

METHOD AND SYSTEM FOR LOCATING A MOBILE SUBSCRIBER IN A CDMA COMMUNICATION SYSTEM

Field of the Invention

5 This invention generally relates to spread spectrum code division multiple access (CDMA) communication systems. More particularly, the present invention relates to a system and method that determines the geographic location of a subscriber unit within a CDMA communication system.

Description of the Prior Art

10 Wireless systems capable of locating a subscriber are presently known in the art. One wireless technique uses the global positioning system (GPS). In GPS, the communication handset receives data transmitted continuously from the 24 NAVSTAR satellites. Each satellite transmits data indicating the satellite's identity, the location of the satellite and the time the message was sent. The handset
15 compares the time each signal was received with the time it was sent to determine the distance to each satellite. Using the determined distances between the satellites and the handset along with the location of each satellite, the handset can triangulate its location and provide the information to a communication base station. However, the incorporation of a GPS within a subscriber unit increases its cost.

Another subscriber location technique is disclosed in U.S. Patent No. 5,732,354. A mobile telephone using time division multiple access (TDMA) as the air interface is located within a plurality of base stations. The mobile telephone measures the received signal strength from each of the base stations and transmits each strength to each respective base station. At a mobile switching center, the received signal strengths from the base stations are compared and processed. The result yields the distance between the mobile telephone and each base station. From these distances, the location of the mobile telephone is calculated.

Wireless communication systems using spread spectrum modulation techniques are increasing in popularity. In code division multiple access (CDMA) systems, data is transmitted using a wide bandwidth (spread spectrum) by modulating the data with a pseudo random chip code sequence. The advantage gained is that CDMA systems are more resistant to signal distortion and interfering frequencies in the transmission path than communication systems using the more common time division multiple access (TDMA) or frequency division multiple access (FDMA) techniques.

There exists a need for an accurate mobile subscriber unit location system that uses data already available in an existing CDMA communication system.

SUMMARY OF THE INVENTION

The invention determines the geographic location of a subscriber unit within a CDMA communication system. At least one base station transmits a spread spectrum signal with a chip code sequence unique to that base station. A subscriber unit receives the base station signal and transmits a spread spectrum signal with a unique chip code sequence time synchronized with the chip code sequence of the received base station signal. The base station receives the subscriber unit signal and compares the chip code sequence of the received subscriber unit signal with the chip code sequence signal transmitted by the base station to determine the location of the subscriber unit.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is an illustration of a simplified, prior art CDMA system.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The preferred embodiments will be described with reference to the drawing figures where like numerals represent like elements throughout.

Shown in **Figure 1** is a simplified CDMA communication system. A data signal with a given bandwidth is mixed with a spreading code generated by a pseudo random chip code sequence generator producing a digital spread spectrum signal. Upon reception, the data is reproduced after correlation with the same pseudo random chip code sequence used to transmit the data. Every other signal within the transmission bandwidth appears as noise to the signal being despread.

For timing synchronization with a receiver, an unmodulated pilot signal is required for every transmitter. The pilot signal allows respective receivers to synchronize with a given transmitter, allowing despreading of a traffic signal at the receiver.

In a typical CDMA system, base stations send global pilot signals to all subscriber units within their communicating range to synchronize transmissions in a forward direction. Additionally, in some CDMA systems, for example a B-CDMA™ system, each subscriber unit sends a unique assigned pilot signal to synchronize transmissions in a reverse direction.

Figure 2 illustrates a CDMA communication system **30**. The communication system **30** comprises a plurality of base stations **36₁**, **36₂** ... **36_n**. Each base station

36₁, 36₂ ... 36_n is in wireless communication with a plurality of subscriber units 40₁, 40₂ ... 40_n, which may be fixed or mobile. Each subscriber unit 40₁, 40₂ ... 40_n communicates with either the closest base station 36₁ or the base station 36₁ which provides the strongest communication signal. Each base station 36₁, 36₂ ... 36_n is in communication with other components within the communication system 30 as shown in Figure 3.

A local exchange 32 is at the center of the communications system 30 and communicates with a plurality of network interface units (NIUs) 34₁, 34₂ ... 34_n. Each NIU is in communication with a plurality of radio carrier stations (RCS) 38₁, 38₂ ... 38_n or base stations 36₁, 36₂ ... 36_n. Each (RCS) 38₁, 38₂ ... 38_n or base station 36₁, 36₂ ... 36_n communicates with a plurality of subscriber units 40₁, 40₂ ... 40_n within its communicating range.

