit's capabilities are optimally utilized for task execution. The processing units subsequently execute these sub-tasks, collaboratively performing the next task.

[3573] In scenarios where multiple algorithms are suitable, the intelligence layer may select multiple algorithms to run in parallel for the generation of sub-tasks. This approach allows the system to compare and select the most effective sub-tasks from those generated by the different algorithms, enhancing the efficiency and effectiveness of task execution.

[3574] The role assignments received by the robotic system can vary and include roles such as an enhanced vision role, a data analysis role, or a decision-making role. Depending on the role, the robotic system may request specific AI models associated with that role from other devices within the fleet. This is particularly relevant when configuring the processing units to perform tasks associated with the role, which may involve assigning and potentially reprogramming an FPGA to execute an assigned AI model, such as a navigation model, an object manipulation model, a language model, or a network optimization model.

[3575] The sub-tasks generated and assigned may include a variety of operations, such as optimizing a network, applying governance frameworks, or performing navigation tasks. If the next task involves training an AI model, the sub-tasks could include generating synthetic data for training the AI model and potentially requesting additional synthetic data from other robotic systems within the fleet.

[3576] If the robotic system receives a fleet controller role, the next task may involve dynamically assigning roles to other robotic systems in communication with it, demonstrating the system's capability to manage and coordinate activities across the fleet.

[3577] The plurality of processing units within the robotic system's integrated chipset may be integrated on a single substrate, enhancing the coordination and efficiency of the processing units. In some configurations, these units are manufactured on a single silicon wafer, while in others, they are separately manufactured and bonded to the single substrate, providing flexibility in the manufacturing process and potential enhancements in system design and functionality.

[3578] In some embodiments, a robotic fleet comprises a plurality of robotic systems, each equipped with an integrated chipset and a set of sensors. Each integrated chipset within these robotic systems may be configured to generate synthetic training data, enabling the robotic systems to simulate various operational scenarios and enhance their AI models based on synthesized experiences. Additionally, the fleet may include a robotic system that is in communication with at least a subset of the plurality of robotic systems. This particular robotic system also contains an integrated chipset that performs several critical functions to optimize the performance of an AI model it executes. The integrated chipset in this central robotic system measures the performance of the AI model and determines when additional training data is needed to enhance the model's effectiveness. Upon identifying the need for more data, it transmits a request for training data to the subset of robotic systems. This request specifies one or more context factors relevant to the robotic system's current operational environment or tasks. In response, the subset of robotic systems generates synthetic training data, which is then sent back to the central robotic system. This synthetic training data is utilized to fine-tune the AI model, optimizing its performance for the specified context factors.

[3579] In embodiments, the robotic system comprises an integrated chipset and an intelligence layer. The integrated chipset may include a plurality of processing units. The intelligence layer may be configured to manage various operations crucial for the autonomous functioning of the robotic system.

[3580] In some embodiments, the intelligence layer first determines a task that needs to be performed by the robotic system. Following this, it selects an appropriate AI model from a range of models that are best suited for executing the determined task. To optimize the selected AI model's performance on the task, the intelligence layer obtains training data. This training data can be retrieved from storage onboard the robotic system or generated anew as synthetic training data.

[3581] In scenarios where synthetic training data is required, the integrated chipset can generate this data using an environment digital twin, incorporating one or more context factors relevant to the robotic system's operational environment. These context factors may include specific requirements, objectives, or methods of performing the task, or they may describe nearby humans or devices that could influence the task's execution.

[3582] Once the training data is obtained, the intelligence layer causes the integrated chipset to retrain the AI model using this data, ensuring that the model is finely tuned to perform the task

effectively. After retraining, the intelligence layer then directs the integrated chipset to execute the retrained AI model to carry out the task.

[3583] In some embodiments, the generation of synthetic training data involves simulating the performance of the task directly or interacting with other robotic systems. The robotic system may transmit a request for training data to other robotic systems in communication with it and receive synthetic training data generated by these systems. This data might include information captured by sensors of the other robotic systems or be based on simulations they perform.

[3584] The selection of the most optimal processing unit within the integrated chipset for retraining the AI model is a critical step. This selection is based on factors such as the processing capability or power efficiency of each processing unit. In cases where an FPGA is the most optimal processing unit, the intelligence layer reprograms the FPGA specifically for executing the retraining of the AI model.

[3585] Further functionalities of the intelligence layer may include monitoring the performance of the task and updating the training data in real-time based on this performance. This allows for continuous improvement of the AI model as it adapts to real-world conditions and changes in the task environment. If the context for performing the task ends, the intelligence layer may also delete the retrained AI model to free up resources and maintain system efficiency.

[3586] The AI models used by the robotic system can include, but are not limited to, navigation models, object manipulation models, language models, network optimization models, or multimodal models that handle various types of data such as audio, image, or video data. The plurality of processing units within the integrated chipset can be integrated on a single substrate, and in some configurations, they may be manufactured on a single silicon wafer, enhancing the integration and coordination of computational resources within the robotic system.

[3587] In embodiments, the robotic fleet comprises a fleet management platform and a robotic system in communication with this platform. The fleet management platform may be configured to assign a plurality of roles to a plurality of robotic systems within the robotic fleet, facilitating specialized and efficient task management across the fleet.

[3588] Upon receiving a role assignment from the fleet management platform, the robotic system can configure its plurality of processing units to perform tasks associated with the assigned role. This configuration supports the tailoring of the system's capabilities to the specific requirements of the role, whether it involves enhanced vision, data analysis, decision-making, or other specialized functions.

[3589] The robotic system may then determine the next task from a task queue designated for performance by the robotic system. Based on various context factors, including the AI model used to perform the task, power efficiency of the configured processing unit, parallelizability of the task, timing requirements, and/or communication speed of the configured processing unit, the system can assign the task to the most appropriate configured processing unit.

[3590] In some embodiments, upon receiving a role assignment, the robotic system may request specific AI models associated with that role from other devices within the fleet. This is

particularly relevant when configuring the processing units to perform tasks associated with the role, which may involve assigning and potentially reprogramming an FPGA to execute an assigned AI model, such as a navigation model, an object manipulation model, a language model, or a network optimization model.

[3591] The fleet management platform may be configured to dynamically re-assign roles among the plurality of robotic systems based on the current state of the robotic fleet. This state encompasses various factors, including the status of each robotic system (such as power levels, availability to perform additional tasks, and processing capabilities), the environment of each robotic system, and the set of tasks assigned to the fleet.

[3592] In some configurations, the fleet management platform may be onboard a controller robotic system. This controller system may have the capability to assign a fleet management role to another robotic system within the fleet, allowing for distributed and adaptive fleet management.

[3593] The plurality of processing units within the robotic system's integrated chipset may be integrated on a single substrate, enhancing the coordination and efficiency of the processing units. In some configurations, these units are manufactured on a single silicon wafer, while in others, they are separately manufactured and bonded to a single substrate.

[3594] In embodiments, the robotic system may comprise an integrated chipset with a plurality of processing units and an intelligence layer. Upon receiving a role assignment from a fleet management platform, the intelligence layer configures the plurality of processing units within the integrated chipset to perform tasks associated with the assigned role. The intelligence layer then determines the next task from a task queue designated for performance by the robotic system. To effectively decompose this task into manageable sub-tasks, the intelligence layer selects an appropriate algorithm for sub-task generation. This algorithm could be based on various methodologies, including reinforcement learning, which might utilize simulations within a digital twin environment, goal decomposition algorithms, hierarchical task networks, or genetic algorithms. The choice of algorithm is made based on its suitability for generating sub-tasks for the specific next task at hand. Once the algorithm is selected, the intelligence layer causes the integrated chipset to execute this algorithm, resulting in the generation of one or more sub-tasks. These sub-tasks are then assigned to the appropriate processing units within the chipset, ensuring that each unit's capabilities are optimally utilized for task execution. The processing units subsequently execute these sub-tasks, collaboratively performing the next task.

[3595] In scenarios where multiple algorithms are suitable, the intelligence layer may select multiple algorithms to run in parallel for the generation of sub-tasks. This approach allows the system to compare and select the most effective sub-tasks from those generated by the different algorithms, enhancing the efficiency and effectiveness of task execution.

[3596] The sub-tasks generated and assigned may include a variety of operations, such as optimizing a network, applying governance frameworks, and performing navigation tasks, among many others. If the next task involves training an AI model, the sub-tasks could include

generating synthetic data for training the AI model and potentially requesting additional synthetic data from other robotic systems within the fleet.

[3597] If the robotic system receives a fleet controller role, the next task may involve dynamically assigning roles to other robotic systems in communication with it, demonstrating the system's capability to manage and coordinate activities across the fleet.

[3598] In embodiments, the integrated chipset uses a clustered architecture featuring a set of processing cores concentrated in the middle portion of the chip. This central cluster is served by a set of I/O capabilities strategically positioned on the perimeter of the chip, optimizing data flow and minimizing signal latency. An off-chip interconnection capability may be placed substantially at the center of the chip, facilitating high-speed communication between the central processing cluster and external components. This arrangement allows for efficient heat dissipation from the core processing units while providing direct access to I/O interfaces, enhancing overall system performance and reliability. The clustered architecture supports advanced parallel processing capabilities, enabling the robotic control circuit, data collection circuit, neural network classifier, and neural network control circuit to operate in concert with minimal interference.

[3599] In some embodiments, the integrated chipset incorporates an advanced bi-directional torus network on chip (NoC) architecture, providing an interconnect solution for the robotic control circuit, data collection circuit, neural network classifier, and neural network control circuit. This torus NoC design creates a mesh-like structure where each node is connected to its nearest neighbors in a wraparound fashion, allowing for multiple parallel paths for data transmission and reducing overall network congestion. The bi-directional nature of the connections enables data to flow in both directions between nodes. This architecture is particularly well-suited for the complex data processing and decision-making requirements of advanced robotic systems, as it facilitates rapid information exchange between different functional units while minimizing latency and maximizing throughput. The bi-directional torus NoC also provides inherent fault tolerance, as it can dynamically reroute data in case of node or link failures, ensuring robust and reliable operation of the integrated chipset in challenging robotic environments.

[3600] In embodiments, the integrated chipset incorporates an advanced optical communication system where optical signals are partitioned by wavelength, enabling selective prioritization and routing of data. This partitioned optical architecture leverages wavelength division multiplexing (WDM) technology to create multiple independent communication channels within a single optical medium. The robotic control circuit, data collection circuit, neural network classifier, and neural network control circuit can all be integrated on this optical chipset, allowing for ultra-high-speed, low-latency communication between components. By assigning different wavelengths to various types of data or priority levels, the chipset can efficiently manage and prioritize critical control signals, sensor data, and neural network computations, enhancing overall system responsiveness and performance. This wavelength-

partitioned optical communication system also allows for easy integration of additional components or expansion of communication bandwidth as robotic system requirements evolve.

[3601] In embodiments, the integrated chipset employs advanced integrated fan-out (IFO) packaging technology, which enables higher integration density and improved thermal management. This packaging technique allows for the incorporation of multiple dies, including the robotic control circuit, data collection circuit, neural network classifier, and neural network control circuit, into a single package with a reduced form factor. The IFO packaging facilitates the integration of a higher number of I/O ports and improves electrical performance by reducing interconnect lengths between components. Additionally, this advanced packaging allows for the incorporation of passive components and potentially other active components within the same package, further enhancing the functionality and performance of the integrated chipset. The use of IFO packaging in the robotic system's chipset results in improved power efficiency, reduced signal latency, and enhanced overall system performance, particularly beneficial for complex robotic control and decision-making processes.

[3602] In embodiments, the integrated chipset uses high numerical aperture, extreme ultraviolet (high-NA EUV) optical technology in its fabrication process. This lithography technique enables the creation of smaller feature sizes on the semiconductor, significantly enhancing the density, speed, and energy efficiency of the integrated circuits. The use of high-NA EUV technology allows for the integration of more transistors into a smaller area, thereby increasing the processing power of the robotic control circuit, data collection circuit, neural network classifier, and neural network control circuit while simultaneously reducing power consumption.

[3603] In embodiments, the integrated chipset incorporates advanced gate-all-around field-effect transistor (GAAFET) technology, providing superior control over the current flow and significantly reducing leakage in the semiconductor components. This transistor architecture enables the integration of more transistors into a smaller area, thereby increasing the processing power and reducing power consumption of the robotic control circuit, data collection circuit, neural network classifier, and neural network control circuit.

[3604] In embodiments, the integrated chipset incorporates advanced gate-all-around nanowire field-effect transistor (GAA-NWFET) technology, offering superior electrostatic control over the channel and significantly reducing leakage in the semiconductor components. This transistor architecture enables the integration of more transistors into a smaller area, thereby increasing the processing power and reducing power consumption of the robotic control circuit, data collection circuit, neural network classifier, and neural network control circuit.

[3605] In embodiments, the integrated chipset employs advanced gate-all-around nanosheet field-effect transistor (GAA-NSFET) technology wherein the gate material fully encapsulates multiple horizontally-stacked silicon nanosheets that form the transistor channel, providing improved control over the flow of electrons. This structure allows for superior performance at smaller node sizes, enabling higher transistor density and improved power efficiency in the robotic control circuit, data collection circuit, neural network classifier, and neural network

control circuit. The use of nanosheets in the GAA-NSFET design contributes to reduced short-channel effects and lower leakage currents, further enhancing the overall efficiency and reliability of the integrated chipset in complex robotic applications. The implementation of GAA-NSFET technology in the chipset supports the demanding computational requirements of advanced AI models and real-time decision-making processes in robotic systems.

[3606] In embodiments, the integrated chipset incorporates advanced gate-all-around complementary field-effect transistor (GAA-CFET) technology, which features a gate structure that completely surrounds the channel, providing superior electrostatic control and significantly reducing leakage currents in both n-type and p-type transistors. The GAA-CFET technology enables the integration of more transistors into a smaller area, thereby increasing the processing power and reducing power consumption of the robotic control circuit, data collection circuit, neural network classifier, and neural network control circuit.

[3607] In embodiments, the integrated chipset leverages carbon nanotube technology, providing superior electrical conductivity and thermal properties for enhanced performance and reliability. This advanced material enables the integration of highly conductive and durable components into a smaller area, significantly increasing processing power while reducing power consumption for the robotic control circuit, data collection circuit, neural network classifier, and neural network control circuit. The use of carbon nanotubes in transistor fabrication allows for smaller feature sizes and improved electron mobility, resulting in faster switching speeds and lower operating voltages compared to traditional silicon-based transistors.

[3608] In embodiments, the integrated chipset incorporates advanced 3D-NAND flash memory technology, significantly enhancing data storage capacity and access speed for the robotic system. This three-dimensional memory architecture allows for vertical stacking of memory cells, enabling higher storage density and improved performance compared to traditional 2D NAND structures. The integration of 3D-NAND flash memory with the robotic control circuit, data collection circuit, neural network classifier, and neural network control circuit facilitates efficient handling and processing of large volumes of data from IoT devices and sensor inputs. This high-capacity, non-volatile memory solution is particularly beneficial for storing and rapidly accessing complex AI models, sensor data, and operational parameters required for sophisticated robotic control and decision-making processes.

[3609] In embodiments, the integrated chipset employs hybrid bonding technology, enabling high-density integration of the robotic control circuit, data collection circuit, neural network classifier, and neural network control circuit. This packaging technique allows for vertical stacking of multiple dies with direct copper-to-copper bonding, significantly reducing the distance between components and improving overall system performance. The use of hybrid bonding facilitates higher interconnect density and improved thermal management, resulting in reduced signal latency and enhanced power efficiency crucial for complex robotic control and decision-making processes.

AI CONVERGENCE SYSTEM OF SYSTEMS

[3610] Referring to FIG. 184, an AI convergence system of systems 31000 is illustrated in accordance with some embodiments. The AI convergence system of systems 31000 represents a sophisticated multi-layered technological framework where platforms are enhanced through the deep integration of AI capabilities with other advanced technologies. This convergence fundamentally transforms how enterprise entities operate by enabling intelligent automation, data-driven decision making, and adaptive responses across all system layers. The system architecture is designed to support complex interactions between different technological components while maintaining operational efficiency and security across the enterprise environment.

[3611] The governance layer 32000 implements comprehensive automated governance and policy enforcement through specialized governance modules 32002. This layer utilizes generative AI technology to ensure proper oversight and compliance while adapting to changing regulatory requirements. The governance modules can automatically implement and enforce policies, manage digital rights infrastructure, monitor content and data flows, and ensure compliance with relevant regulations, contracts, and licensing requirements. The layer also incorporates digital twins and reporting automation capabilities to provide real-time oversight and transparency.

[3612] The enterprise layer 33000 supports various enterprise functions by integrating enterprise management and control platforms with digital infrastructure. This layer enables automated transactional processes, manages listings and user profiles, provides analytics and insights for strategic decision-making, and enforces security and compliance protocols through sophisticated permissions systems.

[3613] The offering layer 34000 leverages an intelligent systems architecture to create, manage and enable system offerings through specialized offering modules 34002. This layer employs advanced content generation intelligence, personalization capabilities, and domain-specific knowledge processing to deliver highly customized experiences. The layer can generate and adapt content based on user profiles, behaviors, current states, environmental factors, and specific requests, while maintaining coherence and quality across multiple formats and domains.

[3614] The transactions layer 35000 provides sophisticated transaction management capabilities through a set of hardware and software-defined transaction modules. This layer implements AI models for automating, optimizing, and executing digital transactions, including digital payments and asset management. It incorporates secure integration frameworks for interfacing with financial institutions, digital marketplaces, and blockchain networks, while maintaining robust authentication and security measures.

[3615] The operations layer 36000 orchestrates the comprehensive management and execution of AI systems through specialized operations modules. These modules handle critical functions including AI system generation, training data set creation, model verification, deployment optimization, and governance oversight. The layer implements sophisticated capabilities for training AI systems using supervised, unsupervised, and reinforcement learning techniques

while maintaining performance metrics and simulated data validation. Through its orchestration capabilities, this layer enables dynamic resource allocation, load balancing, and automated governance of AI workloads across the enterprise ecosystem.

[3616] The network layer 37000 delivers advanced networking capabilities through intelligent adaptation to changing conditions and requirements. This layer facilitates communications among smart network-capable systems while leveraging AI to dynamically adapt network configurations and optimize data flow. It integrates edge computing with cloud services to enable data processing and workflow orchestration closer to data sources, reducing latency and enhancing real-time decision-making capabilities. The layer employs AI algorithms for intelligent routing of various data types through optimal network paths across cellular, WiFi, ORAN, Bluetooth and other protocols.

[3617] The data layer 38000 provides comprehensive data management and intelligence services through a sophisticated system of systems architecture. This layer implements machine learning systems, artificial intelligence systems, and neural networks configured to operate on fused data from diverse sources including sensors, wearables, social media, crowdsourced data, websites, APIs, edge devices, industrial systems, and enterprise platforms. It enables real-time monitoring and analysis while maintaining data sovereignty and security through federated learning techniques.

[3618] The resource layer 39000 enables automated and optimized provisioning of resources across various operational environments through AI-driven capabilities. This layer implements machine learning systems, artificial intelligence systems, and neural networks to optimize allocation of computational, networking, material, and energy resources. It provides dynamic resource management that can adapt to the specific demands of diverse environments like industrial settings, transportation infrastructure, energy facilities, and datacenters while maintaining operational efficiency.

[3619] This interconnected architecture creates a comprehensive technology stack that enables multiple scenarios and use cases across various enterprise contexts. The convergence of AI capabilities throughout these layers establishes an intelligent, adaptive system that can respond to diverse operational requirements while maintaining security, efficiency, and compliance. The system's modular design allows for continuous evolution and enhancement of capabilities across all layers, ensuring sustained value delivery to enterprise operations.

[3620] In embodiments, a computer-implemented system provides a value chain network management platform with multiple integrated layers powered by artificial intelligence capabilities. The platform includes a processor and memory storing instructions that configure the system to implement the various layers working together to improve technological operations. The platform may include specialized integrated chipsets and/or sets of chiplets that include one or more processing units. These processing units may include CPUs, GPUs, TPUs, and Field Programmable Gate Arrays (FPGAs). The FPGAs may be reprogrammed to optimize performance for specific tasks or roles within the value chain network. The intelligence layer

may reprogram FPGAs to efficiently run inference using AI models or to efficiently retrain models that will be executed by other specialized chips.

[3621] The platform's governance layer may implement AI-based learning models to enforce automated governance of value chain networks through policy automation and regulatory compliance monitoring. The governance layer may include embedded policy and governance AI capabilities that autonomously enforce compliance standards across activities, transactions, and operations while maintaining immutable audit trails.

[3622] In embodiments, the enterprise layer can implement AI-based learning models to monitor and/or manage value chain network entities through a value chain control tower. These entities can include physical assets like products, suppliers, manufacturers, retailers, infrastructure facilities, warehouses, maritime ports, airports, airways, waterways, roadways, railways, bridges, tunnels as well as digital assets like software platforms, information technology systems and networks. The control tower may coordinate activities including demand management, procurement, fulfillment, supply chain operations, and many others.

[3623] The offering layer may implement AI-based learning models including deep reinforcement learning for resource allocation, natural language processing for analyzing market signals, computer vision networks for monitoring production processes, and many others. In embodiments, these models can work together to improve product offerings by optimizing features across digital networks and product families.

[3624] In embodiments, the operations layer may implement AI-based learning models to enhance key value chain operations such as transportation routing between facilities, inventory management across warehouses, supplier selection and evaluation, production scheduling in manufacturing plants, cost tracking of operations, goods packing and shipping logistics, delivery status tracking, supplier identification and verification, contract negotiation automation, and quality inspection of goods.

[3625] The network layer may implement AI-based learning models to optimize communications networks through adaptive routing modules. The network layer may include edge intelligence systems that enable localized data processing and communication at network edges where value chain entities operate, reducing latency and enhancing real-time decision making.

[3626] The data layer may process fused data from multiple value chain network sources using AI-based learning models. In embodiments, the data fusion may include combining and analyzing supply chain data about material flows, demand data from customers and markets, shipping data from logistics providers, pricing data from various points in the chain, and transportation data about routes and carriers.

[3627] In embodiments, the resource layer can implement AI-based learning models to automate the provisioning of value chain network resources. The resource layer may implement distributed ledger technology to provide transparent tracking of how resources are allocated across the network while using smart contracts to automate execution of optimization strategies.

[3628] The platform's AI capabilities may be delivered through various types of artificial intelligence (AI)-based learning models including transformer models for processing sequential data, convolutional neural networks for image and pattern recognition, deep learning models trained specifically on value chain outcomes, supervised models trained on labeled examples, semi-supervised models that can learn from both labeled and unlabeled data, unsupervised models that find hidden patterns, and reinforcement learning models that optimize through trial and error.

[3629] In embodiments, the platform includes digital twins that create virtual representations of physical value chain entities, enabling simulation of their properties like operational characteristics, states such as inventory levels, operations including production processes, and behaviors such as response to disruptions. These digital twins help optimize the network by allowing scenario testing.

[3630] In implementations, a centralized value chain network control tower can provide oversight and coordination across all the platform's capabilities. The control tower may implement frameworks for managing networked entities and orchestrating market activities including demand curve management, ecosystem synchronization, intelligent procurement, dynamic fulfillment and analytics.

[3631] Edge intelligence systems in the network layer may enable data processing and decision making to occur close to where value chain entities operate, such as in warehouses, ports, and manufacturing facilities. This reduces latency and enables real-time optimization of local operations while still maintaining coordination with the broader network.

[3632] The resource layer may include distributed ledger technology creates an immutable record of resource allocation decisions, providing transparency and trust in how resources are managed across the value chain network. This enables automated execution of optimization strategies through smart contracts while maintaining accountability.

GOVERNANCE LAYER

SYSTEM OVERVIEW

[3633] An example system such as a multi-layered intelligent system (e.g., AI convergence system of systems 31000) may provide automated governance (e.g., using governance layer 32000 including governance modules 32002) and execution of transactions. In example embodiments, this system may use generative AI technology to provide users and/or organizations with offerings and content that may be customized and personalized based on a profile, behavior, current state (physiological, emotional, or other), environment, location, content, and/or request. For example, a user may use this system to request a particular type of experience with a preferred theme (e.g., including music, video, characters, etc.) or a particular type of organization or presentation of content may be generated to fit with the user's style, mood and current environment.

GOVERNANCE LAYER ARCHITECTURE

[3634] In example embodiments, the system (e.g., AI convergence system of systems 31000) may include systems for automated governance (e.g., using governance layer 32000 including governance modules 32002) and execution of transactions (e.g., using transactions layer 35000 that may include transactions modules 35002). For example, a rights infrastructure system may be included in the AI convergence system of systems 31000 (e.g., specifically in the governance layer 32000).

[3635] In some example embodiments, the system (e.g., system of systems such as SoS and more specifically AI convergence system of systems 31000) may include a governance layer 32000 that performs various governance tasks for the system. In example embodiments, the governance layer 32000 may be deployed to enforce various governance standards, workflows, or rules with respect to AI-driven tasks of the system. The types of governance standards, workflows, and rules that may be deployed in a specific configuration of the system may vary depending on the configuration of the system.

[3636] In example embodiments, the governance layer 32000 may include the set of governance modules 32002 that may be configured to perform a respective governance task. As discussed in the disclosure, governance may be configured for various purposes and in various manners. In some example embodiments, governance modules may be configured to ensure an entity is complying with a set of standards (e.g., internal standards, industry standards, recommended standards, or the like), regulations (e.g., jurisdictional regulations, professional regulations, industry regulations or the like), rules (e.g., internal rules, jurisdictional rules, international rules, or the like), or the like. Examples of the different types of analyses that a governance module may be configured to perform are described throughout the disclosure and may include risk analyses, security analyses, decision tree analyses, ethics analyses, failure mode and effects (FMEA) analyses, hazard analyses, quality analyses, safety analyses, regulatory analyses, legal analyses, and/or other suitable analyses.

[3637] In some example scenarios, a governance module may be configured to ensure an automated task is performed in a manner that complies with jurisdictional and/or governmental rules. In some example embodiments, a governance module may be configured to apply certain workflows or checklists after completion or before performance of an AI-driven task. For example, after a certain type of transaction is completed, a governance module may be configured to ensure that any required post transaction reconciliation, fulfillment, and/or reporting are completed properly. In another example, before a counterparty is transacted with, a governance module may be configured to initiate a "know-your-customer" workflow to determine whether the counterparty has a white-listed account, and if not, to determine whether to approve the counterparty transactor. In another example, a governance module may be configured and deployed to monitor a supply chain to ensure compliance with regulations relating to imported materials (e.g., tariffs are paid, regulated materials are reported, or the like).

[3638] In some example embodiments of the disclosure, a governance module may be configured and deployed to monitor the performance of an AI model (e.g., an LLM, a neural

network, a machine learning model, and/or the like). In these example embodiments, a governance module may be configured to analyze the output of an AI model with respect to one or more governance parameters to determine whether the AI model is producing output that exhibits bias, drift, or the like, as described elsewhere in the disclosure. In some example embodiments, a governance module may halt use of an AI model that is determined to be exhibiting drift or bias. Additionally or alternatively, it may initiate a retraining of the model and/or alert a human user.

[3639] In some example embodiments, a governance module may be configured to analyze an input to a particular AI model. In some example embodiments, a governance module may be configured to analyze a prompt being provided to a large language model to ensure that the prompt is not requesting something that would violate a governance standard of an entity or the model. For example, a governance module may be configured to analyze a user prompt to ensure that the user is not asking the large language model to violate another party's intellectual property rights, use data sets that are not permitted to be used, or otherwise perform tasks that would put the enterprise at risk. In such example scenarios, the governance module may prevent the prompt from being processed by the LLM. Additionally or alternatively, analyzing input to an AI model may include analyzing the data being provided to the model to make a prediction or recommendation to determine whether the data is reliable data. Assuming the input data is reliable, the AI model may be provided with the input data. If, however, the data is deemed to be unreliable (e.g., fake data injection or data from a faulty sensor), a corrective measure may be initiated by the governance module (e.g., preventing the data from being used and/or alerting a human user).

OWNERSHIP AND RIGHTS MANAGEMENT

[3640] In example embodiments, AI agents may be configured for identifying and tracking offerings, content, systems, and services ownership for licensing. This may involve ownership of two or more entities for providing one service or multiple services relating to particular data or content. For example, the AI agents may navigate different pathways in governing ownership of services offered. The ownership may relate, for example, to copyright of media such as software, video, photos, music, and/or scripts or based on companies or individuals that provide at least a portion of the games and/or entertainment. With other services described, the ownership may relate, for example, to the roles of an individual or organization in providing service(s). There may be other logical rules used for determining ownership of content. The AI convergence system of system of systems 31000 may include management platforms that may use fully autonomous software, such as fully autonomous AI, to proceed through steps or a co-pilot software such as an AI co-pilot with a user approving and proceeding with at least some portions of the following process manually.

CONTENT ANALYSIS AND MONITORING

[3641] In example embodiments, AI convergence system of systems 31000 may be configured for tracking and monitoring services or content going into a data model for identifying

ownership of portions of the services across integrated system components or layers (e.g., across offering layer 34000 that may use offering modules 34002, enterprise layer 33000 that may include enterprise modules 33002, and governance layer 32000). In other examples, system 31000 may use various machine learning techniques and artificial intelligence capabilities, such as neural networks, to analyze content before the content data is inputted into a model for a source of the data (e.g., via offering layer 34000 and/or enterprise layer 33000). The source may indicate ownership of different parts of the content that may be assigned to one or more owners. In example embodiments, system 31000 may use intelligent processing (e.g., AI) to analyze the data going into the model as compared against continuously updated reference databases and knowledge models (e.g., a constantly updated Internet model such as a "world" model of all public data) for identifying source information that may be used to find ownership. System 31000 may use the intelligent analysis to identify ownership from various types of information or source information associated with the content. Alternatively, in other example embodiments, automated data collection and analysis tools (e.g., a web crawler, spider, or search engine bot with AI) may be utilized to find ownership. This source information may be based on any portion of the software being used, hardware being used, and other systems being used such as relating to services and content.

POLICY AND LICENSING MANAGEMENT

[3642] In example embodiments, system 31000 may use identified owners as a trigger to find any policies and/or licensing information (including e.g., contracts) that are associated with the content being inputted and/or the owners involved (e.g., using the governance layer 32000). The system 31000 may leverage the AI to find and/or locate the associated policies and/or licensing information by querying the continuously updated reference databases and knowledge models and/or querying publicly available web sources (e.g., using a web crawler, spider, or search engine bot). This querying process may find these policies and/or licensing information through direct or indirect associations to the owners identified and the related or associated content that is being inputted. In example embodiments, the querying process may also find policies and/or contractual information related to owners or at least partial owners of the related or associated services that may be requested by a user of system 31000 (e.g., owner or partial owner of services).

TRANSACTION MANAGEMENT

[3643] In example embodiments, automated transaction and contract management systems (e.g., using smart contracts or other similar semi-autonomous contract systems) may be triggered via intelligent processing modules to provide transactions with a particular use of the content in modeling based on, at least partially, the associated policies, contracts, and/or licensing information discovered from querying. These automated contractual arrangements may be executed through the transaction processing components (e.g., at the transactions layer 35000 of the system 31000). In some examples, the smart contracts may be configured using distributed ledger technology (e.g., blockchain). Alternatively, in other example embodiments,

communications may be automated for users to review/approve and/or automated between the system 31000 and identified owners (e.g., copyright owners of content or owners based on other factors such as development of content) to obtain approval and/or contractual information (e.g., based on, at least partially, the associated policies, contractual, and/or licensing information discovered) before proceeding with particular modeling.

RIGHTS COMPLIANCE AND INFRINGEMENT

[3644] In example embodiments, system 31000 may compare results and/or output from content generation systems (e.g., generative models) against the reference knowledge bases for identifying potential rights infringement (e.g., copyright infringement) based on any substantive similarities (e.g., based on copyright law), trademark infringement, and/or infringing ownership of other rights associated with results outputted from generative models. In example embodiments, the results and/or output from generative models may be various types of services and/or other content data generated as requested via a user interface. In order to compare results, for example, system 31000 may identify similarities between a generative model result and a "world" model and/or compared against a repository of known copyrighted works (e.g., all copyrighted media stored here with fair use data being excluded from this repository). System 31000 may use AI and/or modeling of various laws and/or regulations relating to services (e.g., statutes, rules, and case law as well as copyright law statutes, rules, and case law that relate to region(s) where the generative models are being used) for determining what is considered substantive similarities. System 31000 may use AI and/or modeling to determine whether any thresholds of infringement (e.g., copyright infringement or other ownership infringement) may have been crossed (e.g., based on the legal models or data such as statutes, rules, and case law relating to relevant jurisdiction(s)). The models used to run this analysis may be based on service-related laws and/or copyright laws (e.g., statutes, rules, and case law based on jurisdiction(s) impacted) and then may use case law examples to understand the thresholds between infringement and non-infringement. System 31000 may identify owners for portions of services being infringed or potentially infringed. System 31000 may use identified copyright owners as a trigger to find any policies, contractual, and/or licensing information (including associated contracts) that are associated with the content and/or the owners involved. Identifying owners along with associated policies and/or licensing information may occur using the same or similar approaches as described elsewhere in this disclosure. In example embodiments, system 31000 may run this process across one or more services such as comparing results and/or output from generative models against the continuously updated reference databases and knowledge models for identifying potential ownership infringement through using one or more services. The models used to run this analysis may be based on various service ownership-related laws (e.g., statutes, rules, and case law based on jurisdiction(s) impacted) and then may use case law examples to understand the thresholds between infringement and non-infringement. System 31000 may identify owners for portions of services being infringed or potentially infringed. System 31000 may use identified service owners as a trigger to find any policies, contractual,

and/or licensing information (including associated contracts) that are associated with the services and/or the owners involved.

[3645] In example embodiments, system 31000 (e.g., using transactions layer 35000) may trigger smart contracts (or other similar semi-autonomous contracts) to provide transactions for particular use of resulting generative media going forward (e.g., personal use, display to a company, display to friends/family, display via internet social media channels, display on cable channels, display on streaming channels, etc.) and based on a portion of the generative result potentially infringing. In some examples, the smart contracts may be configured using distributed ledger technology (e.g., blockchain). Alternatively, communications may be generated for users to review/approve and/or automated between the system 31000 and owners to obtain approval and/or contractual information to proceed with particular use of resulting generated media based on a portion potentially infringing. This may also occur with use of resulting generated or suggested services that relate to one or more owners.

[3646] In example embodiments, system 31000 may relate to transactions layer 35000 and operations layer 36000 (e.g., that may use operations modules 36002) by use of automation software technologies to execute various systems.

COMPENSATION AND OWNERSHIP DISTRIBUTION

[3647] In example embodiments, system 31000 (e.g., using enterprise layer 33000 and/or offering layer 34000) trains and deploys AI expert agents/co-pilots that can fill various artistic/creative roles within a service project. The AI expert agents may be configured to determine how to compensate rights holders that created content. For example, the AI expert agent may, when a generative work is created, determine who should be compensated and how based on identification of specific data used to train a model or similarity of the output to identified parties. In example embodiments, different components may have different licensing/compensation models. For example, gaming royalties may be different from music, video, characters, etc. For music, royalties may be awarded to individual rights holders, for example. In example embodiments, the compensation may be determined by the AI based on any combination of a potentially infringing portion of created content used, owners, as well as policies, contractual, and/or licensing information associated with the relevant owners. In some example embodiments, these ownership issues may result in fractional ownership of slot machines that may change or vary based on each instance user request as the content output may change and change during each of these instances. In example embodiments, similar processes may be executed for determining ownership percentages for services being provided especially where there may be two or more owners contributing to an offered service and/or content. Given the different ownership shares that may exist, in some example embodiments, tokenization technologies may be utilized to divide up the ownership as well as allow for the use to pay multiple owners automatically via portions of a token. In these examples, a virtual wallet may be utilized with tokens. Overall, this allows for a customized or personalized result or output based on each user's request from an interface. With services, this allows for a customized or

personalized result or output based on each user's request regarding offerings, content, systems and services.

PREDICTION

[3648] In some example embodiments, the generative AI may suggest and/or automatically provide services to a user based on intelligent analysis of historical data and user preferences (e.g., using a prediction model). This allows the user to use any machine that is able to connect to a personalized custom model of the user for insights on the user's preferences based on historical data of previous usage and requests. The prediction process may be able to improve its prediction based on a variety of factors such as time usage of services, number of times service(s) is/are requested, success rate with some services, selection, time of day preferences, preferred spending, biometric data (e.g., using sensors to check various data points from users that can indicate likes/dislikes such as relating to relaxation vs. stress levels and/or improved focus), etc. In example embodiments, the generative AI may also suggest and/or automatically provide suggested services to a user based on a prediction model from historical data.

MODEL SELECTION

[3649] In example embodiments, the converging technology stack system 31000 selects a model for a particular task (e.g., appropriate processing models). For example, the system 31000 may determine the genus of model to use and within the genus, which specific model to use. System 31000 may select between, for example, a diffusion model or a large language model (LLM). Once a genus is selected, then the system 31000 may select a specific model (e.g., a specific diffusion model or specific LLM) to perform the task.

DIGITAL ASSET MANAGEMENT

[3650] In example embodiments, the system 31000 (e.g., via the transactions layer 35000) may provide for digital payment and asset management capabilities (e.g., using virtual wallets) that may include tokens and/or other payment options for transactions.

EMBEDDED POLICY AND GOVERNANCE, POLICY AUTOMATION, AND COMPLIANCE AUTOMATION

[3651] In example embodiments, the governance layer 32000 of system 31000 may include a set of machine learning systems, artificial intelligence systems, and/or neural networks configured to execute intelligence tasks associated with embedded policy and governance, policy automation, and/or compliance automation. These capabilities may work in conjunction or separately with system 31000 and other subsystems (e.g., rights infrastructure system) as described in the disclosure to provide comprehensive governance across the platform. The governance layer 32000 may automatically implement and enforce policies while ensuring compliance with relevant regulations, contracts, and/or licensing requirements.

DIGITAL TWINS AND REPORTING AUTOMATION

[3652] Building upon the system's ability to track ownership and manage rights, the governance layer 32000 may include and/or use digital twins (e.g., executive digital twins) and/or reporting automation capabilities that provide oversight and transparency. These digital twins may monitor governance processes in real-time, while automated reporting may ensure all stakeholders receive appropriate updates about policy implementation, compliance status, and/or system activities.

DOMAIN-SPECIFIC GOVERNANCE

AUTOMATED GOVERNANCE OF INDUSTRIAL OPERATIONS, TRANSACTIONS, AND/OR VALUE CHAIN NETWORKS (VCNS)

[3653] The governance layer 32000 may extend its capabilities to specific operational domains, including automated governance of industrial operations, transactions, and/or value chain networks (VCNs). This complements the previously described smart contract functionality by providing domain-specific governance controls. For example, in industrial settings, the system may automatically enforce safety protocols while managing operational compliance.

SAFETY AUTOMATION

[3654] The governance layer 32000 may include safety automation capabilities that may work across all operational domains. This safety automation may integrate with the system's existing monitoring and compliance features to ensure safe operations while maintaining regulatory compliance. The safety automation capabilities may adapt to different operational contexts, whether in industrial settings, healthcare environments, or transportation systems.

ENTERPRISE LAYER

[3655] In embodiments, the techniques described herein relate to a computer-implemented system for managing a set of machine learning systems, a set of artificial intelligence systems, and/or set of neural networks within an enterprise ecosystem, the system including: a processor; a memory storing instructions that, when executed by the processor, cause the system to: integrate a set of machine learning systems, a set of artificial intelligence systems, and/or set of neural networks with an enterprise access layer (EAL) that interfaces with a plurality of enterprise resources; automate the collection, storage, presentation, streaming, monitoring and analysis of data, content, processing protocols and the like, and related metadata by interfacing the a set of machine learning systems, a set of artificial intelligence systems, and/or set of neural networks within workflow systems of the enterprise; utilize a data services system to manage enterprise management and control platforms; implement an intelligence system to provide predictive analytics for trends and demand forecasting within the enterprise management and control platforms; enforce security and compliance through a permissions system that controls access to functions of the enterprise management and control platforms; manage digital transactions via a wallets system that interfaces with the enterprise management and control

platforms; and generate reports on platform activity through a reporting system that is communicatively coupled with the enterprise management and control platforms

[3656] In embodiments, the techniques described herein relate to a computer-implemented system for facilitating actions within enterprise management and control platforms, including: a processor; a memory storing instructions that, when executed by the processor, cause the system to: integrate enterprise management and control platforms with an enterprise's digital infrastructure; automate transactional processes by interfacing the enterprise management and control platforms with a workflow system of the enterprise; manage listings, transactions, and user profiles using a data services system; provide analytics and insights for strategic decision-making within the enterprise management and control platforms through an intelligence system; enforce security and compliance protocols via a permissions system that controls access to the enterprise management and control platforms; and facilitate digital transactions through a wallets system that interfaces with the enterprise management and control platforms.

[3657] In embodiments, the EAL may be configured to interact with the platform users (and the ecosystem(s) in which they interact) in a variety of ways. For example, the EAL may be integrated or associated with one or more marketplaces or platforms such that the EAL functions as its own market or platform participant on behalf of the enterprise. By being associated with potentially numerous marketplaces or platforms, the EAL can perform complex or multi-stage actions, including but not limited to transactions, with enterprise assets (e.g., in a series or sequence of timed stages, simultaneously in a set of parallel transactions, or a combination of both).

[3658] In addition to marketplaces, the EAL may interact with platform users via third-party systems, some or all of which may be implemented as third-party services.

[3659] In embodiments, the EAL may include a number of EAL systems (also referred to as modules or EAL modules herein) that enable the functionality of the EAL. In some examples, these EAL systems may be deployed in a container that is specific to the EAL. When deployed in a container for the EAL, this containerized instance means that the EAL may include the necessary tools and computing resources to operate (i.e., host) the EAL systems without reliance on other computing resources associated with the enterprise (e.g., computing resources such as processors and memory dedicated to the EAL). For example, the container for the EAL may include a set of one or more systems, such as software development kits, application programming interfaces (APIs), libraries, services (including microservices), applications, data stores, processors, etc. to execute the functions of the EAL systems that may enable the EAL to provide enterprise management and other functions and capabilities described throughout this disclosure. References herein to "EAL systems" should be understood to encompass any of the foregoing except where context dictates otherwise.

[3660] In some implementations, a set of the EAL systems may leverage computing resources considered to be external to the EAL (e.g., separate from computing resources that have been dedicated to the EAL, such as, in embodiments, computing resources shared with other enterprise applications or systems). In these implementations, the set of EAL systems leveraging

external computing resources may be in communication with computing resources specific to the EAL. This type of arrangement may be advantageous when one or more of the EAL systems are computationally expensive and would increase the computational requirements for an entirely contained EAL, such as when one or more of the EAL systems causes the EAL to be a relatively expensive EAL deployment. For instance, an arrangement leveraging external (e.g., shared) systems may be beneficial for EAL systems that are infrequently utilized. To illustrate, a first enterprise may rarely use an EAL system, such as a reporting system. Here, instead of ensuring that the EAL has the computational capacity to support a reporting system by itself, the enterprise may configure the reporting system to be hosted by and/or supported by computing resources external to the EAL to deploy a relatively lean form of the EAL (i.e., an EAL container that does not include resources dedicated to a reporting system or that includes only limited resources dedicated to the reporting system with the capability to access additional, external resources as needed).

[3661] In some configurations, the EAL or a set of the EAL systems may leverage computing resources considered to be external to the EAL for support. An example of this support may be that the EAL or the set of EAL systems demands greater computing resources at some point in time (e.g., over a resource intensive time period) — for instance, greater may mean more computing resources than a normal or baseline operation state. In this example, for instance, an enterprise resource not dedicated to the EAL or EAL systems can assist or augment the services provided by some aspect of the EAL.

[3662] In embodiments, the deployment of the EAL may be configurable. For example, the enterprise or some associated developer can function as a type of architect for the EAL that best serves the particular enterprise. Additionally, or alternatively, the deployed location of the EAL may influence its configuration. For instance, the EAL may be embedded within an enterprise (e.g., non-dynamically) where it can be specifically configured using various module libraries, interface tools, etc. (e.g., as described in later detail). In some examples, the configuring entity is able to select what EAL systems will be included in its EAL. For instance, the enterprise selects from a menu of EAL systems. Here, when an EAL system is selected by the configuring entity, a configuration routine may request the appropriate resources for that EAL system including SDKs, computing resources, storage space, APIs, graphical elements (e.g., graphical user interface (GUI) elements), data feeds, microservices, etc. In some implementations, in response to the request, the configuring entity can dedicate the identified resources of each selected EAL system. For instance, the configuring entity associates the dedicated resources to a containerized deployment of the EAL that includes the selected EAL systems.

[3663] In embodiments, the EAL may include a set of EAL systems. The set may include an interface system, a data services system, an intelligence system, a scoring system, a data pool system, a workflow system, a transaction system (also referred to as a wallet system or a digital wallet system), a governance system, a permissions system, a reporting system, and a digital twin system. Additionally, although particular types of EAL systems are described herein, the functionality of one or more EAL systems is not limited to only that particular EAL system but

may be shared or configured to occur at another EAL system. For instance, in some configurations, some functionality of a transaction system may be performed by the data services system or functionality of the governance system may be incorporated with an intelligence system. In this respect, the EAL systems may be representative of the capabilities of the EAL more broadly. In embodiments, the set of EAL systems involved in any particular configuration of the EAL may include any of the systems described throughout this disclosure and the documents incorporated by reference herein, such as systems for counterparty discovery, opportunity mining, automated contract configuration, automated negotiation, automated crowdsourcing, automated facilitation of robotic process automation, one or more intelligent agents, automated resource optimization, resource tracking, and others.

[3664] In some embodiments, one or more of these systems may be configurable. The configurations may be done by selecting pre-defined configurations/plugins, by building customized modules, and/or by connecting to third party services that provide certain functionalities.

[3665] In some embodiments, aspects of a configured EAL may be dynamically reconfigured/augmented. In some examples, reconfiguration/augmentation may include updating certain data pool configurations, redefining certain workflows, changing scoring thresholds, or the like. Reconfiguration may be initiated autonomously (for example, the EAL periodically tests configurations of certain aspects of the EAL configuration using the digital twin simulation system and analytics system) or may be expert-driven (e.g., via interactions between an EAL "expert" and an interactive agent via a GUI of the interface system).

[3666] In embodiments, the data services system may perform data services for the EAL, which may include a data processing system and/or a data storage system. This may range from more generic data processing and data storage to specialty data processing and storage that demands specialty hardware or software. In some examples, the data services system includes a database management system to manage the data storage services provided by the data services system. In some configurations, the database management system may be able to perform management functions such as querying the data being managed, organizing data for, during, or upon ingestion, coordinating storage sequences (e.g., chunking, blocking, sharding), cleansing the data, compressing or decompressing the data, distributing the data (including redistributing blocks of data to improve performance of storage systems), facilitating processing threads or queues, etc. In some examples, the data services system couples with other functionality of the EAL. As an example, operations of the data services system, such as data processing and/or data storage, may be dictated by decision-making or information from other EAL systems such as an intelligence system, a workflow system, a transaction system, a governance system, a permissions system, a reporting system, and/or some combination thereof.

[3667] It is appreciated that workflows may be deployed in any number of scenarios. Examples of scenarios where workflows may be deployed by an EAL include permission workflows, access workflows, data collection workflows, data pool workflows, machine learning workflows, artificial intelligence workflows, governance workflows, scoring

workflows, transaction workflows, governance workflows, industry or vertical-specific workflows, enterprise-specific workflows, and other suitable workflows. It is appreciated that the example types of workflows provided above may overlap (e.g., a governance workflow may be an industry-specific and/or enterprise-specific workflow). Furthermore, some workflows may trigger one or more other workflows. For example, when a certain type of transaction is executed by a transaction system of an EAL, a transaction workflow corresponding to the type of transaction may define a series of tasks that are performed before the transaction is executed. In another example, as part of a data pool workflow that establishes a data pool that is accessible by third-parties, the data processing workflow may trigger a governance workflow that ensures that any enterprise data being added to the data pool confirms with certain data sharing rules (e.g., obfuscation of sensitive data, complying with privacy rules, scrubbing metadata, and/or the like) and may trigger a scoring workflow that scores each third-party that will access the data pool. Furthermore, EAL workflows may share a common framework for respective EAL functions and scenarios; however, individual workflows deployed with respect to respective EAL instances may vary in complexity from very basic workflow implementations (e.g., configured to execute on a user device or sensor device) to complex workflows with multiple dependencies and/or embedded "sub-workflows" (e.g., configured to execute by a central server system and/or by multiple enterprise devices).

[3668] In embodiments, a digital twin system may perform simulations of the enterprise's products and services that incorporate real-time data obtained from the various entities of the enterprise or third parties. In some of these embodiments, the digital twin system may recommend decisions to a user interacting with the enterprise digital twins.

[3669] In embodiments, an artificial intelligence module may include and/or provide access to a digital twin module. The digital twin module may encompass any of a wide range of features and capabilities described herein In embodiments, a digital twin module may be configured to provide, among other things, execution environments for and different types of digital twins, such as twins of physical environments, twins of robot operating units, logistics twins, executive digital twins, organizational digital twins, role-based digital twins, and the like.. In example embodiments, a digital twin module may be configured to generate digital twins that are requested by intelligence clients. Further, the digital twin module may be configured with interfaces, such as APIs and the like for receiving information from external data sources. For instance, the digital twin module may receive real-time data from sensor systems of a machinery, vehicle, robot, or other device, and/or sensor systems of the physical environment in which a device operates. In embodiments, the digital twin module may receive digital twin data from other suitable data sources, such as third-party services (e.g., weather services, traffic data services, logistics systems and databases, and the like). In embodiments, the digital twin module may include digital twin data representing features or states, as well as demand entities, such as customers, merchants, stores, points-of-sale, points-of-use, and the like. The digital twin module may be integrated with or into, link to, or otherwise interact with an interface (e.g., a control

tower or dashboard), for coordination of supply and demand, including coordination of automation within supply chain activities and demand management activities.

[3670] In embodiments, a digital twin module may provide access to and manage a library of digital twins. A plurality of artificial intelligence modules may access the library to perform functions, such as a simulation of actions in a given environment in response to certain stimuli.

[3671] In example embodiments, the digital twin(s) may be implemented with smart contracts, such as for digital twin transactions enabled by smart contracts (e.g., using smart contract orchestration engines).

[3672] In embodiments, an enterprise access layer system of systems (ELS) may manage and integrate EAL methods and systems, technological systems, data streams, platforms, and operational processes. Current enterprises face challenges in coordinating across different business units and technology stacks, creating a need for an intelligent enterprise access layer capable of parallel task execution and advanced analytics capabilities. The ELS, as described herein, implements a comprehensive architecture that enables parallel processing of intelligence tasks across multiple domains while maintaining data consistency and security protocols. The system's core architecture comprises processing unit(s) integrated with memory system(s) storing executable instructions, multiple machine learning systems, artificial intelligence engines, and neural network arrays, supported by data storage systems, communication interfaces, security modules and connections or associations with third party systems, platforms or operations.

SIMULATION

[3673] In embodiments, the ELS may execute system simulations utilizing neural network models to provide predictive analytics for business forecasting. In example embodiments, the system may continuously update simulations in real-time based on, for example, operational data, enabling dynamic scenario modeling and analysis for enhanced decision-making processes.

DIGITAL TWINS

[3674] In embodiments, the ELS may implement digital twin and management capabilities, generating Metaverse environments, such as industrial Metaverse environments, that enable real-time synchronization between physical and digital assets. In example embodiments, these digital representations may facilitate virtual testing and validation of industrial systems before physical implementation.

VCN/CONTROL TOWER

[3675] In embodiments, the ELS may establish centralized value chain network control tower operations while simultaneously managing distributed mini control towers for local optimization purposes. In example embodiments, this hierarchical approach may enable comprehensive real-time supply chain visibility and control, supported by sophisticated automated decision support systems for network optimization.

DATA INTEGRATION/IOT

[3676] In embodiments, the ELS may incorporate big data processing and analytics capabilities, seamlessly integrating with Industrial Internet of Things platforms. In example embodiments, this integration may include real-time sensor data analysis and predictive maintenance optimization across industrial operations.

[3677] Process Optimization

[3678] In embodiments, the ELS may deliver automated industrial operational control through AI-driven process optimization systems. In example embodiments, the ELS may continuously perform real-time adjustments of manufacturing parameters while maintaining comprehensive quality control and compliance monitoring protocols.

TRANSACTIONS

[3679] In embodiments, the ELS may enable enterprise system integration through AI-enhanced transaction processing capabilities. In example embodiments, this integration may facilitate automated workflow management and ensures precise cross-system data synchronization across the enterprise environment.

FORECASTING

[3680] In embodiments, the ELS may implement intelligent supply chain optimization algorithms coupled with sophisticated demand shaping and forecasting capabilities. In example embodiments, the system may provide comprehensive inventory management optimization while facilitating effective supplier relationship management processes.

EXECUTIVE DIGITAL TWINS

[3681] In embodiments, the ELS may deploy executive digital twins for fleet management, enabling vehicle simulation and design optimization. In example embodiments, the ELS may manage complex fleet transaction processing while integrating with software-defined vehicle systems for enhanced operational control.

ENERGY MANAGEMENT/DIGITAL TWINS

[3682] In embodiments, the ELS may incorporate energy operations digital twins within a system of systems integration framework for comprehensive energy management. In example embodiments, the system may process energy transactions while performing AI-based energy optimization across the enterprise.

MACHINE/DEEP LEARNING

[3683] In embodiments, the ELS may implement multiple machine learning approaches, including supervised learning algorithms for pattern recognition and unsupervised learning systems for anomaly detection. In example embodiments, the ELS may utilize reinforcement learning for optimization processes and deep learning capabilities for complex analysis tasks.

CNNS

[3684] In embodiments, the ELS may deploy specialized neural network architectures, including convolutional neural networks for image processing applications and recurrent neural networks for sequence analysis. In example embodiments, the system may utilize transformer networks for natural language processing tasks and implements graph neural networks for relationship analysis.

PROCESS OPTIMIZATION

[3685] In embodiments, the ELS may coordinate multiple AI systems through a hierarchical task distribution framework, implementing parallel processing optimization and resource allocation management. In example embodiments, the ELS may enable cross-system learning integration for enhanced operational efficiency.

SECURITY/AUTHENTICATION

[3686] In embodiments, the ELS may implement comprehensive security measures including role-based access control systems and multi-factor authentication protocols. In example embodiments, the system may maintain detailed activity monitoring and logging while enforcing robust security policies.

SECURITY/ENCRYPTION

[3687] In embodiments, the ELS may implement end-to-end encryption protocols and secure data transmission mechanisms. In example embodiments, the system may incorporate privacy preservation techniques while maintaining compliance monitoring and reporting capabilities.

ENTERPRISE PLATFORM INTEGRATION

[3688] In embodiments, the ELS may integrate with existing enterprise resource planning systems, customer relationship management platforms, manufacturing execution systems, and supply chain management systems. In example embodiments, this integration may enable data flow and process coordination across the enterprise environment.

REMOTE THIRD-PARTY CONNECTIVITY

[3689] In embodiments, the ELS may maintain connections with cloud services, partner networks, and external data sources while enabling integration with third-party applications. In example embodiments, this connectivity may ensure data access and process coordination across the extended enterprise ecosystem.

DYNAMIC RESOURCE ALLOCATION

[3690] In embodiments, the ELS may implement horizontal and vertical scaling capabilities supported by dynamic resource allocation mechanisms. In example embodiments, the ELS may maintain load balancing capabilities while performing continuous performance monitoring to ensure optimal system operation.

FAULT TOLERANCE/REDUNDANCY

[3691] In embodiments, the ELS may incorporate fault tolerance mechanisms and redundancy management systems. In example embodiments, the implementation may include disaster recovery capabilities and continuous system health monitoring to ensure sustained operational reliability.

PRODUCTION OPTIMIZATION

[3692] In embodiments, in manufacturing operations, the ELS may enable production optimization through real-time monitoring and adjustment of manufacturing parameters. In example embodiments, the system may continuously analyze production data to automatically optimize resource allocation and scheduling, while maintaining quality control standards. For example, in an automotive manufacturing facility, the ELS may monitor assembly line operations in real-time, automatically adjusting robotic systems and process parameters to maintain optimal production efficiency and product quality.

MAINTENANCE SCHEDULING

[3693] In embodiments, the ELS may implement predictive maintenance scheduling by analyzing equipment sensor data through its IoT integration capabilities. In example embodiments, this may allow manufacturing facilities to prevent unexpected downtime by identifying potential equipment failures before they occur. The ELS may coordinate maintenance activities across multiple production lines while optimizing resource utilization and minimizing operational disruptions.

SUPPLY CHAIN OPTIMIZATION

[3694] In embodiments, in supply chain applications, the ELS may implement optimization through real-time monitoring and analysis of stock levels, demand patterns, and supplier performance. In example embodiments, the system may utilize its forecasting capabilities to predict demand fluctuations and automatically adjust inventory levels across multiple distribution centers. For instance, in a consumer goods supply chain, the system may continuously analyze point-of-sale data, weather patterns, and seasonal trends to optimize stock levels and distribution patterns. The system's value chain network control capabilities may enable logistics planning through its centralized control tower operations. The ELS may coordinate multiple distribution nodes, optimizing delivery routes and transportation resources while maintaining real-time visibility of all shipments. The system may automatically adjust logistics plans based on real-time conditions, such as weather disruptions or transportation delays, ensuring efficient delivery operations.

[3695] In embodiments, the ELS may create digital twin representations of manufacturing facilities and supply chain networks, enabling virtual testing and optimization before physical implementation. For example, in a pharmaceutical manufacturing environment, the system may simulate production processes and supply chain operations, allowing operators to test different scenarios and optimize procedures without disrupting actual operations. In example

embodiments, these digital twins may maintain real-time synchronization with physical assets, providing accurate representations of current operational states.

[3696] In embodiments, the ELS may implement AI-driven process optimization across manufacturing and supply chain operations through its machine learning and neural network architectures. For example, in a chemical manufacturing facility, the ELS may continuously analyze process parameters and product quality data, automatically adjusting production variables to maintain optimal output while ensuring compliance with quality standards. In these example embodiments, the system's reinforcement learning capabilities may enable continuous improvement of operational parameters based on historical performance data.

[3697] In embodiments, within manufacturing environments, the ELS may optimize energy consumption patterns through its energy management capabilities. In example embodiments, the system may analyze production schedules, energy pricing, and operational requirements to optimize energy usage while maintaining production efficiency. For example, in an industrial processing facility, the system may automatically adjust production scheduling to take advantage of off-peak energy rates while ensuring production targets are met.

[3698] In embodiments, the ELS may demonstrate integration capabilities by connecting manufacturing execution systems, supply chain management platforms, and enterprise resource planning systems. This integration may enable data flow and coordination across all operational aspects. For instance, in a consumer electronics manufacturing operation, the system may coordinate production planning with supply chain logistics and inventory management, ensuring efficient resource utilization and timely delivery of finished products.

[3699] In embodiments, the ELS may implement a multi-layered neural network architecture that combines multiple specialized networks for different processing tasks. In example embodiments, the system may utilize convolutional neural networks specifically designed for image processing applications, while implementing recurrent neural networks for analyzing sequential data patterns. Additionally, transformer networks may handle natural language processing tasks, and graph neural networks process relationship analysis across the system. In these example embodiments, the ELS may coordinate these neural networks through a machine learning integration framework that implements multiple advanced approaches. For example, the system may utilize supervised learning algorithms for pattern recognition tasks, while simultaneously deploying unsupervised learning systems for anomaly detection, and/or vice versa. Reinforcement learning capabilities may be implemented for continuous optimization processes, while deep learning systems may handle complex analysis tasks requiring sophisticated pattern recognition. In embodiments, the ELS may manage the practical implementation of these systems through a hierarchical task distribution framework that enables efficient parallel processing optimization. The system may implement sophisticated resource allocation management protocols to ensure optimal utilization of computing resources across different AI subsystems. This framework facilitates cross-system learning integration, allowing different AI components to share and leverage insights across various operational domains.

[3700] In embodiments, the ELS may include a central processing unit that coordinates various AI and machine learning components through integrated memory systems storing executable instructions. In these embodiments, the system architecture may enable parallel processing of intelligence tasks across different domains while maintaining data consistency through synchronization protocols. The implementation may include dedicated data storage systems and communication interfaces that facilitate interaction between different neural network and machine learning components.

[3701] In embodiments, the ELS may implement real-time processing capabilities through its neural network arrays and AI engines. In example embodiments, these components may work in concert to process operational data, enabling continuous updates to simulations and forecasting models. In these example embodiments, the system may maintain real-time synchronization between physical and digital assets through its digital twin implementation, allowing for immediate feedback and adjustment of operational parameters.

[3702] In embodiments, the ELS may include neural network and machine learning systems that operate within a comprehensive security framework that implements end-to-end encryption and secure data transmission protocols. In example embodiments, the system may maintain privacy preservation techniques while enabling the AI components to process and analyze data without compromising security protocols.

[3703] In embodiments, the ELS may enable enterprise system integration through dedicated communication interfaces that connect with ERP systems, CRM platforms, manufacturing execution systems, and supply chain management systems. For external connectivity, the ELS may maintain connections with cloud services, partner networks, external data sources, and third-party applications through its communication interfaces and integration modules. In these example embodiments, the system-of-systems architecture may include communication interfaces and security modules that enable data synchronization while maintaining security protocols. This may include end-to-end encryption for data transmission and privacy preservation techniques for sensitive information exchange.

[3704] In embodiments, the ELS may include an integration framework that supports automated workflow management and cross-system data synchronization capabilities to ensure consistent data flow across connected enterprise systems. For performance optimization, the system may implement horizontal and vertical scaling capabilities along with dynamic resource allocation and load balancing to maintain efficient system integration and data exchange. In these example embodiments, the system's reliability features may include fault tolerance mechanisms and redundancy management to ensure consistent integration performance, while system health monitoring maintains stable connectivity with integrated enterprise systems.

[3705] Example embodiments include, but are not limited to the ELS having a set of machine learning systems, a set of artificial intelligence systems, and/or set of neural networks configured to 1) execute a set of intelligence tasks associated with a set of simulations, and 2) execute a set of intelligence tasks associated with forecasting, and 3) execute a set of intelligence tasks associated with a set of digital twins, and 4) execute a set of intelligence tasks associated with

the Industrial Metaverse, and 5) execute a set of intelligence tasks associated with a value chain network control tower, and 6) execute a set of intelligence tasks associated with a set of value chain network mini control towers, and 7) execute a set of intelligence tasks associated with big data and/or analytics, and 8) execute a set of intelligence tasks associated with a set of executive digital twins, and 9) execute a set of intelligence tasks associated with an industrial internet of things (IIoT) platform, and 10) execute a set of intelligence tasks associated with AI-based industrial operational control, and 11) execute a set of intelligence tasks associated with an AI-driven Industrial Metaverse, and 12) execute a set of intelligence tasks associated with a set of financial executive digital twins, and 13) execute a set of intelligence tasks associated with enterprise transaction systems integration, 14) execute a set of intelligence tasks associated with an enterprise access layer, and 15) execute a set of intelligence tasks associated with AI-based enterprise transactional decision support, and 16) execute a set of intelligence tasks associated with a set of supply chains, and 17) execute a set of intelligence tasks associated with demand shaping integration, and 18) execute a set of intelligence tasks associated with a value chain network system of systems, and 19) execute a set of intelligence tasks associated with a set of executive digital twins for vehicle fleet operations, and 20) execute a set of intelligence tasks associated with a set of vehicle digital twins for design and simulation, and 21) execute a set of intelligence tasks associated with an enterprise access layer for fleet transactions, and 22) execute a set of intelligence tasks associated with software defined vehicle management, and 23) execute a set of intelligence tasks associated with a set of executive digital twins for enterprise energy operations, and 24) execute a set of intelligence tasks associated with enterprise energy system of systems integration, and 25) execute a set of intelligence tasks associated with an enterprise access layer for energy transactions, and 26) execute a set of intelligence tasks associated with AI-based enterprise transactional decision support for energy management.

OFFERING LAYER

GENERAL SYSTEMS

[3706] In embodiments, the system of systems 31000 includes an offering layer 34000 configured to create, manage, and enable offerings of the system of systems 31000 via a plurality of offering modules 34002. The offering layer includes an intelligent systems architecture that includes multiple sophisticated components configured to work together to deliver advanced capabilities across various domains. Referring to FIG. 185, the offering layer may include one or more of a content generation intelligence module 34004, a content personalization module 34006, a smart products intelligence framework module 34008, an AR processing module 34010, an immersive environment generation module 34012, a reality-virtuality fusion module 34014, a cross-reality integration module 34016, an audience segmentation module 34018, a domain-specific knowledge processing module 34020, a large language model (LLM) module 34022, a collaborative filtering module 34024, or an integration architecture module 34026.

CONTENT GENERATION

[3707] In embodiments, the content generation intelligence module 34004 is configured to leverage natural language processing (NLP) models that enable automated creation of diverse content types. The NLP models employ advanced transformer architectures to understand context, maintain coherence, and generate human-like text across multiple domains and styles. One or more deep learning networks dedicated to image and video generation may utilize generative adversarial networks (GANs) and diffusion models to create high-fidelity visual content, incorporating style transfer capabilities and content-aware generation features. One or more transformer-based architectures for multi-modal content synthesis enable seamless integration of text, images, audio, and video, creating cohesive multi-format content. One or more quality assurance and content validation mechanisms employ specialized neural networks that evaluate generated content against predefined quality metrics, ensuring consistency, accuracy, and appropriateness of all outputs.

CONTENT PERSONALIZATION

[3708] In embodiments, the content personalization module 34006 implements sophisticated collaborative filtering neural networks that analyze user interactions and preferences across multiple dimensions. These networks utilize matrix factorization techniques enhanced with deep learning capabilities to identify complex patterns in user behavior. The user behavior analysis models incorporate both explicit and implicit feedback mechanisms, processing real-time interaction data to continuously refine user profiles. Real-time content adaptation engines employ reinforcement learning algorithms to dynamically adjust content presentation based on user responses and contextual factors. The personalization optimization algorithms utilize multi-armed bandit approaches combined with deep learning to balance exploration and exploitation in content recommendations.

[3709] In embodiments, the smart products intelligence framework module 34008 includes product behavior prediction models that utilize recurrent neural networks to forecast usage patterns and potential issues before they arise. The usage pattern recognition systems employ unsupervised learning techniques to identify clusters of similar usage behaviors and anomaly detection to flag unusual patterns. Adaptive learning mechanisms continuously update product parameters based on real-world usage data, optimizing performance through reinforcement learning approaches. The real-time performance monitoring neural networks process sensor data streams to maintain optimal product functionality and predict maintenance needs.

AUGMENTED REALITY

[3710] In embodiments, the AR processing module 34010 includes one or more computer vision neural networks configured to utilize advanced convolutional architectures for real-time object recognition and tracking. Spatial mapping and tracking algorithms combine SLAM (Simultaneous Localization and Mapping) techniques with deep learning to create accurate environmental models. Real-time environment understanding models process multiple sensor inputs to maintain consistent AR experiences across varying conditions. The AR content

placement optimization engines use sophisticated algorithms to determine optimal positioning of virtual elements within the physical space, considering both spatial and contextual factors.

VIRTUAL REALITY

[3711] In embodiments, the immersive environment generation module 34012 includes one or more models within the VR intelligence layer configured to create photorealistic virtual spaces using advanced rendering techniques combined with neural radiance fields. Physics simulation neural networks ensure realistic object behavior and interactions within virtual environments. User interaction prediction systems anticipate user actions to reduce latency and improve responsiveness. Experience optimization algorithms continuously adjust rendering parameters and content delivery based on hardware capabilities and user preferences.

MIXED REALITY

[3712] In embodiments, the reality-virtuality fusion module 34014 enables seamless integration of virtual elements with physical environments through sophisticated scene understanding and rendering techniques. Environmental understanding neural networks process multiple sensor inputs to create accurate representations of physical spaces. Real-time scene analysis systems continuously update environmental models to maintain consistent mixed reality experiences. Interactive element placement algorithms optimize the positioning and behavior of virtual objects within the physical space.

EXTENDED REALITY

[3713] In embodiments, the cross-reality integration module 34016 includes one or more models configured to enable consistent experiences across different reality platforms through unified representation models. Universal XR content adaptation networks automatically optimize content for different display types and interaction methods. Experience synchronization algorithms maintain temporal and spatial consistency across multiple users and devices. Multi-modal interaction processing systems handle various input methods including gesture, voice, and traditional controls.

TARGETED ADVERTISING

[3714] In embodiments, the audience segmentation module 34018 includes one or more neural networks configured to utilize deep learning techniques to identify and categorize user groups based on behavioral and demographic data. Ad performance prediction models employ ensemble learning approaches to forecast campaign effectiveness across different channels. Real-time bidding optimization systems use reinforcement learning to maximize advertising ROI. Campaign effectiveness learning algorithms continuously update targeting strategies based on performance data.

[3715] In embodiments, the domain-specific knowledge processing module 34020 includes one or more models configured to utilize sophisticated knowledge representation schemes combined with neural networks for efficient information retrieval and processing. Decision

support neural networks combine traditional rule-based systems with modern deep learning approaches for improved accuracy. Inference engine optimization systems employ probabilistic reasoning techniques enhanced by machine learning. Rule-based learning algorithms automatically extract and update domain rules from new data.

GENERATIVE AI

[3716] In embodiments, the LLM module 34022 includes one or more models configured to incorporate transformer architectures with multiple (e.g., billions) of parameters for sophisticated text generation capabilities. Diffusion models for media creation utilize advanced noise prediction networks for high-quality image and video generation. Multi-modal synthesis networks enable coordinated generation of content across different modalities. Output quality validation systems employ specialized neural networks to ensure generated content meets quality and safety standards.

RECOMMENDATION SYSTEMS

[3717] In embodiments, the collaborative filtering neural networks module 34024 includes one or more models configured to implement hybrid approaches combining memory-based and model-based techniques for accurate recommendations. Content-based recommendation models utilize deep learning for feature extraction and similarity computation. Hybrid recommendation systems combine multiple approaches through sophisticated ensemble techniques. Real-time preference learning algorithms continuously update user models based on interaction data.

[3718] In embodiments, the integration architecture module 34026 is configured to implement components through a microservices-based deployment model, where each intelligence component operates as an independent service with clearly defined interfaces. Container orchestration manages resource allocation and scaling, while the API-first design ensures consistent interaction patterns across all components. The event-driven architecture enables real-time processing and communication between components through a sophisticated message broker system.

VCN SYSTEMS

[3719] In embodiments, the offering layer includes a smart products intelligence framework including an interconnected set of machine learning systems and neural networks that enable intelligent product functionality across the product lifecycle. The framework utilizes deep learning models for real-time monitoring and optimization of product performance. Product behavior prediction models leverage recurrent neural networks and transformer architectures to analyze usage patterns and predict potential issues before they manifest. The system employs reinforcement learning algorithms that continuously optimize product parameters based on real-world usage data and environmental conditions. Anomaly detection networks identify unusual patterns that may indicate maintenance needs or opportunities for performance enhancement. The framework includes adaptive learning mechanisms that allow products to evolve their

functionality based on individual user interactions while maintaining core safety and operational parameters.

[3720] In embodiments, the offering layer includes a digital product networks system that implements a sophisticated architecture for managing interconnected digital products and their interactions. The system utilizes graph neural networks to model and optimize product network topologies, enabling efficient communication and resource sharing between connected products. Deep learning models analyze network traffic patterns to optimize data flow and reduce latency. The system employs federated learning techniques to enable distributed intelligence across product networks while maintaining data privacy. Advanced clustering algorithms automatically identify and organize product groups based on functionality, usage patterns, and interdependencies. Real-time optimization engines continuously adjust network configurations to maintain optimal performance under varying loads and conditions.

[3721] In embodiments, the offering layer includes a value chain network management platform that incorporates artificial intelligence systems designed to optimize end-to-end supply chain operations. The platform employs deep reinforcement learning models for dynamic resource allocation and scheduling optimization. Natural language processing systems analyze market signals and supplier communications to predict potential disruptions or opportunities. Computer vision networks monitor production processes and quality control in real-time. The platform utilizes multi-agent systems to coordinate complex logistics operations across distributed networks. Predictive analytics models leverage historical data and current market conditions to optimize inventory levels and production schedules. The system includes adaptive pricing models that automatically adjust based on supply chain conditions and market demand.

[3722] In embodiments, the offering layer includes a networked digital product families framework that implements machine learning systems for managing related groups of digital products as cohesive units. The framework employs hierarchical neural networks to model relationships and dependencies between product family members. Genetic algorithms optimize product family configurations based on user needs and system requirements. The system includes transfer learning mechanisms that enable sharing of learned behaviors and optimizations across product family members while maintaining individual product specialization. Advanced classification networks automatically categorize new products and integrate them into appropriate family groups. The framework utilizes collaborative filtering techniques to predict and optimize interactions between product family members.

[3723] In embodiments, the offering layer includes a product lifecycle management intelligence system that incorporates neural networks and AI systems for comprehensive product lifecycle optimization. The system employs deep learning models for predictive maintenance and lifecycle forecasting. Natural language processing networks analyze customer feedback and usage data to inform product evolution. Computer vision systems monitor product degradation and performance changes over time. The system includes reinforcement learning algorithms that optimize product parameters throughout different lifecycle stages. Advanced clustering techniques identify patterns in product lifecycle data to predict and prevent potential issues. The

system utilizes generative models to simulate and optimize future product iterations based on lifecycle learnings.

[3724] In embodiments, the offering layer includes an AI-driven product management platform that implements a comprehensive suite of artificial intelligence systems for strategic product development and management. The platform employs large language models for requirements analysis and feature prioritization. Deep learning networks analyze market trends and customer behavior to inform product roadmap decisions. The system includes neural networks for competitive analysis and market positioning optimization. Reinforcement learning algorithms optimize product development processes and resource allocation. The platform utilizes advanced forecasting models to predict product performance and market acceptance. Recommendation systems suggest optimal feature sets and development priorities based on market conditions and user needs. The platform includes simulation capabilities that enable testing of different product strategies and configurations before implementation.

TRANSACTIONS LAYER

[3725] In some example embodiments, a system-of-systems (SOS) (e.g., system of systems 31000) may include a transaction layer 35000 that includes a set of hardware and/or software-defined transaction modules that may interact with one another and/or other layers of the SOS to automate, optimize, execute, and/or otherwise facilitate digital transactions on behalf of an entity, such as an enterprise. In example embodiments, a transaction layer 35000 may deploys and/or leverages various types of AI models (e.g., generative AI models, neural networks, machine-learning models, and/or other types of models) to perform various tasks associated with a transaction (e.g., transaction execution, transaction fulfillment, transaction reconciliation, opportunity discovery, and/or the like).

[3726] In example embodiments, the transaction layer 35000 may interface with other layers of a SoS 31000. In these example embodiments, the transaction layer 35000 may provide a set of services to one or more layers modules of the SOS and/or request services from the other layers. For example, an enterprise layer 33000 may initiate a transaction in response to receiving an invoice from a third-party service or goods provider by requesting a transaction from the transaction layer. In a related example, the transaction layer 35000 may request approval services from a governance layer 32000 before the transaction layer 35000 executes a requested transaction on behalf of the enterprise using a digital wallet controlled by the transaction layer. Other examples relating to the transaction layer 35000 are discussed below.

[3727] FIG. 186 illustrates an example set of modules of an example transaction layer 35000. These may include API integrations modules 35002, authentication and security modules 35004, transaction execution modules 36005, transaction orchestration modules 35008, transaction discovery modules 35010, transaction fulfillment modules 35012, transaction reconciliation modules 35014, and/or other suitable modules.

[3728] In example embodiments, the transaction layer modules may can include and/or leverage cloud-based virtualized containerization capabilities and services, such as without

limitation a container deployment and operation controller, such as Kubernetes or the like. Cloud-based virtualized containers may provide for data layers to be deployed close to source data, thereby potentially reducing network bandwidth consumption or the potential for network disturbances in a data workflow, especially when addressing voluminous local situations such as in industrial and commercial environments.

[3729] In example embodiments, technologies may be provided by and/or enabled by the data layer system of systems 38000 include intelligence services 38606, such as artificial intelligence, machine learning and the like. These intelligence services 38606 may be provided by the data layer SoSs 38000, or accessed (e.g., as third-party services) via one or more. The data layer control 38560 may be provided access to the intelligence services 38606. In example embodiments, the data layer control 38560 may provide its own set of intelligence services.

INTERFACES AND SECURITY

[3730] In example embodiments, the transaction layer 35000 may implement a secure integration framework for interfacing with external systems, such as financial institutions, digital marketplaces, and/or blockchain networks. In example embodiments, the secure integration framework may include one or more authentication and security module(s) 35006 that manage and facilitate secure connections with external systems. In example embodiments, an authentication and security module 35006 may implement respective security capabilities such as, but not limited to, multi-factor authentication, public key infrastructure (PKI) based certificate management, hardware security modules (HSMs) for cryptographic key storage and management, encrypting communication channels (e.g., using TLS 1.3 or higher), OAuth 2.0 and OpenID Connect for API authorization, IP address whitelisting, API key rotation mechanisms, and/or the like. It is appreciated that the authentication and security module 35006 may implement other respective security capabilities

[3731] In example embodiments, the transaction layer 35002 may implements an API integration framework that may provide standardized interfaces for connecting to different types of external systems (e.g., third party data sources, financial institution platforms, digital marketplaces, blockchains, user devices, IoT devices, and/or the like). In these example embodiments, the transaction layer 35000 may include one or more API integration modules 35002 that implement various types of APIs and protocols including RESTful APIs for financial institution connections, WebSocket implementations for real-time market data streams, FIX protocol integration for trading systems, ISO 20022 message formats for financial transactions, GraphQL interfaces for flexible data querying, webhook handlers for asynchronous transaction notifications, and/or the like.

TRANSACTION EXECUTION

[3732] In example embodiments, the transaction layer 35000 may include one or more transaction execution modules 35006. In example embodiments, a transaction execution module 35006 may be configured to execute transactions on behalf of an entity. In these example embodiments, a transaction execution module 35006 may be configured to control one or more

accounts of the entity. In some of these example embodiments, a transaction execution module 35006 may control one or more entity digital wallets, where each digital wallet may be configured to execute transactions from an entity account and/or one or more marketplaces. For example, a digital wallet may be configured to facilitate blockchain transactions on behalf of the entity using the credentials (e.g., private key and/or public key) of a blockchain account of the entity. In another example, a second digital wallet may be configured to securely interface with the virtual infrastructure of a respective financial institution (e.g., using an API of the financial institution and account credentials of a respective entity) to transfer funds from an account of the entity to another entity (e.g., via a bank-to-bank wire, an account transfer within the bank, or the like). In another example, a digital wallet may interface with one or more digital marketplaces or exchanges (e.g., using an API of the marketplace/exchange). In these example embodiments, the digital wallet may be configured to transact for assets. Examples of assets that may be transacted for via a marketplace may include financial assets (e.g., foreign currencies, stocks, bonds, commodities, and/or the like), physical items (e.g., real estate, fungible goods, collectible items, and/or the like), resources (e.g., energy resources, computing resources, network resources, and/or the like). Examples of the types of transactions (or related actions) that may be performed by a digital wallet on a marketplace may include selling an asset of the entity, purchasing an asset, offering an asset for sale, making a bid on an asset, and/or the like.

[3733] In example embodiments, a transaction execution module 35006 may causes a digital wallet to perform a specific transaction (e.g., instructing a financial institution to transfer a specific amount from a specific account of the entity to a specific recipient/account; instructing a crypto wallet to generate and digitally sign a transfer request for a specific amount of cryptocurrency on a blockchain using the public key and/or private key corresponding to a specific account of the entity on the blockchain; instructing a digital wallet to purchase a specific amount of stock on an exchange; instructing a digital wallet to purchase an amount of a resource on a future or spot resource market; and/or the like).

[3734] In example embodiments, a transaction execution module 35006 may implement specialized digital wallet capabilities that execute different types of transactions using respective transaction channels. For example blockchain transactions, a transaction execution module 35006 may implement multi-signature wallet capabilities with configurable M-of-N schemes, transaction signing (e.g., using elliptic curve cryptography), gas optimization algorithms, smart contract interaction through Application Binary Interface (ABI) encoding/decoding, and/or the like. For traditional financial transactions, a transaction execution module 35006 may implement Automated Clearing House (ACH) transaction processing with NACHA file format support, Society for Worldwide Interbank Financial Telecommunication (SWIFT) message generation for international wire transfers, real-time payment system integration, automated reconciliation using ISO 20022 messages, and/or payment card processing through tokenization services. For example digital marketplace transactions, a transaction execution module 35006 may implement order book management systems, price discovery algorithms, automated trading interfaces,

position management and risk monitoring capabilities, market making functionality with configurable spreads, and/or liquidity aggregation across multiple venues.

[3735] In example embodiments, a security module 35004 may allow a transaction execution module to interface with a respective transaction channels. In these example embodiments, when a transaction execution module 35006 receives a request to execute a transaction, the security module 35004 may authenticate the transaction request and establish a secure connection with the respective transaction channel corresponding to the transaction request. For example, when executing a blockchain transaction, the authentication and security module 35004 may retrieve the private key of the respective blockchain account from a secure credential vault, which may allow a transaction execution module to digital sign the requested transaction that may be provided to a blockchain network to complete the transaction. In another example, when executing a bank transfer, the security module 36006 may retrieve the account credentials from the secure credential vault, verify the authenticity of the transaction request using various authentication protocols, and establish a secure connection with the bank's API. In example embodiments, a secure credential vault may store and manage authentication credentials used by the transaction execution modules 35006. The credential vault may implement hardware-backed key storage, an encrypted credential database, key rotation policies, access control lists, audit logging of credential usage, and/or secure credential injection into API calls.

[3736] In example embodiments, the transaction execution module 35006 may receive an instruction to perform a transaction from another transaction module, another layer of the SoS, and/or from a user associated with the entity. In example embodiments, the transaction execution module 35006 may receive a set of transaction parameters that specify information needed to execute the transaction, such as the account/digital wallet involved in the transaction, the type of transaction (e.g., sending funds, requesting funds, bidding on an item, and/or the like), the transaction amount, the account and/or digital wallet to use for the transaction, and/or any other suitable information. In response, the transaction execution module 35006 may generate an instruction to a selected enterprise digital wallet based on the transaction parameters. In response, the digital wallet may attempt to execute the transaction. In example embodiments, the digital wallet may return an outcome of the transaction (e.g., whether the transaction was successful or unsuccessful) as well as any other relevant metadata (e.g., timestamp, a receipt, an amount transferred, etc.). In response, the transaction execution module 35006 may provide the transaction outcome to various modules of the transaction layer and/or another layer of the SoS.

TRANSACTION ORCHESTRATION

[3737] In example embodiments, the transaction layer 35000 may include one or more transaction orchestration modules 35008 that may be configured and trained to automate and/or manage one or more tasks of a transaction workflow on behalf of an enterprise. In example embodiments, the transaction orchestration module 35008 may be configured to determine a transaction orchestration workflow, initiate various tasks within a transaction orchestration workflow (which may be performed by other transaction modules of the transaction layer

35000), monitor outcomes of those tasks, and/or selectively initiate subsequent tasks based on the outcomes. In example embodiments, a transaction orchestration module 35008 may be configured to deploy an intelligent agent that may be configured and trained to orchestrate the tasks of a transaction on behalf of an enterprise, which may be referred to as a transaction orchestration agent. For example, a transaction orchestration agent transaction orchestration module 35008 may initiate a transaction discovery task that identifies a potential transaction and/or one or more potential counterparties for the potential transaction. In this example, the transaction orchestration agent may be granted authority to selectively initiate a next stage of a transaction workflow based on an outcome of the transaction discovery task or the transaction orchestration agent may be instructed by a user to initiate the next stage. In either scenario, the intelligent transaction orchestration agent may then initiate the generation of a transaction. In some transaction workflows, the generation of a transaction may include determining a set of transaction parameters corresponding to the transaction. For example, if the transaction involves cryptocurrencies and/or a smart contract, the transaction parameters may include the blockchain address of the accounts and/or smart contract involved in the transaction (e.g., the recipient and/or sender of the cryptocurrency and/or the smart contract that is facilitating the blockchain transaction), an amount of cryptocurrency to be sent, a transaction request that is generated for digital signature, an object of the transaction (e.g., an identifier of the digital or real-world asset being transacted for, an identifier of a service being paid for, and/or the like), and/or other suitable transaction parameters. In an example of a real estate transaction, the transaction parameters may include an identifier of the property being transferred, purchaser information, seller information, a purchase price, and/or other supplemental information that may be used to generate documents relating to the real estate transaction and/or transfer of ownership of the property from one entity to a purchasing entity, and/or the like. In some example embodiments, the transaction orchestration agent may automate a contract negotiation with a counterparty to the transaction to determine the set of transaction parameters. Additionally or alternatively, a user of the system may provide some or all of the transaction parameters (e.g., via a user interface).

[3738] In some example embodiments and some types of transaction workflows, the user may designate (e.g., via a user interface) an enterprise account and/or digital wallet to perform the transaction. Alternatively, a transaction orchestration agent may be trained to select appropriate accounts for particular transactions. In some of these example embodiments, a transaction orchestration agent may be trained to determine which accounts to use for a particular transaction by analyzing various transaction parameters and conditions. For example, the transaction orchestration agent may analyze the marketplace and/or location (e.g., country, state, city) where the transaction will take place to determine whether specialized accounts are needed (e.g., accounts that are pre-approved or whitelisted for the location or are compatible with the marketplace). The transaction orchestration agent may also analyze whether the transaction involves blockchain or traditional financial transaction rails to select an account that may be configured for the respective transaction channel. The transaction orchestration agent may also

analyze the transaction amount to determine whether the selected account has sufficient funds or whether the transaction amount exceeds predefined transaction limits for the account. The transaction orchestration agent may also analyze the purpose of the transaction (e.g., whether it is for operational expenses, investment purposes, or other business purposes) to select an account that may be designated for that type of transaction. The transaction orchestration agent may also analyze historical transaction patterns, risk parameters, compliance requirements, and/or enterprise policies to ensure the selected account aligns with enterprise guidelines and risk tolerance levels. In response to determining which account/digital wallet to use, the transaction orchestration module 35008 may then instruct a transaction execution module 35006 to generate and execute the transaction.

[3739] It is appreciated that a transaction orchestration agent may be trained to orchestrate other types of tasks within a transaction workflow. For example, in some example embodiments a transaction orchestration agent may initiate transaction discovery tasks. In this example, the orchestration agent may be deployed to initiate a transaction discovery task (e.g., using a transaction discovery module), and in response to being provided a transaction opportunity, determine whether to proceed with the transaction. In another example, a transaction orchestration agent may initiate post-transaction tasks, such as fulfillment and reconciliation.

TRANSACTION DISCOVERY

[3740] In example embodiments, the transaction layer 35000 may include one or more transaction discovery modules. In example embodiments, a transaction discovery module 35010 may be configured to analyze data from disparate data sources for purposes of identifying potential transactions on behalf of an entity. For instance, the transaction discovery module 35010 may be configured and trained to discover potential in-bound transactions that align with an asset class or a strategy/transaction profile provided by a user. Additionally or alternatively, the transaction discovery module 35010 may be configured and trained to discover potential outbound transactions for an asset or class of assets in response to receiving an indicator of the asset or class of asset. It is appreciated that a transaction discovery module 35010 may be configured to discover different types of transactions that involve different types of asset classes. For example, in some example implementations, a transaction discovery module 35010 may be configured to identify potentially distressed assets that may be potential transaction targets. In another example, a transaction discovery module 35010 may monitor various marketplaces to identify potential arbitrage opportunities and/or opportunities to purchase energy, raw materials, and/or other resources that an enterprise may require in the future.

[3741] In example embodiments, the transaction discovery module 35010 may request or subscribe to data feeds and/or event notifications from the data layer--which may deploy intelligent agents that monitor a large number of data sources from which the data feeds and/or event notifications are mined and/or curated. The transaction discovery module 35010 may include one or more intelligence models (e.g., a set of machine learning models, neural networks, and/or other types of artificial intelligence models) and/or may interface with an

intelligence system that may collectively process the data feeds and/or event notifications received from the data layer and may identify potential in-bound or outbound transactions based on the monitored data feeds and/or event notifications. In some of these example embodiments, the transaction discovery module 35010 may parse, structure, vectorize, and analyze the curated data feeds and/or event data. The transaction discovery module 35010 may then feed this data into its intelligence models, which may output potential transactions that may align with a requested asset class or transaction profile.

[3742] In example embodiments, the transaction discovery module 35010 may utilize data from disparate sources to identify potential transactions. For example, in the context of arbitrage opportunities on decentralized cryptocurrency exchanges, the transaction discovery module 35010 may monitor real-time price feeds and order book data from multiple decentralized exchanges to identify price discrepancies that may present arbitrage opportunities. In these example embodiments, the transaction discovery module 35010 may analyze liquidity pools, calculate potential arbitrage spreads while accounting for transaction costs (e.g., gas fees, slippage), identify optimal routing paths between exchanges, monitor pending transactions in a memory pool that may impact arbitrage opportunities, and track historical price correlations and volatility patterns. The transaction discovery module 35010 may feed this data into its intelligence models to identify and score potential arbitrage opportunities.

[3743] In another example focused on discovery of real estate transaction opportunities, the transaction discovery module 35010 may monitor multiple data sources including property listings, foreclosure notices, tax records, satellite imagery, property condition reports, building permits, construction activity, comparable sales data, demographic data, and economic indicators. The transaction discovery module 35010 may analyze this data to identify properties that may match specific investment criteria (e.g., distressed properties, properties in developing areas, properties with potential for value appreciation). The transaction discovery module 35010 may use its intelligence models to parse and structure the raw data feeds, vectorize text and numerical data, apply natural language processing to unstructured content, identify patterns and correlations across data sources, generate opportunity scores and risk assessments, and rank potential transactions based on their alignment with enterprise investment criteria, etc. In identifying a potential property, the transaction discovery module 35010 may also determine an estimated value of the property and/or a proposed purchase price. In some example embodiments, the transaction discovery module 35010 may output the potential transaction opportunity to a transaction orchestration module 35008, which in turn may notify a decision maker regarding the opportunity, configure an offer to purchase the property, submit a bid on the property (e.g., if for sale or being auctioned), and/or the like.

TRANSACTION FULFILLMENT AND RECONCILIATION

[3744] In example embodiments, the transaction layer 35000 may include one or more transaction fulfillment modules 35012 that may be configured to manage and automate post-execution requirements of a transaction. In example embodiments, a transaction fulfillment

module 35012 may be configured to monitor the status of a transaction after the transaction has been initiated by a transaction execution module 35006. For example, after a transaction execution module 35006 initiates a transfer of funds via a financial institution, the transaction fulfillment module 35012 may monitor the status of the transfer to determine whether the transfer was successful. In another example, after a transaction execution module 35006 initiates a blockchain transaction, the transaction fulfillment module 35012 may monitor the status of the blockchain transaction (e.g., by monitoring the number of block confirmations) to determine whether the transaction has been confirmed on the blockchain. In example embodiments, the transaction fulfillment module 35012 may generate notifications regarding the status of transactions and/or may trigger subsequent actions based on transaction status. For example, the transaction fulfillment module 35012 may generate a notification when a transaction is confirmed or may trigger the generation of transaction documentation (e.g., receipts, confirmations, transfer records, settlement instructions) when a transaction is completed.