Figure 4 depicts a block diagram of the pertinent parts of an existing spread spectrum CDMA communication system. Each independent base station 36₁, 36₂ ... 36_n generates a unique global pilot signal using a global pilot chip code generating means 42₁ and spread spectrum processing means 44₁. The global pilot chip code generating means 42₁ generates a unique pseudo random chip code sequence. The unique pseudo random chip code sequence is used to spread the resultant signals bandwidth such as to 15 MHZ as used in the B-CDMA™ air interface. The spread spectrum processing means modulates the global pilot chip code sequence up to a

desired center frequency. The global pilot signal is transmitted to all subscriber units 40₁ by the base station's transmitter 46₁.

A receiver 48₁ at a subscriber unit 40₁ receives available signals from a plurality of base stations 36₁, 36₂ ... 36_n. As shown in Figure 5, the global pilot 50₁ travels from the base station 36₁ to the subscriber unit 40₁ and can be represented as:

$$\tau_1 = \frac{d_1}{c} \quad \text{Equation (1)}$$

The time the signal travels from the base station 36₁ to the subscriber unit 40₁, τ_1 , equals the distance between the base station 36₁ and subscriber unit 40₁, d_1 , divided by the speed of light, c .

Referring back to Figure 4, a global pilot chip code recovery means 54₁ within the subscriber unit 40₁ can receive global pilot chip code sequences from a plurality of base stations 36₁, 36₂ ... 36_n. The subscriber unit 40₁ generates a replica of a global pilot chip code sequence and synchronizes the generated replica's timing with the received global pilot 50₁. The subscriber unit 40₁ also has a processor 82₁ to perform the many analysis functions of the subscriber unit 40₁.

The subscriber unit 40₁ generates an assigned pilot signal 52₁ using assigned pilot chip code generating means 56₁ and spread spectrum processing means 58₁. The assigned pilot chip code generating means 56₁ generates a pseudo random chip code sequence with its timing synchronized with the recovered global pilot chip code

sequence. As a result, the assigned pilot chip code sequence is delayed by τ_1 with respect to the base station $36_1, 36_2 \dots 36_n$. The spread spectrum processing means 58_1 generates the assigned pilot signal 52_1 by modulating the assigned pilot chip code sequence up to a desired center frequency. The assigned pilot signal 52_1 is transmitted to all base stations $36_1, 36_2 \dots 36_n$ within range to receive the assigned pilot signal 52_1 .

The base station 36_1 receives the assigned pilot signal 52_1 with the base station's receiver 62_1 . The received assigned pilot 52_1 travels the same distance d_1 as the global pilot signal 50_1 as shown in Figure 5. Accordingly, the received assigned pilot signal will be delayed by τ_1 with respect to the mobile unit 40_1 and by $2\tau_1$ with respect to the global pilot 50_1 generated at the base station 36_1 .

Since the chip code sequence of the assigned pilot 52_1 received at the base station 36_1 will be delayed by $2\tau_1$ with respect to the chip code sequence of the global pilot signal 50_1 generated at the base station 36_1 , the round trip propagation delay, $2\tau_1$, can be determined by comparing the timing of the two chip code sequences. Using the round trip propagation delay, $2\tau_1$, the distance d_1 between the base station 36_1 and subscriber unit 40_1 can be determined by:

$$d_1 = c \cdot \frac{2\tau_1}{2}$$

Equation (2)

If a spreading sequence having a chipping rate of at least 80ns is used and the communication system has the ability to track $1/16^{\text{th}}$ of a chip, the distance d_i can be measured to within 2 meters.

Figure 6 is a block diagram of a first embodiment of the present invention.

5 No additional hardware is required in the subscriber unit 40_1 . The only changes are implemented by software within the subscriber unit's processor 82_1 and the processors $66_1, 66_2 \dots 66_n, 68, 70_1, 70_2 \dots 70_n$ located within the base station 36_1 , NIU 34_1 or Local Exchange 32_1 , Precincts $74_1, 74_2 \dots 74_n$ and Ambulance Dispatcher 76 .

10 The subscriber unit 40_1 is sent a signal by a base station 36_1 indicating that a 911 call was initiated and to begin the subscriber location protocol. Upon receipt, the subscriber unit 40_1 will sequentially synchronize its transmission chip code sequence to at least three base stations' chip code sequences. To allow reception by the base stations $36_2, 36_3 \dots 36_n$ outside of the subscriber unit's normal communicating range, these transmissions will be sent at a higher than normal power level temporarily over-riding any adaptive power control algorithms.

15

A processor 66_1 within each base station $36_1, 36_2 \dots 36_n$ is coupled to the assigned pilot chip code recovery means 64_1 and the global pilot chip code generator 42_1 . The processor 66_1 compares the two chip code sequences to determine the round trip propagation delay $\tau_1, \tau_2 \dots \tau_n$ and the respective distance $d_1, d_2 \dots d_n$ between the subscriber unit 40_1 and the respective base station $36_1, 36_2 \dots 36_n$.

20

Within either a NIU 34₁ or the local exchange 32, a processor 68 receives the distances $d_1, d_2 \dots d_n$ from the processors 66₁, 66₂ ... 66_n within all the base stations 36₁, 36₂ ... 36_n. The processor 68 uses the distances $d_1, d_2 \dots d_n$ to determine the location of the subscriber unit 40₁ as follows.

5 By using the known longitude and latitude from three base stations 36₁, 36₂, 36₃ and distances d_1, d_2, d_3 , the location of the subscriber unit 40₁ is determined. As shown in Figure 7 by using the three distances d_1, d_2, d_3 , three circles 78₁, 78₂, 78₃ with radii 80₁, 80₂, 80₃ are constructed. Each circle 78₁, 78₂, 78₃ is centered around a respective base station 36₁, 36₂, 36₃. The intersection of the three circles 78₁, 78₂, 10 78₃ is at the location of the subscriber unit 40₁.

Using the Cartesian coordinates, the longitude and latitude corresponding with each base station 36₁, 36₂ ... 36_n is represented as X_n, Y_n , where X_n is the longitude and Y_n is the latitude. If X, Y represents the location of the subscriber unit 40₁, using the distance formula the following equations result:

$$(X_1 - X)^2 + (Y_1 - Y)^2 = d_1^2 \quad \text{Equation (3)}$$

$$(X_2 - X)^2 + (Y_2 - Y)^2 = d_2^2 \quad \text{Equation (4)}$$

$$(X_3 - X)^2 + (Y_3 - Y)^2 = d_3^2 \quad \text{Equation (5)}$$

In practice due to small errors in calculating the distances d_1, d_2, d_3 , Equations 3, 4 and 5 cannot be solved using conventional algebra. To compensate 20 for the errors, a maximum likelihood estimation is used to determine the location and

are well known to those skilled in the art. For increased accuracy, additional base stations $36_4, 36_5 \dots 36_n$ can be used to calculate additional distances for inclusion in the estimation analysis.

The subscriber unit's location is sent through the communication system 30 to at least one precinct $74_1, 74_2 \dots 74_n$ and an ambulance dispatcher 76. A processor 70_1 within each precinct $74_1, 74_2 \dots 74_n$ and the ambulance dispatcher 76 receives the location of all 911 calls originating in the system and displays the location on a conventional computer monitor 72_1 . The display comprises a listing of all 911 calls and addresses on a geographic map.

An alternate approach reduces the number of processors by transmitting raw data through the communication system 30 and processing the raw data at a single site.

Figure 8 is a second embodiment of a location system. At least two base stations $36_1, 36_2 \dots 36_n$ have their internal timing synchronized with each other and transmit their respective global pilot signals $52_1, 52_2 \dots 52_n$ with time synchronized chip code sequences. The subscriber unit 40_1 receives the global pilots $52_1, 52_2 \dots 52_n$. However, the received global pilots $52_1, 52_2 \dots 52_n$ are not synchronized. The global pilot 52_1 from a first base station 36_1 will travel distance d_1 and is delayed by τ_1 . The global pilot 52_2 from a second base station 36_2 travels distance d_2 and is delayed by τ_2 . The subscriber unit 40_1 recovers each base station's global pilot chip

code sequence with its global pilot chip code recovery means 54₁. A processor 82₁ within the subscriber unit 40₁ is coupled to each global pilot chip code recovery means 54₁, 52₂ ... 54_n. The processor 82₁ compares the chip code sequences of each pair of pilot chip code sequences and calculates the time differences Δt_1 , Δt_2 ... Δt_n between the sequences as follows.