[3745] In example embodiments, the transaction layer 35000 may include one or more transaction reconciliation modules 35014 that may be configured to verify and validate completed transactions across multiple systems of record. In example embodiments, a transaction reconciliation module 35014 may compare transaction records across internal and external systems to identify and flag any discrepancies. For example, a transaction reconciliation module 35014 may compare transaction records in an enterprise accounting system with transaction records from a financial institution to ensure that the records match. In another example, a transaction reconciliation module 35014 may compare blockchain transaction records with internal transaction records to verify that blockchain transactions were executed as intended. In example embodiments, the transaction reconciliation module 35014 may implement one or more machine learning models that may be configured and trained to detect patterns in transaction data, identify potential reconciliation issues, automate the classification of transaction exceptions, and/or suggest resolution actions for common reconciliation scenarios.

[3746] In example embodiments, the transaction reconciliation module 35014 may interface with enterprise accounting systems, financial reporting systems, and/or regulatory compliance systems to ensure accurate transaction recording and reporting. The transaction reconciliation module 35014 may implement standardized reconciliation protocols (e.g., ISO 20022) and may support various data formats (e.g., MT940, BAI2, SWIFT) for automated reconciliation processes. In example embodiments, the transaction reconciliation module 35014 may maintain audit trails of reconciliation activities and may generate exception reports for transactions that require manual review.

OPERATIONS LAYER

[3747] In embodiments, the techniques described herein relate to a computer-implemented system for managing operations of a set of artificial intelligence systems. In embodiments, the computer-implemented system includes a processor and a memory storing instructions that, when executed by the processor, cause the system to store a set of operations, wherein each

operation of the set of operations is associated with at least one artificial intelligence system of the set of artificial intelligence systems, and initiate at least one operation of the stored set of operations with at least one artificial intelligence system of the set of artificial intelligence systems that is associated with the least one operation.

[3748] In embodiments, the AI convergence system of systems 31000 includes an operations layer 36000 that causes the AI convergence system of systems 31000 to store a set of operations. For example, each operation may include a description of the operation to be performed. The description may include computer-readable instructions that are executable by one or more processors of one or more devices (*e.g.*, a server, a workstation, a mobile device, an edge device, a virtual device, or the like, or a combination thereof), which may be internal to and/or external to the AI convergence system of systems 31000. The description may include human-readable instructions that describe an operation in a natural language, such as English. The description may be provided at a high level of detail and/or a low level of abstraction (*e.g.*, a sequence of computer-executable instructions in machine language or a compilable programming language, a script of computer-interpretable expressions in an interpreted programming language, a declarative description of the operation in a declarative language such as XML, a flowchart, a mathematical description of an algorithm, or the like) that a processor may follow to perform the operation. The description may be provided at a low level of detail and/or a high level of abstraction (*e.g.*, a summary or overview of an operation that the AI convergence system of systems 31000 may interpret, design, generate, and execute). The description may include an indication of one or more artificial intelligence systems that may be associated with the operation, such as artificial intelligence systems that may perform the operation, upon which the operation may be performed, and/or that may participate in the design, development, generation, execution, monitoring, and/or refinement of the operation. The description may include an indication of one or more resources associated with the operation (*e.g.*, data sources that provide or receive data associated with the operation, storage devices or locations where data associated with the operation may be stored, and/or processing devices that may participate in the operation). The description may include an indication of one or more conditions under which an operation is to be initiated, performed, and/or stopped (*e.g.*, a schedule for initiating the operation on a periodic basis; a trigger condition that causes a device to initiate, perform, and/or stop the operation; and/or types of artificial intelligence systems that may be included and/or associated with a performance of the operation). The description may include an indication of one or more outcomes of the operation (*e.g.*, an expected outcome when the operation is performed in certain conditions, and/or a log of outcomes of one or more previous performance of the operation). The set of operations may include one or more pregenerated operations that are available to be initiated in various contexts. The set of operations may include one or more *ad-hoc* operations that are generated for a particular instance, context, circumstance, device, artificial intelligence system, or the like. Following initiation and/or completion of an *ad-hoc* operation, the operation layer 36000 may continue storing the operation with the set of operations (*e.g.*, converting the *ad-hoc* operation into a pregenerated operation for future

execution) or may discard the *ad-hoc* operation. The set of operations may include one or more operation templates to serve as a basis for other operations (*e.g.*, a set of device-specific stored operations that are based on a common device-independent operation template, or an *ad-hoc* operation that adapts an operation template for a particular instance).

[3749] In embodiments, the operations layer 36000 causes the AI convergence system of systems 31000 to initiate at least one operation of the set of operations with at least one artificial intelligence system. For example, the initiating may involve initiating execution of the operation on an artificial intelligence system (*e.g.*, a training operation that trains the artificial intelligence system, or an optimization operation that modifies the artificial intelligence system to optimize at least one feature). The initiating may involve invoking an artificial intelligence system to initiate the operation on another aspect of the AI convergence system of systems 31000, such as another artificial intelligence system, software based on a closed-form algorithm, an operating process, a device, a user, or the like. The initiating may involve invoking an artificial intelligence system to generate the operation (*e.g.*, invoking an artificial intelligence system to translate a description of an operation at a low level of detail / high level of abstraction into an executable operation at a high level of detail / low level of abstraction, such as an interpretable script or an executable binary). The initiating may involve invoking an artificial intelligence system to adapt an operation template into an *ad-hoc* operation based on a set of circumstances, which may be provided as input to the artificial intelligence system and/or may be generated by the artificial intelligence system. The initiating may involve invoking an artificial intelligence system to perform the operation, such as a robotic process automation (RPA) artificial intelligence system that is capable of performing a learned sequence of steps comprising a task. The initiating may involve invoking an artificial intelligence system to monitor a performance of the operation (*e.g.*, an artificial intelligence system that serves as a watchdog over the operation to ensure progress and to detect and address problems). The initiating may involve invoking an artificial intelligence system to validate a performance of the operation (*e.g.*, an artificial intelligence system that evaluates one or more outcomes of the operation to ensure that the operation has met one or more objectives for which the operation was initiated). The initiating may involve invoking an artificial intelligence system to record a performance of the operation (*e.g.*, an artificial intelligence system that records the performance of the outcome, documents one or more features of the performance of the operation, and/or summarizes a performance of an operation, one or more measures).

[3750] In embodiments, the operations layer 36000 associates resources of the AI convergence system of systems 31000 with a performance of an operation. For example, the operations layer 36000 may identify one or more artificial intelligence systems, devices, processors, storage locations, data sources, or the like that are to be included in a performance of an operation. The operations layer 36000 may secure the availability of the one or more artificial intelligence systems, devices, processors, storage locations, data sources, or the like to be included in the operation, such as reserving resources from the set of available resources of the AI convergence system of systems 31000 and/or executing transactions to acquire resources for the AI

convergence system of systems 31000 for the performance of the operation. The operations layer 36000 may schedule the performance of the operation (*e.g.*, choosing a time to perform the operation in view of the execution of other planned and/or unplanned operations by the AI convergence system of systems 31000). The operations layer 36000 may organize the resources to cause the operation to be performable and/or performed (*e.g.*, communicating with a set of devices to notify the devices of their participation in the performance of the operation, and/or exchanging data among the devices that is involved in the operation). The operations layer 36000 may measure the allocation of resources to operations (*e.g.*, as a high-level planning feature to allocate the resources of the AI convergence system of systems 31000 to perform all of the planned and/or unplanned operations, to load-balance the operations in view of the resources of the AI convergence system of systems 31000, and to acquire additional resources as may be needed or desired to perform the operations).

[3751] In embodiments, the operations layer 36000 may include a set of operations modules 36002, each of which may be configured to perform and/or capable of performing one or more operations for the operations layer 36000. For example, each operations module 36002 may be specialized for various types of operations, such as a first operations module 36002 that generates artificial intelligence models; a second operations module 36002 that evaluates artificial intelligence models; a third operations module 36002 that deploys artificial intelligence models; and a fourth operations module 36002 that invokes artificial intelligence modules to perform various operations. The operations modules 36002 may be specialized for particular types of artificial intelligence modules (*e.g.*, a first operations module 36002 may be specialized for operations involving traditional artificial neural networks such as perceptron networks, a second operations module 36002 may be specialized for operations involving convolutional neural networks that include convolutional layers, and a third operations module 36002 may be specialized for operations involving large language models that include transformer layers). The operations modules 36002 may be specialized for particular types of artificial intelligence tasks (*e.g.*, a first operations module 36002 may be specialized for performing operations that involve data classification, a second operations module 36002 may be specialized for performing operations that involve computer vision, and a third operations module 36002 may be specialized for performing operations that involve content generation). The operations modules 36002 may be specialized for particular types of data and/or use cases (*e.g.*, a first operations module 36002 may be specialized for performing operations that involve healthcare data or healthcare-related use cases, a second operations module 36002 may be specialized for performing operations that involve information technology data or information technology use cases, and a third operations module 36002 may be specialized for performing operations that involve industrial data and/or industrial use cases). In embodiments, the operations modules 36002 of the operations layer 36000 may interoperate to perform operations involving artificial intelligence systems (*e.g.*, two or more operations modules 36002 may each perform a portion of an operation involving an artificial intelligence system, such as a first operations module 36002

that trains the artificial intelligence system and a second operations module 36002 that evaluates an outcome of the training of the artificial intelligence system).

OPERATIONS LAYER – EXAMPLE OPERATIONS MODULES

[3752] FIG. 187 is an illustration of an example operations layer 36000 that includes a set of operations modules 36002. In the example operations layer 36000 of FIG. 187, each operations module 36002 is provided to perform one set and/or type of operations. Each operations module 36002 may be implemented as one or more artificial intelligence systems, algorithms, devices, processors, data sets, or the like. Although the example operations layer 36000 of FIG. 187 depicts a particular factoring of operations to discrete modules, it is to be appreciated that some embodiments may include a different factoring of the operations to operations modules 36002. For example, in various embodiments, the operations modules 36002 of the operations layer 36000 may be merged, combined, omitted, factored into multiple modules, duplicated, repurposed, or the like. In various embodiments, the operations modules 36002 may be organized based on a different factoring principle, such as operations modules 36002 that each perform various sets of operations for particular types of artificial intelligence systems, and/or operations modules 36002 that each perform various sets of operations for particular use cases. In various embodiments, the operations modules 36002 may be organized for the operations layer 3600 in various ways, such as a centralized set of operations modules 36002 in a data center, a distributed set of operations modules 36002 provided in data centers in different geographic regions, and/or a decentralized set of operations modules 36002 that respectively perform some of the operations of the operations layer 36000 for various subsets of the AI convergence system of systems 31000, such as on behalf of different geographic regions and/or for different clients.

[3753] In embodiments, the operations modules 36002 include an AI system generation module 36004 that is configured and/or provided to generate and store artificial intelligence systems. For example, the AI system generation module 36004 may be configured and/or provided to generate artificial intelligence systems of different types and/or architectures. For example, the AI system generation module 36004 may generate artificial neural networks (ANNs) including various layers, each layer including a number of neurons and a set of interconnections to other neurons. The AI system generation module 36004 may determine the hyperparameters of the artificial neural networks, such as the number and types of inputs received by the artificial neural network, numbers and types of neural layers, the numbers and interconnections of neurons, the features of the neurons such as activation functions, additional layer features such as per-layer biases, and the number and types of outputs of the artificial neural network. For an artificial intelligence system including a random forest, the AI system generation module 36004 may determine the number and types of inputs to the random forest, the number of decision trees included in the random forest, the sequence of features to be processed by each decision, a manner of combining the outputs of the decision trees, and the number and types of outputs of the random forest. For an artificial intelligence system including

a reinforcement learning (RL) network, the AI system generation module 36004 may determine the number and types of inputs to the reinforcement learning network, the organization and capacity of the reinforcement learning network, an optimization policy to guide the functioning of the reinforcement learning network, and the number and types of outputs to the reinforcement learning network. In embodiments, the AI system generation module 36004 generates and stores artificial intelligence systems in advance of a need or use of the generated artificial intelligence systems, such as a pregenerated set of foundation artificial intelligence systems that are available for future tasks. In embodiments, the AI system generation module 36004 generates and stores artificial intelligence systems in response to a determination of a need for an artificial intelligence system to perform a task, such as determination that a software architecture in development could include an artificial intelligence system to perform a particular task such as data classification or pattern recognition. In embodiments, the AI system generation module 36004 generates and stores artificial intelligence systems in response to a request from another component of the AI convergence system of systems 31000, a processor, a device, a user, or the like, such as a request for an artificial neural network. In embodiments, the AI system generation module 36004 receives a set of hyperparameters describing a type of artificial intelligence system and generates the artificial intelligence system according to the received set of hyperparameters. In embodiments, the AI system generation module 36004 receives or determines a high-level description of an artificial intelligence system (*e.g.*, a convolutional neural network that is capable of detecting images of a selected size, resolution, bit depth, or the like), determines a set of hyperparameters of an artificial intelligence system that matches the high-level description, and generates the artificial intelligence system based on the determined set of hyperparameters. In embodiments, the AI system generation module 36004 generates a set of artificial intelligence systems that are capable of performing a task in different ways (*e.g.*, a set of convolutional neural networks configured to perform a same or similar type of computer vision task, wherein each convolutional neural network is configured to operation on images of a particular size, resolution, bit depth, or the like). In embodiments, the AI system generation module 36004 stores, in a data store of the AI convergence system of systems 31000 or elsewhere, the resources of a generated artificial intelligence system (*e.g.*, as a model file including a set of hyperparameters and parameters that comprise an artificial neural network). In embodiments, the AI system generation module 36004 provisionally reserves, in a data store of the AI convergence system of systems 31000 or elsewhere, storage capacity for the resources of an artificial intelligence system that may be generated in the future (*e.g.*, a reservation of data storage that may be sufficient for an artificial intelligence system of a particular type). In embodiments, the AI system generation module 36004 stores, in a data store of the AI convergence system of systems 31000 or elsewhere, resources for generating one or more artificial intelligence systems in the future (*e.g.*, an interpretable script, a compilable source code repository, an executable code module, or a declarative set of hyperparameters), wherein an occurrence of a future need or desire for an artificial intelligence system may be fulfilled using the resources stored by the AI system generation module 36004. In embodiments, the AI system

generation module 36004 curates a set of stored artificial intelligence systems (*e.g.*, reorganizing the stored artificial intelligence systems based on use or demand, discarding unused or underperforming artificial intelligence systems, and/or generating new artificial intelligence systems to replace less performant artificial intelligence systems).

[3754] In embodiments, the AI system generation module 36004 may generate one or more generative AI systems that are configured to generate content. For example, in response to a request to generate content of a particular type (*e.g.*, text, an image, a video, a sound, a data file, or the like) and/or having certain subjects (*e.g.*, one or more entities such as people or animals, one or more objects, one or more scenes such as a story, one or more events such as a timeline, and/or one or more interactions such as a conversation), the AI system generation module 36004 may select one or more generative AI systems that correspond to the requested content type and/or subjects. In embodiments, the AI system generation module 36004 generates a plurality of generative AI systems that produce content that is to be combined (*e.g.*, an audio generative AI system that generates audio such as music, speech, and/or sound effects, and a video generative AI system that generates still images and/or motion video, wherein the output of the combined AI systems includes a video with corresponding audio). In embodiments, the AI system generation module 36004 generates one or more AI systems to generate primary content (*e.g.*, speech) and one or more AI systems to generate supplemental content for the primary content (*e.g.*, captions and/or a transcript of the speech). In embodiments, the AI system generation module 36004 generates one or more AI systems to generate content (*e.g.*, an image) and one or more AI systems to generate metadata associated with the content (*e.g.*, a description of the content of the image). In embodiments, the AI system generation module 36004 generates one or more AI systems to generate content (*e.g.*, an image) and one or more AI systems to modify, extend, and/or otherwise further process the content (*e.g.*, one or more image filters applied to the image). In embodiments, the AI system generation module 36004 generates one or more AI systems to generate a description of content to be generated (*e.g.*, a narrative of a story) and one or more AI systems to generate content based on the description (*e.g.*, images, videos, and/or sounds that convey the story according to the narrative). In embodiments, the AI system generation module 36004 generates one or more AI systems to generate content (*e.g.*, an image) and one or more AI systems to review (*e.g.*, critique, rate, score, rank, analyze, compare, and/or verify) the content (*e.g.*, a discriminator network that identifies artifacts of the content that indicate its synthetic provenance). The AI system generation module 36004 may further configure the one or more generative AI systems to alter the content to address one or more issues indicated in the review; to generate replacement content that replaces initially generated content; and/or to be retrained to address issues identified in the review. In these and other scenarios, the AI system generation module 36004 may generate AI systems, including combinations of AI systems that operate independently and/or together, to plan, generate, supplement, review, and/or present content.

[3755] In embodiments, the AI system generation module 36004 may generate one or more AI agents that are configured to act in an autonomous manner. For example, the AI system

generation module 36004 may generate an AI agent that is configured to monitor a set of conditions (*e.g.*, rules, heuristics, reflexes, or the like) and to take responsive actions based on a detected fulfillment of the conditions, even if the AI agent has not received a request, instruction, prompt, or the like to perform the responsive action. In embodiments, the AI system generation module 36004 generates an AI agent that includes a policy, heuristic, objective, goal, or the like, that identifies actions that may be taken to promote and/or maintain the policy, heuristic, objective, goal, or the like, and to initiate and/or perform the actions to promote and/or maintain the policy, heuristic, objective, goal, or the like, even if the AI agent has not received a request, instruction, prompt, or the like to perform the responsive action. The policy, heuristic, objective, goal, or the like may be specified by the AI system generation module 36004; may be specified by one or more users; and/or may be received from a data source (*e.g.*, a law, regulation, or policy defined by a government, organization, the AI convergence system of systems 31000, or the like). In embodiments, the AI system generation module 36004 configures the AI agent to learn a policy, heuristic, objective, goal, or the like based on experience (*e.g.*, by monitoring an environment such as the AI convergence system of systems 31000; by monitoring the actions of a human and the consequences of such actions (*e.g.*, robotic process automation (RPA)); by monitoring the actions of AI agents, including itself, and the consequences of such actions; or the like. In embodiments, the AI system generation module 36004 configures an AI agent to reflect on one or more policies, heuristics, objectives, goals, or the like to identify synergy (*e.g.*, actions that promote two or more policies); positive feedback loops (*e.g.*, a first policy that, if achieved, positively affects or promotes a second policy); conflicts and/or negative feedback loops (*e.g.*, a first policy that, if achieved, negatively affects or interferes with a second policy). In embodiments, the AI system generation module 36004 configures an AI agent to modify a policy, heuristic, objective, goal, or the like (*e.g.*, reducing or discarding a policy that negatively affects another policy). The AI system generation module 36004 may configure the AI agent to identify, alter, and/or operate according to priorities among two or more policies, heuristics, objectives, goals, or the like (*e.g.*, determining that a first policy is of higher priority than a second policy, and preferentially selecting actions that promote the first policy over actions that promote the second policy). In embodiments, the AI system generation module 36004 configures an AI agent to communicate about policies, heuristics, objectives, goals, or the like with AI systems or other AI agents (*e.g.*, sharing and/or comparing experiences and/or learned features) and/or to adapt policies, heuristics, objectives, goals, or the like based on information received from AI systems or other AI agents. In embodiments, the AI system generation module 36004 configures an AI agent to report on its policies, heuristics, objectives, goals, or the like, and/or about actions taken and/or not taken based on policies, heuristics, objectives, goals, or the like, to one or more AI systems (*e.g.*, supervising AI systems that occasionally review the autonomous actions of an AI agent for verification, correction, auditing, logging, or the like).

[3756] In embodiments, the operations modules 36002 include an AI system training data set generation module 36006 that is configured and/or provided to generate training data sets for

training artificial intelligence systems. For example, the AI system training data set generation module 36006 may be configured and/or provided to collect data from one or more data sources for inclusion in a training data set. In embodiments, the AI system training data set generation module 36006 collects data for training data sets from one or more other modules or resources of the AI convergence system of systems 31000 (*e.g.*, from the transaction layer 35000, the network layer 37000, the data layer 38000, or the like). In embodiments, the AI system training data set generation module 36006 collects data for training data sets from other entities, facilities, or resources associated with the AI convergence system of systems 31000 (*e.g.*, from edge devices included in an industrial facility that is managed by the AI convergence system of systems 31000). In embodiments, the AI system training data set generation module 36006 collects data for training data sets from one or more external data repositories, such as news services, information repositories such as libraries, public data sources such as public databases, social networks including social media networks, communication channels, and/or the Internet. In embodiments, the AI system training data set generation module 36006 organizes and/or routes collected data into one or more training data sets. For example, the training data sets may be organized to serve the training of one or more artificial intelligence systems (*e.g.*, a first training data set for traditional artificial neural networks, a second training data set for random forests, and a third training data set for graph neural networks). The training data sets may be organized by data types (*e.g.*, a first training data set including text, a second training data set including mathematical equations or numeric measurements, and a third training data set including images). The training data sets may be organized by sources (*e.g.*, a first training data set for data collected from other modules of the AI convergence system of systems 31000, a second training data set for data collected from a local area network or a facility, a third training data set for data collected from the Internet). The training data sets may be organized by trust or reliability (*e.g.*, a first training data set of verified reliable data, a second training data set of verified unreliable data, and a third training data set of unverified data). The training data sets may be organized by provenance (*e.g.*, a first training data set of authentically generated content, a second training data set of synthetically generated content, and a third training data set of data of unknown provenance). The training data sets may be organized by use cases (*e.g.*, a first training data set including data associated with industrial manufacturing, a second training data set including data associated with healthcare, and a third training data set including data associated with a service industry). In embodiments, the AI system training data set generation module 36006 curates the training data included in each training data set (*e.g.*, normalizing, regularizing, standardizing, anonymizing, and/or cleaning the data to be included in each training data set). In embodiments, the AI system training data set generation module 36006 partitions each training data set into one or more partitions (*e.g.*, a training data set, a validation data set for periodic evaluation during training, and a test data set for use in a tiered training regimen). In embodiments, the AI system training data set generation module 36006 analyzes the training data sets for training issues (*e.g.*, underrepresentation, overrepresentation, bias, and/or inconsistency). In embodiments, the AI system training data set generation module 36006

requests and/or directs a collection and/or creation of data to address one or more training issues associated with one or more training data sets (*e.g.*, a request or instruction to collect more data related to a particular class that is underrepresented in a training data set). In embodiments, the AI system training data set generation module 36006 generates training data sets for use with a particular training regimen, such as bootstrap aggregation ("bagging") training data sets that are partitioned in different ways for combinatorial training of an AI system In embodiments, the AI system training data set generation module 36006 stores training data sets for various training uses (*e.g.*, a first training data set for training mobile devices to perform computer vision tasks, a second training data set for training workstations to perform computer vision tasks, and a third training data set for training supercomputers to perform computer vision tasks).

[3757] In embodiments, the operations modules 36002 include an AI system training data set augmentation module 36008 that is configured and/or provided to augment training data sets for training artificial intelligence systems. For example, the AI system training data set augmentation module 36008 may be configured and/or provided to generate synthetic data to augment one or more training data sets. In embodiments, the AI system training data set augmentation module 36008 generates synthetic data in response to a request or instruction from an AI system training data set generation module 36006 (*e.g.*, based on a determination that a particular class is underrepresented in a training data set, the AI system training data set augmentation module 36008 may receive some data samples of the particular class and may generate additional synthetic data samples of the class that are similar to the received data samples of the class). In embodiments, the AI system training data set augmentation module 36008 generates synthetic data to address a particular issue with a training data set (*e.g.*, in response to a determination that a training data set of images includes too few images in low-light-level environments, the AI system training data set augmentation module 36008 may synthetically modify some existing high-light-level images to simulate low-light-level conditions). In embodiments, the AI system training data set augmentation module 36008 generates synthetic data using various augmentation techniques. For example, for training data sets including text, the AI system training data set augmentation module 36008 may generate synthetic text that modifies words and/or word ordering of authentic text; that modifies passages of text by generating replacement text; that supplements the text with generated text; and/or that combines two or more authentic passages of text to generate a synthetic text. For training data sets including images, the AI training data set augmentation module 36008 may crop, mirror, scale, shear, adjust colors, increase or decrease noise, insert or remove objects, and/or distort an authentic image to produce one or more synthetic images. For training data sets including data collected from sensors connected to industrial machines, the AI training data set augmentation module 36008 may generate synthetic data based on simulation of the sensors and/or industrial machines. The AI system training data set augmentation module 36008 may evaluate synthetic data for hallmarks of synthetic data (*e.g.*, using a discriminator network of a generative adversarial network (GAN) to determine whether synthetic data can be distinguished from authentic data) and may adapt the augmentation techniques to reduce artifacts of synthetic data.

The AI system training data set augmentation module 36008 may transmit synthetic and/or augmented data to the AI system training data set generation module 36006 for inclusion in one or more training data sets.

[3758] In embodiments, the operations modules 36002 include an AI system training module 36010 that is configured and/or provided to train artificial intelligence systems. For example, the AI system training module 36010 may be configured and/or provided to train one or more artificial intelligence systems for a particular task, such as classification, pattern recognition, object detection, and/or content generation. The AI system training module 36010 may be configured to pretrain standard models for common tasks (*e.g.*, pretraining a convolutional neural network to detect generic objects, and/or pretraining a large language model to understand common features of a natural language such as English). The AI system training module 36010 may be configured to train a generated artificial intelligence system for a particular task (*e.g.*, in response to the AI system generation module 36004 receiving a request for an artificial neural network to perform a particular classification task, the AI system generation module 36004 may generate the artificial neural network with a suitable set of hyperparameters, and the AI system training module 36010 may train the generated artificial neural network to perform the classification task). The AI system training module 36010 may be configured to train a generated artificial intelligence system using a particular training data set (*e.g.*, in response to the AI system training data set generation module 36006 receiving and/or collecting data for a particular training data set, such as a corpus of text in a particular language, the AI system training module 36010 may initiate training of a large language model train using the corpus of text). The AI system training module 36010 may be configured to adapt a pretrained model to perform a particular task (*e.g.*, upon receiving a request for a large language model that can generate a specialized type of text in a natural language, the AI system training module 36010 may identify a large language model that has previously been pretrained on the natural language and may conduct additional training of the pretrained large language model using examples of the specialized type of text). The AI system training module 36010 may use one or more types of training techniques to train AI systems, such as backpropagation, zero-shot and/or few-shot learning, supervised learning, semi-supervised learning, unsupervised learning, bootstrap aggregation ("bagging") of training data sets, reinforcement learning, genetic training, or the like. The AI system training module 36010 may evaluate a performance of an AI system during training to detect progression of the training, completion of the training, mistraining (*e.g.*, loss of performance during training), and/or training problems such as overtraining, and may adapt the training according to the evaluation (*e.g.*, ending training when the AI system exhibits performance that at least satisfies a minimum performance threshold). The AI system training module 36010 may restart training to address problems (*e.g.*, reinitiating training with a different training regimen, and/or with a different training data set, to address mistraining or overtraining of an AI system). The AI system training module 36010 may test a performance of a trained AI system (*e.g.*, validating performance of the trained models using a validation data set, and/or verifying a trained performance of an AI system using a test data set). The AI system training

module 36010 may holistically allocate the resources of the AI convergence system of systems 31000 (*e.g.*, planning, scheduling, and/or adapting training of the AI systems based on performance, demand, the availability and/or costs of compute and/or storage, or the like) to meet the need to train a set of AI systems for the set of operations of the AI convergence system of systems 31000.

[3759] In embodiments, the operations modules 36002 include an AI system verifying module 36012 that is configured and/or provided to verify generated artificial intelligence systems. For example, the AI system verifying module 36012 may be configured and/or provided to test one or more trained and/or untrained AI systems based on various criteria, such as accuracy, precision, recall, F1 score, bias, consistency, efficiency, latency, or the like. For generative AI systems such as large language models and diffusion networks, the AI system verifying module 36012 may be configured to evaluate content generated by the AI system based on features such as coherence, creativity, and variance. In embodiments, the AI system verifying module 36012 compares, scores, ranks, or otherwise considers the output of multiple AI systems (*e.g.*, to determine comparative strengths and weaknesses of the respective AI systems for performing various operations, such as generating content for particular uses). In embodiments, the AI system verifying module 36012 generates recommendations for saving, using, modifying, combining, and/or discarding various AI systems based on the verifying (*e.g.*, a first recommendation for an AI system generation module 36004 to store a first AI system that is verified as performing well; a second recommendation for an AI system training module 36010 to train or retrain a second AI system that is performing inadequately; and a third recommendation for an AI system generation module 36004 to discard and/or replace an AI system that is performing poorly). In embodiments, the AI system verifying module 36012 identifies one or more deficiencies in various AI models (*e.g.*, poor performance of the AI systems on a particular type of data, or poor performance of the AI systems in satisfying a particular task) and generates recommendations for addressing the identified deficiencies (*e.g.*, recommending an AI system training data set generation module 36006 to include additional data that is associated with an underrepresented and/or inconsistently represented class; recommending an AI system training data set augmentation module 36008 to generate certain types of augmented data, or to refrain from augmenting data in a certain way, for inclusion in training data sets; and/or recommending an AI system training module 36010 to adjust a training regimen and/or scoring model to focus on a particular issue exhibited by the AI systems).

[3760] In embodiments, the operations modules 36002 include an AI system adaptation module 36014 that is configured and/or provided to adapt a set of artificial intelligence systems to perform various operations and/or tasks. The adapting may include optimizing one or more AI systems in the performance of various operations and/or tasks, such as performing with improved accuracy, precision, recall, F1 scores, bias, consistency, efficiency, latency, or the like. Herein, the term "optimizing" may mean an improvement either to a globally optimal or best state, locally optimal or best state within a given domain, improving relative to a previous state, or the like. For example, the AI system adaptation module 36014 may be configured and/or

provided to receive a request to adapt a pretrained AI system (*e.g.*, a partially trained large language model) for a specific task, device, data type, deployment, use case, or the like. For example, the AI system adaptation module 36014 may be configured to adapt an AI system that is configured to receive, process, and output a first type of data (*e.g.*, images of a first size, resolution, bit depth, or the like) so that the AI system can process a second type of data (*e.g.*, images of a second size, resolution, bit depth, or the like). The AI system adaptation module 36014 may be configured to adapt an AI system that is configured to receive, process, and output data in a first context (*e.g.*, text associated with documents of a first type) so that the AI system can process a second type of data (*e.g.*, text associated with documents of a second type). The AI system adaptation module 36014 may be configured to adapt an AI system that is configured to receive, process, and output data in a first context (*e.g.*, data received from sensors in an industrial environment) so that the AI system can process data in a second context (*e.g.*, data received from sensors in a healthcare environment). The AI system adaptation module 36014 may be configured to adapt an AI system that is configured to receive, process, and output data on a first type of device (*e.g.*, a workstation including a graphics processing unit (GPU)) so that the AI system can process data on a second type of device (*e.g.*, an embedded device featuring only a traditional central processing unit (CPU) and/or a field-programmable gate array (FPGA)). The AI system adaptation module 36014 may be configured to adapt an AI system that is configured to receive, process, and output data to perform a first task on a data set (*e.g.*, data classification) so that the AI system can process data on a second task on the same data set (*e.g.*, pattern detection). In view of these and other types of adaptations, the AI system adaptation module 36014 may identify one or more AI systems stored by an AI system generation module 36004 and one or more adaptations of the one or more AI systems that may adapt the AI system according to a request or instruction. The adaptation may include preprocessing an input to an AI system to alter the input received by the AI system, such as adding a preprocessing denoising filter to the input of an AI system to reduce noise and improve the processing, output, and performance of the denoised data. The adaptation may include altering an AI system to receive a different type of input, such as adapting a convolutional neural network to receive and process images of a different size, resolution, color depth, or the like than the images on which the convolutional neural network was previously trained. The adaptation may include reconfiguring an architecture of an AI system, such as adding one or more architectural features (*e.g.*, a long short-term memory (LSTM) unit, a gated recurrence unit (GRU), a transformer layer, a filter layer, a pooling layer, or the like), removing one or more architectural features, replacing one or more architectural features with a different architectural feature, or the like. The adaptation may include altering an AI system to process data differently, such as appending one or more fine-tuning layers to a pretrained artificial neural network to provide additional processing for a specific set of data. The adaptation may include altering an AI system to generate different output, such as adapting an artificial neural network that processes input to select a class from a first set of classes, such that the artificial neural network performs the same or similar processing of the input to select a class from among a second,

different set of classes. The adaption may include postprocessing an output generated by the AI system to alter an output of the AI system, such as adding a postprocessing denoising feature to reduce noise in content generated by a generative AI system. The adaptation may include selectively limiting a processing of input by the AI system to a subset of input for which the AI system is determined to perform well. The adaptation may include requesting a continued training or retraining of an AI system by the AI system training module 36010, comparing a performance of the additionally trained AI system with the original AI system, and determining one or more adaptations of the AI system based on the comparison. The adaptation may include altering a set of resources provided to the AI system (*e.g.*, altering an amount of memory allocated for the AI system, an amount or type of computation performed by or for the AI system, such as to reduce latency of a time-sensitive model and/or a context window size of a time series model or a large language model to improve memory and/or performance). In embodiments, the AI system adaptation module 36014 may consider a set of possible adaptations of an AI system for addressing one or more issues or problems of the AI system (*e.g.*, poor accuracy, poor consistency, poor coherence, high latency, or the like), comparing the predicted and/or determined effects of various adaptations and combinations thereof of the AI system, selecting one or more adaptations to apply to the AI system based on the comparison, and adapting the AI system based on the selection.

[3761] In embodiments, the operations modules 36002 include an AI system aggregation module 36016 that is configured and/or provided to aggregate artificial intelligence systems. The AI system aggregation module may combine two or more AI systems into a hybrid AI system that combines the heterogeneous processing capabilities of AI systems with different architectures. For example, the AI system aggregation module 36016 may combine an AI system with one or more other AI systems to produce a hybrid system that generates aggregated and improved output as compared with the individual AI systems (*e.g.*, a "boosted" ensemble of inadequately performing AI systems, from which a consensus output may be derived that presents higher-performance output than from any of the individual AI systems). The aggregation may include adding an AI system to a set of AI systems, each of which may be determined to perform well over a subset of input, wherein a particular input to the set of AI systems may be selectively processed by a particular AI system that is recognized to perform well over the subset of input that includes the particular input. In embodiments, the AI system aggregation module combines two or more AI systems into an ensemble AI system that features a collection of homogeneous or heterogeneous AI systems that together generate an output (*e.g.*, by consensus). In embodiments, the AI system aggregation module combines two or more AI systems into a sequence or chain of AI systems, wherein an output of a first AI system is received as input by a second AI system. The aggregation may include connecting at least one output of a first AI system to at least one input of a second AI system (*e.g.*, a chain-of-processing generative system in which data generated by a generative AI system is refined, expanded, reformatted, verified, analyzed, augmented, edited, or otherwise further processed by a second AI system). In some embodiments, the AI system aggregation module 36016 generates

a swarm of AI systems that operate independently of one another but collectively to achieve a task, such as a set of AI agents that are configured to operate individually but that interact with other AI agents and shared resources to achieve the task. In some embodiments, the AI system aggregation module 36016 aggregates AI systems by inserting at least a portion of a first AI system into a second AI system (*e.g.*, inserting one or more layers of a classifier network between two layers of a convolutional neural network to inform further processing of the convolutional neural network based on the classification of the partially-processed input data). The aggregation may include conditioning the processing of data by a first AI system based on the processing of the data by a second AI system (*e.g.*, partially generating content by a generative AI system, and then conditioning a completion of the generated content on an initial assessment of the partially generated content by a second AI system, such as a discriminator network). The aggregation may include combining a first AI system to select, design, and/or validate a processing of data by a combination of one or more other AI systems (*e.g.*, an expert determining AI system that determines, from a set of AI systems that are respectively experts in various domains, one or more AI systems that are to be invoked to process input data that is relevant to one or more domains). The aggregation may include attaching a first AI system as an administrator, regulator, controller, or the like of a second AI system (*e.g.*, a content moderation AI system that determines whether a generative AI system is permitted to process certain kinds of prompts and/or generate certain kinds of data, and that controls the processing of the generative AI system based on the determined permission). In embodiments, the AI system aggregation module 36016 identifies one or more aggregations of pregenerated AI systems for various contexts (*e.g.*, combinations of pregenerated AI systems that may be specialized and/or proficient at certain types of processing, such as generating certain forms of content, generating classifications above a classification threshold, and/or completing processing within a latency window). In embodiments, the AI system aggregation module 36016 generates and stores one or more descriptions of techniques for selecting and aggregating AI systems for various contexts (*e.g.*, an interpretable script for selecting and combining AI systems to generate chain-of-thought reasoning for various contexts), wherein a particular task or invocation of the AI systems may be fulfilled by applying one of the aggregation techniques generated by the AI system aggregation module 36016 to select and aggregate AI systems for the indicated context. Such aggregating may be advantageous, for example, for *ad-hoc* aggregations of AI systems for unusual, specialized, and/or previously unseen processing tasks (*e.g.*, a request to aggregate AI systems to generate a hybrid large language model for execution on a particular device and/or over a particular type of data).

[3762] In embodiments, the operations modules 36002 include an AI system deployment module 36018 that is configured and/or provided to deploy artificial intelligence systems. For example, the AI system deployment module 36018 may be configured and/or provided to deploy one or more AI systems generated by the AI system generation module 36004 to one or more devices, such as a set of workstations, servers, or mobile devices. For example, the AI system deployment module 36018 may receive a request to deploy a large language model to a device

having a certain set of computational resources, such as processing cores operating at a defined clock rate, memory, and storage. The AI system deployment module 36018 may review a set of AI systems generated by the AI system generation module 36004 to identify a suitable large language model in view of the computational resources of the device. The AI system deployment module 36018 may select the large language model for deployment, determine a location of the resources of the selected large language model, package the resources of the large language model for deployment (*e.g.*, retrieving and compressing a description of the architecture of the large language model and a set of parameters of the large language model), and transmit the packaged resources for deployment on the device. In embodiments, the AI system deployment module 36018 is configured to deploy an AI system for a particular type of task, such as a particular classification task, pattern recognition task, computer vision task, or content generation task. The AI system deployment module 36018 may select a particular AI system from the set of AI systems generated by the AI system generation module 36004 to identify an AI system that is suitable for the identified task. The AI system deployment module 36018 may package the identified AI system for deployment to the device and/or environment for the identified task, and may transmit the packaged AI system to the device and/or environment. In embodiments, the AI system deployment module 36018 is configured to deploy an AI system to include a particular feature set, such as a large language model that supports a particular natural language and features a particular context window size, and may deploy a pregenerated or adapted AI system to fulfill the deployment that features the indicated feature set. In embodiments, the AI system deployment module 36018 is configured to deploy an AI system for execution in a particular execution environment, such as within a defined memory space, using a particular AI framework such as TensorFlow or Torch, and/or using a particular set of hardware that is available to the device, such as a particular graphics processing unit (GPU), neural processing unit (NPU), tensor processing unit (TPU), or the like. In embodiments, the AI system deployment module 36018 is configured to adapt an AI system for deployment to a particular device and/or context (*e.g.*, identifying an AI system that is suitable for a particular task but that is based on a TensorFlow environment, adapting the AI system for execution in a Torch environment, and transmitting a packaged version of the Torch-based AI system to a device featuring a Torch execution environment).To achieve the adapting for the deployment, the AI system deployment module 36018 may transmit a request to the AI system adaptation module 36014 to adapt a stored AI system in view of the details of a particular deployment, may receive an adapted AI system from the AI system adaptation module 36014 based on the request, and may package and deploy the adapted AI system to satisfy the deployment. In embodiments, the AI system deployment module 36018 may transmit the resources of one or more AI systems to one or more devices that are intended to execute the AI systems. In embodiments, the AI system deployment module 36018 may transmit the resources of an AI system to two or more devices for redundant and/or distributed execution of the AI system (*e.g.*, as a primary system and a failover system, as two or more devices that provide scalable capacity for execution of the AI systems, as a distributed system in which a first system executes a first

AI system that transmits an output to a second device for input to a second AI system, and/or as a federated system in which respective devices execute a portion of the AI system). In embodiments, the AI system deployment module 36018 may deploy an AI system within the AI convergence system of systems 31000, such as by reserving resources (*e.g.*, processing capacity, storage, one or more dedicated devices, or the like) for the execution of an AI system to serve a particular context, and/or by transmitting the resources of an AI system (*e.g.*, the parameters of an artificial neural network) to one or more devices within the AI system deployment module 36018. In embodiments, the AI system deployment module 36018 may deploy an AI system by transmitting an interface to the AI system to one or more devices, such as end-user devices that are configured to collect input, transmit input through the interface to one or more AI systems executed on other devices, and/or receive and present output received from one or more AI systems. For example, the AI system deployment module 36018 may retrieve, generate, and/or transmit an application programming interface (API) to the one or more devices in order to interconnect the one or more devices with the AI system. The AI system deployment module 36018 may reserve one or more communication endpoints to enable one or more devices to communicate with the AI system. The AI system deployment module 36018 may configure permissions and/or security tokens to enable one or more external devices to communicate securely with one or more AI systems.

[3763] In embodiments, the operations modules 36002 include an AI system invocation module 36020 that is configured and/or provided to invoke artificial intelligence systems to perform various operations and/or tasks. For example, the AI system invocation module 36020 may be configured and/or provided to receive one or more requests to perform a task. The request may be initiated by another component of the AI convergence system of systems 31000; by a device, software process, or entity that is served by the AI convergence system of systems 31000; and/or by an external device, software process, or entity. The request may be spontaneously initiated by the AI system invocation module 36020 (*e.g.*, based on a set of conditions monitored by the AI system invocation module 36020, wherein fulfillment of a condition instructs the AI system invocation module 36020 to invoke an AI system). The request may indicate one or more AI systems that are to be invoked to execute the request. Alternatively or additionally, the request may indicate one or more tasks, and the AI system invocation module 36020 may determine one or more AI systems that may be invoked to fulfill the task. In some cases, the request may specify a request that includes one or more non-AI systems (*e.g.*, a hardware component or a traditional software component, such as a graphics rendering or simulation system), and the AI system invocation module 36020 may identify one or more AI systems that may be invoked to perform the task in place of the one or more non-AI systems. In embodiments, the AI system invocation module 36020 verifies a permission and/or security of a request to invoke an AI system before initiating the invocation of the AI system. In embodiments, the AI system invocation module 36020 initiates the invocation of the AI system in response to the request (*e.g.*, by instantiating the AI system, by transmitting input to the AI system, and/or by securing the resources for the invocation of the AI system). In embodiments,

the AI system invocation module 36020 notifies a requester of the status of a request to invoke an AI system (*e.g.*, indicating a status, progress, estimated completion time, and/or outcomes of the processing of the request by the AI systems). In embodiments, the AI system invocation module 36020 mediates communication between the AI system and the requester (*e.g.*, by transmitting the request and/or input received from the requester and/or another source to the AI system to invoke the AI system for the request, and/or by transmitting one or more outputs of the AI system to the requester and/or another destination to fulfill the request). In embodiments, the AI system invocation module 36020 translates the request and/or one or more inputs received from the requester and/or another source for intake and processing by the AI system, and/or translates one or more output of the AI system for transmission to the requester and/or another destination).

[3764] In embodiments, the AI system invocation module 36020 may invoke one or more generative AI systems that are configured to generate content in response to a request. For example, in response to a request to generate content of a particular type (*e.g.*, text, an image, a video, a sound, a data file, or the like) and/or having certain subjects (*e.g.*, one or more entities such as people or animals, one or more objects, one or more scenes such as a story, one or more events such as a timeline, and/or one or more interactions such as a conversation), the AI system invocation module 36020 may select and invoke one or more generative AI systems that correspond to the requested content type and/or subjects. In embodiments, the AI system invocation module 36020 invokes a plurality of generative AI systems that produce content that is to be combined (*e.g.*, an audio generative AI system that generates audio such as music, speech, and/or sound effects, and a video generative AI system that generates still images and/or motion video, wherein the output of the combined AI systems includes a video with corresponding audio). In embodiments, the AI system invocation module 36020 invokes one or more AI systems to generate primary content (*e.g.*, speech) and one or more AI systems to generate supplemental content for the primary content (*e.g.*, captions and/or a transcript of the speech). In embodiments, the AI system invocation module 36020 invokes one or more AI systems to generate content (*e.g.*, an image) and one or more AI systems to generate metadata associated with the content (*e.g.*, a description of the content of the image). In embodiments, the AI system invocation module 36020 invokes one or more AI systems to generate content (*e.g.*, an image) and one or more AI systems to modify, extend, and/or otherwise further process the content (*e.g.*, one or more image filters applied to the image). In embodiments, the AI system invocation module 36020 invokes one or more AI systems to generate a description of content to be generated (*e.g.*, a narrative of a story) and one or more AI systems to generate content based on the description (*e.g.*, images, videos, and/or sounds that convey the story according to the narrative). In embodiments, the AI system invocation module 36020 invokes one or more AI systems to generate content (*e.g.*, an image) and one or more AI systems to review (*e.g.*, critique, rate, score, rank, analyze, compare, and/or verify) the content (*e.g.*, a discriminator network that identifies artifacts of the content that indicate its synthetic provenance). Based on the review, the AI system invocation module 36020 may invoke one or more AI systems to alter

the generated content to address one or more issues indicated in in the review; to generate replacement content that replaces initially generated content; and/or to retrain the generative AI systems to address issues identified in the review. In these and other scenarios, the AI system invocation module 36020 may invoke AI systems, including combinations of AI systems that operate independently and/or together, to plan, generate, supplement, review, and/or present content.