Within the subscriber unit 40₁, the chip code sequences used by each base station 36₁, 36₂ ... 36_n are stored. After synchronizing with the first base station's pilot 36₁, the processor 82₁ will store where within the sequence synchronization was obtained. This process is repeated for the other base stations 36₂, 36₃ ... 36_n. The synchronization process can be done sequentially (synchronizing to the first base station's chip code sequence then the second, etc.) or in parallel (synchronizing to all base stations at the same time).

By using the relative time difference between τ_1 , τ_2 , ... τ_n each base station's chip code sequence and knowing that each base station's pilot was sent at the same time, with two base stations the time differences are calculated as follows:

$$\Delta t_1 = \tau_2 - \tau_1 \quad \text{Equation (6)}$$

$$\Delta t_2 = \tau_3 - \tau_2 \quad \text{Equation (7)}$$

The time differences Δt_1 , Δt_2 ... Δt_n are transmitted to at least one of the base stations 36₁.

At least one base station 36₁ recovers the time difference data from the received signals using time difference recovery means 84₁. The time difference data is sent with the distance data d_1 through the communications system to a processor 68. The processor 68 determines the location of the subscriber unit 40₁ using the time difference data $\Delta t_1, \Delta t_2 \dots \Delta t_n$ and the distance data $d_1, d_2 \dots d_n$ as follows.

Using information from only two base stations 36₁, 36₂ as shown in Figure 9, the processor uses distances d_1, d_2 to create two circles 78₁, 78₂. Using the time difference, Δt_1 , a hyperbola 86₁ can be constructed as follows.

All the points along the hyperbola 86₁ receive the global pilot signals 52₁, 52₂ from the synchronized base stations 36₁, 36₂ with the same time difference, Δt_1 . The time difference Δt_1 can be converted to a distance difference Δd_1 by substituting Δt_1 for t_1 and Δd_1 for d_1 in Equation 1. Using the distance formula and X, Y as the location of the subscriber unit 40₁, the following equation results:

$$\Delta d_1 = \sqrt{(X_1 - X)^2 + (Y_1 - Y)^2} - \sqrt{(X_2 - X)^2 + (Y_2 - Y)^2} \quad \text{Equation (8)}$$

By using Equation 8 with Equations 3 and 4 in a maximum likelihood estimation, the location of the subscriber unit 40₁ can be determined. The subscriber unit's location is subsequently sent to the nearest police precinct 74₁, 74₂ ... 74_n and ambulance dispatcher 76 in the cellular area.

For improved accuracy, additional base stations $36_1, 36_2 \dots 36_n$ are used. Figure 10 shows the invention used with three base stations $36_1, 36_2, 36_3$. The distances d_1, d_2, d_3 are used to create three circles $78_1, 78_2, 78_3$. Using time differences $\Delta t_1, \Delta t_2$, two intersecting hyperbolas $86_1, 86_2$ are constructed. With maximum likelihood estimation, the subscriber units' location calculated with two hyperbolas $86_1, 86_2$, and three circles $78_1, 78_2, 78_3$ yields greater accuracy.

As shown in Figure 8, the subscriber unit 40_1 is required to process each global pilot chip code sequence to determine the time differences $\Delta t_1, \Delta t_2 \dots \Delta t_n$. An alternate approach removes the processing from the subscriber unit 40_1 .

With reference to Figure 6, the mobile unit 40_1 will synchronize the assigned pilot to one of the base station's global pilot chip code sequences, such as the nearest base station 36_1 with a delay of τ_1 . The assigned pilot 50_1 is transmitted to all base stations $36_1, 36_2 \dots 36_n$. The assigned pilot 50_1 will be received at each base station with a respective delay, $\tau_1 + \tau_1, \tau_1 + \tau_2, \tau_1 + \tau_3$. Each base station $36_1, 36_2 \dots 36_n$ will send the delayed chip code sequence along with the calculated distance to a processor 68 located in a NIU 34_1 or local exchange 32. The processor 68 will calculate the time differences $\Delta t_1, \Delta t_2 \dots \Delta t_n$ by comparing the received assigned pilot chip code sequences. Since all received assigned pilot chip code sequences are delayed by τ_1 , the τ_1 delay will cancel out of the resultant time differences $\Delta t_1, \Delta t_2$

... Δt_n . Accordingly, the subscriber unit 40₁ can be located using hyperbolas 86₁, 86₂ as previously described.