[3765] In embodiments, the operations modules 36002 include an AI system data set orchestration module 36022 that is configured and/or provided to orchestrate a set of artificial intelligence systems to perform various operations and/or tasks. For example, the AI system orchestration module 36022 may be configured and/or provided to orchestrate operation of at least a portion of the set of AI systems of the AI convergence system of systems 31000 to fulfill a set of requests. In embodiments, the AI system orchestration module 36022 interconnects two or more AI systems to perform a particular task (*e.g.*, interconnecting the output of a first AI system, such as a pattern recognition system, to the input of a second AI system, such as a large language model that can generate summaries and/or descriptions of the detected patterns). In embodiments, the AI system orchestration module 36022 performs scheduling of the invocation of AI systems (*e.g.*, based on processing loads or queues and/or throughput of the AI systems and/or the urgency and/or priority of the requests to invoke the AI systems). In embodiments, the AI system orchestration module 36022 performs load-balancing of the requests to invoke AI systems for various tasks (*e.g.*, by monitoring a processing load and/or processing queue of each of the AI systems, and by routing requests to AI systems that have available capacity based on the load-balancing). In embodiments, the AI system orchestration module 36022 maps or remaps requested tasks to AI systems based on load-balancing, scheduling, or the like (*e.g.*, remapping a task from a first AI system that is overloaded to a second AI system that is capable of equivalently performing the task and that has available capacity). In embodiments, the AI system orchestration module 36022 adjusts allocations, provisions, and/or reservations of resources of the AI convergence system of systems to enable the AI systems to fulfill the requested invocations (*e.g.*, by acquiring more computational capacity, storage, devices such as servers or processing cores, or the like to handle an increased number of requests and/or an increased computational load of the requests, and/or by reallocating computational capacity, storage, devices such as servers or processing cores, or the like to handle a decreased number of requests and/or a decreased computational load of the requests). In embodiments, the AI system orchestration module 36022 plans and/or manages the acquisition, retention, location, installation, use, maintenance, reallocation, and/or decommissioning of the resources of the AI convergence system of systems 31000 in view of future scheduled and/or predicted demands, volumes of requests, and/or computational loads. In embodiments, the AI system orchestration module 36022 reorganizes the resources of the AI convergence system of systems 31000 based on changes in the demand for processing by the AI systems (*e.g.*, based on new types of requests that the AI systems are capable of handling, such as low-latency AI system processing requests in particular real-time contexts and/or the processing of new types of data, such as

LIDAR point-cloud data). In embodiments, the AI system orchestration module 36022 reorganizes the resources of the AI convergence system of systems 31000 based on changes in the available and/or feasible AI systems (*e.g.*, allocating increased computation and/or storage for large language models and hybrid systems of increased size and/or computational complexity).

[3766] In embodiments, the AI system orchestration module 36022 may include routing data and/or interactions between and/or among data sources, clients, AI systems, hardware and/or software components, or the like. In embodiments, the AI system orchestration module 36022 determines and implements a route between a source of a request or task (*e.g.*, a client, user, requesting device, or the like) to one or more AI systems that are capable of fulfilling the request and/or performing the task (*e.g.*, AI systems that exhibit capabilities that correspond to requirements of the request and/or task). the AI system orchestration module 36022 determines and implements a route from a first AI system (*e.g.*, a generative AI system that outputs generated content) as input to a second AI system (*e.g.*, a reviewing AI system that reviews content generated by the generative AI system). In embodiments, the AI system orchestration module 36022 determines and implements a route between a data source of data (*e.g.*, a sensor, a database, a camera, or the like) and one or more AI systems that are configured to process the data (*e.g.*, a convolutional neural network that is configured to analyze images generated by camera). In embodiments, the AI system orchestration module 36022 determines and implements a route between one or more AI systems that generate output (*e.g.*, a classifier network) and a consumer of the output (*e.g.*, a client, database, or another AI system that stores, uses, or otherwise consumes the output). In embodiments, the AI system orchestration module 36022 partitions data into portions and determines and implements routes between a source of the data and a plurality of AI systems that respectively process a portion of the data (*e.g.*, two or more AI systems that operate in parallel and/or in tandem), which may reduce latency of processing the data. In embodiments, the AI system orchestration module 36022 routes data to each of two or more AI systems, each of which may perform a same or similar type of processing (*e.g.*, redundant processing of the data by redundant AI systems) and/or different types of processing (*e.g.*, performing different tasks on the data, such as a first task of verifying the data and a second task of supplementing the data). In embodiments, the AI system orchestration module 36022 determines and implements routes between and/or among AI systems to enable interoperation to complete the task (*e.g.*, a communication path between two or more AI agents that operate independently to perform different portions of a task, such as a transaction negotiating AI agent that identifies and negotiates transactions and a transaction execution AI agent that generates and executes smart contracts to complete the transactions). In embodiments, the AI system orchestration module 36022 determines and implements routes between and/or among AI systems based on a set of available routes, such as a set of candidate communication paths by which the AI systems may communicate (*e.g.*, various network paths in a wide-area network, and/or different communication modalities such as Bluetooth, Wi-Fi, cellular, infrared, wired connections such as Ethernet, or the like). In embodiments, the AI

system orchestration module 36022 determines and implements routes based on an evaluation of the requirements of a request and/or task (*e.g.*, a priority, a deadline, an amount of data, a budget, a security consideration, or the like) and corresponding features of candidate routes (*e.g.*, throughput, availability, cost, reliability, security, or the like, of various communication modalities such as Bluetooth, Wi-Fi, cellular, infrared, wired connections such as Ethernet, or the like). In embodiments, the AI system orchestration module 36022 determines and implements routes between and/or among AI systems by acquiring, purchasing, developing, reserving, provisioning, dedicating, and/or allocating one or more routes or the like (*e.g.*, reserving a communication path between two or more AI systems that are intended to communicate with high performance).

[3767] In embodiments, the operations modules 36002 include an AI system monitoring module 36024 that is configured and/or provided to analyze the performance of artificial intelligence systems while performing various operations and/or tasks. For example, the AI system monitoring module 36024 may be configured and/or provided to analyze a performance of one or more AI systems of the AI convergence system of systems 31000 to measure and compare various performance metrics, such as accuracy, precision, recall, F1 score, bias, consistency, efficiency, latency, or the like. The AI system monitoring module 36024 may perform such evaluation using training data on which an AI system was previously trained, new training data that the AI system has not previously processed (*e.g.*, a test data set), live data that is associated with a deployment of the AI system, and/or synthetic data generated for the monitoring. The AI system monitoring module 36024 may perform such evaluation using data that is the same as or similar to data that the AI system was deployed to process and/or based on new data that the AI system was not deployed to process (*e.g.*, based on new data types that are different than those associated with the training and/or initial deployment of the AI system). The AI system monitoring module 36024 may compare the performance of an AI system at a current time with a performance of the same or similar AI system at a previous time (*e.g.*, at a time of completion of training and/or deployment). The AI system monitoring module 36024 may compare the performance of an AI system operating under a first set of conditions (*e.g.*, on a first device and/or with a first set of computational resources) with a performance of the same or similar AI system under a second set of conditions (*e.g.*, on a second device and/or with a second set of computational resources). The AI system monitoring module 36024 may compare the performance of an AI system at a current time with a simulated performance of the AI system at the current time (*e.g.*, a digital twin of the AI system). The AI system monitoring module 36024 may compare the performance of an AI system on a first data set (*e.g.*, a first set of images depicting items of a first class) with the performance of the AI system on a second data set (*e.g.*, a second set of images depicting items of a second class) The AI system monitoring module 36024 may compare the performance of an AI system with the performance of another AI system of the same or similar type (*e.g.*, comparing a performance of an artificial neural network classifier trained with a first training data set with a performance of an artificial neural network classifier trained with a second training data set). The AI system monitoring

module 36024 may compare the performance of an AI system with the performance of another AI system of a different type (*e.g.*, comparing a performance of an artificial neural network classifier on a data set with a performance of a Bayesian classifier on the same data set). In embodiments, the AI system monitoring module 36024 performs comparisons using two or more performance metrics (*e.g.*, accuracy, precision, and recall) and, optionally, based on relative priorities of the performance metrics (*e.g.*, associating different relative weights and/or penalties to measurements of accuracy, precision, and recall). In embodiments, the AI system monitoring module 36024 tracks changes in the performance metrics over time and identifies trends in the performance metrics (*e.g.*, the development of AI system "drift" due to trends in the features of the data processed by the AI system, changes in the execution of the AI system, and/or the continued training of the AI system). In embodiments, the AI system monitoring module 36024 invokes a first AI system to evaluate a second AI system, and receives, from the first AI system, an indication of the performance of the second AI system. In embodiments, the AI system monitoring module 36024 monitors each AI system according to a schedule (*e.g.*, periodically testing the AI system and recording performance measurements for each period). In embodiments, the AI system monitoring module 36024 collects information from one or more other components or systems that are associated with an AI system (*e.g.*, a sensor whose functionality depends upon the performance of an AI system) and determines a performance measurement of the AI system based on the performance of the other components or systems. In embodiments, the AI system monitoring module 36024 solicits, collects, and/or receives information from one or more entities that are associated with an AI system (*e.g.*, feedback from users or clients) and determines a performance of an AI system based on the solicited, collected, and/or received information. In embodiments, the AI system monitoring module 36024 monitors each AI system in response to a detected event or condition (*e.g.*, upon receiving an indication that a performance of an AI system may have changed, such as when an execution context of the AI system changes, or when another system detects a change in a performance of the AI system). In embodiments, the AI system monitoring module 36024 records measurements, changes, trends, and the like of the AI systems. In embodiments, the AI system monitoring module 36024 stores the measurements, changes, trends, or the like in one or more data stores or repositories, such as a database or a performance log. In embodiments, the AI system monitoring module 36024 stores the measurements, changes, trends, or the like, such as to an AI system analyzing module 36028 of the operations modules 36002.

[3768] In embodiments, the operations modules 36002 include an AI system analyzing module 36026 that analyzes the performance of the AI systems. For example, the AI system analyzing module 36026 may be configured and/or provided to analyze the performance metrics collected stored by the AI system monitoring module 36024 for various AI systems. In embodiments, in response to a detected or determined change in a performance of an AI system, the AI system analyzing module 36026 initiates a further evaluation of the AI system to determine a cause for the change in the performance (*e.g.*, a change in the data provided as input to the AI system; a change in an execution environment of the AI system; and/or a change in a performance of the

AI system due to continued training). The AI system analyzing module 36026 may use a variety of techniques to determine a cause of a change in performance, such as simulation of the AI system by one or more digital twins, Monte Carlo analysis based on sampling the effects of changes to the operation of the AI system, and/or root cause analysis that involves a determination of causal relationships among various elements of the AI system and the AI convergence system of systems 31000. In embodiments, in response to a detected or determined change in a performance of an AI system, the AI system analyzing module 36026 changes an execution environment of the AI system to improve performance (*e.g.*, increasing computational resources allocated to the AI system, such as computational load, memory, and/or storage to improve performance). In embodiments, in response to a detected or determined change in a performance of an AI system, the AI system analyzing module 36026 adjusts an allocation of AI systems of the AI convergence system of systems 31000 to the requests for invocations of the AI systems (*e.g.*, optionally by interoperating with the AI system orchestration module 36022) such that requests are handled by AI systems that are capable of meeting performance requirements of the requests. In embodiments, in response to a detected or determined change in a performance of an AI system, the AI system analyzing module 36026 initiates a redevelopment of the AI system by an AI system redevelopment module 36034 (*e.g.*, a retraining and/or replacement of the AI system with another AI system).

[3769] In embodiments, the operations modules 36002 include an AI system updating module 36028 that is configured and/or provided to update deployed artificial intelligence systems. In embodiments, in response to a detected or determined change in a performance of an AI system, the AI system updating module 36028 causes input to the AI system to be changed (*e.g.*, reformatting, annotating, curating, editing, or otherwise changing the input to the AI system to improve the performance of the AI system). In embodiments, in response to a detected or determined change in a performance of an AI system, the AI system updating module 36028 causes an architecture of an AI system to be changed to improve the performance of the AI system (*e.g.*, increasing a context window size of an AI system to process more data, and/or increasing a number of layers of the AI system to increase learning capacity). In embodiments, in response to a detected or determined change in a performance of an AI system, the AI system updating module 36028 causes output of the AI system to be changed (*e.g.*, reformatting, annotating, curating, editing, or otherwise changing the output to the AI system to improve the performance of the AI system). In embodiments, the AI system updating module 36028 experimentally evaluates potential updates to an AI system to determine effects of the updates on the performance of the AI system (*e.g.*, experimentally increasing the computational resources allocated to AI system and measuring an effect of the increased computational resources on one or more performance metrics of the AI system). In embodiments, the AI system updating module 36028 experimentally adjusts the inputs and/or processing of an AI system, or of a simulation of the AI system (*e.g.*, of a digital twin), to determine the effect of the adjustments on the AI system. If the adjustments result in improved performance of the AI system, the AI system updating module 36028 may apply and/or commit the update to the AI

system to realize and/or maintain the improvement in performance. In embodiments, in response to a detected or determined improvement in a performance of an AI system, the AI system updating module 36028 applies one or more features of the AI system that is associated with the improved performance to at least one other AI system, thereby enabling the at least one other AI system to exhibit a same or similar performance improvement.

[3770] In embodiments, the operations modules 36002 include an AI system governance module 36030 that is configured and/or provided to maintain governance of deployed artificial intelligence systems. For example, the AI system governance module 36030 may be configured and/or provided to govern one or more AI systems based on legal, social, practical, and/or regulatory policies (*e.g.*, policies relating to truthfulness and/or avoidance of harm). In embodiments, the AI system governance module 36030 monitors invocations of one or more AI systems to detect and prevent unauthorized, unintended, and/or harmful uses of the AI systems (*e.g.*, requests that are not permitted or that may contribute to harm and/or the violation of policies). In embodiments, the AI system governance module 36030 monitors input to one or more AI systems to detect and prevent unauthorized, unintended, and/or harmful inputs to the AI systems (*e.g.*, inputs that include or are associated with objectionable and/or harmful content). In embodiments, the AI system governance module 36030 monitors the processing of one or more AI systems to detect and prevent unauthorized, unintended, and/or harmful processing by the AI systems (*e.g.*, the avoidance of reasoning that may be considered deceptive or illegal). In embodiments, the AI system governance module 36030 monitors output of one or more AI systems to detect and prevent unauthorized, unintended, and/or harmful outputs of the AI systems (*e.g.*, outputs that include or are associated with objectionable and/or harmful content). In embodiments, the AI system governance module 36030 monitors uses of the output of the AI systems by requesters and/or systems to determine unauthorized, unintended, and/or harmful uses of the AI systems (*e.g.*, malicious use of the processing capabilities and/or output of the AI systems). In embodiments, the AI system governance module 36030 responds to detected requests, inputs, processing, outputs, and/or uses of the AI systems in various ways, such as modifying, censoring, editing, redacting, and/or blocking a request, input, processing, output, and/or use of the AI system. In embodiments, the AI system governance module 36030 receives, generates, adjusts, and/or reports policies based on the monitoring and governance, such as generating guidelines and/or tests to evaluate the requests, inputs, processing, outputs, and/or uses of the AI systems that may be associated with malicious, unauthorized, unintended, and/or harmful content or activities. In embodiments, the AI system governance module 36030 generates, adapts, and/or monitors one or more governance mechanisms applied to an AI system, such as monitoring an effectiveness of a rule set applied to the requests and/or inputs of an AI system to ensure that the processing and/or outputs of the AI system do not include unauthorized, unintended, and/or harmful content. In embodiments, the AI system governance module 36030 is configured to detect attempts to circumvent, subvert, remove, or otherwise avoid governance mechanisms applied to one or more AI systems (*e.g.*, attempts to present input that is unauthorized, unintended, and/or harmful, but that is disguised to avoid detection by a

governance rule set) and to update the policies and/or governance mechanisms of the AI systems to detect, reduce, alleviate, prevent, report, and/or penalize such avoidance. In embodiments, the AI system governance module 36030 is configured to detect attempts to violate the security, integrity, and/or availability of the AI systems (*e.g.*, denial-of-service attacks, AI system "poisoning" attacks, and/or AI system exploration, eavesdropping, or data exfiltration) and to take steps to reduce, alleviate, prevent, report, and/or penalize such attacks.

[3771] In embodiments, the AI system governance module 36030 configures and/or provides supervision of one or more AI systems. For example, the AI systems may include one or more generative AI systems, and the AI system governance module 36030 may supervise the generation of content to promote positive features (*e.g.*, quality, accuracy, coherence, or the like) and/or to reduce or prevent negative features (*e.g.*, inaccuracy, incoherence, harmfulness, or the like). The AI system governance module 36030 may apply such supervision to the inputs to the generative AI systems (*e.g.*, prompts and/or content sources provided as input), to the processing of the generative AI systems (*e.g.*, to particular forms of information and/or reasoning used by the generative AI system), to the output of the generative AI systems (*e.g.*, to content generated based on prompts and/or input), and/or to the uses of the generative AI systems (*e.g.*, to the purposes for which generated content is used). The AI system governance module 36030 may apply such supervision based on rules, guidelines, heuristics, principles, comparisons with positive and negative content and/or processing, or the like. The AI system governance module 36030 may apply such supervision by generating and/or applying a supervising AI system to another AI system (*e.g.*, a classifier network that classifies the output of a generative AI system as potentially negative). AI system governance module 36030 may apply such supervision with input from human reviewers (*e.g.*, the AI system governance module 36030 may involve humans for spot-checking content, for scoring or rating content, for reviewing content generated by the AI systems that has been flagged as potentially negative, and/or for responding to reports of negative content generated by the AI systems). The AI system governance module 36030 may use the results of automated and/or human supervision to modify generated content; to modify the AI systems (*e.g.*, training, retraining, and/or replacing the AI systems); to create, modify, and/or refine the supervision (*e.g.*, modifying the rules, heuristics, principles, or the like to prevent the generation of further negative content by the AI systems); to create, modify, and/or refine supervising AI systems that are connected to other AI systems (*e.g.*, training, retraining, and/or replacing a supervising AI system with an improved supervising AI system); and/or to generate reports about the AI systems (*e.g.*, reports of the prompts, performance, types, and/or uses of content generated by the AI systems).

[3772] In embodiments, the operations modules 36002 include an AI system redevelopment module 36032 that is configured and/or provided to redevelop deployed artificial intelligence systems. For example, in response to the AI system analyzing module 36026 detecting reduced performance of an AI system, the AI system redevelopment module 36032 may be configured and/or provided to initiate retraining of the AI system using additional training data (*e.g.*, additional synthetic training data generated by the AI system training data set augmentation

module 36008 corresponding to new data that the AI system has not previously been trained to receive and process). In embodiments, in response to the AI system analyzing module 36026 detecting reduced performance of an AI system, the AI system redevelopment module 36032 causes the AI system training module 36010 to train a replacement AI system, and causes the AI system verifying module 36012 to verify that the replacement AI system addresses the reduced performance of the AI system. Based on such verifying, the AI system redevelopment module 36032 may cause the AI system deployment module 36018 to deploy the replacement AI system to substitute for the original AI system. In embodiments, the AI system redevelopment module 36032 may experimentally task the AI system training module 36010 with developing candidate AI systems that might replace an existing AI system. As compared with an existing AI system, a candidate AI system may be trained on different training data, with a different training regimen, with a different AI system type and/or architecture. A candidate AI system may be trained in a same or similar manner as an existing AI system, but may result in different and possibly improved performance due to the stochastic nature of AI system training. The AI system redevelopment module 36032 may initiate the redevelopment and/or experimental testing of candidate AI systems in response to a change of priority of tasks related to an AI system (*e.g.*, an updated indication that a particular type of error is more harmful and/or more common than was previously initiated). The AI system redevelopment module 36032 may initiate the redevelopment and/or experimental testing of candidate AI systems in response to a change in the resources of the AI convergence system of systems 31000 (*e.g.*, increased computational capacity may enable a candidate AI system with greater learning capacity to outperform an existing AI system). The AI system redevelopment module 36032 may initiate the redevelopment and/or experimental testing of candidate AI systems in response to advances in AI systems research or technology (*e.g.*, a development of new model types, a new training regimen, new types of AI system hardware and/or software, or scientific discoveries relating to AI system performance and/or performance optimization techniques). Based on a candidate AI system exhibiting improved performance relative to an existing AI system, the AI system redevelopment module 36032 may initiate a deployment of the candidate AI system to replace the existing AI system.

[3773] In embodiments, the operations modules 36002 include an AI system logging module 36034 that is configured and/or provided to log the activities of artificial intelligence systems and/or operations modules 36002 while performing various operations and/or tasks. In embodiments, the AI system logging module 36034 is configured and/or provided to detect and log the operations of the AI system generation module 36004 in generating and/or storing new AI systems. In embodiments, the AI system logging module 36034 is configured and/or provided to detect and log the operations of the AI system training data set generation module 36006 in generating training data sets for the training of various AI systems. In embodiments, the AI system logging module 36034 is configured and/or provided to detect and log the operations of the training data set augmentation module 36008 in the number, kinds, sources, techniques, and examples of synthetic data generated for various training data sets, as well as the

circumstances for such augmentation (*e.g.*, the issues with a training data set that synthetic data was generated to address). In embodiments, the AI system logging module 36034 is configured and/or provided to detect and log the operations of the AI system training module 36010 in selecting, initiating, monitoring, validating, and completing the training of the AI systems of the AI convergence system of systems 31000, as well as the resulting performance of the trained AI systems (*e.g.*, the performance, accuracy, recall, F1 score, bias, consistency, efficiency, and/or latency of respective trained AI systems). In embodiments, the AI system logging module 36034 is configured and/or provided to detect and log the operations of the AI system verifying module 36012 in verifying the generated AI systems (*e.g.*, measurements of the performance of trained AI models on test data sets). In embodiments, the AI system logging module 36034 is configured and/or provided to detect and log the operations of the AI system adaptation module 36014 in adapting AI systems for particular devices, execution environments, data types, tasks, contexts, use cases, or the like. In embodiments, the AI system logging module 36034 is configured and/or provided to detect and log the operations of the AI system aggregation module 36016 in aggregating AI systems to generate and interconnect two or more AI systems to form hybrids, ensembles, sequences or chains, managed AI systems, AI system swarms, or the like. In embodiments, the AI system logging module 36034 is configured and/or provided to detect and log the operations of the AI system deployment module 36018 to deploy AI systems in response to various requests, which may originate within the AI convergence system of systems 31000 or external to the AI convergence system of systems 31000. In embodiments, the AI system logging module 36034 is configured and/or provided to detect and log the operations of the AI system invocation module 36020 to invoke one or more AI systems to fulfill one or more requests. In embodiments, the AI system logging module 36034 is configured and/or provided to detect and log the operations of the AI system orchestration module 36022 to organize the invocations of the AI systems of the AI convergence system of systems 31000 to meet the requirements of the requests and/or tasks, such as changes due to load-balancing or scheduling. In embodiments, the AI system logging module 36034 is configured and/or provided to detect and log the operations of the AI system monitoring module 36024 to monitor the performance of the AI systems of the AI convergence system of systems 31000, such as the planned and/or completed schedule of measuring and monitoring the performance of the AI systems and/or the results of the performance measurements. In embodiments, the AI system logging module 36034 is configured and/or provided to detect and log the operations of the AI system analyzing module 36026 to analyze the measured performance of the AI systems and the steps taken by the AI system analyzing module 36026 or other modules to respond to changes in performance (*e.g.*, retraining AI systems, replacing AI systems, and/or adapting some AI systems to include features that resulted in performance improvements of other AI systems). In embodiments, the AI system logging module 36034 is configured and/or provided to detect and log the operations of the AI system updating module 36028 to update various AI systems in response to the analyses performed by the AI system analyzing module 36028. In embodiments, the AI system logging module 36034 is configured and/or provided to detect and log the

operations of the AI system governance module 36030 to manage and/or govern the AI systems based on legal, social, practical, and/or regulatory policies (*e.g.*, policies relating to truthfulness and/or avoidance of harm). In embodiments, the AI system logging module 36034 is configured and/or provided to detect and log the operations of the AI system redevelopment module 36032 to redevelop the AI systems based on the performance of the AI systems, the resources of the AI convergence system of systems 31000, and/or the development of new AI systems. In embodiments, the AI system logging module 36034 correlates the activities of various modules to determine causal relationships between the operations modules 36002 (*e.g.*, a first event involving a deployment of an AI system in an environment that is associated with a second event involving a performance measurement of another AI system in the same environment; a first event involving an adaptation of an AI system followed by a second event involving a performance measurement of the adapted AI system; or a first event involving a reorganization of the AI convergence system of systems 31000 by the AI system orchestration module 36022 followed by a second event involving a change in a performance measurement of an AI system by the AI system monitoring module 36024). In embodiments, the AI system logging module 36034 logs the operations of the AI models and/or the operations modules 36002 in one or more event logs.

OPERATIONS LAYER – EXAMPLE USE CASES

[3774] In embodiments, the operations modules 36002 are configured to serve one or more digital product networks. For example, a digital product network may be provided to generate digital products for various circumstances, such as content for a media project (*e.g.*, music or sound effects for a film, story board images to illustrate a story, or three-dimensional models for an animation). The digital products may be generic (*e.g.*, stock media, content libraries, and/or media pieces that may be added to a variety of other projects, such as pieces of narration or dialogue), specialized (*e.g.*, media that is suitable for a particular type of project, such as a genre), and/or bespoke (*e.g.*, media generated for a specific project, character, scene, photo, story, or the like). The digital products may be generated wholly by AI systems of the AI convergence system of systems 31000 (*e.g.*, a persona or avatar created anew from no precursor material) and/or based on feedback, input, and/or prompting from one or more other AI systems, software, components, users, or the like (*e.g.*, fully detailed content generated by a generative AI system based on a general sketch or high-level description of content). The digital products may be generated spontaneously by AI systems of the AI convergence system of systems 31000 (*e.g.*, content that the generative AI system suggests for inclusion in a project in the absence of a request, instruction, and/or prompt to do so) and/or responsive to a request for content (*e.g.*, content that a generative AI system generates in response to a request, instruction, and/or prompt). In embodiments, the operations modules 36002 generate and/or invoke AI systems, including combinations of AI systems (*e.g.*, hybrids, ensembles, chains, or the like) that generate digital products for a digital product network. In embodiments, the operations modules 36002 generate content for specific entities of the digital product network (*e.g.*, for specific content

producers, content publishers, content vendors, and/or content consumers such as users). In embodiments, the operations modules 36002 generate and/or invoke AI systems that review, analyze, critique, rate, score, rank, and/or recommend digital products in a digital product network (*e.g.*, AI-based recommender systems that identify and present digital products that are likely to be of interest to a user). In embodiments, the operations modules 36002 generate and/or invoke AI agents to participate in digital product networks (*e.g.*, AI agents that discuss digital products with users, that generate derivates such as mashups of digital products, and/or that participate in the generation, presentation, and/or consumption of digital products, such as AI agents that participate as artists, actors, players, and/or characters in digital products).

[3775] In embodiments, the operations modules 36002 are configured to serve one or more value chain networks. For example, a value chain network may involve a series of entities that participate in a serial or sequential process, such as an incremental creation of content by respective entities. As an example, a first entity (*e.g.*, an artist, publisher, generative AI system, or the like) may generate first content; a second entity may generate additional content based on the first content, such as supplemental content; and a third entity may combine the first content and the second content to produce finished content. Each entity in the value chain may participate in the value chain (*e.g.*, as a workflow) to perform a particular step, task, function, role, or responsibility of the value chain, thereby incrementally adding value to the value chain process. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to participate in the value chain network. For example, a first AI system (*e.g.*, a generative neural network, such as a large language model or a diffusion network) may generate first content; a second AI system may generate additional content based on the first content, such as supplemental content; and a third AI system may combine the first content and the second content to produce finished content. The operations modules 36002 and/or AI systems generated and invoked thereby may communicate with one another, and/or with entities outside of the AI convergence system of systems 31000 (*e.g.*, external AI systems, external hardware or software components, users, organizations, or the like) to coordinate the steps, tasks, functions, roles, and/or responsibilities of the value chain network, in general (*e.g.*, a communication of capabilities and availability to perform certain functions) and/or in the context of a particular project (*e.g.*, a communication of capability and availability to fulfill one or more roles in a specific project). The operations modules 36002 and/or AI systems generated and invoked thereby may communicate as to the initiation, progress, status, requirements, methods, outcomes, and/or completion of various steps, tasks, functions, roles, and/or responsibilities of the value chain network, including with regard to a particular project. The operations modules 36002 and/or AI systems generated and invoked thereby may initiate one or more projects on the value chain network, such as generating the initial details or "pitch" and/or workflow of a project. The operations modules 36002 and/or AI systems generated and invoked thereby may select, designate, delegate, and/or suggest particular components of the AI convergence system of systems 31000 and/or external entities to fulfill certain features of one or more projects of the value chain network. The operations modules

36002 and/or AI systems generated and invoked thereby may review, track, revise, and/or recommend changes to a project of the value chain network based on the progress of the project, the resources of the value chain network, the assigned and participating entities, and/or external circumstances such as social, political, economic, scientific, and/or technical developments.

[3776] In embodiments, the operations modules 36002 are configured to serve one or more supply chain networks. For example, a supply chain network may involve a set of resources that are available from various sources. The resources may include physical resources such as materials, chemicals, biologic species, artifacts, supplies, physical tools, machinery, equipment, hardware devices, products, or the like. The resources may include digital resources such as data, media, metadata, files, software binaries, scripts, executing software processes, or the like. The resources may include services such as production services, physical and/or digital transportation services, physical and/or digital storage services, physical and/or virtual interactions, physical and/or logical curation of resources, monitoring, auditing, logging, governance, or the like. The supply chain network may involve a series of operations that provide a supply of a resource to meet a demand, such as a mining operation, a manufacturing operation, a packaging operation, a transportation operation, a storage operation, and a delivery operation to deliver a resource (*e.g.*, fuel, minerals, hardware, software, or the like) to a consumer of the resource. Each entity in the supply chain may participate in the supply chain (*e.g.*, as a workflow) to perform a particular step, task, function, role, or responsibility of the supply chain, thereby incrementally advancing the supply of a resource from inception to a consumer. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to participate in the supply chain network. For example, a first AI system (*e.g.*, an AI system that controls a mining machine) may extract a resource such as a chemical or a mineral; a second AI system may refine the resource, such as purifying the chemical or mineral; and a third AI system may deliver the refined resource to a consumer, such as a pipeline or cargo ship. The operations modules 36002 and/or AI systems generated and invoked thereby may communicate with one another, and/or with entities outside of the AI convergence system of systems 31000 (*e.g.*, external AI systems, external hardware or software components, users, organizations, or the like) to coordinate the steps, tasks, functions, roles, and/or responsibilities of the supply chain network, in general (*e.g.*, a communication of capabilities and availability to supply resources to a market) and/or in the context of a particular project (*e.g.*, a communication of capability and availability to fulfill one or more roles in the supply of a specific resource to a specific consumer). The operations modules 36002 and/or AI systems generated and invoked thereby may communicate as to the initiation, progress, status, requirements, methods, outcomes, and/or completion of various steps, tasks, functions, roles, and/or responsibilities of the supply chain network, including with regard to a particular project. The operations modules 36002 and/or AI systems generated and invoked thereby may initiate one or more projects on the supply chain network, such as identifying an initial need for a resource that may be supplied by the supply chain network. The operations modules 36002 and/or AI systems generated and invoked thereby may select, designate, delegate, and/or suggest

particular components of the AI convergence system of systems 31000 and/or external entities to fulfill certain features of one or more projects of the supply chain network. The operations modules 36002 and/or AI systems generated and invoked thereby may review, track, revise, and/or recommend changes to a project of the supply chain network based on the progress of the project, the resources of the supply chain network, the assigned and participating entities, and/or external circumstances such as social, political, economic, scientific, and/or technical developments.

[3777] In embodiments, the operations modules 36002 are configured to serve one or more smart product operations. For example, a product such as a machine, appliance, vehicle, educational apparatus, or toy may be designed, configured, and/or provided to perform certain functions or roles. Such products may be made "smart" by supplementing the operation of the products with intelligent functions that resemble cognition and that improve the operation of the products. For example, a kitchen appliance may perform a task such as food preparation, storage, and/or cleaning, while a "smart" version of such a kitchen appliance may include cognitive features that improve the functions of the appliance, such as proactively initiating the functions, predicting and avoiding problems, adapting the functionality based on detected features and/or changing circumstances, communicating with users, and/or coordinating with other kitchen appliances. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features for such products. For example, the operations modules 36002 may generate and/or invoke an AI system that adds a predictive "smart" feature to a product, such as a kitchen appliance that begins preparing food in anticipation of a need of a person for a meal. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an adaptive "smart" feature to a product, such as a kitchen appliance that adapts a preparation of food based on detected food preferences of a user. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an interactive "smart" feature to a product, such as a kitchen appliance that engages in a dialogue with a user to determine a type and/or manner of preparing food for the user. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a coordinating "smart" feature to a product, such as a kitchen appliance that coordinates with other kitchen appliances to plan and/or execute a preparation of food for the user. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a maintenance "smart" feature to a product, such as a kitchen appliance that detects maintenance problems with the appliance, diagnoses causes of the maintenance problems, identifies solutions to the maintenance problems, determines a plan for solving the maintenance problems, and/or executes solutions to the maintenance problems.

[3778] In embodiments, the operations modules 36002 are configured to serve one or more smart asset operations. For example, an asset may comprise a fund, an amount of currency such as an accumulation of cryptocurrency, a digital contract, a valuable object, or the like. Such assets may be made "smart" by supplementing the asset with intelligent functions that resemble cognition and that improve the features of the asset, such as value, security, and/or longevity.

For example, a fund may be made "smart" by predicting or detecting events that may positively or negatively affect the value of the fund, identifying steps that may be taken responsive to the events, and/or executing the steps. A digital contract may be made "smart" by predicting or detecting events that may positively or negatively affect the execution of the smart contract by one or more parties, identifying steps that may be taken responsive to the events, and/or executing the steps. A valuable object may be made "smart" by predicting or detecting events that may positively or negatively affect the value of the object, identifying steps that may be taken responsive to the events, and/or executing the steps. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features for such assets. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to an asset, such as an AI system that monitors social, political, economic, scientific, and/or technical events and extrapolates positive and/or negative effects of the current events on a current and/or future value of the asset. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a reactive "smart" feature to an asset, such as an AI system that identifies actions that can be taken regarding the asset in response to social, political, economic, scientific, and/or technical events. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an executive "smart" feature to an asset, such as an AI system that executes actions to promote the value, security, and/or longevity of the asset in response to social, political, economic, scientific, and/or technical events.

[3779] In embodiments, the operations modules 36002 are configured to serve one or more deployments of smart infrastructure. For example, the infrastructure of an organization such as a government, a university, a hospital, or the like may include a set of interconnected infrastructure systems, such as power, communication, information technology, inventory management, transportation, maintenance, cleaning, and auditing. Each infrastructure system may include a set of resources, such as power infrastructure including power storage, wiring, regulation such as circuit breakers, switches for failover and load-balancing, and the like. The infrastructure may be made "smart" by supplementing the infrastructure with intelligent functions that resemble cognition and that improve the functionality of the infrastructure, such as availability, security, efficiency, and/or maintenance. For example, power infrastructure may be made "smart" by predicting and proactively addressing potential power failures due to events such as weather patterns, climate change, events in energy markets, and/or changes in the availability of energy-related supplies such as wiring and batteries. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features to infrastructure. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to infrastructure, such as an AI system that monitors social, political, economic, scientific, and/or technical events and extrapolates positive and/or negative effects of the current events on a current and/or future operation of various systems of the infrastructure. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to

add a reactive "smart" feature to the infrastructure, such as an AI system that identifies actions that can be taken to promote and/or maintain the availability, security, efficiency, and/or maintenance of the infrastructure system. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an executive "smart" feature to the infrastructure, such as an AI system that executes actions to promote the availability, security, efficiency, and/or longevity of the infrastructure in response to social, political, economic, scientific, and/or technical events.

[3780] In embodiments, the operations modules 36002 are configured to serve one or more smart machines. For example, an industrial machine in a mining facility may include a number of mining-related functions, such as extracting a mineral, refining a mineral, and assessing the refined mineral for quality, quantity, purity, and/or value. The machine may be made "smart" by supplementing the machine with intelligent functions that resemble cognition and that improve the functionality of the machine, such as performance, efficiency, and/or longevity. For example, the machine may be made "smart" by adapting the manner of extracting minerals to promote the speed, efficiency, completeness, security, and/or integrity of the extraction process. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features to the machine. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to the machine, such as an AI system that predicts how changes in the mine and/or other machines of the mine may impact the current and/or future operation of the machine. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a reactive "smart" feature to the machine, such as an AI system that identifies actions that can be taken to promote and/or maintain the performance, efficiency, and/or longevity of the machine (*e.g.*, physical changes or upgrades of the machine, changes to the manner and/or timing of operation of the machine, and/or maintenance actions regarding various components of the machine). In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an executive "smart" feature to the machine, such as an AI system that executes actions to promote the performance, efficiency, and/or longevity of the machine (*e.g.*, automatically arranging maintenance of components of the machine that are at risk of wear and/or failure).

[3781] In embodiments, the operations modules 36002 are configured to serve one or more smart containers. For example, a shipping container may store cargo such as machines, raw materials, fuel, food, chemicals, electronics, plants, livestock, or the like, and may provide a number of features for the cargo, such as physical isolation and protection of the cargo from outside elements, physical organization and cushioning of the cargo inside the container, and physical security to prevent unauthorized access. The container may be made "smart" by supplementing the container with intelligent functions that resemble cognition and that improve the functionality of the container, such as protection, maintenance, and monitoring of the cargo. For example, the container may be made "smart" by adding features such as tracking and reporting of the status and/or location of the cargo, and/or of servicing the cargo, such as

physically manipulating the cargo and supplying water, oxygen, or nutrients. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features to the container. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to the container, such as an AI system that predicts how changes in the location, orientation, environment, climate, and/or physical status of the container and/or cargo may impact the current and/or future operation of the container and/or cargo. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a reactive "smart" feature to the container, such as an AI system that identifies actions that can be taken to promote and/or maintain the protection, security, and/or maintenance of the container and/or cargo. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an executive "smart" feature to the container, such as an AI system that executes actions to promote the protection, security, and/or maintenance of the container and/or cargo (*e.g.*, communicating with transportation services to arrange for a change of location, orientation, or environment of the container to protect the container and/or cargo).

[3782] In embodiments, the operations modules 36002 are configured to serve one or more smart container ports. For example, a port such as a warehouse, a transport exchange point, a marketplace, or the like may store, organize, transport, and/or exchange containers that include various kinds of cargo, and may provide a number of features for the containers, cargo, transportation vehicles (*e.g.*, ships, aircraft, trains, and trucks), and equipment of the port, such as physical isolation and protection of the containers, cargo, transportation vehicles, and resources of the ports from weather elements, physical organization of the containers in the port and/or during transport, and physical security to prevent unauthorized access to the containers, cargo, transportation vehicles, and resources of the port. The port may be made "smart" by supplementing the port with intelligent functions that resemble cognition and that improve the functionality of the port, such as protection, maintenance, and monitoring of the containers, cargo, transportation vehicles, and resources of the port. For example, the container may be made "smart" by adding features such as tracking and reporting of the status and/or location of the containers, cargo, transportation vehicle, and/or resources of the port, such as physical integrity, capacity, and fuel status. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features to the port. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to the port, such as an AI system that predicts how changes in the location, orientation, environment, climate, and/or physical status of the port may impact the containers, cargo, transportation vehicles, and/or resources of the port. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a reactive "smart" feature to the port, such as an AI system that identifies actions that can be taken to promote and/or maintain the protection, security, and/or maintenance of the containers, cargo, transportation vehicles, and/or resources of the port. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to

add an executive "smart" feature to the port, such as an AI system that executes actions to promote the protection, security, and/or maintenance of the containers, cargo, transportation vehicles, and/or resources of the port (*e.g.*, communicating with owners of the containers, cargo, and/or transportation vehicles to arrange the arrival, pickup, transportation, and/or maintenance of the containers, cargo, and/or transportation vehicles).

[3783] In embodiments, the operations modules 36002 are configured to serve one or more shipping operations. For example, a shipping operation may include a number of transportation vehicles, such as ships, aircraft, trains, and/or trucks, as well as resources such as warehouses, drivers, cargo handlers, and auditors. The shipping operation may coordinate these resources to arrange the receipt, transportation, storage, delivery, and maintenance of cargo and containers thereof, and may provide a number of features for the cargo and containers, such as physical isolation and protection from weather elements, physical organization of the cargo and containers during shipping, and physical security to prevent unauthorized access to the cargo and containers. The shipping operation may be made "smart" by supplementing the shipping operation with intelligent functions that resemble cognition and that improve the functionality of the shipping operation, such as the selection of delivery routes that improve the speed, safety, and efficiency of shipping and delivery of the cargo and containers. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features to the shipping operation. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to the shipping operation, such as an AI system that predicts how changes in the location, orientation, environment, climate, cargo, and/or containers of the shipping operation may impact the containers, cargo, transportation vehicles, and/or resources of the shipping operation, including the storage, transportation, and delivery of the cargo and containers. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a reactive "smart" feature to the shipping operation, such as an AI system that identifies actions that can be taken to promote and/or maintain the protection, security, and/or maintenance of the containers, cargo, transportation vehicles, and/or resources of the shipping operation, including the storage, transportation, and delivery of the cargo and containers. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an executive "smart" feature to the shipping operation, such as an AI system that executes actions to promote the protection, security, and/or maintenance of the containers, cargo, transportation vehicles, and/or resources of the port, including the storage, transportation, and delivery of the cargo and containers (*e.g.*, communicating with owners of the cargo and containers to coordinate the arrival, pickup, transportation, and/or maintenance of the cargo and containers).

[3784] In embodiments, the operations modules 36002 are configured to serve one or more robotic operations. For example, a robotic operation may include a fleet of robots, each having a set of capabilities (*e.g.*, sensors, modes of transportation, tools, end effectors, and the like) and requirements (*e.g.*, fuel or power storage, protection from elements such as water or electrical shock, and periodic maintenance), and each being assigned to perform one or more tasks (*e.g.*,

transporting materials, monitoring a location, and/or serving a user). The robotic operation may be made "smart" by supplementing the robotic operation with intelligent functions that resemble cognition and that improve the functionality of the robotic operation, such as the assignment of robots to tasks, the maintenance and upgrading of the robotic fleet, and the performance of tasks by the robots. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features to the robotic operation. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to the robotic operation, such as an AI system that predicts how changes in the location, orientation, environment, climate, cargo, and/or containers of the robotic operation may impact the performance of the tasks by the robotic fleet, such as obstacles or interruptions of service that might prevent the robots from completing one or more tasks. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a reactive "smart" feature to the robotic operation, such as an AI system that identifies actions that can be taken to promote the performance, reliability, efficiency, and/or completion of the tasks by the robotic fleet, including adapting the assignment, scheduling, and/or prioritization of the robots of the robotic fleet to the set of available tasks. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an executive "smart" feature to the robotic operation, such as an AI system that executes actions to promote the performance, reliability, efficiency, and/or completion of the tasks by the robotic fleet, such as automatically deploying, assigning, reassigning decommissioning, and/or upgrading robots to perform the tasks of the robotic operation, and/or automatically maintaining and/or upgrading the robotic fleet to preserve and/or add capabilities to the robotic fleet.

[3785] In embodiments, the operations modules 36002 are configured to serve one or more autonomous vehicle operations. For example, an autonomous vehicle operation may include a number of autonomous vehicles, such as taxis, buses, ambulances, trucks, trains, monorails, trolleys, aircraft, ferries, and cargo ships, as well as resources such as garages, fuel depots, roads, waterways, railways, and airspaces. The autonomous vehicle operation may coordinate the autonomous vehicles and resources to arrange the pickup, transport, and delivery of drivers, operators, passengers, clients, and/or cargo, and may provide a number of features for the drivers, operators, passengers, clients, and/or cargo, such as physical isolation and protection from weather elements, comfort and privacy of the drivers, operators, passengers, clients, and/or cargo, and physical security of the drivers, operators, passengers, clients, and cargo during transit. The autonomous vehicle operation may be made "smart" by supplementing the autonomous vehicle operation with intelligent functions that resemble cognition and that improve the functionality of the autonomous vehicle operation, such as the selection of transportation routes that improve the speed, safety, and efficiency of transporting the drivers, operators, passengers, clients, and/or cargo. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features to the autonomous vehicle operation. In embodiments, the operations

modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to the autonomous vehicle operation, such as an AI system that predicts how changes in the environment, population, and/or maintenance of transit resources (*e.g.*, roads or railways), autonomous vehicles, drivers, operators, passengers, clients, and/or cargo may impact the safe and/or timely transportation of the drivers, operators, passengers, clients, and/or cargo, such as an arrival time at a destination and/or a condition of the drivers, operators, passengers, clients, and/or cargo upon arrival. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a reactive "smart" feature to the autonomous vehicle operation, such as an AI system that identifies actions that can be taken to promote and/or maintain the protection, security, and/or maintenance of the autonomous vehicles, drivers, operators, passengers, clients, and/or cargo (*e.g.*, scheduling a stop along a route for the rest, relaxation, maintenance, and/or fulfillment of needs of the drivers, operators, passengers, clients, and/or cargo). In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an executive "smart" feature to the autonomous vehicle operation, such as an AI system that executes actions to protection, security, and/or maintenance of the autonomous vehicles, drivers, operators, passengers, clients, and/or cargo (*e.g.*, automatically updating a route of an autonomous vehicle to improve an estimated arrival time at a destination and/or to promote the rest, relaxation, maintenance, and/or fulfillment of needs of the drivers, operators, passengers, clients, and/or cargo).

[3786] In embodiments, the operations modules 36002 are configured to serve one or more UAV operations. For example, a UAV operation may include a fleet of unmanned aerial vehicles, such as drones, light aircraft, helicopters, balloons, dirigibles, airships, rockets, satellites, or the like. The unmanned aerial vehicles may be autonomously controlled by onboard or remote AI systems to perform the takeoff, route selection and correction, airborne maneuvers, status monitoring, and landing of the aircraft. The UAV operation may assign various UAVs of the UAV fleet to various tasks, such as monitoring or measuring a particular geographic region or a subject such as a field of crops, livestock, or an industrial or military operation; deploying substances such as water, fire suppression substances, fertilizer, or pesticide; transporting cargo between various locations; delivering fuel and/or power to other UAVs; or providing first-responder services such as transporting first responders or equipment to address health emergencies or public safety events. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features to the UAV operation. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to the UAV operation, such as an AI system that predicts how changes in the environment, climate, traffic, wildlife, population, and/or equipment may impact the performance of the tasks by the UAV fleet, such as obstacles or interruptions of service that might prevent the UAVs from completing one or more tasks. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a reactive "smart" feature to the UAV operation, such as an AI system that identifies actions that can be taken to promote the performance, reliability, efficiency, and/or

completion of the tasks by the UAV fleet, including adapting the assignment, scheduling, and/or prioritization of the UAVs of the UAV fleet to the set of available tasks. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an executive "smart" feature to the UAV operation, such as an AI system that executes actions to promote the performance, reliability, efficiency, and/or completion of the tasks by the UAV fleet, such as automatically deploying, assigning, reassigning decommissioning, and/or upgrading UAVs to perform the tasks of the UAV operation, and/or automatically maintaining and/or upgrading the UAV fleet to preserve and/or add capabilities to the UAV fleet.