Another embodiment shown in Figures 11, 12 and 13 uses a base station 36₁ with multiple antennas 88₁, 88₂ ... 88_n. Two of the antennas 88₁, 88₂ lie along a centerline 92 at a known distance, l , apart as shown in Figure 11. Both antennas 88₁, 88₂ receive the assigned pilot signal 90₁, 90₂ from the subscriber unit 40₁. However, the antenna 88₂ further away from the subscriber unit 40₁ receives the signal over a slightly longer distance d_1' and with a slight delay with respect to the nearer antenna 88₁. This delay results in a carrier phase difference, ϕ , between the signals received at each antenna as shown on Figure 13. A processor 66 using the received carrier phase difference and the chip code sequence recovered by each assigned pilot chip code recovery means 96₁, 96₂ ... 96_n can determine the location of the subscriber unit 40₁ as follows.

As shown in Figure 12, the subscriber unit 40₁ is located at distance d_1 at angle α from the centerline 92 of the antennas 88₁, 88₂. As seen at the scale of Figure 12 both received assigned pilot signals 90₁, 90₂ appear to be coincident. However, as shown in Figure 11, the received assigned pilot signals 90₁, 90₂ are slightly separated. The received assigned pilot signal 90₁ returning to the first antenna 88₁ travels a distance d_1 . The received assigned pilot signal 90₂ returning

to the second antenna 88₂ travels a slightly longer distance d_1' . As shown in Figure 11, the difference between the two distances d_1, d_1' is a distance m .

Since the distances d_1, d_1' between the antennas 88₁, 88₂ and the subscriber unit 40₁ are much larger than the distance l between the antennae 88₁, 88₂ both received assigned pilot signals 90₁, 90₂ follow approximately parallel paths. By constructing a right triangle using a point 94 which is distance d_1 from the subscriber unit 40₁ as shown in Figure 11, the angle α can be determined by the following geometric relationship:

$$\alpha = \cos^{-1}(m/l). \quad \text{Equation (9)}$$

The distance m can be determined by using the carrier phase difference, ϕ , between the two received signals 90₁, 90₂ as follows:

$$m = \frac{\phi \cdot \lambda}{2\pi} \quad \text{Equation (10)}$$

The distance m equals the phase difference between the two signals, ϕ , in radians multiplied by the wavelength of the signal, λ , divided by 2π . The wavelength, λ , can be derived from the known frequency f of the assigned pilot signal as follows:

$$\lambda = c/f. \quad \text{Equation (11)}$$

The processor 68 also compares the chip code sequences of the global pilot generating means 42₁ with the recovered assigned pilot chip code sequence to determine the distance d_1 as shown in Figure 6. Using both the angle α and distance d_1 , the processor 66₁ locates the subscriber unit 40₁ using simple geometry. There are many techniques well known to those skilled in the art to eliminate the ambiguity between locations above and below the antennas 88₁, 88₂. One such technique is using antennas employing sectorization. Subsequently, the subscriber unit's location is sent to the precincts 74₁, 74₂ ... 74_n and ambulance dispatcher 76. Additional antennas may be used to improve on the accuracy of the system.

An alternate embodiment uses more than one base station 36₁, 36₂ ... 36_n. A processor 68 located within either a NIU 34₁ or the local exchange 32 collects distance and angle information from more than one base station 36₁, 36₂ ... 36_n as well as the time differences Δt_1 , Δt_2 ... Δt_n , between the base stations 36₁, 36₂ ... 36_n. Using the maximum likelihood estimation technique, the processor 68 determines a more accurate location of the subscriber unit 40₁.

A fourth embodiment corrects for multipath. Figure 14 illustrates multipath. A signal such as a global pilot signal is transmitted from a base station 36₁. The signal follows a multitude of paths 98₁, 98₂ ... 98_n between the base station 36₁ and subscriber unit 40₁.

Figure 13 is a graph showing the impulse response 136 of the received multipath components. Since each received multipath component travels a unique path, it arrives at a receiver with a propagation delay determined by the length of the path $98_1, 98_2 \dots 98_n$. The impulse response 106 shows the collective signal magnitude of all the multipath components received at each propagation delay.