[3787] In embodiments, the operations modules 36002 are configured to serve one or more additive manufacturing operations. For example, an additive manufacturing operation may include an array of 3D printers, each configured to receive a three-dimensional model and to generate one or more physical objects corresponding to the three-dimensional model via additive manufacturing (*e.g.*, fused deposition modeling (FDM) and/or resin printing). Each 3D printer may include capabilities (*e.g.*, print speeds, print quality, temperatures ranges, material types, and object sizes) and may provide various functions during printing (*e.g.*, monitoring, troubleshooting, adaptation of printing to accommodate various materials and/or techniques, object post-processing, object assembly, and/or object delivery). The additive manufacturing operation may receive a set of work orders for various objects and may assign each work order to one or more 3D printers by matching the requirements of each work order to the capability and/or availability of the respective 3D printers. The additive manufacturing operation may be made "smart" by supplementing the additive manufacturing operation with intelligent functions that resemble cognition and that improve the functionality of the additive manufacturing operation, such as the assignment of 3D printers to work orders, the maintenance and upgrading of the 3D printers, and the execution of work orders by the 3D printers. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features to the additive manufacturing operation. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to the additive manufacturing operation, such as an AI system that predicts how changes in the environment or climate, the availability and condition of 3D printing materials, and the conditions of the 3D printers may impact the execution of the work orders by the 3D printers, such as obstacles or interruptions of service that might prevent the 3D printers from completing one or more work orders. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a reactive "smart" feature to the additive manufacturing operation, such as an AI system that identifies actions that can be taken to promote the performance, reliability, efficiency, and/or completion of the work orders by the 3D printers, including adapting the assignment, scheduling, and/or prioritization of the work orders by the 3D printers. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an executive "smart" feature to the additive manufacturing operation, such as an AI system that executes actions to promote the performance, reliability, efficiency, and/or completion of the work orders by the 3D printers,

such as automatically deploying, assigning, reassigning decommissioning, and/or upgrading 3D printers to perform the tasks of the additive manufacturing operation, and/or automatically maintaining and/or upgrading the 3D printers fleet to preserve and/or add capabilities to the additive manufacturing operation.

[3788] In embodiments, the operations modules 36002 are configured to serve one or more human-machine cooperative operations. For example, a human-machine cooperative operation may involve one or more tasks that are performed by one or more humans cooperating with one or more machines in fields such as mining, manufacturing, surveying, construction, healthcare, education, emergency response, or the like. A human and a machine may cooperate to perform a physical task together, such as carrying a piece of equipment, furniture, or a material such as a pane of glass. A human and a machine may cooperate to choose a plan for completing a task, such as surveying a geographic region to measure a population of wildlife. A human and a machine may cooperate by the human supervising the performance of a task by a machine, such as a robot engaging in a manufacturing or construction operation while a human monitors the operation of the robot to detect and address problems. A human and a machine may cooperate by the robot observing the human during the performance of a task to learn how to perform the task, such as a robotic process automation (RPA) task that enables the robot to perform the task autonomously in the future. A human and a machine may cooperate by the human observing the robot during the performance of a task to learn how to perform the task, such as a skill-sharing operation where a robot teaches a human to perform a task, which may have been learned from another human. The human-machine cooperative operation may be made "smart" by supplementing the human-machine cooperative operation with intelligent functions that resemble cognition and that improve the functionality of the human-machine cooperative operation, such as the mapping of tasks to combinations of one or more humans and one or more machines. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features to the human-machine cooperative operation. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to the human-machine cooperative operation, such as an AI system that predicts which humans and which machines will cooperate well together to perform a particular task. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a reactive "smart" feature to the human-machine cooperative operation, such as an AI system that identifies the occurrence and/or causes of current and/or future disagreements between a human cooperating with a machine. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an executive "smart" feature to the human-machine cooperative operation, such as an AI system that executes actions to address disagreements between a human cooperating with a machine, such as conversations, mediation by the AI system or by another human and/or machine, clarification of communication between the human and the machine, review and analysis of previous interaction between the human and the machine that resulted in the

disagreement, and/or adjustments of the assignment of humans and machines to various cooperative tasks.

[3789] In embodiments, the operations modules 36002 are configured to serve one or more automated machine monitoring operations. For example, an automated machine monitoring operation may involve monitoring operations of a machine to detect the occurrence, progress, and/or quality of the performance of tasks, the status of the machine (*e.g.*, temperature, inventory of consumables, and/or freedom from defects and/or anomalous behavior), and interactions between the machine and other machines of a facility. The automated machine monitoring operation may be made "smart" by supplementing the automated machine monitoring operation with intelligent functions that resemble cognition and that improve the functionality of the automated machine monitoring operation, such as monitoring the completion of tasks by the machine, monitoring the status of the machine, and monitoring the interactions between the machine and other machines of a facility. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features to the automated machine monitoring operation. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to the automated machine monitoring operation, such as an AI system that predicts how changes to a facility (*e.g.*, the locations, orientations, and byproducts of other machines of a facility) may positively or negatively impact the monitoring of the performance, status, or interaction of a machine with other machines of a facility (*e.g.*, organization of a facility that resulted in a blockage of a view of a machine by a monitoring camera and/or interference with the monitoring of the machine by a sensor). In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a reactive "smart" feature to the automated machine monitoring operation, such as an AI system that identifies causes of problems with the monitoring of the performance of tasks by the machine, the status of the machine, and/or the interaction of the machine with other machines of the facility (*e.g.*, determining that the location of materials in a facility interferes with a monitoring of a machine of the facility by the AI system). In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an executive "smart" feature to the automated machine monitoring operation, such as an AI system that executes actions to address, reduce, and/or prevent problems with the monitoring of the performance of tasks by the machine, the status of the machine, and/or the interaction of the machine with other machines of the facility (*e.g.*, autonomously instructing a robot of the facility to relocate materials in the facility to address a blockage of a monitoring process).

[3790] In embodiments, the operations modules 36002 are configured to serve one or more maintenance operations. For example, a maintenance operation may involve surveying, testing, resupplying, repairing, reprogramming, refreshing, cleaning, and/or replacing a machine or one or more components of a machine. The maintenance operation may be made "smart" by supplementing the maintenance operation with intelligent functions that resemble cognition and that improve the functionality of the maintenance operation, such as refining the maintenance

operations for improved efficiency, speed, availability, reliability, completion, and/or recordation of the maintenance operations. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features to the maintenance operation. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to the maintenance operation, such as an AI system that predicts how changes to the machine or an environment of the machine may positively or negatively impact the relevance, urgency, timeliness, extent, and/or completeness of maintenance operations for the machine.

[3791] In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a reactive "smart" feature to the maintenance operation, such as an AI system that improves the diagnostic accuracy, reliability, and/or efficiency of the maintenance operations of the machine in view of changes to the machine, uses of the machine (*e.g.*, the materials and/or tasks for which the machine is used), and/or an environment of the machine. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an executive "smart" feature to the maintenance operation, such as an AI system that executes actions to improve the diagnostic accuracy, reliability, and/or efficiency of the maintenance operations, such as automatically adjusting a maintenance schedule in response to changes to the machine, uses of the machine (*e.g.*, the materials and/or tasks for which the machine is used), and/or an environment of the machine.

[3792] In embodiments, the operations modules 36002 are configured to serve one or more robotic process automation (RPA) operations. For example, an RPA operation may involve a learning software process that observes a human during the performance of a task (*e.g.*, a physical task, a cognitive process, and/or an interaction between the human and one or more other humans, robots, and/or software processes such as user interfaces) in order to learn to perform the task in a corresponding and/or equivalent autonomous manner using software, hardware, and/or robotic processes. The RPA operation may be made "smart" by supplementing the RPA operation with intelligent functions that resemble cognition and that improve the functionality of the RPA operation, such as improving the accuracy, clarity, reliability, and/or situational awareness of the learning software process while learning and/or autonomously performing the task. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features to the RPA operation. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to the RPA operation, such as an AI system that predicts deficiencies in the learning process, such as features of the task that may not be or may not have been adequately conveyed to and/or learned by a learning software process (*e.g.*, lack of clarity, incomplete explanations, confusion, inconsistency, and/or incomplete records of the performance of the task by the human). In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a reactive "smart" feature to the RPA operation, such as an AI system that identifies ways to address deficiencies in the learning process (*e.g.*, requests that may be presented to the human, such as requests to explain certain

aspects of the task or the context of the task and/or requests for an additional performance of the task). In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an executive "smart" feature to the RPA operation, such as an AI system that executes actions to address, reduce, and/or prevent problems with the performance of tasks by the machine, the status of the machine, and/or the interaction of the machine with other machines of the facility.

[3793] In embodiments, the operations modules 36002 are configured to serve one or more converged information technology / operational technology (IT/OT) operations. For example, a converged IT/OT operation may involve a combination of a traditional, general-purpose information technology environment and resource set (*e.g.*, general-purpose networking, data storage, software and device deployment, and an information security model) with operation-specific resources and operations (*e.g.*, specific industrial machines, controllers, communication protocols, and monitoring). The converged IT/OT operation may be made "smart" by supplementing the converged IT/OT operation with intelligent functions that resemble cognition and that improve the functionality of the converged IT/OT operation, such as improving the synergy, adaptability, reliability, and robustness of the mapping of IT resources to specific industrial operations and resources. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features to the converged IT/OT operation. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to the converged IT/OT operation, such as an AI system that predicts how changes to the industrial environment may affect the industrial operations and the assignment of information technology resources thereto (*e.g.*, increases of new industrial machines and/or workloads that could potentially create shortages of information technology resources, such as network capacity and/or storage capacity). In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a reactive "smart" feature to the converged IT/OT operation, such as an AI system that identifies opportunities to acquire, map, provision, reserve, deploy, configure, and/or use generic IT resources for specific industrial operations in order to provide capabilities, improve features, and/or address potential problems of the industrial operations such as yield, quality, and/or efficiency. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an executive "smart" feature to the converged IT/OT operation, such as an AI system that executes actions to address, reduce, and/or prevent problems with the mapping of information technology resources to specific industrial operations, such as automatically acquiring and/or reassigning information technology resources to the industrial operations based on demand, requirements, priorities, timing, side-effects, statuses, and/or outcomes of the industrial operations.

[3794] In embodiments, the operations modules 36002 are configured to serve one or more insurance, underwriting, and/or risk management operations. For example, an insurance, underwriting, and/or risk management operation may involve a determination of one or more risks related to an entity, resource, asset, operation, venture, objective, or the like, wherein the

risks may affect a condition, value, availability, suitability, longevity, functionality, and/or reputation of the entity, resource, asset, operation, venture, objective, or the like. The insurance, underwriting, and/or risk management operation may also involve an assessment of an overall risk profile, options that may mitigate such risks, and/or the availability, security, reliability, cost, and/or value of insurance and/or underwriting of such entity, resource, asset, operation, venture, objective, or the like, including options for predicting, detecting, mitigating, compensating, and/or alleviating such risks. The insurance, underwriting, and/or risk management operation may be made "smart" by supplementing the insurance, underwriting, and/or risk management operation with intelligent functions that resemble cognition and that improve the functionality of the insurance, underwriting, and/or risk management operation, such as improving the accuracy, likelihood, clarity, extent, and/or outcomes of predicted risks and/or the availability, security, reliability, cost, and/or value of insurance and/or underwriting of such risks. In such contexts, and in embodiments, the operations modules 36002 are configured to generate and/or invoke one or more AI systems to provide "smart" features to the insurance, underwriting, and/or risk management operation. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a predictive "smart" feature to the insurance, underwriting, and/or risk management operation, such as an AI system that predicts how social, political, economic, scientific, and/or technical developments are likely to affect predictions of risks and/or insurance and/or underwriting thereof. In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add a reactive "smart" feature to the insurance, underwriting, and/or risk management operation, such as an AI system that recommends adjustments to an entity, resource, asset, operation, venture, objective, or the like to reduce or mitigate a risk profile in view of social, political, economic, scientific, and/or technical developments, and/or adjustments to an insurance and/or underwriting policy (*e.g.*, informing individuals of changes to risk profiles regarding an entity, resource, asset, operation, venture, objective, or the like, and/or generating and presenting recommendations to adjust a scope, redundancy, and/or cost of coverage by insurance and/or underwriting in response to social, political, economic, scientific, and/or technical developments). In embodiments, the operations modules 36002 generate and/or invoke one or more AI systems to add an executive "smart" feature to the insurance, underwriting, and/or risk management operation, such as an AI system that executes actions to adjust an entity, resource, asset, operation, venture, objective, or the like (*e.g.*, changing a level of security of an entity, resource, asset, operation, venture, objective, or the like, and/or automatically executing transactions to scale a level, scope, redundancy, and/or cost of coverage by insurance and/or underwriting in response to social, political, economic, scientific, and/or technical developments).

NETWORK LAYER

NETWORK MODULES

[3795] Referring to FIG. 184 and FIG. 188, the AI convergence system of systems 31000 may include a network layer 37000 having a set of network modules 37002. In embodiments, the

network modules 37002 may include an adaptive network routing module 37004, an adaptive error correction module 37006, an adaptive network storage module 37008, an adaptive protocol selection module 37010, an adaptive block size module 37012, an adaptive transmission window module 37014, an edge networking module 37016, a cloud networking module 37018, a communication network 37020, a cellular module 37022, a WiFi module 37024, an ORAN module 37026, a Bluetooth module 37028, a satellite module 37030, an IoT network module 37032, a mesh network module 37034, a social network module 37036, and an insurance network module 37038. In embodiments, the set of network modules 37002 may further include a power grid module, a shipping network module, a delivery network module, a distributed energy network module, a healthcare network module, an IoT-in-a-box module, an industrial IT/OT module, a transaction network module, a financial network module, a payments network module, a transportation network module, a value chain network module, and a supply chain network module.

[3796] In some embodiments, each network module of the network layer 37000 may include one or more processors and one or more memories storing computer-executable instructions that, when executed by the one or more processors, cause the one or more processors to implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to perform an intelligence task related to that particular network module. Such intelligence tasks may relate to optimization tasks, generative tasks, predictive tasks, detection and/or identification tasks, decision support tasks, automation tasks, configuration and/or control tasks, and the like.

[3797] The machine learning systems may be trained using supervised, unsupervised, or reinforcement learning techniques on diverse types of data, including simulated data (e.g., data generated from a simulation engine, a foundation world model, a set of digital twins, or the like). The neural networks may comprise multiple layers including, but not limited to, convolutional layers, recurrent layers, and fully connected layers. The artificial intelligence systems may implement various algorithms including decision trees, random forests, and gradient boosting machines. The network layer 37000 may further include a simulation engine or set of foundation world models operating in parallel with the machine learning systems, artificial intelligence systems, and/or neural networks, wherein the simulation engine and/or set of foundation world models are configured to generate real-time simulations of scenarios associated with each intelligence task, validate decisions, and provide feedback to the machine learning models for continuous improvement and adaptation to changing conditions. In embodiments, the simulation engine may employ physics-based modeling, discrete event simulation, or agent-based modeling techniques to accurately represent the dynamics of real-world behavior.

ADAPTIVE NETWORK ROUTING MODULE

[3798] For example, an adaptive network routing module 37004 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize network routing paths in real time. Additional

and/or alternative intelligence tasks may involve predictive tasks like forecasting traffic patterns across nodes, detection and identification tasks to recognize network bottlenecks or anomalies, automation tasks to dynamically adjust routing configurations based on current network conditions, decision support tasks by recommending optimal paths for high-priority data and configuration tasks to enforce changes across the network infrastructure to ensure efficient data flow and minimized latency, and the like.

ADAPTIVE ERROR CORRECTION MODULE

[3799] In another example, an adaptive error correction module 37006 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to identify, predict, and/or correct errors in network communication in real time. Additional and/or alternative intelligence tasks may involve predictive tasks like anticipating potential error-prone scenarios based on historical data, detection and identification tasks to isolate and classify errors in data packets or transmissions, automation tasks to dynamically apply error correction protocols or retransmission strategies, decision support tasks to recommend optimal recovery mechanisms for maintaining data integrity, and configuration tasks to adjust system parameters to prevent future errors, among many others.

ADAPTIVE NETWORK STORAGE MODULE

[3800] In yet another example, an adaptive network storage module 37008 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize the allocation, retrieval, and management of storage resources across the network. Additional and/or alternative intelligence tasks may involve predictive tasks like forecasting storage capacity requirements based on historical usage patterns, detection and identification tasks to monitor and address storage bottlenecks or underutilized resources, automation tasks to dynamically allocate or reallocate storage to maintain optimal performance, decision support tasks to recommend data replication or tiering strategies for improved efficiency and reliability, configuration tasks to enforce policies for storage redundancy and access control, and the like.

ADAPTIVE PROTOCOL SELECTION MODULE

[3801] In yet another example, an adaptive protocol selection module 37010 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to dynamically select the most appropriate communication protocols based on real-time network conditions and requirements. Additional and/or alternative intelligence tasks may involve predictive tasks like forecasting protocol performance under varying loads, detection and identification tasks to assess protocol compatibility or inefficiencies, automation tasks to switch protocols during transmission, decision support tasks to recommend protocols for specific scenarios, configuration tasks to optimize protocol settings for maximum efficiency, and the like.

ADAPTIVE BLOCK SIZE MODULE

[3802] In yet another example, an adaptive block size module 37012 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to determine and adjust block sizes dynamically to optimize data transfer efficiency. Additional and/or alternative intelligence tasks may involve predictive tasks like estimating optimal block sizes based on network latency and bandwidth, detection and identification tasks to flag inefficiencies caused by suboptimal block sizes, automation tasks to adjust block sizes in real time during data transfers, decision support tasks to recommend configurations for specific network conditions, configuration tasks to enforce block size policies across the network, and the like.

ADAPTIVE TRANSMISSION WINDOW MODULE

[3803] In yet another example, an adaptive transmission window module 37014 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to dynamically adjust transmission windows to optimize data flow and minimize congestion. Additional and/or alternative intelligence tasks may involve predictive tasks like forecasting optimal transmission windows based on traffic patterns, detection and identification tasks to identify bottlenecks or excessive retransmissions, automation tasks to modify transmission windows in real time to balance throughput and reliability, decision support tasks to suggest window sizes for specific workloads, configuration tasks to apply policies for transmission efficiency, and the like.

EDGE NETWORKING MODULE

[3804] In yet another example, an edge networking module 37016 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to enable localized data processing and communication at the network edge. Additional and/or alternative intelligence tasks may involve predictive tasks like anticipating traffic loads at edge nodes, detection and identification tasks to monitor edge device performance or connectivity issues, automation tasks to redistribute workloads between edge and central resources, decision support tasks to recommend edge deployment strategies, configuration tasks to manage edge resource allocation, and the like.

CLOUD NETWORKING MODULE

[3805] In yet another example, a cloud networking module 37018 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize the connectivity and resource utilization of cloud-based infrastructures. Additional and/or alternative intelligence tasks may involve predictive tasks like forecasting bandwidth demands for cloud applications, detection and identification tasks to diagnose cloud network performance issues, automation tasks to balance traffic between virtual network nodes, decision support tasks to optimize network configurations for cloud workloads, configuration tasks to manage cloud network policies, and the like.

COMMUNICATION NETWORK

[3806] In yet another example, a communication network module 37020 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to manage and optimize end-to-end data communication across the network. Additional and/or alternative intelligence tasks may involve predictive tasks like forecasting communication delays or outages, detection and identification tasks to locate and resolve data packet loss, automation tasks to reroute traffic for maximum efficiency, decision support tasks to enhance network configurations for specific use cases, configuration tasks to implement fault tolerance strategies, and the like.

CELLULAR MODULE

[3807] In yet another example, a cellular module 37022 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize the performance and reliability of cellular network communication. Additional and/or alternative intelligence tasks may involve predictive tasks like estimating cellular network load during peak times, detection and identification tasks to monitor signal quality or interference, automation tasks to adjust handover mechanisms between cells, decision support tasks to improve frequency allocation, configuration tasks to enhance network scalability, and the like.

WIFI MODULE

[3808] In yet another example, a WiFi module 37024 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize wireless local area network (WLAN) connectivity and performance. Additional and/or alternative intelligence tasks may involve predictive tasks like forecasting WiFi congestion in high-density areas, detection and identification tasks to analyze signal strength or interference sources, automation tasks to dynamically adjust channel allocations or access point settings, decision support tasks to enhance network configurations for specific environments, configuration tasks to enforce security protocols, and the like.

ORAN MODULE

[3809] In yet another example, an ORAN (Open Radio Access Network) module 37026 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize and manage ORANs. Additional and/or alternative intelligence tasks may involve predictive tasks like forecasting traffic loads across base stations, detection and identification tasks to monitor ORAN performance, automation tasks to adjust radio resource allocations dynamically, decision support tasks to enhance multi-vendor ORAN configurations, configuration tasks to optimize spectrum usage, and the like.

BLUETOOTH MODULE

[3810] In yet another example, a Bluetooth module 37028 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize short-range wireless communication for connected devices. Additional and/or alternative intelligence tasks may involve predictive tasks like anticipating device pairing or traffic patterns, detection and identification tasks to analyze signal interference or connectivity issues, automation tasks to adjust device priorities dynamically, decision support tasks to enhance Bluetooth mesh configurations, configuration tasks to manage device security, and the like.

SATELLITE MODULE

[3811] In yet another example, a satellite module 37030 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize satellite communication. Additional and/or alternative intelligence tasks may involve predictive tasks like forecasting weather-related signal degradation, detection and identification tasks to monitor satellite link performance, automation tasks to reroute traffic dynamically between satellites, decision support tasks to recommend satellite placement strategies, configuration tasks to optimize bandwidth utilization, and the like.

IOT NETWORK MODULE

[3812] In yet another example, an IoT network module 37032 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to manage and optimize connectivity for Internet of Things (IoT) devices. Additional and/or alternative intelligence tasks may involve predictive tasks like estimating device activity patterns, detection and identification tasks to flag malfunctioning or compromised devices, automation tasks to dynamically allocate network resources for IoT traffic, decision support tasks to improve IoT gateway configurations, configuration tasks to enforce security measures, and the like.

MESH NETWORK MODULE

[3813] In yet another example, a mesh network module 37034 of the network layer 37000 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize and manage a set of decentralized and/or mesh networks. Additional and/or alternative intelligence tasks may involve predictive tasks like forecasting node connectivity or load imbalances, detection and identification tasks to locate failing or underperforming nodes, automation tasks to reroute traffic dynamically within the mesh, decision support tasks to improve network scalability and resilience, configuration tasks to optimize node configurations, and the like.

SOCIAL NETWORK MODULE

[3814] In yet another example, a social network module 37036 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize user engagement, content delivery, and network connectivity across a social network. Additional and/or alternative intelligence tasks may involve predictive tasks like forecasting user activity patterns or viral content trends, detection and identification tasks to flag illegal content, automation tasks to curate personalized content feeds dynamically, decision support tasks to recommend moderation or community management strategies, configuration tasks to enforce privacy and security policies, and the like.

SHIPPING NETWORK MODULE

[3815] In yet another example, a shipping network module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize the movement, tracking, and logistics of goods across a global shipping network. Additional and/or alternative intelligence tasks may involve predictive tasks like forecasting shipping demand or port congestion, detection and identification tasks to monitor shipment delays or container misplacements, automation tasks to dynamically adjust shipping routes for efficiency, decision support tasks to recommend resource allocation at ports, configuration tasks to streamline customs and documentation processes, and the like.

DELIVERY NETWORK MODULE

[3816] In yet another example, a delivery network module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize last-mile logistics, package tracking, and delivery efficiency across a delivery network. Additional and/or alternative intelligence tasks may involve predictive tasks like estimating delivery times and forecasting traffic patterns, detection and identification tasks to monitor delivery route bottlenecks or failed deliveries, automation tasks to dynamically reroute delivery vehicles for improved efficiency, decision support tasks to enhance fleet management strategies, configuration tasks to prioritize high-value or time-sensitive deliveries, and the like.

INSURANCE NETWORK MODULE

[3817] In yet another example, an insurance network module 37038 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize policy management, claims processing, and risk assessment within an insurance network. Additional and/or alternative intelligence tasks may involve predictive tasks like estimating policyholder risk profiles or fraud likelihood, detection and identification tasks to flag fraudulent claims or discrepancies, automation tasks to streamline underwriting and claims approval processes, decision support tasks to recommend pricing or policy bundling strategies, configuration tasks to align operations with regulatory compliance, and the like.

VALUE CHAIN NETWORK MODULE

[3818] In yet another example, a value chain network module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize processes across a value chain network. Additional and/or alternative intelligence tasks may involve predictive tasks like estimating supply and demand fluctuations, detection and identification tasks to flag inefficiencies or disruptions in the value chain, automation tasks to streamline workflows across partners, decision support tasks to recommend resource allocation strategies, configuration tasks to ensure compliance with value chain policies, and the like.

SUPPLY CHAIN NETWORK MODULE

[3819] In yet another example, a supply chain network module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize resource usage across a supply chain network. Additional and/or alternative intelligence tasks may involve predictive tasks like forecasting demand and inventory levels, detection and identification tasks to monitor supply chain bottlenecks or disruptions, automation tasks to dynamically adjust procurement or distribution strategies, decision support tasks to enhance supplier collaboration, configuration tasks to implement just-in-time (JIT) inventory practices, and the like.

ADAPTIVE NETWORKING AND QOS PLATFORM

[3820] At the network layer 37000, AI capabilities for adaptive networking enable a platform for providing integrated, adaptive networking and quality of service (QoS) ("the adaptive networking and QoS platform") for various enterprise and/or operational environments (in some implementations having various sets of facilities and/or environments contained therein). For example, enterprise and/or operational environments may include industrial environments, manufacturing environments, warehouse environments, shipping environments (e.g., container ports, shipping containers, shipyards, and the like), energy environments (e.g., fossil fuel energy environments such as oil rigs, pipelines, and refineries or nuclear energy environments such as nuclear power plants), retail environments, transportation environments (e.g., airports, train stations, bus stops, airplanes, train cars, and the like), transaction and banking environments, datacenter environments, compute environments, hospitality environments, gaming environments, and entertainment environments, among many others.

[3821] The adaptive networking and QoS platform may include, without limitation, caching of AI content and generative AI content (e.g., pre-generated instructions for operating machinery, customer risk assessments, pre-generated customer support responses, pre-generated explanations of medical conditions, optimal delivery routes for recurring logistics paths, path optimization results for robot pickers in commonly used zones, workload distribution recommendations, predictions for server failure risks, customer preference data, product recommendation results for repeat customers, pre-generated personalized marketing emails, and pre-generated maintenance instructions or escalation workflows for hardware issues, among

many others); caching of AI models (e.g., predictive AI models such as predictive maintenance models for specific machinery, recommendation models, optimization models such as for optimizing factory floor layouts, credit risk assessment models, fraud detection models, load forecasting models, anomaly detection models, diagnostic models, inventory tracking models, pathfinding models, workload balancing models, pricing optimization models, resource allocation models, and the like) and generative AI models (such as for efficient, localized generation of AI content based on localized, contextual inputs and/or for localized, customized use); handling via edge capabilities of transaction events (including point-of-sale transactions, fraud detection, payment processing, energy trading, toll collection, bet placement, payouts, buy-ins, room booking, food and beverage purchases, event ticket purchases, loyalty and rewards transactions (e.g., points earning, points redemption, and membership upgrades), promotional transactions, reporting, payment resolution, and other transaction functions); execution by edge capabilities of gaming engine functions (such as enabling efficient, localized generation of AI-driven environments (e.g., large-scale foundation models for training intelligent agents), simulations, characters or personnel (including physical robots as well as software-based personnel for customer-facing interactions and/or other operations, as well as AI-based attributes, behaviors, and interactions for virtual or augmented systems, including AR/VR-enabled simulations, training modules, operational overlays, and the like); execution by edge capabilities of experience orchestration (such as generating immersive and interactive experiences tailored to localized context, operational needs, and/or personalization of generative content based on real-time understanding of target cohorts, operational conditions, or individual user preferences across various environments, including AR/VR simulations, dynamic visualizations, and situationally adaptive content delivery); and/or the like.

[3822] In embodiments, edge capabilities may be provided in edge systems, devices, switches, chipsets and other embodiments. Edge capabilities may include converged capabilities where a set of artificial intelligence capabilities, such as generative or other AI capabilities, are integrated with other networking capabilities, such as by providing them as part of the same device or system, providing them with shared or coordinated input/output channels, providing them with coordinated access to the same data, or the like.

ADAPTIVE NETWORK CAPABILITIES

[3823] In embodiments, the adaptive networking and QoS platform includes caching of AI models for operations and use cases for various environments. In embodiments, the foregoing capabilities are enabled by adaptive networking capabilities as described in this disclosure and the documents incorporated by reference herein, such as by adapting a networking capability based on one or more of network conditions, based on a set of prioritization parameters, based on the content to be generated by a sender (e.g., an edge device) and or delivered over the network from a sender, based on the capabilities of a receiver, and/or based on the nature of usage by a receiver, among others. Such adaptive networking capabilities, based on such factors, may include, without limitation: a) adaptive selection of a networking protocol (e.g., a

physical layer, transport layer, media access control layer, or other networking protocol); b) adaptive generation of content by an edge or other networking device that is capable of content generation, such as by generation of content of a suitable format, file type, size (e.g., by adaptive chunking of generative content into suitable block sizes or the like); c) adaptive storage of data on a network storage device, including caching for rapid access and/or long term storage; d) adaptive routing of network traffic, including based on QoS or channel conditions, cost of routing, and other factors; e) adaptive network coding, including setting of random linear network coding or other coding parameters; f) adaptive block sizing; g) adaptive data rate (including dynamically adjusting data rate according to a linear, convex, or concave adjustment curve); h) adaptive error correction, including adaptive setting of forward error correction parameters; i) adaptive session management, including setting timing of session initiative, termination and duration; j) adaptive and/or dynamic spectrum access management, including slicing usage available cellular or other spectrum based on any of the factors noted above; k) adaptive setting of mesh networking parameters; l) adaptive setting of software filters for repeaters, switches, routers and other software-defined transmission devices; m) adaptive configuration of mobile ad hoc network parameters; and others. Any one or more of these capabilities may be provided in an adaptive networking device or system that further includes a set of other AI capabilities, including generative AI capabilities for generation of content that is to be handled by the converged device or system.

[3824] In embodiments, the network layer 37000 may be configured to facilitate communications among smart network-capable systems, their users, and the like while leveraging AI to dynamically adapt network configurations and optimize data flow. The integration of edge computing with cloud services ensures that data processing and transaction and workflow orchestration can occur closer to the data source, reducing latency and enhancing real-time decision-making capabilities. AI algorithms may be capable of intelligently routing data (e.g., IoT data, sensor data, edge data, transaction data, behavior data, social data, web data, crowdsourced data, media data, vector data, distributed data, and the like) through the most efficient network paths, whether they be cellular, WiFi, Open Radio Access Network (ORAN), Bluetooth, IoT communication protocols, and other communication protocols. For implementation, the network modules 37002 may utilize AI for predictive network traffic management, ensuring bandwidth is allocated where it is needed most, and cryptographic techniques for securing data at the edge. AI-driven anomaly detection systems may be employed to monitor network health and preemptively address potential disruptions.

[3825] In embodiments, the network layer 37000 may provide advanced computing capabilities at the edge of the network to process and manage transactions locally to improve response times, conserve bandwidth, enhance security, and the like. The network layer 37000 may be supported by edge devices, edge data centers, edge computing platforms, and the like. In embodiments, blockchain may be used to handle distributed transactions across multiple edge devices, offering security and transparency of transactions. AI may be used at the edge to make

intelligent decisions based on the data processed, which may be particularly useful for personalized user experiences.

[3826] At the network layer 37000, caching of generative AI may be used for reducing the computational resources and energy consumption required for AI workloads, benefits that may optimize down to the resource layer 39000. In implementations, caching of AI workloads may involve output caching, feature caching, model state caching, and the like. Output caching may refer to storing outputs previously generated by the AI model. For example, output caching may involve caching previously generated output. Feature caching may refer to input data that has been pre-processed and transformed into a format suitable for model training or inference. Model state caching may refer to caching the state of the model at different points during its operation. Outputs, features, model states, and the like may be stored in a readily accessible storage layer, allowing for quick retrieval of information. In implementations, caching of AI workloads at the network layer 37000 may be enabled by a cache management system.

[3827] In embodiments, network layer 37000 may provide a content delivery network (CDN) for enabling the delivery of generative AI content. The integration of generative AI with CDNs can significantly enhance the functionality of CDNs with respect to content optimization, personalization, real-time content generation, and the like. For example, generative AI models may be configured to utilize user preferences, user behavior, and others to generate personalized content in real-time at the edge and/or demographic data, location data, and others to generate targeted content in real-time at the edge. In embodiments, each CDN may be configured as a network of distributed servers that are designed to deliver content. The CDNs may support caching of generative AI content, serving cached content from edge servers closest to users. The CDNs may be configured to perform load balancing during periods of high traffic. In embodiments, the CDNs may restrict access to content based on geographic locations in compliance with state laws and regulations. In some embodiments, the CDNs may use token authentication to control access to content (e.g., validating user's request to access content based on time restrictions, IP address limitations, the number of times content can be accessed, and the like).

[3828] In embodiments, content distribution may be significantly enhanced through the use of smart network-capable devices. Smart network-capable devices may include smart sensors, smart products, connected robotics, wearables, programmable logic controllers (PLCs), 3D printers, smart conveyors, smart containers, smart shelving systems, drones, distributed energy resources (DERs), smart machines, smart cooling systems, smart point-of-sale (POS) systems, smart TVs, and smart streaming devices, among many others. In embodiments, the smart network-capable devices can leverage AI functionalities for operations by analyzing user preferences, user behavior, user interactions, historical data, and the like. In embodiments, generative AI models may modify or generate content based on viewing conditions or user feedback. For example, AI can dynamically adjust video quality based on available bandwidth. In embodiments, the smart network-capable devices may use geolocation data to enforce geographic restrictions on activities, and the like.

[3829] In embodiments, a computer-implemented system may provide a value chain network management platform with a network layer comprising network modules that may implement AI-based learning models. The network modules may execute intelligence tasks through processors that may execute instructions stored in memory to optimize network operations.

[3830] The network modules may include adaptive capabilities through specialized modules - an adaptive network routing module may optimize data paths, an adaptive error correction module may identify and correct transmission errors, an adaptive network storage module may manage distributed storage resources, an adaptive protocol selection module may choose optimal communication protocols, an adaptive block size module may adjust data block sizes, and an adaptive transmission window module may control data flow rates across the value chain network.

[3831] The platform may implement diverse communication capabilities through modules that may support cellular networks for mobile connectivity, WiFi for local wireless access, ORAN for open radio access, Bluetooth for short-range communication, satellite for global coverage, IoT networks for connected devices, and mesh networks for resilient peer-to-peer connectivity across value chain operations.

[3832] The network layer may incorporate specialized modules for value chain operations including: shipping network modules that may manage logistics connectivity, delivery network modules that may coordinate last-mile operations, transportation network modules that may optimize fleet communications, value chain network modules that may integrate end-to-end operations, and supply chain network modules that may connect suppliers and manufacturers.

[3833] The AI-based learning models may be trained using multiple approaches: supervised learning with labeled value chain data like classified network events and known outcomes, unsupervised learning to discover patterns in unlabeled network traffic data, and reinforcement learning to optimize routing decisions. The training data may include supply chain data about material flows, demand data from customers, shipping data from logistics providers, pricing data from various points in the chain, and transportation data about routes and carriers.

[3834] The intelligence tasks executed by the network modules may span multiple categories: optimization tasks like route planning and resource allocation, generative tasks like creating new network configurations, predictive tasks like forecasting network loads, detection tasks like identifying anomalies, identification tasks like classifying traffic patterns, decision support tasks like recommending routing changes, automation tasks like self-healing networks, and control tasks like dynamic bandwidth allocation.

[3835] A simulation engine may operate alongside the AI models to create real-time simulations of network scenarios like congestion events, equipment failures, and demand spikes. The engine may validate decisions about network changes and may provide feedback to continuously improve the AI models' performance as network conditions evolve.

[3836] The network modules may implement both edge and cloud capabilities - edge networking may enable processing close to value chain entities like warehouses and factories,

while cloud networking may provide scalable resources for intensive processing. This hybrid approach may enable distributed processing across the entire value chain network.

[3837] The network modules may support localized data processing at network edges where value chain entities operate, such as in warehouses, ports, and manufacturing facilities. This may reduce latency and may enable real-time optimization of local operations while maintaining coordination with the broader network.

[3838] The network modules may optimize data flows by considering multiple variables: data types like sensor readings versus video streams, protocols such as TCP/IP or industrial protocols, network congestion levels across different paths, timing requirements for real-time versus batch processing, and data volumes from different sources. The modules may dynamically route traffic across multiple paths based on these factors.

AI MODEL-DRIVEN GAMING ENGINE EDGE SYSTEM

[3839] In embodiments, an AI model integrated with or supporting a gaming engine or other gaming system may be integrated with edge networking capabilities, such as for caching relevant content and/or producing generative AI content relevant to efficient, localized, personalized and/or or customized digital twin, virtual reality, augmented reality, metaverse or similar content experiences. This may include various edge networking device embodiments, such as by integrating the generative AI and gaming capabilities into a network box, router, switch, edge device, IoT system, mesh networking node, networking chip or chipset, networking system on chip (SoC), FPGA, or the like. Collectively these may be referred to herein, for simplified reference, as an AI model-driven gaming engine edge system.

[3840] In embodiments, the AI model-driven gaming engine edge system may be integrated with financial infrastructure systems, such as to enable embedded marketplaces and transactions, as described elsewhere in this disclosure and the documents incorporated by reference herein.

[3841] In embodiments, the AI model-driven gaming engine edge system may be configured to integrate with data handling systems that are capable of sensor and data fusion, i.e., receiving and processing content that provides an understanding of the context in which the information handled by the AI model-driven gaming engine edge system is used. This may include sensor data that provides information about a set of users (e.g., data detected from wearable devices or physiological data, data from IoT devices or cameras indicating information about the user or the user's environment, or the like); behavioral data about the user (e.g., clickstream data indicating the user's navigation patterns, transactional data, user purchases of content or other items, and other sources); demographic, psychographic and geographic data about populations users (including as determined by various similarity and clustering algorithms) and the like; and/or user-generated content data, including explicit indications of preferences, such as ratings, collaborative filtering and surveys and indirect indications, such as tastes, preferences and styles indicated by user-generated content, such as social media content (e.g., showing a style of dress or preference for a genre of music or content), written content, such as reflecting interests in particular content and/or indicators of user personality, and user interaction content, such as user

interactions within interactive game play (e.g., user dialog, navigation and other choices), with digital twins, and/or within virtual reality, augmented reality and/or metaverse environments. In embodiments, data and sensor fusion provide a holistic understanding of user content that can be used to train AI models (either at the edge or in the cloud) to have an accurate understanding of a user's position, duties, status, condition, preferences, personality, or the like. Once trained, the AI models can be deployed in the AI model-driven gaming engine edge system to generate content that is highly tuned to the context and preferences of the user.

[3842] In embodiments, the AI model-driven gaming engine edge system may be configured and trained to understand a user profile across different platforms, such as traditional linear media, enterprise platforms, entertainment platforms (e.g., music, film, television, streaming, and the like), and/or interactive platforms (e.g., sports betting, gaming, digital twin, social media, metaverse, virtual reality, augmented reality, and many others). Once the profile is understood, a resulting set of models may be deployed in the AI model-driven gaming engine edge system to provide highly tuned content and experiences to the user across all such channels. Such AI models may include long-term models that provide a general understanding of stable characteristics of the user (e.g., personality, long-term interests, relationships with other users, affinity for subjects, relationships with organizations) and short-term models that provide an understanding of immediate context and interests (e.g., content that is highly relevant to the user's current location).

[3843] In embodiments, different forms of content may be cached for efficient delivery to the user at the AI model-driven gaming engine edge system, and they may be presented in a set of integrated content-access interfaces that make different content forms available. As an understanding of an individual user (stable/long-term and/or immediate/contextual) is embedded in a set of AI models as noted above (aided by data and sensor fusion), that understanding can be linked to suites of content of any and all types, which can be gathered and cached by the AI model-driven gaming engine edge system and used to organize suites of content for presentation to the user, either in a unified "home screen" type interface or in forms where links to any one type of content are embedded into the other forms of content. Once content is gathered, it may be used both to configure content offerings and to generate, locally at the AI model-driven gaming engine edge system, generative content, such as text, images, videos, audio, offers, promotions, and many others. The AI model-driven gaming edge system may thus serve as an important enabling component for a broader platform as described herein that links various multiplatform content experiences, models that are trained on a holistic understanding of the user, including based on cross-platform interactions, are deployed at the edge to configure offerings and to generate relevant content for the user.

[3844] As implied by the above, the AI model-driven gaming engine edge system may include a set of distinct models, a set of hybrid models, or the like. For example, one AI model (or component) may be used to understand a long-term profile of a user, another AI model may be used to understand a short-term context of a user, another AI model may be used to discover, gather and/or configure a set of content for the user, other models may be used to generate

highly personalized or customized generative content (such as involving text, voice, music, images, videos, offers, promotions, or mixed modes of the above), and other models may be used to resolve transactions. In one such configuration, a set of models is used to predict a set of immediate preferences of the user and another set of models is used to generate a configuration of content or other content that is designed to satisfy those preferences.

[3845] In embodiments, an instance of an AI model-driven gaming engine edge system may be configured, provisioned and deployed for a single specific user, a defined set of similar users, or a defined specific group of users (such as a family or workgroup). The system may then be trained over time to learn the profile of the user or set, to gather and configure content and other content, and/or to generate highly relevant generative works.

[3846] In embodiments, the AI model-driven gaming engine edge may be trained to learn the personality of a user by observation of the user's cross-platform behavior (including various aspects noted in the discussion of sensor and data fusion above). By observing behavior (e.g., by machine vision), transactions, content consumption, interactions, and generated content, as well as by driving interactions that are designed to elicit indicators of personality (such as collaborative filtering, surveys and dialog), the AI model can classify the user according to psychometric or neurometric measures of personality (e.g., a Jungian, Myers-Briggs, or Keirsey Temperament type, other the like). These can be augmented by other indicators, such as social media and writing content by the individual, content preferences, and the like. With an understanding of personality embedded into an AI model, the personality can be used as an input to a content discovery and/or configuration system and/or a generative AI system to produce content that is appealing to the personality.

[3847] By integrating these technical features, the network layer 37000 is capable of supporting the complex networking requirements of various operational environments.

DATA LAYER

[3848] In embodiments, an artificial intelligence-enabled system of systems can have a data layer system of systems, a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to operate on fused data that can be the output of a sensor and/or data fusion system.

[3849] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include sensor data.

[3850] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include wearable device data.

[3851] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include social media data.

[3852] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include crowdsourced data.

[3853] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include website data.

[3854] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include distributed data.

[3855] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include API data.

[3856] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include edge data.

[3857] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include mobile data collector data.

[3858] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include industrial data.

[3859] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include transactional data.

[3860] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include transportation data.

[3861] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include value chain network data.

[3862] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include supply chain data.

[3863] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include demand data.

[3864] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include shipping data.

[3865] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include energy data.

[3866] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include enterprise data.

[3867] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include public data.

[3868] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include market data.

[3869] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include news data.

[3870] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include weather data.

[3871] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include contextual data.

[3872] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include health data.

[3873] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include demographic data.

[3874] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include insurance data.

[3875] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include simulation data.

[3876] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include experimental data.

[3877] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include synthetic data.

[3878] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include echoed data.

[3879] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include communication data.

[3880] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include behavioral data.

[3881] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include location data.

[3882] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include pricing data.

[3883] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include sales data.

[3884] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include tax data.

[3885] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include historical data.

[3886] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include physiological data.

[3887] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include environmental data.

[3888] In embodiments, the data layer system of systems having a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks can be configured to operate on fused data that can include key performance indicator (KPI) data.

[3889] In embodiments, an artificial intelligence-enabled system of systems 31000 can have a data layer system of systems 38000. With continuing reference to FIG. 189, the data layer system of systems 38000 can incorporate data modules 38002. The data layer system of systems 38000 can cooperate with a set of machine learning systems 38010, a set of artificial intelligence systems 38020, and/or a set of neural networks 38030 configured to operate on fused data 38050. By way of these examples, the fused data 38050 can be formed from the output of a sensor 38060 and/or a data fusion system 38070 each of which can be associated with one or

more data sources 38500. The one or more data sources 38500 can include sensor data 38100, wearable device data 38110, social media data 38120, crowdsourced data 38130, website data 38140, and distributed data 38150. The one or more data sources 38500 can also include API data 38160 that can be accessed through various APIs at 38550 in FIG. 190. With continuing reference to 189, the one or more data sources 38500 can also include edge data 38170, mobile data collector data 38180, and industrial data 38190. In further examples, one or more data sources 38500 can include transactional data 38200 in a financial infrastructure environment. In additional examples, one or more data sources 38500 can include transportation data 38210, which can be used to support transportation systems, self-driving vehicles, software-defined vehicles, and software-enabled vehicles. In yet more examples, one or more data sources 38500 can include value chain network data 38220, supply chain data 38230, demand data 38240, and/or shipping data 38250, which can be used to further the understanding of entity demand and supply management. In additional examples, one or more data sources 38500 can include energy data 38260, which can be used to further facilitate energy delivery, compute power, and data management at various edge applications. In further examples, one or more data sources 38500 can include enterprise data 38270, public data 38280, market data 38290, news data 38300, and weather data 38310. In additional examples, one or more data sources 38500 can include contextual data 38320 in various settings. In yet further examples, one or more data sources 38500 can include health data 38330 in support of various digital health and healthcare platforms. In additional examples, one or more data sources 38500 can include demographic data 38340, insurance data 38350, simulation data 38360, experimental data 38370, synthetic data 38380, echoed data 38390, communication data 38400, behavioral data 38410, location data 38420, pricing data 38430, sales data 38440, tax data 38450, historical data 38460, physiological data 38470, environmental data 38480, and key performance indicator data 38490.

[3890] FIG. 190 depicts additional exemplary features, capabilities, and interfaces of exemplary embodiments of a data layer system of systems 38000. In embodiments, the API data 38160 can be accessed by multiple APIs at 38550. By way of these examples, the APIs at 38550 can include one each of an ingestion 38552, parse 38554, analyze 38556, and elements that can be interconnected for providing intelligence-based and other derivatives of data sources, such as the multitude of data sources 38500. These elements may be controlled, configured and adjusted by a data layer control 38560.

[3891] In embodiments, data sources may be retrieved and/or received through the APIs 38550. In embodiments, the APIs may be an open/standardized APIs that, among other things, may equip the data layer system of systems 38000 for integration with and into current and emerging ecosystems. By way of these examples, APIs can further enable data layers to integrate into a wide range of data workflows and access the API data 38160 and various data sources 38500, such as corporate internal workflows, metadata for visual content, source data, inter-jurisdiction data workflows, digital rights management and the like.

[3892] In embodiments, the data layer system of systems 38000 can include, reference, and/or provide market orchestration elements 38570 that may facilitate use of data layer capabilities for various aspects of market orchestration, including, without limitations, software orchestrated transactions, software orchestrated marketplaces, and the like. Market orchestration elements 38570 may facilitate deployment of a data layer, such as a web service embodiment, as an integrated function of a market orchestration platform, such as an automated market orchestration system of systems as described herein. In embodiments, the data layer system of systems 38000 may provide data and network pipeline capabilities for market orchestration.

[3893] The data layer system of systems 38000 can include reference and/or provide cross-market interaction capabilities 38580 that may enable leveraging various types of intelligence data layer, computation capabilities, and storage and data sourcing capabilities, as well as intelligence capabilities for cross-market interactions. Cross-market interaction capabilities 38580 may include interfaces to one or more marketplaces, transaction environments, and the like, so that, among other things, a data layer supportive of a system of systems (SoSs) may be configured with one market in a cross-market integration deployment as a source of data and with another market in the cross-market integration deployment as a consumer of the data layer. In embodiments, a similar arrangement may be constructed between two or more markets so that data in either market can be used as one or more data sources and can be influenced by data from another market. By way of these examples, cross-market interactions 38580 may be accomplished through one or more market-to-market data layers that form data pipelines for intelligent exchange of data among markets, such as data about buyers in one market and about sellers in another.

[3894] The data layer system of systems 38000 can include functions and processes 38590, for an exemplary market-oriented deployment may include software-oriented transaction functions and processes, automatic transaction transactions and processes, and the like. Functions and processes 38590 for the data layer system of systems 38000 may include signaling availability of data (e.g., emergence of an occurrence of source data) that impacts data produced by the data layer of the platform. Other exemplary functions and processes 38590 may include embedding into smart contracts, tokens, or other occurrence (e.g., an initiation of a smart contract and the like). Yet other functions and processes may include payments between/among machines and the like.

[3895] In embodiments, the data layer system of systems 38000 may include and/or be associated with data layer technology enablers 38600, such as 5G networking, artificial intelligence, visualization technology (e.g., VR/AR/XR), distributed ledger, and the like.

[3896] In embodiments, the data layer system of systems 38000 can include and/or leverage cloud-based virtualized containerization capabilities and services 38602, such as without limitation a container deployment and operation controller, such as Kubernetes 38604 and the like. Cloud-based virtualized containers 38602 provide for data layers to be deployed close to source data, thereby potentially reducing network bandwidth consumption or the potential for

network disturbances in a data workflow, especially when addressing voluminous local situations such as in industrial and commercial environments.

[3897] In embodiments, technologies may be provided by and/or enabled by the data layer system of systems 38000 include intelligence services 38606, such as artificial intelligence, machine learning and the like. These intelligence services 38606 may be provided by the data layer SoSs 38000, or accessed (e.g., as third-party services) via one or more. The data layer control 38560 may be provided access to the intelligence services 38606. In embodiments, the data layer control 38560 may provide its own set of intelligence services.

[3898] In embodiments, the data layer system of systems 38000 may include transaction/market-oriented capabilities, and services that may include market platforms 38610, transaction flows 38612, users 38614, and content providers 38616. For multi-party transaction environments, the data layer SoSs 38000 may be configured and operated to satisfy a range of consumer needs for market analysis, transaction efficiencies, cost containment, buy/sell decisions and the like.

[3899] In embodiments, the data layer system of systems 38000 may include an exemplary intelligent data layer architecture 38650, as depicted in FIG. 191. The exemplary intelligent data layer architecture 38650 can include a controlled pipeline of data processing stages that process data from one of multiple data sources 38660. The controlled pipeline includes an ingestion stage 38662, an analysis stage 38664, a derived intelligence stage 38668, and a consumer visualization portal 38670. By way of these examples, the ingestion stage 38662 can receive and/or harvest data from one or more of the plurality of sources 38660. Processing at the ingestion stage 38662 may include parsing content of data sources, such as to determine structure, content, relationships among data elements, intended meaning of the data elements, relationships between data, structure, and meaning, and the like. In embodiments, an ingestion facility that may operate at the ingestion stage 38662 may be configured to be aware of data source aspects, such as structure, etc. Ingestion stage 38662 may be configured or adjusted by an operator of the layer, a platform controller, the data layer control 38560, and the like. Configuration of the ingestion stage 38662 may be based on one or more data structures that represent aspects of one or more of the data sources 38660. One such aspect is a location of the data source, such as an Internet or other type of address (e.g., URL, port number, stream identifier, publication and/or broad channel, sensor output location, and the like) from which data may be accessed, queried, pulled, downloaded, streamed or otherwise accessed. Further aspects of a data source may include interface methods and/or protocols, such as through data transfer handshakes, Internet Protocols, and/or query languages. Data block size, access rate (e.g., maximum, frequency, or other timing-related parameter related to accessing the data source), and the like may also be adjusted or configured. Yet other aspects of data source 38660 and the data layer architecture 38650 may include one or more meanings of data from the data source, such as may be represented through a data source ontology and the like. Information such as units, scalars and the like for numerical values may be provided. In an example of data sources providing measurement data, a first source may provide numerical values in inches, a

second source may provide values in meters, and a third source may provide values in light years. This local data source context may prove useful for relating data sources. In an example of data sources providing reputation rating values, an ontology for each source that establishes a minimum value, maximum value, and adjustable increments between the two provide a way of establishing meaning of a data element from such a source.

[3900] In further examples, the data sources may impose or be arranged with a geometry/structure that may imbue meaning on data values, relationships among data values, and the like. Exemplary embodiments of structures that can impact the meaning and relationships of data value from a data source can be a hierarchical arrangement of the data.

[3901] In embodiments, the data layer system of systems 38000 can be configured to receive/retrieve and process data that is configured as a hierarchy and can be configured to assign a relationship attribute to a pair of data values that are configured as parent/child in the hierarchy. Likewise, a rule that may be applied in the hierarchy, such as certain types of changes to a parent data value impacting a corresponding child data value establish an immutable relationship between the data values as they are processed through the ingestion processing pipeline (e.g., ingestion, analysis, and intelligence).

[3902] In embodiments, automation can be introduced through programmatic configuration of data values in an ingestion stage execution data structure. These data values may be retrieved from, for example, an ingestion parameter portion of a data layer control data store 38672. Machine learning may facilitate training an artificial intelligence system to identify aspects of a data source that are relevant for configuring the ingestion stage 38662 to receive and process its data.

[3903] In embodiments, the data layer control 38560 may develop an understanding of data sources, such as meaning of data values. In embodiments, developing an understanding may be in context of an expected use of data from one or more data sources, such as use of the data for determining a status of a term of a smart contract, a result of a software orchestrated transaction, and the like. Further data from data sources may be understood within a context of other data sources. In an example of such understanding, a plurality of marketplace monitors may capture data regarding activity within a marketplace.

[3904] In embodiments, the data layer control 38560 may further be configured to maintain a schedule of collection activity for one or more of the data sources 38560. A collection schedule may be one of a plurality of aspects associated with ingestion that may be influenced by data sources and by data layer pipeline processing needs (e.g., to satisfy needs of a user of the data layer). Such a collection schedule may be based on a rate or occurrence of availability of new or revised data from a source. In embodiments, some data sources may produce new/updated data on a schedule determined from activities associated with the data source, such as a sample schedule of the sensor 38060, the data fusion 38062, and the like. In an example, a rule for a system that produces data available through a data source may limit data releases periodically (e.g., such as at the end of a work shift, once per day, and the like). In another example of data source-dependent collection activity may be motivated by events, such as completion of

marketplace transactions and the like. In embodiments, the data layer control 38560 may monitor a port on a data network for an indication of data availability at a data source. When an indication is detected (e.g., a change in a data value of the port), an ingestion process may commence.

[3905] By way of these examples, other information of processes related to ingestion may include costs, such as costs to perform data source access, ingestion processing and the like. The cost for data collection may include access fees charged by a data source (e.g., subscription costs, access event costs, demand-based costs, and the like). Costs for data collection may be based at least in part on an amount that a consumer (e.g., a user of capabilities and output from a data layer) pays for access to information produced by the data layer that is based at least in part on data from the data source. By way of these examples, there may be a range of cost structures for source data access, at least some of which may be based on data source reputation, relevance of data from the data source, timeliness of updates of the data from the data source, and the like. In embodiments, a data layer may access data from a data source and utilize it a plurality of times to produce layer intelligence for a plurality of users of the data layer. Costs for access and for the occurrences of use of the accessed data may be different from each other, such as a cost to access may be a multiple of (e.g., 2-time, 10-times and the like) of a cost for each subsequent occurrence of use of the accessed data.

[3906] In embodiments, the data layer system of systems 38000 may be configured as a producer of source data, so that a corresponding ingestion facility may be owned (and optionally operated) by the data producer. In an example of data source closely held within the data layer system of systems 38000, a data source may retain privacy of its source data by exposing, such as through publication and the like, an output of the owned data, which may include information derived from the source data or select portions of the source data, such as non-confidential information associated with marketplace transactions and the like.

[3907] In embodiments, further operation of the data layer architecture 38650 can include ingestion operation that may also be based on a method of data collection. In embodiments, the data sources 38660 may be part of a data supply chain. Exemplary embodiments of a data supply chain may include a physical chain, such as may be embodied by a set of physical sensors (e.g., industrial internet of things sensors) that capture physical activity (e.g., of an industrial machine, and the like) and provide a representation of that activity as a form of data. A physical connection, such as a set of networked devices (e.g., the Internet), may convey the representation of the activity produced by the sensor(s) to, for example, a physical access port (e.g., a networked computer and the like) from which a data layer may ingest this data. Other types of data collection may include logical supply chains, such as data marts, data marketplaces, aggregated data publishers, and the like. In embodiments, data representative of a physical activity, such as a production machine in an enterprise, may be provided through a physical interface that presents the data from a corresponding sensor as it changes in near real time. That same data may be provided through a logical interface, such as a data base that

facilitates access to a plurality of values of data from the sensor, optionally with a capture time, capture sequence and the like to enable batched or delayed use of data from the data source.

[3908] In embodiments, the data layer control 38560 may execute in virtual containers on, for example, cloud computing systems that are distinct from a physical embodiment of the data layer control 38560.

[3909] In embodiments, the data layer architecture 38650 may include the analyze stage 38664 that may receive data from the ingestion stage 38662. The analyze stage 38664 may receive raw ingestion data, adapted ingestion data (e.g., contextually adjusted), data derived from ingestion data (e.g., differences between sequential accesses of a single data source), metadata associated with the ingestion data (e.g., validity window, units, access costs, and the like), and the like.

[3910] In embodiments, the analyze stage 38664 may perform various operations on ingestion stage parsing and other ingestion activity results based on a range of factors, such as comparing data from a plurality of sources for similarity, fitness to a purpose, differences, based on types of data within or across data sources and the like. In embodiments, analysis may include comparing sources against a target use of intelligence derived from a data source. Analysis of ingestion results may attempt to determine if one or more data elements from a data source may meet consumption target requirements, such as meeting a validity time constraint, an accuracy constraint, a frequency of update constraint, relevance to a consumption subject matter focus, and the like. In embodiments, a data layer may target providing intelligence for buyers of services in a software orchestrated transaction marketplace. The data layer architecture 38650 may include functionality to publish or otherwise convey requests for data, such as types of data, and the like that one or more data sources may attempt to meet. The data layer control 38560 may determine if ingested data meets requirements of the published request for data, such as if the data complies with one or more parameters in the request.

[3911] In embodiments, the data layer control 38560 may facilitate configuring data in the layer for publication, such as configuring one or more advertisements that characterize the ingested data in terms of potential intelligence value, relevance and the like. Examples include making data, such as derived intelligence data available on a marketplace (e.g., configuring indexing schemes and the like), making the content searchable (e.g., identifying keywords, terms, values, or the like that may facilitate discovery of intelligence derived from the ingested data through use of a search capability. The data layer control 38560 may facilitate access visibility to information of the data layer by publishing, communicating, or broadcasting samples of the data over a network, directly to potential consumers and the like.

[3912] In embodiments, the analyze stage 38664 may suggest, predict, and/or estimate value of data for a plurality of different consumers. These estimates may be used by the data layer control to impact intelligent data layer functions, such as data layer intelligence pricing and the like that may be differentiated for different users. Further, such analysis may indicate that intelligence derived from a first data source may be more or less valuable to different target consumers.

[3913] In embodiments, the data layer control 38560 may use feedback from intelligent data layer users regarding, among other things, usefulness of intelligence derived from one or more

data sources 38660 to facilitate ingestion and analysis activities and the like. In an example, positive feedback on intelligence derived from a data source may result in the data layer control 38560 to make use of the data source for deriving other types of intelligence and the like.

[3914] In embodiments, the data layer control 38560 may ingest data from a plurality of data sources; each such set of data may be individually analyzed. In embodiments, data from a plurality of data sources may be parsed, so that data with similar characteristics (e.g., data that is indicative of a buyer reputation) may be aggregated and analyzed. Examples of multiple data sources that may provide data with similar characteristics include mobile devices, types of sensors, media-focused transaction systems (e.g., content buying, advertising placement, rights management and the like). As noted above, the data layer control 38560 may communicate configuration data (e.g., sets of data that enable the analyze stage 38664 to perform various analysis functions). In embodiments, the data layer control 38560 may provide a set of analysis algorithms that may execute on one or more processors.

[3915] In embodiments, the data layer architecture 38650 may include the intelligence stage 38668. By way of many examples, an intelligence stage 38668 may utilize artificial intelligence capabilities to develop an understanding about data sources including, among things, uses of data, values of data, applicability of data, collection patterns and relevance to intelligence consumption and the like. Additional intelligence that may be derived by intelligence stage may include, without limitation, layer specific data relevance, relevance of data from one layer to another, value of intelligence to a consumer, such as to a transactor. By way of many examples, intelligence stage may derive intelligence useful for forming new marketplaces from transactional data gathered from an existing marketplace.

[3916] In embodiments, the data layer architecture 38650 may include a consumer visualization portal 38670 that may communicate with elements of the data layer pipeline, such as the intelligence stage 38668 from which the consumer visualization portal may receive derived intelligence. In embodiments, the consumer visualization portal 38670 may facilitate access to derived intelligence (and optionally to other data of the data layer architecture 38650). The consumer visualization portal may announce availability of derived intelligence to a preconfigured set of consumers and candidate consumers through use of a messaging channel (e.g., SMS messaging and the like). The consumer visualization portal may announce derived intelligence through various other techniques including, broadcasting across one or more communication channels (e.g., TWITTER™, X™, and the like). The consumer visualization portal may deliver at least select derived intelligence to intelligent data layer consumers based on a subscription or similar arrangement between the consumer(s) and the data layer. In embodiments, the consumer visualization portal may reference publication configuration data that may identify which consumers are to receive which portion(s) of intelligence derived from which data source and cause the derived intelligence to be provided to (and/or made available to) one or more consumers based on this intelligence publication data. The consumer visualization portal may also communicate with the data layer control 38560, such as to receive configuration, access intelligence data, analyzed data, ingested data and the like.

[3917] In embodiments, the consumer visualization portal 38670 may further receive from one or more data layer data consumers, consumer preferences for interfacing with the consumer, requests for updates to previously communicated derived intelligence data, requests for onboarding, feedback on uses of derived intelligence data and the like. In embodiments, a consumer may communicate a derived intelligence delivery schedule to the consumer visualization portal where it may be combined with other intelligence delivery data, such as other consumer delivery schedules, and the like and utilized by the consumer visualization portal and/or the data layer control when performing derived intelligence delivery and communication functions.

[3918] In embodiments, the data layer control 38560 may provide configuration, control, storage, and processing capabilities, such as for providing access to algorithms from an algorithm portal 38680, facilitating access by the data layer control 38560 to intelligence services 38682, managing storage of a data store, managing storage of intelligent data layer ingestion data and outcomes, analysis outcomes, derived intelligence and the like in a data store 38672, and without limitation providing a mechanism by which a user, such as an owner and/or operator of the data layer architecture 38650 can configure and otherwise interface with system of the data layer system of systems 38000.

[3919] In another exemplary embodiment, the data layer control 38560 may facilitate access to analysis algorithms by the analyze stage 38664. Further the data layer control 38560 may work cooperatively with an algorithm portal 38680 to receive algorithms for analysis, ingestion, deriving intelligence, and the like. By way of many examples, the data layer control 38560 and the data source 38500 may identify and/or provide one or more ingestion algorithms for performing ingestion actions on data provided. The algorithm may be provided through the algorithm portal 38680 received and optionally vetted by the data layer control 38560 and stored in the data store 38672. In another exemplary embodiment of use of the algorithm portal 38680, a consumer may provide an algorithm for deriving intelligence from data under the consumer's control, such as in a marketplace transaction environment in which a seller provides transaction data as a source of data to the data layer for processing, optionally with other relevant data, for deriving intelligence associated with seller marketplace activities. In embodiments, deployment of a data layer as part of a data workflow for an enterprise may involve adapting existing workflow steps with intelligent data layer capabilities. By way of many examples, a purchasing department of an enterprise may have a set of algorithms that are used to process sales forecast data for generating purchasing guidelines. A data layer may be constructed for the enterprise that produces intelligence regarding the generated purchasing guidelines by utilizing sales forecast processing algorithms that have been uploaded through, for example, the algorithm portal 38680.

[3920] In embodiments, the intelligence services 38682 may include a range of intelligence functions and capabilities including, without limitation artificial intelligence functions, machine learning functions, neural network functions, prediction capabilities, and many others. In an example of intelligence services 38682 for the data layer system of systems 38000, an ingestion

stage 38662 may provide data from the data sources 38660, along with associated descriptive information (e.g., metadata, structural data, ontology data and the like) to a self-learning neural network capability of the intelligence services 38682 to aid in determining an approach to parsing the data source.

[3921] In embodiments, the intelligence services 38682 may further have access to subject matter associated intelligence, such as cross-market intelligence gathered through processing, optionally external to the data layer architecture 38650, marketplace configuration, operational, and transaction outcomes for different sets of cross-market offerings. By way of further examples using intelligence services for ingestion, this subject matter intelligence can be applied when a data source is determined to be related to a product or other offering that is similar to products or offerings on which the subject matter intelligence is based. In such instances when a source of data relates to a product (e.g., mobile device) and subject matter intelligence known to the intelligence services 38682 is based on or associated with mobile device technology, the corresponding intelligence services may be utilized for enhancing/optimizing pipeline operations being performed on the source data.

[3922] In embodiments, the exemplary data layer architecture 38650 can include a user interface 38690 through which a user, such as an operator and the like, may interface with systems of the data layer and the like (e.g., query and maintain data in the data layer data store 38672). The user interface 38690 may facilitate configuring portions of the data layer, such as the algorithm portal, data retention rules for accessed by the data layer control 38560, prioritization of use of the data layer resources by data consumers, and the like.

[3923] The data layer system of systems 38000 may serve as a flexible and scalable infrastructure designed to enable the seamless integration, ingestion, and analysis of data from an extensive range of sources positioned within the artificial intelligence convergence system of systems 31000. The data layer system of systems 38000 can be positioned within the multi-layered architectures artificial intelligence convergence system of systems 31000 and can support the generation of actionable intelligence and foster integration across diverse ecosystems. The data layer system of systems 38000 supports a modular design to support corporate operations, market orchestration, and cross-functional workflows, as these systems of systems become important for organizations navigating both established and emerging technologies.

SENSOR DATA 38100

[3924] Sensor data may include real-time readings from devices monitoring environmental, industrial, or physical conditions. These sensors can provide valuable inputs for applications such as manufacturing quality control, environmental monitoring, and smart city management. For example, in an industrial setting, sensors might monitor machinery vibrations to predict maintenance needs. In environmental monitoring, air quality sensors may track pollution levels, enabling responsive public health measures. The data layer system of systems may process such high-frequency inputs, ensuring timely integration into decision-making frameworks.

WEARABLE DEVICE DATA 38110

[3925] Wearable devices may generate diverse datasets ranging from health metrics, such as heart rate and activity levels, to geolocation tracking. These devices often serve applications in healthcare, fitness, and workforce management. A healthcare provider, for instance, might leverage wearable data to monitor chronic conditions and deliver personalized care plans. The data layer system of systems can analyze this data in real-time, identifying trends and generating predictive insights to improve health outcomes.

SOCIAL MEDIA DATA 38120

[3926] Social media platforms may produce vast volumes of unstructured and structured data, including text, images, and videos. Businesses can use this data to gauge public sentiment, analyze trends, and optimize marketing strategies. For instance, a retail brand might monitor customer feedback on social platforms to refine its offerings. The data layer system of systems may enable sentiment analysis and predictive modeling to help businesses adapt to market demands effectively.

CROWDSOURCED DATA 38130

[3927] Crowdsourced data may encompass information contributed by a distributed network of individuals, such as reviews, surveys, and collaborative maps. This data can be crucial for applications requiring diverse perspectives, such as urban planning or product development. For example, transportation authorities might use crowdsourced traffic reports to optimize routes and reduce congestion. The data layer system of systems can aggregate and contextualize such data to provide actionable insights.

WEBSITE DATA 38140

[3928] Website data may include user interactions, clickstreams, and behavioral patterns. This data is invaluable for e-commerce, digital marketing, and user experience optimization. For instance, an online retailer might analyze browsing habits to recommend products, enhancing customer satisfaction and sales. The data layer system of systems can process large volumes of web traffic data, while its intelligence services may identify patterns to improve user engagement.

DISTRIBUTED DATA 38150

[3929] Distributed data may refer to datasets stored across multiple locations, such as cloud services or decentralized networks. This type of data is essential for global enterprises and blockchain applications. For example, a supply chain management system might rely on distributed data to track goods across international borders. The data layer system of systems may harmonize distributed datasets, ensuring consistency and enabling comprehensive analysis.

API DATA 38160

[3930] API data may provide programmatic access to external systems, enabling the integration of third-party services and real-time data retrieval. Applications may include weather

forecasting, financial market analysis, and social media monitoring. For example, a fintech platform might use API data to retrieve real-time stock prices and integrate them into portfolio management tools. The data layer system of systems may seamlessly ingest and process API data, supporting dynamic and responsive applications.

EDGE DATA 38170

[3931] Edge data may originate from devices operating at the periphery of a network, such as IoT devices in remote locations. This data is often used in scenarios requiring low-latency processing, such as autonomous vehicles or industrial automation. For instance, edge devices in a factory might monitor production line conditions and trigger immediate adjustments. The data layer system of systems may process edge data locally or in the cloud, enabling rapid responses and enhanced operational efficiency.

MOBILE DATA COLLECTOR DATA 38180

[3932] Mobile data collectors may gather information from field operations, such as surveys, inspections, or environmental sampling. This data is vital for industries like agriculture, construction, and utilities. For example, agricultural researchers might use mobile devices to record soil conditions and crop health. The data layer system of systems may aggregate and analyze this data, providing actionable insights for field operations.

INDUSTRIAL DATA 38190

[3933] Industrial data may encompass metrics from manufacturing processes, such as temperature, pressure, and production rates. This data is critical for optimizing operations, ensuring quality, and predicting maintenance needs. For instance, a factory might use the data layer system of systems to monitor and analyze machine performance, reducing downtime and improving efficiency.

TRANSACTIONAL DATA 38200

[3934] Transactional data may include records of financial or operational exchanges, such as purchases, sales, or payments. This data is foundational for industries like retail, finance, and logistics. A retail chain might use the data layer system of systems to analyze point-of-sale transactions, identifying trends and informing inventory strategies.

TRANSPORTATION DATA 38210

[3935] Transportation data may include vehicle telemetry, traffic patterns, and logistics tracking. This data is essential for optimizing supply chains and improving urban mobility. For example, a logistics provider might analyze transportation data to reduce delivery times and fuel consumption. The data layer system of systems may process this data in real-time, enhancing decision-making capabilities.

VALUE CHAIN NETWORK DATA 38220

[3936] Value chain network data may map relationships and dependencies across suppliers, manufacturers, and distributors. This data can support strategic planning and risk management. For instance, a manufacturer might use the data layer system of systems to visualize its supply chain and identify bottlenecks, improving overall efficiency.

SUPPLY CHAIN DATA 38230

[3937] Supply chain data may track the movement of goods, inventory levels, and supplier performance. This data is critical for ensuring timely deliveries and managing costs. A retailer might use the data layer system of systems to monitor supply chain performance and predict potential disruptions, enabling proactive measures.

DEMAND DATA 38240

[3938] Demand data may capture customer preferences, market trends, and purchasing patterns. This data is vital for forecasting and aligning production with market needs. A consumer goods company might use the data layer system of systems to analyze demand data, optimizing product availability and marketing strategies.

SHIPPING DATA 38250

[3939] Shipping data may include information about freight movements, carrier performance, and delivery timelines. This data is crucial for logistics and e-commerce. For instance, an online retailer might use the data layer system of systems to track shipments and provide real-time updates to customers.

ENERGY DATA 38260

[3940] Energy data may capture metrics from utilities, such as consumption rates, production levels, and grid performance. This data supports sustainability initiatives and operational efficiency. A smart grid operator might use the data layer system of systems to balance supply and demand, reducing energy waste.

ENTERPRISE DATA 38270

[3941] Enterprise data may encompass internal records, such as HR files, financial statements, and operational metrics. This data is essential for decision-making and regulatory compliance. A corporation might use the data layer system of systems to integrate and analyze enterprise data, supporting strategic planning.

PUBLIC DATA 38280

[3942] Public data may include datasets from government agencies, NGOs, and other public entities. This data can inform policy-making, research, and community initiatives. For example, a city planner might use the data layer system of systems to analyze public transportation data, improving service delivery.

MARKET DATA 38290

[3943] Market data may capture financial metrics, stock prices, and commodity trends. This data is crucial for investment and trading strategies. A hedge fund might use the data layer system of systems to analyze market data, identifying opportunities and mitigating risks.

NEWS DATA 38300

[3944] News data may include headlines, articles, and broadcasts. This data can inform sentiment analysis, trend detection, and crisis management. A public relations firm might use the data layer system of systems to monitor news coverage, shaping communication strategies.

WEATHER DATA 38310

[3945] Weather data may include forecasts, historical records, and real-time observations. This data supports agriculture, logistics, and disaster response. A logistics company might use the data layer system of systems to optimize routes based on weather conditions.

CONTEXTUAL DATA 38320

[3946] Contextual data may provide situational awareness by integrating multiple data sources. This data supports decision-making in dynamic environments. A retailer might use the data layer system of systems to combine sales data with demographic insights, tailoring marketing efforts.

HEALTH DATA 38330

[3947] Health data may include patient records, diagnostic results, and public health statistics. This data supports personalized medicine and population health management. A healthcare provider might use the data layer system of systems to analyze health data, improving care delivery.

DEMOGRAPHIC DATA 38340

[3948] Demographic data may capture information about populations, such as age, income, and education levels. This data informs marketing, policy-making, and resource allocation. A non-profit organization might use the data layer system of systems to target programs effectively.

INSURANCE DATA 38350

[3949] Insurance data may include claims, risk assessments, and policy details. This data supports underwriting, fraud detection, and customer service. An insurance company might use the data layer system of systems to analyze claims data, reducing losses and improving customer satisfaction.

SIMULATION DATA 38360

[3950] Simulation data may model hypothetical scenarios, such as financial projections or disaster response plans. For example, an organization planning for disasters from weather can continue its preparations by using simulation data processed through the data layer system of

systems 38000. This data can allow the modeling of potential impacts and the development of optimized response strategies. A financial institution may also employ simulation data to project future market trends or assess the implications of new investment strategies. By integrating simulation outputs, the data layer system of systems can enable informed decision-making and facilitate the testing of complex hypotheses across diverse industries.

EXPERIMENTAL DATA 38370

[3951] Experimental data may originate from controlled tests and research activities, capturing observations, measurements, and results. For instance, pharmaceutical companies may conduct clinical trials and generate experimental data related to drug efficacy. This data can then be processed and analyzed by the data layer system of systems 38000 to identify patterns and support regulatory submissions. Similarly, an automotive company might analyze experimental data from vehicle safety tests to enhance design standards. The flexibility of the data layer system allows for integration of experimental data into broader analytical frameworks, fostering innovation and development.

SYNTHETIC DATA 38380

[3952] Synthetic data may refer to artificially generated datasets that mimic real-world data patterns. These datasets are often used in scenarios where privacy concerns limit the availability of real data, such as training machine learning models. For example, a financial institution may generate synthetic transaction data to test fraud detection algorithms. The data layer system of systems 38000 can synthesize, store, and validate such datasets, enabling organizations to derive insights while adhering to privacy regulations. This capability is particularly valuable for advancing AI and machine learning applications.

ECHOED DATA 38390

[3953] Echoed data may involve data derived from repetitions or feedback loops, often used to validate or enhance existing datasets. For instance, a recommendation system may use echoed data to refine its predictions by analyzing user responses to previous suggestions. The data layer system of systems 38000 can seamlessly manage echoed data streams, incorporating them into real-time analytics to improve service delivery and user experience.

COMMUNICATION DATA 38400

[3954] Communication data may include emails, messages, and voice recordings, providing insights into interpersonal or organizational interactions. For example, businesses may analyze communication data to identify collaboration patterns and improve team productivity. The data layer system of systems 38000 can process such data while ensuring compliance with privacy and security standards. Applications in customer service, for instance, may benefit from sentiment analysis of customer interactions to enhance support experiences.

BEHAVIORAL DATA 38410

[3955] Behavioral data may capture individual or group actions and preferences, often derived from online activities, app usage, or consumer interactions. A retail company might analyze behavioral data to personalize marketing campaigns or optimize product recommendations. The data layer system of systems 38000 can integrate behavioral data with other sources, enabling organizations to uncover trends and enhance customer engagement strategies.

LOCATION DATA 38420

[3956] Location data may include GPS coordinates, geofencing insights, and spatial movement patterns. This data can support applications in transportation, urban planning, and retail. For instance, logistics companies may use location data to optimize delivery routes, while urban planners may analyze it to improve public infrastructure. The data layer system of systems 38000 provides a robust framework for processing and integrating location data to support geospatial analytics and decision-making.

PRICING DATA 38430

[3957] Pricing data may encompass historical price points, market comparisons, and promotional effects. Retailers may use this data to optimize pricing strategies, ensuring competitiveness and profitability. The data layer system of systems 38000 can process large volumes of pricing data, integrating it with demand and market data to enhance predictive pricing models.

SALES DATA 38440

[3958] Sales data may include transaction records, customer purchase histories, and revenue trends. Businesses can analyze sales data to identify growth opportunities and optimize inventory management. For instance, a retailer might use the data layer system of systems 38000 to track sales performance across regions and refine marketing campaigns accordingly.

TAX DATA 38450

[3959] Tax data may involve records of tax filings, liabilities, and regulatory compliance. Corporations can use this data to ensure accuracy in financial reporting and minimize audit risks. The data layer system of systems 38000 may facilitate the integration of tax data with financial and enterprise data, streamlining compliance processes.

HISTORICAL DATA 38460

[3960] Historical data may provide context by capturing trends and events from the past. This data is invaluable for forecasting, policy-making, and research. A financial institution might use historical market data to identify cycles and predict future trends. The data layer system of systems 38000 can enable efficient storage and retrieval of historical data, enhancing long-term analysis and strategic planning.

PHYSIOLOGICAL DATA 38470

[3961] Physiological data may include metrics such as heart rate, blood pressure, and respiratory rate, often collected through medical devices or wearables. Healthcare providers may use this data for personalized treatment plans and remote monitoring. The data layer system of systems 38000 can process physiological data in real-time, supporting advanced health analytics and early detection of medical conditions.

ENVIRONMENTAL DATA 38480

[3962] Environmental data may encompass metrics related to air quality, temperature, and water levels, often used in sustainability and disaster response efforts. For example, environmental monitoring organizations might analyze this data to predict and mitigate climate impacts. The data layer system of systems 38000 can integrate environmental data with simulation and public datasets to support comprehensive environmental management strategies.

KEY PERFORMANCE INDICATOR DATA 38490

[3963] Key performance indicator KPI data may track metrics aligned with organizational objectives, such as customer satisfaction scores or operational efficiency rates. Businesses can use this data to evaluate performance and inform strategic initiatives. The data layer system of systems 38000 may enable real-time monitoring and analysis of KPIs, ensuring that organizations remain agile and focused on their goals.

RESOURCE LAYER

RESOURCE MODULES

[3964] Referring to FIG. 184 and FIG. 192, the AI convergence system of systems 31000 may comprise a resource layer system of systems ("resource layer") 39000 having a set of resource modules 39002. In embodiments, the set of resource modules 39002 may include an advanced compute resources module 39004, a quantum computing resources module 39006, an edge computing resources module 39008, an intelligent agent resources module 39010, a model resources module 39012, an expert resources module 39014, an attention resources module 39016, a sensor resources module 39018, a robotic resources module 39020, a natural resources module 39022, a food resources module 39024, a geological resources module 39026, a physical storage resources module 39028, a physical security resources module 39030, a human resources module 39032, a machine resources module 39034, an advertising resources module 39036, a communication resources module 39038, a cloud-based resources module 39040, an enterprise resources module 39042, a facility resources module 39044, a heating resources module 39046, a cooling resources module 39048, an equipment resources module 39050, an information technology (IT) resources module 39052, a networking resources module 39054, and/or a material resources module 39056. In some embodiments, the resource modules 39002 of the resource layer 39000 may further include an energy resources module, a distributed energy resources module, and/or a renewable energy resources module. In some embodiments,

the resource modules 39002 of the resource layer 39000 may further include a healthcare resources module. In implementations, the resource modules 39002 of the resource layer 39000 may include an industrial resources module. In embodiments, the resource modules 39002 may include a financial resources module and/or a transactional resources module. In some implementations, the resource modules 39002 may further include a transportation resources module, a physical delivery resources module, and/or a vehicular resources module. In some embodiments, the resource modules 39002 of the resource layer 39000 may further comprise a shipping container resources module, a shipping resources module, and/or an additive manufacturing resources module.

[3965] In embodiments, the resource layer 39000 enables the automated and optimized provisioning of resources used to support various systems and services of an enterprise and/or operational environment. For example, operational environments may include industrial environments, manufacturing environments, warehouse environments, shipping environments (e.g., container ports, shipping containers, shipyards, and the like), energy environments (e.g., fossil fuel energy environments such as oil rigs, pipelines, and refineries or nuclear energy environments such as nuclear power plants), retail environments, transportation environments (e.g., airports, train stations, bus stops, airplanes, train cars, and the like), research environments, transaction and banking environments, datacenter environments, compute environments, hospitality environments, gaming environments, and entertainment environments, among many others.

[3966] Each resource module of the resource layer 39000 may include one or more processors and one or more memories storing computer-executable instructions that, when executed by the one or more processors, cause the one or more processors to implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize the provisioning of the set of resources corresponding to that particular module. The machine learning systems may be trained using supervised, unsupervised, or reinforcement learning techniques on historical resource allocation data, usage patterns, performance metrics, and simulated data (e.g., data generated from a simulation engine, a foundation world model, a set of digital twins, or the like). The neural networks may comprise multiple layers including, but not limited to, convolutional layers, recurrent layers, and fully connected layers, wherein the layers are configured to process input data and generate output predictions for resource optimization. The artificial intelligence systems may implement various algorithms including decision trees, random forests, and gradient boosting machines to analyze resource utilization patterns and make real-time optimization decisions. The resource layer 39000 may further include a simulation engine or set of foundation world models operating in parallel with the machine learning systems, artificial intelligence systems, and/or neural networks, wherein the simulation engine and/or set of foundation world models are configured to generate real-time simulations of resource allocation scenarios, validate optimization decisions, and provide feedback to the machine learning models for continuous improvement and adaptation to changing conditions. In embodiments, the simulation engine may employ

physics-based modeling, discrete event simulation, or agent-based modeling techniques to accurately represent the dynamics of resource utilization and system behavior. In some embodiments, each resource module of the resource layer 39000 may include one or more processors and one or more memories storing computer-executable instructions that, when executed by the one or more processors, cause the one or more processors to implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to perform an intelligence task related to that particular resource module. Such intelligence tasks may include other types of optimizations, as well as predictive intelligence tasks, detection and/or identification intelligence tasks, decision support tasks, automation tasks, configuration and/or control intelligence tasks, and the like.

ADVANCED COMPUTE RESOURCE MODULE

[3967] For example, the advanced compute resource module 39004 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of advanced compute resources. In embodiments, advanced compute resources may include high-performance computing (HPC) systems, graphics processing units (GPUs), tensor processing units (TPUs), field-programmable gate arrays (FPGAs), AI accelerators, distributed computing systems, and the like.

QUANTUM COMPUTING RESOURCES MODULE

[3968] In another example, the quantum computing resources module 39006 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of quantum computing resources. In embodiments, quantum computing resources may include quantum processing units (QPUs), quantum annealers, gate-based quantum processors, quantum error correction systems, and the like.

EDGE COMPUTING RESOURCES MODULE

[3969] In another example, the edge computing resources module 39008 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of edge computing resources. In embodiments, edge computing resources may include Internet of Things (IoT) gateways, edge servers, edge AI accelerators, real-time analytics platforms, and the like.

INTELLIGENT AGENT RESOURCES MODULE

[3970] In another example, the intelligent agent resources module 39010 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of

intelligent agent resources. In embodiments, intelligent agent resources may include autonomous agents, chatbot frameworks, multi-agent systems, decision-making algorithms, and the like.

MODEL RESOURCES MODULE

[3971] In another example, the model resources module 39012 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of model resources. In embodiments, model resources may include predictive models, prescriptive analytics models, simulation models, and the like.

EXPERT RESOURCES MODULE

[3972] In another example, the expert resources module 39014 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of expert resources. In embodiments, expert resources may include rule-based systems, decision-support systems, expert knowledge bases, and the like.

ATTENTION RESOURCES MODULE

[3973] In another example, the attention resources module 39016 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of attention resources. In embodiments, attention resources may refer to the human, computational, and/or AI-driven focus allocated to specific tasks, processes, or decision-making. For example, AI models may be trained to focus on anomalies in sensor data or prioritize alerts in high-traffic environments. In embodiments, attention resources may be hybrid attention resources, such as a combination of human and AI focus, where AI filters or highlights critical information for human review.

SENSOR RESOURCES MODULE

[3974] In another example, the sensor resources module 39018 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of sensor resources. In embodiments, sensor resources may include environmental sensors, motion sensors, imaging sensors, health sensors, and the like.

ROBOTIC RESOURCES MODULE

[3975] In another example, the robotic resources module 39020 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of robotic resources. In embodiments, robotic resources may include industrial robots, collaborative robots (cobots), autonomous mobile robots (AMRs), material handling robots, pick-and-place robots, robotic

arms, robotic dock workers, maintenance robots, hospitality robots, cleaning robots, pipeline inspection robots, baggage handling robots, security robots, cargo loading robots, and the like.

NATURAL RESOURCES MODULE

[3976] In another example, the natural resources module 39022 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of natural resources. In embodiments, natural resources may include water resources, mineral resources, forest resources, and the like.

FOOD RESOURCES MODULE

[3977] In another example, the food resources module 39024 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of food resources. In embodiments, food resources may include agricultural produce, processed foods, perishable items, and the like.

GEOLOGICAL RESOURCES MODULE

[3978] In another example, the geological resources module 39026 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of geological resources. In embodiments, geological resources may include minerals, fossil fuels, underground water reserves, and the like.

PHYSICAL STORAGE RESOURCES MODULE

[3979] In another example, the physical storage resources module 39028 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of physical storage resources. In embodiments, physical storage resources may include warehouses, cold storage facilities, data storage units, and the like.

PHYSICAL SECURITY RESOURCES MODULE

[3980] In another example, the physical security resources module 39030 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of physical security resources. In embodiments, physical security resources may include surveillance systems, access control systems, alarm systems, locking systems, and the like.

HUMAN RESOURCES MODULE

[3981] In another example, the human resources module 39032 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of human resources.

MACHINE RESOURCES MODULE

[3982] In another example, the machine resources module 39034 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of machine resources.

ADVERTISING RESOURCES MODULE

[3983] In another example, the advertising resources module 39036 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of advertising resources. In embodiments, advertising resources may include digital ad placements, social media campaigns, targeted marketing systems, and the like.

COMMUNICATION RESOURCES MODULE

[3984] In another example, the communication resources module 39038 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of communication resources. In embodiments, communication resources may include email systems, messaging platforms, telecommunication networks, and the like.

CLOUD-BASED RESOURCES MODULE

[3985] In another example, the cloud-based resources module 39040 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of cloud-based resources. In embodiments, cloud-based resources may include virtual machines, containerized services, distributed databases, and the like.

ENTERPRISE RESOURCES MODULE

[3986] In another example, the enterprise resources module 39042 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of enterprise resources. In embodiments, enterprise resources may include financial systems, operational workflows, customer relationship management (CRM) platforms, and the like.

FACILITY RESOURCES MODULE

[3987] In another example, the facility resources module 39044 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by facility management systems, the provisioning of the set of facility resources. In embodiments, facility resources may include factories, textile mills, assembly plants, manufacturing facilities, distribution centers, fulfillment centers, storage facilities, warehouse facilities, container ports and terminals, shipyards, freight forwarding facilities, oil rigs and offshore platforms, refineries, natural gas processing plants, pipeline pump stations,

coal mining facilities, nuclear power plants, uranium enrichment facilities, retail facilities, airport facilities, bus terminal facilities, platforms and waiting areas, ticketing facilities, maintenance facilities, banking facilities, ATMs and kiosks, call center facilities, office facilities, datacenters, high-performance computing (HPC) facilities, cloud computing facilities, hospitality facilities, and entertainment facilities, among many others.

HEATING RESOURCES MODULE

[3988] In another example, the heating resources module 39046 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of heating resources. In embodiments, heating resources may include boilers, geothermal heating systems, district heating networks, and the like.

COOLING RESOURCES MODULE

[3989] In another example, the cooling resources module 39048 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of cooling resources. In embodiments, cooling resources may include HVAC systems, liquid cooling systems, evaporative cooling units, and the like.

EQUIPMENT RESOURCES MODULE

[3990] In another example, the equipment resources module 39050 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of equipment resources. In embodiments, equipment resources may include industrial tools, construction equipment, diagnostic machines, and the like.

INFORMATION TECHNOLOGY RESOURCES MODULE

[3991] In another example, the information technology (IT) resources module 39052 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of IT resources. In embodiments, IT resources may include servers, data management systems, and the like.

NETWORKING RESOURCES MODULE

[3992] In another example, the networking resources module 39054 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of networking resources. In embodiments, networking resources may include switches, routers, hubs, bridges, network interface cards (NICs), access points (APs), modems, firewalls, network management software, virtual private networks (VPNs), network operating systems, software-defined networking (SDN) platforms, load balancers, wireless networking resources (e.g., Wi-Fi

networks, cellular networks, and satellite networks), edge networking devices, IoT gateways, content delivery networks (CDNs), traffic analyzers, and many others.

MATERIAL RESOURCES MODULE

[3993] In another example, the material resources module 39056 may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of material resources. In embodiments, material resources may include raw materials (e.g., metals and minerals), natural resources, processed materials, energy-related materials (e.g., fuels), construction materials, 3D printing materials, components and parts, agricultural products, biomaterials, recycled materials, and many others.

ENERGY RESOURCES MODULE

[3994] In another example, the energy resources module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of energy resources. In embodiments, energy resources may include power grids, fossil fuel power plants, and the like.

DISTRIBUTED ENERGY RESOURCES MODULE

[3995] In another example, the distributed energy resources module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of distributed energy resources. In embodiments, distributed energy resources may include solar panels, wind turbines, battery storage systems, and the like.

RENEWABLE ENERGY RESOURCES MODULE

[3996] In another example, the renewable energy resources module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of renewable energy resources. In embodiments, renewable energy resources may include solar farms, wind farms, hydroelectric systems, and the like.

HEALTH RESOURCES MODULE

[3997] In another example, the health resources module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of health resources. In embodiments, health resources may include diagnostic tools, patient records systems, telemedicine platforms, and the like.

INDUSTRIAL RESOURCES MODULE

[3998] In another example, the industrial resources module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of industrial resources. In embodiments, industrial resources may include assembly lines, heavy machinery, manufacturing systems, and the like.

FINANCIAL RESOURCES MODULE

[3999] In another example, the financial resources module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of financial resources. In embodiments, financial resources may include trading platforms, risk management tools, credit scoring systems, and the like.

TRANSACTIONAL RESOURCES MODULE

[4000] In another example, the transactional resources module may include a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of transactional resources. In embodiments, transactional resources may include payment gateways, point-of-sale systems, blockchain networks, and the like.

TRANSPORTATION RESOURCES MODULE

[4001] In another example, the transportation resources module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of transportation resources. In embodiments, transportation resources may include trains, buses, logistics platforms, autonomous vehicles, and the like.

PHYSICAL DELIVERY RESOURCES MODULE

[4002] In another example, the physical delivery resources module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of physical delivery resources. In embodiments, physical delivery resources may include delivery trucks, drones, parcel sorting systems, and the like.

VEHICULAR RESOURCES MODULE

[4003] In another example, the vehicular resources module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of vehicular resources. In embodiments, vehicular resources may include electric vehicles, autonomous vehicles, taxis, forklifts, trucks, utility vehicles, material transport vehicles, automated guided vehicles (AGVs), refrigerated trucks, oil tanker trucks, emergency response vehicles, armored

vehicles, and the like), ships, tugboats, smart containers, trains, buses, aircraft, unmanned aerial vehicles (UAVS), electric bikes, electric scooters, and the like.

SHIPPING CONTAINER RESOURCES MODULE

[4004] In another example, the shipping container resources module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of shipping container resources. In embodiments, shipping container resources may include smart containers, container tracking systems, container storage systems, and the like.

SHIPPING RESOURCES MODULE

[4005] In another example, the shipping resources module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of shipping resources. In embodiments, shipping resources may include cargo ships, freight tracking systems, shipping schedules, and the like.

ADDITIVE MANUFACTURING RESOURCES MODULE

[4006]

[4007] In another example, the additive manufacturing resources module may implement a set of machine learning systems, a set of artificial intelligence systems, and/or a set of neural networks configured to optimize, by computing hardware, the provisioning of the set of additive manufacturing resources. In embodiments, additive manufacturing resources may include 3D printers, 3D printer subsystems, and the like.

[4008] In embodiments, a computer-implemented system provides a value chain network management platform that includes a resource layer configured to implement AI-based learning models. The resource layer may optimize value chain network resources through automated provisioning and allocation. The system includes processors that execute instructions stored in memory to implement the resource layer's optimization capabilities.

[4009] The resource layer may implement various types of AI-based learning models including transformer models for processing sequential data, convolutional neural networks for pattern recognition, deep learning models specifically trained on value chain outcomes, supervised models trained on labeled examples, semi-supervised models that can learn from both labeled and unlabeled data, unsupervised models that find hidden patterns, and reinforcement learning models that optimize through trial and error.

[4010] In embodiments, the resource layer can manage and optimize multiple types of value chain network resources including infrastructure resources for production facilities, shipping resources for logistics operations, warehousing resources for storage facilities, retailing resources for distribution centers, components and materials resources for manufacturing, energy resources for operations, and computation resources for processing needs.

[4011] A simulation engine may operate in parallel with the AI-based learning models to generate real-time simulations of different resource allocation scenarios within the value chain network. The simulation engine may validate optimization decisions made by the AI models and provide continuous feedback to improve the models' performance over time as conditions change.

[4012] The resource layer may implement distributed ledger technology to create an immutable record of resource allocation decisions across the value chain network. This provides transparency in resource management while enabling automated execution of optimization strategies through smart contracts.

[4013] The resource layer may analyze historical resource allocation data, usage patterns, and performance metrics from value chain network operations to optimize how resources are allocated. This data-driven approach can enable the system to learn from past resource utilization to improve future allocation decisions.

[4014] Digital twins may be implemented within the resource layer to create virtual representations of physical value chain resources and simulate different allocation scenarios before actual deployment, which enables testing and validation of resource optimization strategies in a risk-free virtual environment.

[4015] In embodiments, the resource layer performs predictive intelligence tasks using its AI models to forecast future resource needs across different parts of the value chain network. This forward-looking capability can help ensure resources are provisioned appropriately to meet anticipated demands.

[4016] The resource layer may implement various modeling techniques including physics-based modeling to simulate physical resource behavior, discrete event simulation to model resource allocation events, and agent-based modeling to represent dynamic interactions between resources. These techniques enable accurate representation of resource utilization patterns.

[4017] The resource layer may continuously monitor conditions across the value chain network and adapt resource allocation in real-time based on changing circumstances. This dynamic optimization can ensure that resources are allocated efficiently as network conditions evolve.

MULTI-FACTOR RESOURCE OPTIMIZATION PLATFORM

[4018] At the resource layer 39000, AI capabilities for resource optimization enable a platform for providing multi-factor optimization of resources ("the multi-factor resource optimization platform"). Multi-factor resource optimization may refer to the process of achieving the best possible resource allocation outcome and/or solution that meets several objectives simultaneously. Multi-factor resource optimization objectives for operations of may include profitability, cost reduction, improved customer experience and satisfaction, employee satisfaction, sustainability, market expansion, innovation, operational efficiency, risk management, fraud prevention, safety, corporate social responsibility, and the like.

[4019] In some implementations, the resource layer 39000 may have AI capabilities for financial resource optimization associated with the use of AI workloads, including generative AI workloads in various applications. Generative AI workloads may refer to a set of tasks and/or processes that are handled or augmented by generative intelligence technologies. These workloads may comprise a range of activities where generative AI systems generate, enhance, or modify offerings and communications, content, experiences, and the like. Generative AI media workloads may also include personalization and/or localization workloads, such as when generative AI is used for tailoring content or experiences to individual or regional preferences, editing workloads, visual effects workloads, marketing generation workloads, or any other workloads described throughout this disclosure.

[4020] For example, generative AI may be utilized to generate maintenance instructions, reports, product designs, production plans, marketing materials, training materials, simulations, AR/VR experiences and the like; simulate process flows, vehicle routes, foot traffic, layouts, product demand scenarios, and the like; and many others. In embodiments, generative AI may be used to provide personalized and/or localized content, offers, promotions, experiences, and many others. In embodiments, financial costs for the use of generative AI workloads may include compute costs associated with generative AI, licensing costs associated with the use of generative AI (such as for the use of generative AI models trained on copyrighted data sets), and the like.

[4021] In embodiments, the compute costs may refer to the expenses associated with the computational resources needed to train and run AI models, including generative AI models. These costs may vary depending on model complexity, training data volume, training duration, hardware requirements (e.g., GPUs, TPUs, or the like), and cloud services/infrastructure, energy consumption, maintenance, scaling, software and/or development tools (e.g., such as software and development tools that facilitate generative AI model training and deployment), and the like.

[4022] In embodiments, the resource layer 39000 may have AI capabilities for computational resource optimization of generative AI workloads. In embodiments, the computational resources for generative AI media workloads may include hardware resources such as graphics processing units (GPUs), tensor processing units (TPUs), central processing units (CPUs), high-performance computing (HPC) clusters, and the like; software and frameworks such as machine learning frameworks, AI development platforms, data processing software, and the like; data storage solutions; networking infrastructure (e.g., high bandwidth networks); cloud computing platforms; and energy resources; among others.

[4023] In some implementations, the resource layer 39000 may have AI capabilities for computational resource optimization for workloads involving other types of computation, including, but not limited to HPC, quantum computing, distributed computing, gaming engines (e.g., the Unreal Engine), cloud computing, edge computing, other types of artificial intelligence models, neural networks, deep learning, and many others. In embodiments, these computational resources may be used in tandem with generative AI computational resources. For instance,

generative AI models may be used with the Unreal Engine to generate casino gaming experiences and/or content.

[4024] Strategies for computational resource optimization (e.g., for advanced computation) at the resource layer 39000 may include the use of parallelization (e.g., data parallelization, model parallelization, pipeline parallelization, and hybrid parallelization), efficient algorithms (e.g., optimization algorithms, data sampling techniques, dimensionality reduction, quantization and pruning, sparse representations and the like), dynamic resource allocation based on computational load, optimization based on energy efficiency, load balancing, caching, and many others.

[4025] In embodiments, quality of service (QoS) optimization may converge with AI capabilities of resource layer 39000 to enable resource optimization for AI workloads. Performance optimization may ensure that the AI models meet speed and responsiveness requirements, which may involve model simplification, efficient algorithms, hardware acceleration (e.g., using GPUS and TPUs), load balancing, and resource allocation. To achieve scalability, techniques such as elastic scaling may be leveraged to dynamically adjust computational resources based on demand. Failover mechanisms, redundancy, and error handling may be used to ensure the reliability and availability of the AI models. Latency management may be utilized to minimize delays in AI processing to meet real-time requirements. Techniques such as computational resource scheduling, job queue management, caching, and the like may be used to optimize the use of AI and other computational resources. Monitoring and analytics tools, AI model management techniques, and load testing and simulation may also be used to optimize the use of computational resources for AI workloads.

[4026] In some implementations, blockchain risk management may converge with AI capabilities 23002 of resource layer 39000 to enable resource optimization for generative AI workloads. Blockchain can facilitate the use of decentralized computational resources and decentralized computational resource marketplaces. Further, smart contracts can be used to automatically manage the allocation of computational resources based on predefined requirements and/or real-time needs. Computational resource usage and computational resource-related transactions may be recorded on a blockchain, providing a record of how resources are being used.

[4027] At the resource layer 39000, AI capabilities for resource optimization may utilize AI-driven predictive analytics, machine learning algorithms, AI-driven optimization algorithms, AI-driven digital twins that use simulations to test different scenarios or strategies, AI-driven autonomy, and any of the AI capabilities discussed throughout this disclosure.

[4028] In embodiments, the resource layer 39000 may manage and optimize a common set of resources that are used across different sets of enterprise and/or operational applications and/or use cases. This may include dynamic resource allocation and optimization strategies applicable to complex and varied environments such as industrial settings (e.g., manufacturing plants and warehouses), transportation infrastructures (e.g., airports and shipping ports), energy facilities (e.g., oil rigs and nuclear power plants), retail operations, datacenters, hospitality venues, and

the like. By implementing a flexible resource management approach, the resource layer 39000 can dynamically adjust computational, logistical, and operational resources to meet the specific demands of these diverse environments.

[4029] The core functionality of the resource layer 39000 involves intelligent resource provisioning, which enables adaptability across different operational contexts. For instance, in a manufacturing environment, it might optimize machine utilization and energy consumption, while in a shipping context, it could manage container tracking, logistics routing, and real-time inventory management. Similarly, in datacenter and compute environments, the resource layer 39000 would focus on workload distribution, server resource allocation, and energy efficiency.

AI SUBSYSTEM INTEGRATOR SYSTEM

[4030] Referring now to Fig. 193, an AI subsystem integrator system 39100 is illustrated in accordance with embodiments described herein. Artificial intelligence (AI) and machine learning (ML) systems disclosed herein may be used to facilitate the automation of data integration, networking integration and other technology integration by system 39100. For example, the AI subsystem integrator system 39100 may train an integrator 39102 that includes at least one AI/ML system trained according to training workflows 39104 and training inputs 39106 to integrate a plurality of platforms and their respective subsystems A-n. For example, the training workflows 39104 and training inputs 39106 may utilize various methods and inputs disclosed herein and in the documents incorporated by reference (e.g., based on technical data sets, existing models, human supervision, deep learning on outcomes and/or robotic process automation learning on human execution of tasks, among others), across both the internal subsystems A-n within each of the platforms and across the different platforms and their subsystems. In the example provided, integrator 39102 includes a data integrator 39108, a network integrator 39110, an attribution integrator 39112, and other integrators 39114. For example, a set of AI systems may be trained to generate an intra-platform integration system 39116 that integrates various subsystems A-n within each of the platforms. Similarly, a set of AI systems may be trained with reference to the intra-platform integration system 39116 to generate a trans-platform integration system 39118 that facilitates interaction between the platforms. For example, integrator 39102 may learn the interfaces of a subsystem of a first platform and a subsystem of a second platform and to generate a data and network connection among them, as well as an interface by which a user, or an AI agent, may manage the data and network connection. Thus, disclosed herein is an artificial intelligence system that is configured and trained to generate a set of configurable integration capabilities across the internal subsystems and services of a set of platforms. Such an artificial intelligence system may be referred to herein as the "AI subsystem integrator system" and may integrate data and/or network communication, data storage (local and/or network), management interfaces, energy resources, and other capabilities. It may be noted that at scale an AI subsystem integrator system may generate a fully integrated or converged system that has massively parallel connectivity across the internal subsystems of the respective platforms, translating them from

isolated platforms into a converged platform. This may evolve from various pairwise converged platforms among the various members of the platforms into a fully converged platform that encompasses subsystem elements of all of them.

[4031] In each case, a cross-service resource optimization system, which may comprise or employ a set of AI agents trained in ways noted above, may be used to manage, configure, deploy, provision, and/or optimize the respective subsystems or services that operate within a linked, integrated or converged system (the respective subsystems and/or services having previously been isolated to their respective standalone platform(s)).

[4032] For example, across any two or more subsystems or services across platforms may be optimized by measuring and allocating the energy that is used across the platforms, such as use of battery storage by devices, use of energy by GPUs in cloud computing or data centers (such as for generative AI workloads), and the like. Thus, in embodiments, methods and systems are provided for measuring and/or optimizing energy resources across the subsystems and services of at least two platforms.

[4033] As another example, across any two or more subsystems or services across platforms may be optimized by measuring and allocating the data storage resources that are used across the platforms, such as use of storage by devices, by cloud computing or data centers (such as for generative AI workloads), and in particular by network resources, such as use of network storage for caching content to reduce latency and improve efficiency of use of network connectivity resources. Thus, in embodiments, methods and systems are provided for measuring and/or optimizing data storage resources across the subsystems and services of at least two platforms.

[4034] As another example, across any two or more subsystems or services across platforms may be optimized by measuring and allocating the networking resources that are used across the platforms, such as use of bandwidth of network resources by devices, by cloud computing or data centers, and the like to reduce latency and improve efficiency of use of the network or connectivity resources. Thus, in embodiments, methods and systems are provided for measuring and/or optimizing network resources across the subsystems and services of at least two platforms.

[4035] As another example, across any two or more subsystems or services across platforms may be optimized by measuring and allocating the computation storage resources that are used across the platforms, such as use of computation resources by devices, by cloud computing or data centers (such as for generative AI workloads), and the like. Thus, in embodiments, methods and systems are provided for measuring and/or optimizing computation resources across the subsystems and services of at least two platforms.

[4036] In embodiments, higher level management systems may collectively optimize across multiple factors, such as energy, computation and network resources, including use of artificial intelligence systems (alone or in combination with analytic models) that are trained as noted herein to achieve multifactor optimization across resource types.

MULTIPLATFORM ATTENTION MANAGEMENT SYSTEM

[4037] Referring now to Fig. 194, a higher-level multiplatform attention management system 39200 may be used to track and optimize attention across platforms (e.g., across integrated subsystems 39202, 39204, and 39206), such as by understanding where overall attention by customers (or by intelligent agents that operate on their behalf) may be increased by encouraging transitions across platforms, rather than maximizing only within a platform. This may include a multiplatform experience orchestration system 39208 for orchestrating experiences that are intentionally designed to encourage a user to move from platform to. The multiplatform attention management system 39200 may be used to monitor attention and provide input to a multiplatform attention orchestration system 39210 in order to improve the overall attention by users across the respective platforms. This may include any two platforms, or a converged platform among two or more platforms, or an overall converged platform in which the respective subsystems or services are fully integrated (including by AI as noted above).

[4038] In embodiments, a higher-level multiplatform revenue management system may be used to track and optimize revenue across platforms, such as by understanding where overall revenue by customers (or by intelligent agents that operate on their behalf) may be increased by encouraging transitions across platforms, rather than maximizing only within a platform. This may include the multiplatform experience orchestration system for orchestrating experiences (such as VR, entertainment, and other experiences) that are intentionally designed to encourage a user to move from platform to platform. The revenue management system may be used to monitor attention and other factors that drive short-term revenue and long-term customer value and provide input to the orchestration system in order to improve the overall revenue from users across the respective platforms. This may include any two platforms, or a converged platform among two or more platforms, or an overall converged platform in which the respective subsystems or services are fully integrated (including by AI as noted above).

CLOSING THE LOOP BY BUILDING TRUST AND DISTRIBUTING DECISIONS IN DIGITAL TWINS TO ENABLE AGILITY AND EFFICIENCY

[4039] Throughout this disclosure and the documents incorporated by reference herein, various embodiments are provided of digital twin platforms and systems that leverage sensors and other information sources, robust connectivity, and intelligence systems to allow users to experience accurate representations of the states and activities of the many entities that are involved in the workflows of an individual, group or enterprise (e.g., a company, business unit, department, government, household, non-profit, or other enterprise). These include, among others, role-based digital twins that can be configured, or that self-configure, how data is collected, stored, processed and/or presented in ways that account for the roles of respective users (e.g., ones directed to financial users, strategic users, operational users, many others). Digital twins also include adaptive digital twins that leverage intelligence systems, such as artificial intelligence, analytic systems, expert systems, or hybrids involving various permutations and combinations

thereof, to adapt how data is collected, stored, processed and/or presented based on context, such as based on the content of the information that is collected and processed. Among these adaptive digital twins, a subset, AI-driven digital twins, may use component artificial intelligence systems at any of the stages of the pipeline of information from a sensor or other basic information source to the presentation of content to a user. Artificial intelligence systems can provide outputs along a spectrum of autonomy, including: a) presenting reports, alerts, classifications, predictions, recommendations, analyses and other outputs for human review and action; b) undertaking human-supervised control of one or more aspects of a workflow, where the artificial intelligence system (acting as a co-pilot, assistant, intelligent agent, or the like to a human user) outputs a prediction and/or a recommendation for an action (which may be embodied in an instruction that can be processed by a system), and a human confirms, or adjusts, the nature of the action before it is implemented; and c) undertaking autonomous control of one or more systems or subsystems, where the artificial intelligence processes relevant information, completes necessary classifications, predictions and other decision-making steps (including where applicable, confirming risk management, governance, self-reflection or other steps) and triggers an action (such as by providing an instruction, control signal, or the like) to a system or component.

[4040] Along this spectrum from basic reporting to full autonomy, there is a varying extent to which there is a human being in the decision-making loop. Artificial intelligence systems have enormous promise to automate individual, group and enterprise workflows, providing more reliable, seamless monitoring of ongoing activities, faster response times to unexpected events, and more efficient execution of many types of tasks, among many other benefits. However, the extent to which AI systems can be trusted can vary widely, such as based on: a) the stakes involved (e.g., are there risks to human life, health or property in making a wrong decision?); b) how the AI system was trained (e.g., are there reasons to believe that there is bias in the training data that will be carried forward into the outputs of the AI system); c) how the AI system is governed or supervised (e.g., is in compliance with regulatory, legal or other governance frameworks embedded in the workloads of the system as contemplated in this disclosure and the documents incorporated by reference herein, or is there a need for separate governance or supervision?); d) how the AI system performs, in absolute terms and relative to other available systems, including other AI systems, analytic systems, or human beings (experts, other individuals, groups, or crowds, for example); e) the quality, type and/or availability of data (which can include factoring in the cost of the data); f) the quality, type and/or availability of connectivity (which can include factoring in the cost of the connectivity); g) the quality, type and/or availability of computational resources (which can include factoring in the cost of the computational resources); h) the quality, type and/or availability of other necessary resources (e.g., energy); i) environmental or contextual parameters of the workflow to which the AI system will be applied (such as the complexity of a physical environment, the presence of human beings in proximity, or the like); and other factors. As an example among many, a well-trained AI system may be highly capable of driving a vehicle down a highway during daylight,

doing so more safely than a human being who could be prone to sleepiness or distraction, but if computational, networking, or other resources are uncertain, it may be decided that the AI system should not be trusted to perform the task. Decisions about the extent to which one can trust an artificial intelligence system can be very difficult, and the extent of trust is a major factor in determining whether or not AI systems, and their many benefits, can be unlocked.

[4041] A major benefit of the various digital twin systems disclosed herein is that a digital twin platform, particularly one that is adaptive and self-configuring, can provide an ideal environment for decision making. Good decisions usually need a combination of a) fresh, accurate, relevant information; b) application of some degree of expertise; c) use of judgment to consider tradeoffs of risks; and/or d) leadership to cause implementation (which may encompass, among other things, taking on the consequences when outcomes are unfavorable). Each of these attributes can be supported by the data collection, storage and processing systems, connectivity systems, computational systems and intelligence systems described throughout this disclosure and the documents incorporated by reference herein. For example, a pipeline of IoT and edge devices and high QoS networks (adaptive networking) can pass granular, real-time sensor data about all entities in an operating environment (machines, components, humans, infrastructure, etc.), which manifests in visibility, such as for big data analytics and consulting use cases, as well as data for machine learning. Data architectures (e.g., adaptive sensing and data collection; edge query language; intelligent data storage and processing layers) and advanced computational architectures (hybrid cloud, edge, and quantum computing) can be used to optimize conditions for application of human and machine intelligence. For example, data architectures can adapt visual representations for human cognitive processing (including based on the skillset, role, experience, expertise, or cognitive parameters of a human, such measured by neurometrics, psychometrics, or other systems) and/or prepare and stage data for artificial intelligence systems (including by cleansing, deduplication, generation of synthetic data, entity resolution, normalization and other processing, generation of various embeddings that use one AI system (e.g., a trained neural network) to transform and/or compressed input data into outputs that are suitable for efficient processing by AI systems, and the like). Computational architectures can be adapted to use an appropriate mix of cloud, edge and on-device processing systems (including various chipsets described herein, such as AI chipsets and hybrid chipsets involving AI and other functions integrated together). This can include quantum computing where beneficial. Systems integration, including various configurations of systems, systems-of-systems and the like into platform and infrastructure solutions (including PaaS and IaaS configurations), with various architectures, including service-oriented architectures, microservices architectures, and the like, can integrate all relevant systems across an individual's or group's set of activities, an enterprise, or an entire business ecosystem, such that a digital twin can have access to current state and activity parameters for many relevant entities. Data and sensor fusion, such as involving sensor data and many other data sets can assist in tracking or predicting outcomes (environmental data, market data, transaction data and many others). Advanced artificial intelligence techniques can combine with human insight to generate

expert systems and models that understand and predict operational states, flows and more complex behaviors reflected in data (big data analytics and advanced artificial intelligence techniques), including compact models that are capable of operating effectively on sparse data and/or constrained computational architectures at the edge, as well as generative AI outputs that provide summaries, creative content, instructions, reports, and many other outputs from various inputs, including text, image, video, audio and multi-modal generative AI systems. AI-driven stakeholder interfaces can adaptively filter, prioritize, and distribute information for planning, simulation, decision making and operational action to appropriate stakeholders across an entire enterprise.

[4042] With the above stack of integrated systems, taking the form of the many embodiments disclosed herein and in the document incorporated herein by reference, distribution of control, of the various disparate systems, systems-of-systems, components, platforms, infrastructure elements, and other entities involved in the activities of an individual, group, or various levels and roles of enterprise can be enabled, with consideration being given, as noted above, to factors such as latency, security, safety, operational efficiency, reliability and trust.

[4043] The untapped power of the digital twin is its ability to enable collaboration, and to distribute decision making, to the right mix of human beings, artificial intelligence systems and other systems, whether in an enterprise or in the activities of an individual or group. The digital twin allows incremental change, experimentation, and easily reversible implementation, removing fear of closing the loop. For example, a digital twin can include a simulation environment that simulates, based on actual historical and current data, what outcomes most likely ensue from deployment of particular configurations of human and artificial intelligence elements in decision making and control loops. The digital twin can also provide a planning environment for deployment of artificial intelligence systems, as well as the data collection, data processing, networking, connectivity, energy, and computational systems and architectures that support them; for example, an enterprise can, using the digital twin, plan various scenarios for obtaining resources to enable more powerful AI systems, comparing projected outcomes at various resource levels and mixes. The digital twin can enable graceful migration among humans, human-AI mixes (e.g., with agents and co-pilots) and autonomous AI systems, including deploying them in ways that can be rapidly adjusted, or reversed, such as based on changing performance capabilities, contextual and environmental factors, and events; for example, an AI system might be permitted to control transactions during normal daily operations, but it could be removed from the loop, or provided with greater human supervision, in the case of major shifts in an environment, such as during severe swings in the market, after an environmental catastrophe, or the like. Thus, provided herein is a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity. Also provided herein is a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to

enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations. The resources may include ones for data collection, data processing, networking, connectivity, energy, and computational systems and architectures that support them.

[4044] As noted throughout this disclosure and the documents incorporated by reference herein disclose the training of machine learning systems in various configurations, including deep learning, supervised learning, semi-supervised learning, and the like. In many such embodiments, a human expert provides input data that is used to train the AI system, such as by tagging data sets to assist in AI classification systems; by producing code, text, images, audio, video and other inputs that are used to train generative AI systems to predict a set of outputs from a prompt; by undertaking activities and behaviors that indicate preferences to train AI systems to generate recommendations; by configuring systems, platforms and architectures that can be used to train AI systems to generate similar configurations and recommendations; by undertaking decisions in various contexts and environments that are used to train AI systems to produce recommendations, make decisions and/or output control signals in similar contexts and environments, among others. In embodiments, any of the machine learning systems or other artificial intelligence systems disclosed herein or in the documents incorporated by reference herein may be embedded in a digital twin for the purpose of enabling training of the digital twin. This may include designating a set of users (such as domain experts, managers, operational supervisors, executives, or the like) as trainers for the AI system, including based on the role, core competency, expertise, experience, or other aspects of the set of users. In embodiments, this may include designating one set of users to provide input data for initial training of a particular AI system and another set of users (possibly overlapping in part with the first set) to supervise the outputs of the AI system. Thus, disclosed herein is a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin. Also disclosed herein is a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin.

[4045] In embodiments, provided herein is a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows. This may be implemented at the level of an individual component or system, such as by allowing a user to configure, within the digital twin, the conditions under which a human (or group of humans, a combined system (human and AI co-pilot, for example), or an AI system alone will be designated as the authority for making a decision. This can include permanent settings ("never" or "always"), semi-permanent settings (e.g., ones that are reviewed on a systematic or episodic basis) and dynamic settings (i.e., where contextual conditions, environmental conditions, or other factors are

processed in real time to determine what set of entities will be designed at the decision making authority). In embodiments, decision making authority may be distributed within the digital twin based on a broader decision making framework, such as a hierarchical framework (such as an enterprise hierarchy in which individual workers are organized into groups, with lines of reporting and supervision), a rules-based framework (such as a set of voting rules by which disputes about a decision are resolved), a collaborative framework (such as where prospective alternatives are presented and discussed by a set of contributors seeking a consensus recommendation, optionally involving simulations and planning capabilities noted above), a simulation framework (where, as noted above, the digital twin can simulate outcomes based on historical and real-time data), an enterprise planning framework (which may include integration of the digital twin with enterprise planning systems and dashboard), a competitive framework (such as where alternative options are configured to compete with each other to determine which is superior, optionally involving genetic programming or other evolutionary computing systems, as noted elsewhere in this disclosure), a peer-to-peer framework (e.g., where decisions are negotiated bi-laterally or multi-laterally among entities involved); an algorithmic framework (such as where decisions are reached by a defined set of stages, possibly involving various other frameworks as hybrids in parallel, in series, in iterative loops, or the like), a principles-based framework (such as where a set of personal, group, or enterprise principles (e.g., ethical principles, values, mission statements, or the like) are codified for use when certain contextual decisions are presented), or others. As an example, many daily operational decisions might be configured to be executed autonomously by AI systems, but if those decisions are determined to have an aggregate impact on an element of the mission of an enterprise (such as a mission to continue to develop and employ a set of individuals), then the digital twin can highlight the need to bring an appropriate set of human decision makers into the loop. Thus, in embodiments, provided herein is a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework.

[4046] In embodiments, a digital twin may display various metrics to facilitate decisions about what sets and configurations of human and AI systems should be selected for a given system, system-of-systems, component, or the like. These metrics may be calculated using the data available to the digital twin through its processing functions (such as real time information about the user, available human workers, resource availability for AI systems, contextual and environmental information, information about states and activities of the entities involved in various workflows and the like) as well as by using external data sources, such as data indicating performance metrics for individuals (which may include the general population or domain experts, groups (which may include expert groups, crowds (including by crowdsourcing as disclosed elsewhere herein)) or for AI systems (including how the systems perform under

various resource conditions). Metrics may include indicators of training history, such as educational experience, work experience, and job reviews, among many others, for humans. Metrics may include training data or metadata for artificial intelligence systems, including the size of the training data set, the vintage of the training data set, the configuration of neural networks used in training, the presence or absence of synthetic data in the training data set, metrics indicating the quality of the training data set (including indicators of bias, autocorrelation, heteroskedasticity or other statistical or econometric indicators), metrics about the expertise or capabilities of the human beings used to seed and/or supervise the AI systems, and many others. As an example, two similar generative AI systems may be presented along with indicators of the time period over which they were trained, allowing a user to evaluate whether the AI systems are likely to miss important context (e.g., where training data from a time period outside one of the sets is likely to have a major influence on the outcome) or generate hallucinations (such as where a spike in unusual training data during a training period may have unduly swayed results). Thus, in embodiments, provided herein is a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. Also provided herein, in embodiments, is a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. Also provided herein, in embodiments, is a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin.

[4047] In embodiments, metrics provided within the digital twin may include performance metrics for one or more sets of human and AI entities. Human performance metrics may include metrics for individuals, experts, and groups (including crowds) of the many types, and collected by the many methods and systems, disclosed herein and in the documents incorporated by reference. For individuals, these may include various cognitive, neurometric, psychometric, emotional, attention and other metrics, including ones disclosed herein and in the documents incorporated herein, including collected by neuro-metric measurement systems (e.g., EEG, fMRI and other scanning systems), genomic and transportomics systems, psychometric testing, physiological monitoring systems (including wearable sensors, cameras, IoT systems and many others as disclosed throughout this disclosure), systems for detecting emotional state (e.g., anxiety, distress, anger, calm and others, and others), systems for measuring attention, and others. Human performance metrics may also include metrics of task performance, including quality metrics, output metrics, job assessment metrics, indicators of specific skills, expertise or competencies (e.g., educational credentials, publications and certifications), indicators of success (e.g., rates of return of a business led by the individual) and many others. Human metrics can include metrics for groups, including crowds; for example, outcome metrics from a crowdsourcing system that accumulates the "wisdom of the crowd" for a set of predictions, ideas, solutions, or the like can be compared to those of individual experts and those of various AI systems (including standalone systems and human-AI combinations). AI performance

metrics may include a wide range of metrics, including metrics of predictive accuracy, metrics indicating outcomes from use of the systems (including ones accounting for context of use), metrics of computational speed and latency, metrics of resource utilization (e.g., computation, energy, network resources, and the like), and many others. In embodiments, the digital twin may present comparative metrics across human, human-AI combinations and autonomous AI systems (including multiple options for each), so that a user of the digital twin can select, accounting for context of use, an appropriate configuration. Thus, provided herein, in embodiments, is a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. Also provided herein, in embodiments, is a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. Also provided herein, in embodiments, is a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. Also provided herein, in embodiments, is a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin.

[4048] It should be noted that an intelligent agent (referred to in some cases herein as an opportunity miner) can be used to discover sets of available sets of humans, human-AI combinations, and/or artificial intelligence systems that may be capable of improving outcomes of one or more systems, systems-of-systems or other entities represented in the digital twin. In embodiments, a user of a digital twin may configure a set of intelligent agents to undertake discovery based on prioritization by the user, such as where a user flags elements of an enterprise workflow that are perceived (or determined by metrics) to be most in need of improvement, or most likely to benefit from artificial intelligence. Thus, a digital twin system may be used as a tool for exploration of applications of artificial intelligence as well as for configuring decisions around deployment of artificial intelligence once discovered. Thus, provided herein is an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. Also provided herein is a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function.

[4049] In embodiments, a user of a digital twin may configure a set of intelligent agents to undertake discovery based on prioritization by the user, such as where a user flags elements of an enterprise workflow that are perceived (or determined by metrics) to be most in need of improvement, or most likely to benefit from artificial intelligence.

[4050] In embodiments, an artificial intelligence system may be trained, such as based on a set of human decisions, a set of outcomes, or the like, and used to configure (or recommend configuration of) deployment of one or more appropriate sets of human, human-AI combinations and autonomous AI systems. This deployment configuration system for artificial intelligence may be integrated or embedded as an enabling service or utility within a digital twin, or it may be a standalone system used to determine what options are to be presented to a user of a digital twin. Thus, provided herein is an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. Also provided herein is a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems.

[4051] In embodiments, the various discovery and configuration systems noted above may be based on general metrics of performance (e.g., comparing how humans in general perform relative to artificial intelligence systems at performing particular tasks). In other embodiments, the comparison may be highly contextual and situational, such as comparing the capabilities of specific sets of individuals that will be available at the time of decision making and the capabilities of artificial intelligence systems that will be available, either to operate as standalone systems or to work in human-AI combinations (including the general performance capabilities of the AI systems, and also the available computational, networking, energy and other resources that will be needed to run them). Situational comparison can include contextual factors, such as time of day, workforce availability, market and environmental data, and many others, such that a discovery or configuration system can recommend an appropriate configuration for a particular system, at a given place and time. For example, a moderately expensive AI system that performs well autonomously may be recommended or selected for an overnight control task, where human experts are not likely to be available and where computational, energy, or other resources are less constrained (and less expensive). An intelligent agent, as noted above, may be configured to generate a recommendation, or a configuration, based on multi-factor optimization, using various decision frameworks noted above, including being trained on a set of human decisions and/or on feedback of outcomes from past configuration actions.

[4052] Thus, provided herein is an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource

availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed.

[4053] In embodiments, as noted throughout this disclosure, smart contracts can be integrated with one or more systems of a digital twin, such that they operate on input data (e.g., detection of various events) and produce outputs that reflect transactional terms embedded in the smart contract. This may include, for example, a set of smart contracts that set liability terms relating to the consequences of the outputs of a system to which the smart contract relates. For example, a smart contract may be configured such that the provider of an AI system embedded in the digital twin (or in a system to which the digital twin has access) agrees to provide indemnification, proof of insurance, acceptance of liability, or the like for some set of consequences of using the AI system. Such terms can also include various limitations (e.g., constraints on permitted use; limitations of liability), exclusions, restrictions, and the like, thus providing, in the digital twin, a mechanism for expressly allocating the consequences of selection of a particular mix of human and AI systems to the appropriate person or organization. By referencing the performance metrics noted above, operating in real time on operational and other data, a decision maker can be aided to make a rational decision about implementation of AI, guided by a more reliable estimation of the expected value of implementing a particular mix of human and AI systems, rather than being governed by emotional factors. Thus, provided herein are methods and systems having a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin. The system displayed in the digital twin may be an artificial intelligence system.

[4054] As good decisions made within a digital twin environment or other decision making platform lead to better outcomes, trust in the reliability of machine recommendations increases, which can be tested and validated by outcome metrics. Individuals, groups and enterprises can gradually migrate decision making from centralized authority to the operating environment and from human action through various degrees of supervision to autonomy, with appropriate checks and balances at all stages (automated governance), reversing direction when the situation calls for it. Over time as trust builds in the capabilities of artificial intelligence, or human-AI combinations, to outperform humans alone, an enterprise can increasingly close loops among information technology, operations technology, and artificial intelligence technologies, enabling low-latency, highly efficient, well governed autonomous response to changing conditions at the operational level. Operators that don't ultimately close the loop will be slower than their competitors to respond to changing conditions, less efficient in their operations, and less effective in their decision making.

[4055] Individuals, groups and enterprises can unlock great benefits by properly distributing decision making and control where and when it is most effective throughout an enterprise, enabled by the integrated stack of technologies that enable a digital twin, each enhanced by artificial intelligence as described throughout this disclosure and the documents incorporated by reference herein. The true power of the convergence of information technology and operations

technology (IT/OT convergence) can be realized when decision making is optimally distributed across humans and machines, an outcome that is achieved by progressively building trust in intelligence technologies and the people who supervise them. Organizations that progress more rapidly to a more optimal state will have significant competitive advantages in operational efficiency (particularly through closed loop automation) and agility to respond to shifting market and competitive dynamics.

[4056] In embodiments, various embodiments of digital twins, intelligent agents for discovery and configuration, decision making frameworks and other methods and systems disclosed herein may be used to facilitate configuration and allocation of decision making across the various resources, entities, activities, operations, transactions, offerings and workflows involved in various supply chain, demand management, commercial, retail and point of use environments that comprise the value chain networks described throughout this disclosure and the documents incorporated by reference herein.

[4057] In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the

digital twin. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and a digital twin system that

displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of

human and artificial intelligence systems in the decision making or control workflows of an entity and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having a digital twin having a simulation environment that simulates, based on data for the entities, states and activities processed and displayed by the digital twin, a simulation of a set of outcomes predicted to result upon deployment of a set of human and artificial intelligence systems in the decision making or control workflows of an entity and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4058] In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a

prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the

outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented

in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a

set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having a digital twin that includes a planning system for deployment of a set of artificial intelligence systems and the resources required to enable the artificial intelligence systems, wherein the planning system provides a prediction of the outcomes of deployment of at least a plurality of distinctive sets of artificial intelligence systems or a plurality of distinctive sets of resource configurations and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4059] In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the

artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a

digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as trainers for the creation of an artificial

intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4060] In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based

platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and an intelligent agent that operates as a deployment

configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having a digital twin system with an interface system for designating a set of users as supervisors for an artificial intelligence system that is represented in the digital twin, wherein the artificial intelligence system operates on the data that is used to populate the digital twin and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4061] In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows and a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of options for distribution of decision making authority or

control across various systems, systems-of-systems or components across a set of entities and workflows and a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows and a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows and a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows and a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows and a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows and a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows and a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows and an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired

function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows and a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of options for distribution of decision making authority or control across various systems, systems-of-systems or components across a set of entities and workflows and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4062] In embodiments, provided herein is an AI-based platform having a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a

principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework. In embodiments, provided herein is an AI-based platform having a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework and a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework and a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework and a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework and a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework and a digital twin system that

displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework and a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework and a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework and an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework and a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision

making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having a digital twin wherein authority for decision making about what set of entities among human beings, human-AI systems, or autonomous AI systems is distributed within the digital twin based on a decision making framework selected from a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4063] In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of humans that are available

to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4064] In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments,

provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system that displays

a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4065] In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin

system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based

platform having a digital twin system that displays a set of training metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4066] In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein

is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of humans that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4067] In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that automatically discovers sets

of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of hybrid human-AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4068] In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments,

provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for

the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of performance metrics for a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4069] In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a

digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having a digital twin system that displays a set of comparative performance metrics among one or more of a set of individual humans, a human-led enterprise, a crowd of humans, a human-AI combination system, or a set of AI systems that are available to perform a set of decision making tasks for a set of entities presented in the digital twin and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4070] In embodiments, provided herein is an AI-based platform having an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function and a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment

parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having an intelligent agent that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4071] In embodiments, provided herein is an AI-based platform having a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. In embodiments, provided herein is an AI-based platform having a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. and an intelligent agent that operates as a deployment configuration system to

at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having a digital twin system having an embedded intelligent agent system that automatically discovers sets of available systems, among human systems, combined human-AI systems and standalone artificial intelligence systems that are capable of performing a desired function. and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4072] In embodiments, provided herein is an AI-based platform having an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems and a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or

automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4073] In embodiments, provided herein is an AI-based platform having a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. In embodiments, provided herein is an AI-based platform having a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. and an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having a digital twin system having an integrated intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems. and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4074] In embodiments, provided herein is an AI-based platform having an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed. In embodiments, provided herein is an AI-based platform having an intelligent agent that operates as a deployment configuration system to at least one of recommend a set of deployment configuration parameters for or automatically

configure a set of deployment parameters for a set of human, human-AI combinations or autonomous AI systems, wherein a deployment configuration is determined at least in part on a set of situational factors, the situational factors being among one or more of a set of availability factors for human resources or artificial intelligence resources, a set of capability factors for human resources or artificial intelligence resources, a set of resource availability factors for enabling a set of human resources or artificial intelligence resources, or a set of contextual or environmental factors for the system to which the configuration is to be deployed and a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4075] In embodiments, provided herein is an AI-based platform having a smart contract system embedded in a digital twin that sets terms and conditions for liability resulting from the output of a system that is displayed in the digital twin.

[4076] In embodiments, a computer-implemented system may provide a value chain network management platform with a digital twin system that enables distribution of decision making authority. The digital twin system may display options for distributing decision making authority across value chain network entities such as manufacturing facilities, warehouses, logistics providers, and retail operations. The system may receive outcome data from these distributed decision points, analyze it using AI-based learning models, and automatically adjust the distribution of authority based on demonstrated performance.

[4077] The distribution of decision making authority may be implemented through various frameworks. A hierarchical framework may organize decision rights according to organizational structure, while a rules-based framework may use defined voting or approval processes. A simulation framework may test decisions in a virtual environment before deployment, an enterprise planning framework may align with strategic objectives, and a principles-based framework may encode organizational values into the decision process. Collaborative frameworks may enable consensus-building, peer-to-peer frameworks may support direct negotiation, and competitive frameworks may allow options to compete based on performance.

[4078] The digital twin system may create virtual representations that simulate properties like production capacity, states such as inventory levels, operations including manufacturing processes, and behaviors such as response to disruptions. These simulations may be used to validate the performance impact of different decision authority distributions before they are implemented in the actual value chain network.

[4079] The system may be configured to identify situations where automated decisions should be escalated for human review. For example, if an AI system's decisions could impact core mission objectives like workforce development or customer relationships, the digital twin may highlight the need for human oversight based on defined criteria and principles.

[4080] Performance metrics may be tracked across different decision-making approaches. The system may compare outcomes when decisions are made by human operators alone, by humans working with AI assistance, or by autonomous AI systems. Metrics may include operational efficiency, cost reduction, customer satisfaction, and other key performance indicators.

[4081] The digital twin system may enable gradual migration of decision authority from centralized control to distributed operating environments. As performance data validates the effectiveness of distributed decision making, additional authority may be incrementally granted to local decision points while maintaining appropriate oversight.

[4082] If performance metrics indicate degraded outcomes - such as increased costs, delayed deliveries, or quality issues - the system may automatically reverse decision authority distributions and return control to previous configurations that demonstrated better results.

[4083] Automated governance capabilities may ensure that decision authority distributions comply with defined constraints like regulatory requirements, safety protocols, risk limits, and operational standards. The system may validate proposed changes against these constraints before implementation.

[4084] The digital twin system may facilitate collaboration between different decision makers. For example, a warehouse optimization decision may involve human managers providing strategic input, AI systems processing operational data, and human-AI teams coordinating across multiple facilities to achieve optimal results.

[4085] The AI-based learning models analyzing decision outcomes may include transformer models for processing sequential data, convolutional neural networks for pattern recognition, deep learning models trained specifically on value chain outcomes, supervised models trained on labeled examples, semi-supervised models that can learn from both labeled and unlabeled data, unsupervised models that find hidden patterns, and reinforcement learning models that optimize through trial and error.

VISUAL SEARCH WITHIN DIGITAL TWIN

[4086] In embodiments, a visual search engine may be embedded within a digital twin, wherein a user may enter an image-based query (such as by pasting an image, a set of image metadata, or the like, by drawing or otherwise creating the image, or by describing the image with a set of keywords), and the visual search engine will process the query and a set of data structures supporting the digital twin to find a set of potentially matching elements in the digital twin (such as by finding matching image identifying information, matching tags, matching or correlated metadata, or the like, or by finding images having characteristics (such as shape, color, semantic or symbolic meaning, or other attributes) that match or are correlated to the query. In embodiments, matching elements may be listed (such as in a menu bar) and/or highlighted in the visual representation of the digital twin, such as by changes in font, color, brightness, or the like. In one non-limiting example, a user of a digital twin of a building, such as an architect, designer, builder, owner, operator, tenant, visitor, or other users, may enter a picture of a space that is believed to be within the building, containing elements such as fixtures, furnishings, equipment and the like, and the visual search engine may parse the picture, find matching elements in the digital twin of the building, and present one or more options that represent likely location of the space, along with other data or representations of the space, including guidance how to reach the space, additional data on contents, and the like. For

example, a visiting maintenance professional may enter a picture of a machine that was captured on an earlier visit by a colleague or by a customer, and the visual search engine may find where the machine is now located in the digital twin and route the professional to the current location. In embodiments, the visual search engine may use artificial intelligence, in one of the many forms described herein or in the documents incorporated by reference, such as to parse queries (in natural language or in image formats); to recognize and classify objects, faces, spaces, and other visual elements, to match or correlate images and image content, text, or the like; to rank results or recommendations, such as based on the likelihood of relevance, including based on past user responses, ratings, utilization, or other measures of feedback; to optimize the presentation of results; and many other elements.

[4087] In embodiments, a digital twin of an environment, such as the interior of a home, may be automatically constructed from an arbitrary set of photos that are taken over time, such as snapshots of people, pets, and other subjects contained in the photo library of a consumer, whereby common elements within the photographs are linked by a set of artificial intelligence systems, such as object recognition systems, subsequent to which the comment elements enable a user to orient, resize, and otherwise manipulate image elements to provide a stitched view of the environment. In embodiments, a large training data set may be captured as expert users stitch view of multiple environments, such that a robotic process automation system may be trained to automatically stitch a digital twin of an environment upon receiving an input data set. In embodiments, incremental information may be added to the digital twin, such as additional images as they are captured and other content, such as information from other data sources about the environment, including data about or from IoT devices in the environment, about objects purchased for the environment, about workflows in the environment, about individuals in the environment (such as user behavior data) and the like. In embodiments, image information and other information about the environment may be captured in a blockchain. The blockchain may support a distributed ledger of transactions or events related to the environment. The blockchain may support a smart contract as described elsewhere in this disclosure. The blockchain may be augmented by a set of interfaces, such as for controlling access to the information, such as to enable private portions and public portions. In embodiments, public portions may allow third parties, such as vendors, suppliers, service providers, technology providers and others to obtain sufficient relevant information from the digital twin to meet specific needs of an owner or operator of the environment, or a worker within it, without providing access to the entire set of information contained in the digital twin.

[4088] In embodiments, a computer-implemented system may provide a value chain network management platform with a visual search engine embedded within digital twins. The visual search engine may enable users to enter image-based queries to locate and interact with elements represented in the digital twins. For example, a maintenance professional may enter a picture of manufacturing equipment captured during a previous visit, and the visual search engine may identify the current location of that equipment within the digital twin representation of a facility.

[4089] The visual search engine may accept different types of image-based input queries. Users may paste existing images directly into the interface, provide image metadata like equipment serial numbers or specifications, create drawings or sketches of items they are searching for, or enter keyword descriptions of visual elements they wish to locate. For example, a warehouse operator may sketch the shape of a specialized container they need to locate among storage areas.

[4090] The system may employ AI-based learning models to parse and process queries by recognizing objects, spaces, and visual elements within the value chain network environment. The models may analyze characteristics such as the shape of equipment, color coding of containers, semantic meaning of signage, and symbolic attributes of safety markers to identify matching elements within the digital twin representations.

[4091] When matches are found, the visual search engine may present results in multiple ways - matching elements may be listed in a menu bar for easy selection, or highlighted directly within the visual representation of the digital twin through enhanced visibility features like modified font styles, color highlighting, or increased brightness. For example, all matching storage containers may be highlighted in bright yellow within the warehouse digital twin view.

[4092] The system may provide practical guidance for physically locating matched elements, such as optimal routing through a facility to reach equipment, or step-by-step navigation instructions from current location to a specific warehouse bay. Additional contextual information may be presented, such as maintenance histories, operating parameters, or contained inventory details.

[4093] The visual search engine may leverage artificial intelligence to rank and prioritize results based on their likely relevance to the user's needs. The AI system may learn from user feedback about which results were most helpful, adapting over time to improve result rankings. For example, if maintenance staff frequently select certain types of equipment views, those may be prioritized in future similar searches.

[4094] The search capabilities may span multiple integrated digital twins representing different value chain entities - for example, searching across twins of multiple warehouses, manufacturing facilities, and distribution centers to locate specific products or equipment. This enables comprehensive visibility across the value chain network.

[4095] For each matching element found, the system may provide rich supplementary data such as specifications, status information, historical records, and guidance for physical access. For example, when matching a particular machine, the system may show maintenance records, current operating status, and instructions for reaching its location.

[4096] The presentation of search results may be optimized based on the user's role and previous interactions with the system. A maintenance technician may see detailed technical specifications, while a warehouse operator may see inventory and logistics information. The system may learn from how different user roles utilize the search results to further refine and customize the presentation.

[4097] The visual search engine may employ machine vision systems that can process real-time video and image feeds to maintain current representations of value chain entities in the digital twins. This enables the system to provide up-to-date search results that accurately reflect the current state of physical assets and environments.

[4098]

HARDWARE, SOFTWARE, AND SPECIAL-PURPOSE SYSTEMS

[4099] Special-purpose systems include hardware and/or software and may be described in terms of an apparatus, a method, or a computer-readable medium. In various embodiments, functionality may be apportioned differently between software and hardware. For example, some functionality may be implemented by hardware in one embodiment and by software in another embodiment. Further, software may be encoded by hardware structures, and hardware may be defined by software, such as in software-defined networking or software-defined radio.

[4100] The methods and/or processes described in the disclosure, and steps associated therewith, may be realized in hardware, software or any combination of hardware and software suitable for a particular application. The hardware may include a general-purpose computer and/or dedicated computing device or specific computing device or particular aspect or component of a specific computing device. The processes may be realized in one or more microprocessors, microcontrollers, embedded microcontrollers, programmable digital signal processors or other programmable devices, along with internal and/or external memory. The processes may also, or instead, be embodied in an application specific integrated circuit, a programmable gate array, programmable array logic, or any other device or combination of devices that may be configured to process electronic signals. It will further be appreciated that one or more of the processes may be realized as a computer executable code capable of being executed on a machine-readable medium.

[4101] In this application, including the claims, the term module refers to a special-purpose system. The module may be implemented by one or more special-purpose systems. The one or more special-purpose systems may also implement some or all of the other modules. In this application, including the claims, the term module may be replaced with the terms "controller" or "circuit." In this application, including the claims, the term platform refers to one or more modules that offer a set of functions. In this application, including the claims, the term system may be used interchangeably with module or with the term special-purpose system.

[4102] The special-purpose system may be directed or controlled by an operator. The special-purpose system may be hosted by one or more of assets owned by the operator, assets leased by the operator, and third-party assets. The assets may be referred to as a private, community, or hybrid cloud computing network or cloud computing environment. For example, the special-purpose system may be partially or fully hosted by a third party offering software as a service (SaaS), platform as a service (PaaS), and/or infrastructure as a service (IaaS). The special-purpose system may be implemented using agile development and operations (DevOps) principles. In example embodiments, some or all of the special-purpose system may be

implemented in a multiple-environment architecture. For example, the multiple environments may include one or more production environments, one or more integration environments, one or more development environments, etc.

[4103] A special-purpose system may be partially or fully implemented using or by a mobile device. Examples of mobile devices include navigation devices, cell phones, smart phones, mobile phones, mobile personal digital assistants, palmtops, netbooks, pagers, electronic book readers, tablets, music players, etc. A special-purpose system may be partially or fully implemented using or by a network device. Examples of network devices include switches, routers, firewalls, gateways, hubs, base stations, access points, repeaters, head-ends, user equipment, cell sites, antennas, towers, etc.

[4104] A special-purpose system may be partially or fully implemented using a computer having a variety of form factors and other characteristics. For example, the computer may be characterized as a personal computer, as a server, etc. The computer may be portable, as in the case of a laptop, netbook, etc. The computer may or may not have any output device, such as a monitor, line printer, liquid crystal display (LCD), light emitting diodes (LEDs), etc. The computer may or may not have any input device, such as a keyboard, mouse, touchpad, trackpad, computer vision system, barcode scanner, button array, etc. The computer may run a general-purpose operating system, such as the WINDOWS operating system from Microsoft Corporation, the MACOS operating system from Apple, Inc., or a variant of the LINUX operating system. Examples of servers include a file server, print server, domain server, internet server, intranet server, cloud server, infrastructure-as-a-service server, platform-as-a-service server, web server, secondary server, host server, distributed server, failover server, and backup server.

[4105] The term hardware encompasses components such as processing hardware, storage hardware, networking hardware, and other general-purpose and special-purpose components. Note that these are not mutually-exclusive categories. For example, processing hardware may integrate storage hardware and vice versa.

[4106] Examples of a component are integrated circuits (ICs), application specific integrated circuit (ASICs), digital circuit elements, analog circuit elements, combinational logic circuits, gate arrays such as field programmable gate arrays (FPGAs), digital signal processors (DSPs), complex programmable logic devices (CPLDs), etc.

[4107] Multiple components of the hardware may be integrated, such as on a single die, in a single package, or on a single printed circuit board or logic board. For example, multiple components of the hardware may be implemented as a system-on-chip. A component, or a set of integrated components, may be referred to as a chip, chipset, chiplet, or chip stack. Examples of a system-on-chip include a radio frequency (RF) system-on-chip, an artificial intelligence (AI) system-on-chip, a video processing system-on-chip, an organ-on-chip, a quantum algorithm system-on-chip, etc.

[4108] The hardware may integrate and/or receive signals from sensors. The sensors may allow observation and measurement of conditions including temperature, pressure, wear, light,

humidity, deformation, expansion, contraction, deflection, bending, stress, strain, load-bearing, shrinkage, power, energy, mass, location, temperature, humidity, pressure, viscosity, liquid flow, chemical/gas presence, sound, and air quality. A sensor may include image and/or video capture in visible and/or non-visible (such as thermal) wavelengths, such as a charge-coupled device (CCD) or complementary metal-oxide semiconductor (CMOS) sensor.

[4109] The methods and systems described herein may be deployed in part or in whole through a machine that executes computer software, program codes, and/or instructions on a processor. The present disclosure may be implemented as a method on the machine, as a system or apparatus as part of or in relation to the machine, or as a computer program product embodied in a computer readable medium executing on one or more of the machines. In example embodiments, the processor may be part of a server, cloud server, client, network infrastructure, mobile computing platform, stationary computing platform, or other computing platforms. A processor may be any kind of computational or processing device capable of executing program instructions, codes, binary instructions and the like, including a central processing unit (CPU), a general processing unit (GPU), a logic board, a chip (e.g., a graphics chip, a video processing chip, a data compression chip, or the like), a chipset, a controller, a system-on-chip (e.g., an RF system on chip, an AI system on chip, a video processing system on chip, or others), an integrated circuit, an application specific integrated circuit (ASIC), a field programmable gate array (FPGA), an approximate computing processor, a quantum computing processor, a parallel computing processor, a neural network processor, an approximate computing processor, a quantum computing processor, a parallel computing processor, a neural network processor, a signal processor, a digital processor, a data processor, an embedded processor, a microprocessor, and a co-processor. The co-processor may provide additional processing functions and/or optimizations, such as for speed or power consumption, or other type of processor. Examples of co-processors include a math co-processor, a graphics co-processor, a communication co-processor, a video co-processor, and an artificial intelligence (AI) co-processor. The processor may be or may include a signal processor, digital processor, data processor, embedded processor, microprocessor or any variant such as a co-processor (math co-processor, graphic co-processor, communication co-processor, video co-processor, AI co-processor, and the like) and the like that may directly or indirectly facilitate execution of program code or program instructions stored thereon. In addition, the processor may enable execution of multiple programs, threads, and codes. The threads may be executed simultaneously to enhance the performance of the processor and to facilitate simultaneous operations of the application. By way of implementation, methods, program codes, program instructions and the like described herein may be implemented in one or more threads. The thread may spawn other threads that may have assigned priorities associated with them; the processor may execute these threads based on priority or any other order based on instructions provided in the program code.

[4110] The processor, or any machine utilizing one, may include non-transitory memory that stores methods, codes, instructions and programs as described herein and elsewhere. The processor may access a non-transitory storage medium through an interface that may store

methods, codes, and instructions as described herein and elsewhere. The storage medium associated with the processor for storing methods, programs, codes, program instructions or other type of instructions capable of being executed by the computing or processing device may include but may not be limited to one or more of a CD-ROM, DVD, memory, hard disk, flash drive, RAM, ROM, cache, network-attached storage, server-based storage, and the like. The computer software, program codes, and/or instructions may be stored and/or accessed on machine readable media that may include: computer components, devices, and recording media that retain digital data used for computing for some interval of time; semiconductor storage known as random access memory (RAM); mass storage typically for more permanent storage, such as optical discs, forms of magnetic storage like hard disks, tapes, drums, cards and other types; processor registers, cache memory, volatile memory, non-volatile memory; optical storage such as CD, DVD; removable media such as flash memory (e.g., USB sticks or keys), floppy disks, magnetic tape, paper tape, punch cards, standalone RAM disks, Zip drives, removable mass storage, off-line, and the like; other computer memory such as dynamic memory, static memory, read/write storage, mutable storage, read only, random access, sequential access, location addressable, file addressable, content addressable, network attached storage, storage area network, bar codes, magnetic ink, network-attached storage, network storage, NVME-accessible storage, PCIE connected storage, distributed storage, and the like.

[4111] A processor may include one or more cores that may enhance speed and performance of a multiprocessor. In example embodiments, the process may be a dual core processor, quad core processors, other chip-level multiprocessor and the like that combine two or more independent cores (called a die).

[4112] The methods and systems described herein may be deployed in part or in whole through a machine that executes computer software on a server, client, firewall, gateway, hub, router, or other such computer and/or networking hardware. The software program may be associated with a server that may include a file server, print server, domain server, internet server, intranet server, cloud server, and other variants such as secondary server, host server, distributed server, and the like. The server may include one or more of memories, processors, computer readable transitory and/or non-transitory media, storage media, ports (physical and virtual), communication devices, and interfaces capable of accessing other servers, clients, machines, and devices through a wired or a wireless medium, and the like. The methods, programs, or codes as described herein and elsewhere may be executed by the server. In addition, other devices required for execution of methods as described in this application may be considered as a part of the infrastructure associated with the server.

[4113] The processor may enable execution of multiple threads. These multiple threads may correspond to different programs. In various embodiments, a single program may be implemented as multiple threads by the programmer or may be decomposed into multiple threads by the processing hardware. The threads may be executed simultaneously to enhance the performance of the processor and to facilitate simultaneous operations of the application. A processor may be implemented as a packaged semiconductor die. The die includes one or more

processing cores and may include additional functional blocks, such as cache. In various embodiments, the processor may be implemented by multiple dies, which may be combined in a single package or packaged separately.

[4114] The networking hardware may include one or more interface circuits. In some examples, the interface circuit(s) may implement wired or wireless interfaces that connect, directly or indirectly, to one or more networks. Examples of networks include a cellular network, a local area network (LAN), a wireless personal area network (WPAN), a metropolitan area network (MAN), and/or a wide area network (WAN). The networks may include one or more of point-to-point and mesh technologies. Data transmitted or received by the networking components may traverse the same or different networks. Networks may be connected to each other over a WAN or point-to-point leased lines using technologies such as Multiprotocol Label Switching (MPLS) and virtual private networks (VPNs).

[4115] Examples of cellular networks include GSM, GPRS, 3G, 4G, 5G, LTE, and EVDO. The cellular network may be implemented using frequency division multiple access (FDMA) network or code division multiple access (CDMA) network. Examples of a LAN are Institute of Electrical and Electronics Engineers (IEEE) Standard 802.11-2020 (also known as the WIFI wireless networking standard) and IEEE Standard 802.3-2018 (also known as the ETHERNET wired networking standard). Examples of a WPAN include IEEE Standard 802.15.4, including the ZIGBEE standard from the ZigBee Alliance. Further examples of a WPAN include the BLUETOOTH™ wireless networking standard, including Core Specification versions 3.0, 4.0, 4.1, 4.2, 5.0, and 5.1 from the Bluetooth Special Interest Group (SIG). A WAN may also be referred to as a distributed communications system (DCS). One example of a WAN is the internet.

[4116] Storage hardware is or includes a computer-readable medium. The term computer-readable medium, as used in this disclosure, encompasses both nonvolatile storage and volatile storage, such as dynamic random access memory (DRAM). The term computer-readable medium only excludes transitory electrical or electromagnetic signals propagating through a medium (such as on a carrier wave). A computer-readable medium in this disclosure is therefore non-transitory, and may also be considered to be tangible.

[4117] Examples of storage implemented by the storage hardware include a database (such as a relational database or a NoSQL database), a data store, a data lake, a column store, and a data warehouse. Examples of storage hardware include nonvolatile memory devices, volatile memory devices, magnetic storage media, a storage area network (SAN), network-attached storage (NAS), optical storage media, printed media (such as bar codes and magnetic ink), and paper media (such as punch cards and paper tape). The storage hardware may include cache memory, which may be collocated with or integrated with processing hardware. Storage hardware may have read-only, write-once, or read/write properties. Storage hardware may be random access or sequential access. Storage hardware may be location-addressable, file-addressable, and/or content-addressable.

[4118] Examples of nonvolatile memory devices include flash memory (including NAND and NOR technologies), solid state drives (SSDs), an erasable programmable read-only memory device such as an electrically erasable programmable read-only memory (EEPROM) device, and a mask read-only memory device (ROM). Examples of volatile memory devices include processor registers and random access memory (RAM), such as static RAM (SRAM), dynamic RAM (DRAM), synchronous DRAM (SDRAM), synchronous graphics RAM (SGRAM), and video RAM (VRAM). Examples of magnetic storage media include analog magnetic tape, digital magnetic tape, and rotating hard disk drive (HDDs). Examples of optical storage media include a CD (such as a CD-R, CD-RW, or CD-ROM), a DVD, a Blu-ray disc, and an Ultra HD Blu-ray disc.

[4119] Examples of storage implemented by the storage hardware include a distributed ledger, such as a permissioned or permissionless blockchain. Entities recording transactions, such as in a blockchain, may reach consensus using an algorithm such as proof-of-stake, proof-of-work, and proof-of-storage. Elements of the present disclosure may be represented by or encoded as non-fungible tokens (NFTs). Ownership rights related to the non-fungible tokens may be recorded in or referenced by a distributed ledger. Transactions initiated by or relevant to the present disclosure may use one or both of fiat currency and cryptocurrencies, examples of which include bitcoin and ether. Some or all features of hardware may be defined using a language for hardware description, such as IEEE Standard 1364-2005 (commonly called "Verilog") and IEEE Standard 1076-2008 (commonly called "VHDL"). The hardware description language may be used to manufacture and/or program hardware.

[4120] A special-purpose system may be distributed across multiple different software and hardware entities. Communication within a special-purpose system and between special-purpose systems may be performed using networking hardware. The distribution may vary across embodiments and may vary over time. For example, the distribution may vary based on demand, with additional hardware and/or software entities invoked to handle higher demand. In various embodiments, a load balancer may direct requests to one of multiple instantiations of the special purpose system. The hardware and/or software entities may be physically distinct and/or may share some hardware and/or software, such as in a virtualized environment. Multiple hardware entities may be referred to as a server rack, server farm, data center, etc.

[4121] Software includes instructions that are machine-readable and/or executable. Instructions may be logically grouped into programs, codes, methods, steps, actions, routines, functions, libraries, objects, classes, etc. Software may be stored by storage hardware or encoded in other hardware. Software encompasses (i) descriptive text to be parsed, such as HTML (hypertext markup language), XML (extensible markup language), and JSON (JavaScript Object Notation), (ii) assembly code, (iii) object code generated from source code by a compiler, (iv) source code for execution by an interpreter, (v) bytecode, (vi) source code for compilation and execution by a just-in-time compiler, etc. As examples only, source code may be written using syntax from languages including C, C++, JavaScript, Java, Python, R, etc. The computer executable code may be created using a structured programming language such as C, an object

oriented programming language such as C++, or any other high-level or low-level programming language (including assembly languages, hardware description languages, and database programming languages and technologies) that may be stored, compiled or interpreted to run on one of the devices described in the disclosure, as well as heterogeneous combinations of processors, processor architectures, or combinations of different hardware and software, or any other machine capable of executing program instructions. Computer software may employ virtualization, virtual machines, containers, dock facilities, portainers, and other capabilities. In example embodiments, methods described in the disclosure and combinations thereof may be embodied in computer executable code that, when executing on one or more computing devices, performs the steps thereof. In another aspect, the methods may be embodied in systems that perform the steps thereof and may be distributed across devices in a number of ways, or all of the functionality may be integrated into a dedicated, standalone device or other hardware. In another aspect, the means for performing the steps associated with the processes described in the disclosure may include any of the hardware and/or software described in the disclosure. All such permutations and combinations are intended to fall within the scope of the disclosure.

[4122] The elements depicted in the flow chart and block diagrams or any other logical component may be implemented on a machine capable of executing program instructions. Thus, while the foregoing drawings and descriptions set forth functional aspects of the disclosed systems, no particular arrangement of software for implementing these functional aspects should be inferred from these descriptions unless explicitly stated or otherwise clear from the context. Similarly, it will be appreciated that the various steps identified and described in the disclosure may be varied, and that the order of steps may be adapted to particular applications of the techniques disclosed herein. All such variations and modifications are intended to fall within the scope of this disclosure. As such, the depiction and/or description of an order for various steps should not be understood to require a particular order of execution for those steps, unless required by a particular application, or explicitly stated or otherwise clear from the context.

[4123] Software also includes data. However, data and instructions are not mutually-exclusive categories. In various embodiments, the instructions may be used as data in one or more operations. As another example, instructions may be derived from data. The functional blocks and flowchart elements in this disclosure serve as software specifications, which can be translated into software by the routine work of a skilled technician or programmer. Software may include and/or rely on firmware, processor microcode, an operating system (OS), a basic input/output system (BIOS), application programming interfaces (APIs), libraries such as dynamic-link libraries (DLLs), device drivers, hypervisors, user applications, background services, background applications, etc. Software includes native applications and web applications. For example, a web application may be served to a device through a browser using hypertext markup language 5th revision (HTML5).

[4124] Software may include artificial intelligence systems, which may include machine learning or other computational intelligence. For example, artificial intelligence may include one or more models used for one or more problem domains. When presented with many data

features, identification of a subset of features that are relevant to a problem domain may improve prediction accuracy, reduce storage space, and increase processing speed. This identification may be referred to as feature engineering. Feature engineering may be performed by users or may only be guided by users. In various implementations, a machine learning system may computationally identify relevant features, such as by performing singular value decomposition on the contributions of different features to outputs.

[4125] Examples of the models include recurrent neural networks (RNNs) such as long short-term memory (LSTM), deep learning models such as transformers, decision trees, support-vector machines, genetic algorithms, Bayesian networks, and regression analysis. Examples of systems based on a transformer model include bidirectional encoder representations from transformers (BERT) and generative pre-trained transformers (GPT). Training a machine-learning model may include supervised learning (for example, based on labelled input data), unsupervised learning, and reinforcement learning. In various embodiments, a machine-learning model may be pre-trained by their operator or by a third party. Problem domains include nearly any situation where structured data can be collected, and includes natural language processing (NLP), computer vision (CV), classification, image recognition, etc.

[4126] Some or all of the software may run in a virtual environment rather than directly on hardware. The virtual environment may include a hypervisor, emulator, sandbox, container engine, etc. The software may be built as a virtual machine, a container, etc. Virtualized resources may be controlled using, for example, a DOCKER container platform, a pivotal cloud foundry (PCF) platform, etc.

[4127] In a client-server model, some of the software executes on first hardware identified functionally as a server, while other of the software executes on second hardware identified functionally as a client. The identity of the client and server is not fixed: for some functionality, the first hardware may act as the server while for other functionality, the first hardware may act as the client. In different embodiments and in different scenarios, functionality may be shifted between the client and the server. In one dynamic example, some functionality normally performed by the second hardware is shifted to the first hardware when the second hardware has less capability. In various embodiments, the term "local" may be used in place of "client," and the term "remote" may be used in place of "server."

[4128] Some or all of the software may be logically partitioned into microservices. Each microservice offers a reduced subset of functionality. In various embodiments, each microservice may be scaled independently depending on load, either by devoting more resources to the microservice or by instantiating more instances of the microservice. In various embodiments, functionality offered by one or more microservices may be combined with each other and/or with other software not adhering to a microservices model.

[4129] Some or all of the software may be arranged logically into layers. In a layered architecture, a second layer may be logically placed between a first layer and a third layer. The first layer and the third layer would then generally interact with the second layer and not with

each other. In various embodiments, this is not strictly enforced – that is, some direct communication may occur between the first and third layers.

FURTHER INFORMATION AND USE OF TERMS

[4130] The background description is presented simply for context, and is not necessarily well-understood, routine, or conventional. Further, the background description is not an admission of what does or does not qualify as prior art. In fact, some or all of the background description may be work attributable to the named inventors that is otherwise unknown in the art.

[4131] While only a few embodiments of the disclosure have been shown and described, it will be obvious to those skilled in the art that many changes and modifications may be made thereunto without departing from the spirit and scope of the disclosure as described in the following claims. All patent applications and patents, both foreign and domestic, and all other publications referenced herein are incorporated herein in their entireties to the full extent permitted by law. While the disclosure has been disclosed in connection with the preferred embodiments shown and described in detail, various modifications and improvements thereon will become readily apparent to those skilled in the art. Accordingly, the spirit and scope of the disclosure is not to be limited by the foregoing examples, but is to be understood in the broadest sense allowable by law.

[4132] The detailed description includes specific examples for illustration only, and not to limit the disclosure or its applicability. The examples are not intended to be an exhaustive list, but instead simply demonstrate possession by the inventors of the full scope of the currently presented and envisioned future claims. Variations, combinations, and equivalents of the examples are within the scope of the disclosure. No language in the specification should be construed as indicating that any non-claimed element is essential or critical to the practice of the disclosure.

[4133] While the foregoing written description enables one skilled to make and use what is considered presently to be the best mode thereof, those skilled in the art will understand and appreciate the existence of variations, combinations, and equivalents of the specific embodiment, method, and examples herein. The disclosure should therefore not be limited by the above-described embodiment, method, and examples, but by all embodiments and methods within the scope and spirit of the disclosure.

[4134] Each publication referenced in this disclosure, including foreign and domestic patent applications and patents, is hereby incorporated by reference in its entirety as if fully set forth herein.

[4135] The terms "comprising," "with," "including," and "containing" are to be construed as open-ended terms (i.e., meaning "including, but not limited to") unless otherwise noted. Unless otherwise specified, the terms "comprising," "having," "with," "including," and "containing," and their variants, are open-ended terms, meaning "including, but not limited to."

[4136] The term "exemplary" simply means "example" and does not indicate a best or preferred example. The use of any and all examples, or exemplary language (e.g., "such as")

provided herein, is intended merely to better illuminate the disclosure and does not pose a limitation on the scope of the disclosure unless otherwise claimed.

[4137] The use of the terms "a," "an," "the," and similar referents in the context of describing the disclosure (especially in the context of the following claims) is to be construed to cover both the singular and the plural, unless otherwise indicated herein or clearly contradicted by context.

[4138] Recitations of ranges of values herein are merely intended to serve as a shorthand method of referring individually to each separate value falling within the range, unless otherwise indicated herein, and each separate value is incorporated into the specification as if it were individually recited herein. All methods described herein can be performed in any suitable order unless otherwise indicated herein or otherwise clearly contradicted by context.

[4139] The phrase "at least one of A, B, and C" should be construed to mean a logical (A OR B OR C), using a non-exclusive logical OR, and should not be construed to mean "at least one of A, at least one of B, and at least one of C."

[4140] The term "set" may include a set with a single member. The term "set" does not necessarily exclude the empty set — in other words, in some circumstances a "set" may have zero elements. The term "non-empty set" may be used to indicate exclusion of the empty set — that is, a non-empty set must have one or more elements. The term "subset" does not necessarily require a proper subset. In other words, a "subset" of a first set may be coextensive with (equal to) the first set. Further, the term "subset" does not necessarily exclude the empty set — in some circumstances a "subset" may have zero elements.

[4141] Physical (such as spatial and/or electrical) and functional relationships between elements (for example, between modules, circuit elements, semiconductor layers, etc.) are described using various terms. Unless explicitly described as being "direct," when a relationship between first and second elements is described, that relationship encompasses both (i) a direct relationship where no other intervening elements are present between the first and second elements and (ii) an indirect relationship where one or more intervening elements are present between the first and second elements. Example relationship terms include "adjoining," "transmitting," "receiving," "connected," "engaged," "coupled," "adjacent," "next to," "on top of," "above," "below," "abutting," and "disposed."

[4142] Although each of the embodiments is described above as having certain features, any one or more of those features described with respect to any embodiment of the disclosure can be implemented in and/or combined with features of any of the other embodiments, even if that combination is not explicitly described. In other words, the described embodiments are not mutually exclusive, and permutations of multiple embodiments remain within the scope of this disclosure.

[4143] One or more elements (for example, steps within a method, instructions, actions, or operations) may be executed in a different order (and/or concurrently) without altering the principles of the present disclosure. Unless technically infeasible, elements described as being in series may be implemented partially or fully in parallel. Similarly, unless technically infeasible, elements described as being in parallel may be implemented partially or fully in series.

[4144] While the disclosure describes structures corresponding to claimed elements, those elements do not necessarily invoke a means plus function interpretation unless they explicitly use the signifier "means for." Unless otherwise indicated, recitations of ranges of values are merely intended to serve as a shorthand way of referring individually to each separate value falling within the range, and each separate value is hereby incorporated into the specification as if it were individually recited.

[4145] While the drawings divide elements of the disclosure into different functional blocks or action blocks, these divisions are for illustration only. According to the principles of the present disclosure, functionality can be combined in other ways such that some or all functionality from multiple separately-depicted blocks can be implemented in a single functional block; similarly, functionality depicted in a single block may be separated into multiple blocks. Unless explicitly stated as mutually exclusive, features depicted in different drawings can be combined consistent with the principles of the present disclosure.

[4146] In the drawings, reference numbers may be reused to identify identical elements or may simply identify elements that implement similar functionality. Numbering or other labeling of instructions or method steps is done for convenient reference, not to indicate a fixed order. In the drawings, the direction of an arrow, as indicated by the arrowhead, generally demonstrates the flow of information (such as data or instructions) that is of interest to the illustration. For example, when element A and element B exchange a variety of information but information transmitted from element A to element B is relevant to the illustration, the arrow may point from element A to element B. This unidirectional arrow does not imply that no other information is transmitted from element B to element A. As one example, for information sent from element A to element B, element B may send requests and/or acknowledgements to element A.

CLAIMS

1. A computer-implemented system comprising:

a processor and memory storing instructions that, when executed, configure the system to implement:

a value chain network management platform comprising:

a governance layer configured to implement a set of AI-based learning models to enforce automated governance of a set of value chain networks;

an enterprise layer configured to implement a set of AI-based learning models to monitor a set of value chain network entities;

an offering layer configured to implement a set of AI-based learning models to improve a set of value chain network product offerings;

a transactions layer configured to implement a set of AI-based learning models to execute a set of value chain network transactions;

an operations layer configured to implement a set of AI-based learning models to improve a set of value chain network operations;

a network layer configured to implement a set of AI-based learning models to improve a set of communications networks associated with a set of value chain networks;

a data layer configured to implement a set of AI-based learning models to process fused data from at least two value chain network data sources; and

a resource layer configured to implement a set of AI-based learning models to automate provisioning of value chain network resources.

2. The system of claim 1, wherein the set of AI-based learning models include at least one of: a transformer model, a convolutional neural network, a deep learning model, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model.

3. The system of claim 1, wherein the set of value chain network entities comprise at least one of: products, suppliers, producers, manufacturers, retailers, businesses, owners, operators, operating facilities, customers, consumers, workers, mobile devices, wearable devices, distributors, resellers, supply chain infrastructure facilities, supply chain processes, logistics processes, reverse logistics processes, demand prediction processes, demand management processes, and demand aggregation processes.

4. The system of claim 1, wherein the set of value chain network operations comprise at least one of: transportation routing, inventory management, supplier selection, production scheduling, cost tracking, goods packing and shipping, delivery tracking, supplier identification, contract negotiation, and goods inspection.

5. The system of claim 1, wherein the fused data comprises at least two of: supply chain data, demand data, shipping data, logistics data, pricing data, and transportation data.

6. The system of claim 1, wherein the value chain network management platform includes a set of digital twins configured to simulate at least one of: properties, states, operations, and behaviors of the value chain network entities.

7. The system of claim 1, further comprising a value chain network control tower.

8. The system of claim 1, wherein the network layer comprises edge intelligence systems configured to enable localized data processing and communication at network edges for value chain entities.

9. The system of claim 1, wherein the resource layer implements distributed ledger technology for transparent tracking of resource allocation decisions.

10. A computer-implemented method comprising:

executing, by a processor, instructions stored in memory to:

implement a value chain network management platform comprising:

implementing a set of AI-based learning models through a governance layer to enforce automated governance of a set of value chain networks;

implementing a set of AI-based learning models through an enterprise layer to monitor a set of value chain network entities;

implementing a set of AI-based learning models through an offering layer to improve a set of value chain network product offerings;

implementing a set of AI-based learning models through a transactions layer to execute a set of value chain network transactions;

implementing a set of AI-based learning models through an operations layer to improve a set of value chain network operations;

implementing a set of AI-based learning models through a network layer to improve a set of communications networks associated with a set of value chain networks;

implementing a set of AI-based learning models through a data layer to process fused data from at least two value chain network data sources;

implementing a set of AI-based learning models through a resource layer to automate provisioning of value chain network resources.

11. The method of claim 10, wherein the set of AI-based learning models include at least one of: a transformer model, a convolutional neural network, a deep learning model, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model.

12. The method of claim 10, wherein the set of value chain network entities comprise at least one of: products, suppliers, producers, manufacturers, retailers, businesses, owners, operators, operating facilities, customers, consumers, workers, mobile devices, wearable devices, distributors, resellers, supply chain infrastructure facilities, supply chain processes, logistics processes, reverse logistics processes, demand prediction processes, demand management processes, and demand aggregation processes.

13. The method of claim 10, wherein the set of value chain network operations comprise at least one of: transportation routing, inventory management, supplier selection, production scheduling, cost tracking, goods packing and shipping, delivery tracking, supplier identification, contract negotiation, and goods inspection.

14. The method of claim 10, wherein the fused data comprises at least two of: supply chain data, demand data, shipping data, logistics data, pricing data, and transportation data.

15. The method of claim 10, wherein the value chain network management platform includes a set of digital twins configured to simulate at least one of: properties, states, operations, and behaviors of the value chain network entities.

16. The method of claim 10, further comprising implementing a value chain network control tower.

17. The method of claim 10, wherein the network layer comprises edge intelligence systems configured to enable localized data processing and communication at network edges for value chain entities.

18. The method of claim 10, wherein the resource layer implements distributed ledger technology for transparent tracking of resource allocation decisions.

19. A computer-implemented system comprising:

executing, by a processor, instructions stored in memory to:

implement a value chain network management platform comprising:

a resource layer configured to implement a set of AI-based learning models to optimize a set of value chain network resources.

20. The system of claim 19, wherein the set of AI-based learning models include at least one of: a transformer model, a convolutional neural network, a deep learning model trained on value chain outcomes, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model.

21. The system of claim 19, wherein the set of value chain network resources comprise at least one of: infrastructure resources, shipping resources, warehousing resources, retailing resources, components and materials resources, energy resources, and computation resources.

22. The system of claim 19, further comprising a simulation engine operating in parallel with the set of AI-based learning models to generate real-time simulations of resource allocation scenarios, validate optimization decisions, and provide feedback for continuous improvement.

23. The system of claim 19, wherein the resource layer implements distributed ledger technology for transparent tracking of resource allocation decisions and smart contracts for automated execution of optimization strategies.

24. The system of claim 19, wherein the resource layer is configured to optimize allocation of resources based on historical resource allocation data, usage patterns, and performance metrics from value chain network operations.

25. The system of claim 19, wherein the resource layer implements digital twins to simulate resource allocation scenarios before deployment in the value chain network.

26. The system of claim 19, wherein the resource layer is configured to perform predictive intelligence tasks to forecast resource needs across the value chain network.

27. The system of claim 19, wherein the resource layer employs at least one of: physics-based modeling, discrete event simulation, or agent-based modeling techniques to represent dynamics of resource utilization.

28. The system of claim 19, wherein the resource layer is configured to adapt resource allocation in real-time based on changing conditions in the value chain network.

29. A computer-implemented method comprising:
executing, by a processor, instructions stored in memory to:
implement a value chain network management platform comprising:
implementing a set of AI-based learning models through a resource layer to optimize a set of value chain network resources.

30. The method of claim 29, wherein the set of AI-based learning models include at least one of: a transformer model, a convolutional neural network, a deep learning model trained on value chain outcomes, a supervised model, a semi-supervised model, an unsupervised model, or a reinforcement model.

31. The method of claim 29, wherein the set of value chain network resources comprise at least one of: infrastructure resources, shipping resources, warehousing resources, retailing resources, components and materials resources, energy resources, and computation resources.

32. The method of claim 29, further comprising operating a simulation engine in parallel with the set of AI-based learning models to generate real-time simulations of resource allocation scenarios, validate optimization decisions, and provide feedback for continuous improvement.

33. The method of claim 29, wherein implementing the resource layer comprises implementing distributed ledger technology for transparent tracking of resource allocation decisions and smart contracts for automated execution of optimization strategies.

34. The method of claim 29, wherein implementing the resource layer comprises optimizing allocation of resources based on historical resource allocation data, usage patterns, and performance metrics from value chain network operations.

35. The method of claim 29, wherein implementing the resource layer comprises implementing digital twins to simulate resource allocation scenarios before deployment in the value chain network.

36. The method of claim 29, wherein implementing the resource layer comprises performing predictive intelligence tasks to forecast resource needs across the value chain network.

37. The method of claim 29, wherein implementing the resource layer comprises employing at least one of: physics-based modeling, discrete event simulation, or agent-based modeling techniques to represent dynamics of resource utilization.

38. The method of claim 29, wherein implementing the resource layer comprises adapting resource allocation in real-time based on changing conditions in the value chain network.

39. A computer-implemented system comprising:
executing, by a processor, instructions stored in memory to:
implement a value chain network management platform comprising:
a network layer comprising:
a set of network modules wherein the network modules implement a set of AI-based learning models to execute a set of intelligence tasks.

40. The system of claim 39, wherein the set of network modules comprises at least one of: an adaptive network routing module, an adaptive error correction module, an adaptive network

storage module, an adaptive protocol selection module, an adaptive block size module, and an adaptive transmission window module.

41. The system of claim 39, wherein the set of network modules comprises communication modules for at least one of: cellular, WiFi, ORAN, Bluetooth, satellite, IoT network, and mesh network communications.

42. The system of claim 39, wherein the set of network modules comprises at least one of: a shipping network module, a delivery network module, a transportation network module, a value chain network module, and a supply chain network module.

43. The system of claim 39, wherein the set of AI-based learning models are trained using at least one of: supervised, unsupervised, or reinforcement learning techniques on value chain network data.

44. The system of claim 39, wherein the set of intelligence tasks comprise at least one of: optimization tasks, generative tasks, predictive tasks, detection tasks, identification tasks, decision support tasks, automation tasks, and control tasks for value chain network operations.

45. The system of claim 39, further comprising a simulation engine operating in parallel with the AI-based learning models to generate real-time simulations of value chain network scenarios, validate decisions, and provide feedback for continuous improvement.

46. The system of claim 39, wherein the network modules implement edge networking and cloud networking capabilities to enable distributed processing across the value chain network.

47. The system of claim 39, wherein the network modules enable localized data processing and communication at network edges for value chain entities.

48. The system of claim 39, wherein the network modules are configured to optimize data flow between nodes over multiple data paths based on networking variables including at least one of: data types, protocols, network congestion, timing, and volumes.

49. A computer-implemented method comprising:

executing, by a processor, instructions stored in memory to:

implement a value chain network management platform comprising:

implementing a network layer comprising:

implementing a set of network modules wherein the network modules implement a set of AI-based learning models to execute a set of intelligence tasks.

50. The method of claim 49, wherein the set of network modules comprises at least one of: an adaptive network routing module, an adaptive error correction module, an adaptive network storage module, an adaptive protocol selection module, an adaptive block size module, and an adaptive transmission window module.

51. The method of claim 49, wherein the set of network modules comprises communication modules for at least one of: cellular, WiFi, ORAN, Bluetooth, satellite, IoT network, and mesh network communications.

52. The method of claim 49, wherein the set of network modules comprises at least one of: a shipping network module, a delivery network module, a transportation network module, a value chain network module, and a supply chain network module.

53. The method of claim 49, wherein the set of AI-based learning models are trained using at least one of: supervised, unsupervised, or reinforcement learning techniques on value chain network data.

54. The method of claim 49, wherein the set of intelligence tasks comprise at least one of: optimization tasks, generative tasks, predictive tasks, detection tasks, identification tasks, decision support tasks, automation tasks, and control tasks for value chain network operations.

55. The method of claim 49, further comprising operating a simulation engine in parallel with the AI-based learning models to generate real-time simulations of value chain network scenarios, validate decisions, and provide feedback for continuous improvement.

56. The method of claim 49, wherein implementing the network modules comprises implementing edge networking and cloud networking capabilities to enable distributed processing across the value chain network.

57. The method of claim 49, wherein implementing the network modules comprises enabling localized data processing and communication at network edges for value chain entities.

58. The method of claim 49, wherein implementing the network modules comprises optimizing data flow between nodes over multiple data paths based on networking variables including at least one of: data types, protocols, network congestion, timing, and volumes.

59. A computer-implemented system comprising:

a processor and memory storing instructions that, when executed, configure the system to implement:

a value chain network management platform comprising:

a digital twin system configured to:

display options for distribution of decision making authority across value chain network entities;

receive outcome data associated with different distributions of decision making authority;

analyze the outcome data using AI-based learning models to evaluate performance of different decision making authority distributions; and

automatically update the distribution of decision making authority based on the analyzed performance data.

60. The system of claim 59, wherein the distribution of decision making authority is based on at least one of: a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework.

61. The system of claim 59, wherein the digital twin system is configured to simulate properties, states, operations, and behaviors of the value chain network entities to validate performance before updating decision making authority distributions.

62. The system of claim 59, wherein the digital twin system is configured to highlight when automated decisions require human review based on defined mission criteria and enterprise principles.

63. The system of claim 59, wherein the digital twin system is configured to track comparative performance metrics among human decisions, human-AI combined decisions, and autonomous AI decisions.

64. The system of claim 59, wherein the digital twin system is configured to incrementally migrate decision making from centralized authority to operating environments based on validated performance metrics.

65. The system of claim 59, wherein the digital twin system is configured to reverse decision making authority distributions when performance metrics indicate degraded outcomes.

66. The system of claim 59, wherein the digital twin system includes automated governance to validate that decision making authority distributions comply with defined operational constraints.

67. The system of claim 59, wherein the digital twin system is configured to enable collaborative decision making between combinations of human beings, human-AI systems, and autonomous AI systems.

68. The system of claim 59, wherein the AI-based learning models comprise at least one of: transformer models, convolutional neural networks, deep learning models, supervised models, semi-supervised models, unsupervised models, or reinforcement models trained on value chain network outcomes.

69. A computer-implemented method comprising:

executing, by a processor, instructions stored in memory to:

implement a value chain network management platform comprising:

implementing a digital twin system configured to:

display options for distribution of decision making authority across value chain network entities;

receive outcome data associated with different distributions of decision making authority;

analyze the outcome data using AI-based learning models to evaluate performance of different decision making authority distributions; and

automatically update the distribution of decision making authority based on the analyzed performance data.

70. The method of claim 69, wherein the distribution of decision making authority is based on at least one of: a hierarchical framework, a rules-based framework, a simulation framework, an enterprise planning framework, an algorithmic framework, a principles-based framework, a collaborative framework, a peer-to-peer framework, or a competitive framework.

71. The method of claim 69, wherein implementing the digital twin system comprises simulating properties, states, operations, and behaviors of the value chain network entities to validate performance before updating decision making authority distributions.

72. The method of claim 69, wherein implementing the digital twin system comprises highlighting when automated decisions require human review based on defined mission criteria and enterprise principles.

73. The method of claim 69, wherein implementing the digital twin system comprises tracking comparative performance metrics among human decisions, human-AI combined decisions, and autonomous AI decisions.

74. The method of claim 69, wherein implementing the digital twin system comprises incrementally migrating decision making from centralized authority to operating environments based on validated performance metrics.

75. The method of claim 69, wherein implementing the digital twin system comprises reversing decision making authority distributions when performance metrics indicate degraded outcomes.

76. The method of claim 69, wherein implementing the digital twin system comprises validating that decision making authority distributions comply with defined operational constraints through automated governance.

77. The method of claim 69, wherein implementing the digital twin system comprises enabling collaborative decision making between combinations of human beings, human-AI systems, and autonomous AI systems.

78. The method of claim 69, wherein the AI-based learning models comprise at least one of: transformer models, convolutional neural networks, deep learning models, supervised models, semi-supervised models, unsupervised models, or reinforcement models trained on value chain network outcomes.

79. A computer-implemented system comprising:

a processor and memory storing instructions that, when executed, configure the system to implement:

a value chain network management platform comprising:

a visual search engine embedded within a digital twin configured to:

receive image-based queries related to value chain network entities;

process the queries using AI-based learning models to identify matching elements in the digital twin;

highlight matching elements in a visual representation of the digital twin;

present data and representations associated with the matching elements.

80. The system of claim 79, wherein the image-based queries comprise at least one of: pasted images, image metadata, drawn images, or keyword descriptions of images.

81. The system of claim 79, wherein the AI-based learning models are configured to parse queries and recognize objects, spaces, and visual elements within the value chain network.

82. The system of claim 79, wherein the visual search engine processes image characteristics including shape, color, semantic meaning, and symbolic attributes to find matching elements.

83. The system of claim 79, wherein matching elements are presented through at least one of: listing in a menu bar or highlighting in the visual representation through changes in font, color, or brightness.

84. The system of claim 79, wherein the visual search engine provides guidance on reaching physical locations corresponding to matching elements in the digital twin.

85. The system of claim 79, wherein the visual search engine uses artificial intelligence to rank results based on likelihood of relevance including based on user feedback.

86. The system of claim 79, wherein the visual search engine processes queries to find matching elements across multiple integrated digital twins representing different value chain entities.

87. The system of claim 79, wherein the visual search engine provides additional data about matching elements including guidance on reaching locations and content about contained items.

88. The system of claim 79, wherein the visual search engine optimizes presentation of results based on user roles and feedback on result utilization.

89. A computer-implemented method comprising:

executing, by a processor, instructions stored in memory to:

implement a value chain network management platform comprising:

implementing a visual search engine embedded within a digital twin configured to:

receive image-based queries related to value chain network entities;

process the queries using AI-based learning models to identify matching elements in the digital twin;

highlight matching elements in a visual representation of the digital twin;

present data and representations associated with the matching elements.

90. The method of claim 89, wherein receiving image-based queries comprises receiving at least one of: pasted images, image metadata, drawn images, or keyword descriptions of images.

91. The method of claim 89, wherein processing the queries comprises using AI-based learning models to parse queries and recognize objects, spaces, and visual elements within the value chain network.

92. The method of claim 89, wherein processing the queries comprises analyzing image characteristics including shape, color, semantic meaning, and symbolic attributes to find matching elements.

93. The method of claim 89, wherein presenting matching elements comprises at least one of: listing in a menu bar or highlighting in the visual representation through changes in font, color, or brightness.

94 The method of claim 89, wherein presenting data comprises providing guidance on reaching physical locations corresponding to matching elements in the digital twin.

95 The method of claim 89, wherein processing the queries comprises using artificial intelligence to rank results based on likelihood of relevance including based on user feedback.

96. The method of claim 89, wherein processing the queries comprises finding matching elements across multiple integrated digital twins representing different value chain entities.

97. The method of claim 89, wherein presenting data comprises providing additional data about matching elements including guidance on reaching locations and content about contained items.

98. The method of claim 89, wherein presenting data comprises optimizing presentation of results based on user roles and feedback on result utilization.