The previously described subscriber unit location techniques assumed the subscriber unit 40_1 synchronizes with the line of sight multipath component 98_1 traveling distance d_1 . However, if the subscriber unit synchronizes with a non-line of sight multipath component $98_1, 98_2 \dots 98_n$, the distance calculation will be in error due to the delay MD_1 as shown in Figure 15.

Figure 16 is a system correcting for errors resulting from multipath. The global pilot 50_1 is sent from the base station 36_1 to subscriber unit 40_1 . The subscriber unit 40_1 collects all of the multipath components using a multipath receiver 102_1 such as disclosed in U.S. Patent Application No. 08/669,769, Lomp et al., incorporated here by reference. A processor 82_1 within the subscriber unit 40_1 analyzes the impulse response 100 of the received global pilot signal 50_1 .

Since the line of sight multipath component 98_1 travels the shortest distance d_1 , the first received component 98_1 is the line of sight component. If the line of sight component is not received, the first received component 98_1 will be the closest and, accordingly, the best available estimate for the line of sight component. The

processor 82₁ compares the chip code sequence of the first received component 98₁ with the chip code sequence used to synchronize the assigned pilot chip code sequence. This comparison determines the delay due to multipath, MD₁. The multipath delay, MD₁, is transmitted to the base station 36₁.

5 A processor 66₁ and multipath receiver 104₁ within the base station 36₁ perform the same analysis on the received assigned pilot signal. As a result, the multipath delay, MD₂, of the assigned pilot signal is determined. Additionally, multipath delay recovery means 106₁ recovers the transmitted global pilot signal's multipath delay MD₁ for use by the processor 66₁. The processor 66₁ compares the
10 generated global pilot chip code sequence to the recovered assigned pilot chip code sequence to determine the round trip propagation delay 2τ₁. To correct for multipath, the processor 66₁ subtracts both the global pilot signal's multipath delay MD₁ and the assigned pilot signals multipath delay MD₂ from the calculated round trip propagation delay, 2τ₁. The corrected round trip propagation delay is used to
15 determine the subscriber unit's location in one of the techniques as previously described.

Although the invention has been described in part by making detailed reference to certain specific embodiments, such detail is intended to be instructive rather than restrictive. It will be appreciated by those skilled in the art that many

variations may be made in the structure and mode of operation without departing from the scope of the invention as disclosed in the teachings herein.

CLAIMS

1. A method for geographically locating a subscriber unit within a CDMA communication system having base stations with fixed locations, the method comprising:

5 (a) transmitting a first spread spectrum signal with a first pseudo random chip code sequence from a base station;

(b) receiving of said first spread spectrum signal including first signal multipath components at said subscriber unit;

(c) determining a first received component of the received first signal multipath components;

10 (d) transmitting a second spread spectrum signal with a second pseudo random chip code sequence from said subscriber unit, said second pseudo random chip code sequence being time synchronized with said received first spread spectrum signal;

15 (e) receiving said second spread spectrum signal including second signal multipath components at said base station;

(f) determining a first received component of the received second signal multipath components;

(g) determining a distance between said base station and said subscriber unit based on the first received component of said second signal; and

20 (h) determining said subscriber unit's geographic location based on said distance determination.

2. The method of claim 1 wherein steps (a)-(g) are performed respectively for each of three base stations, each base station associated with a different fixed location, and step (h) determines said subscriber unit's geographic location based on said distance determinations for each of said three base stations.

3. The method of claim 1 further comprising the steps of:

performing steps (a)-(g) for both a first and a second base station, each base station associated with a different fixed location;

5 time synchronizing said first base station's first spread spectrum signal with said second base station's first spread spectrum signal; and

determining a time difference between said first base station's and said second base station's first spread spectrum signals received at said subscriber unit; and

wherein step (h) determines said subscriber unit's geographic location using said distance determinations and said determined time difference.

4. The method of claim 1 further comprising the steps of:

performing steps (a)-(g) for both a first and a second base station, each base station associated with a different fixed location;

receiving at said second base station said second spread spectrum signal
5 which is time synchronized with said first base station's spread spectrum signal, said first base station's second signal received at said second base station including first base station's second signal multipath components;

determining a first received component of said received first base station's second signal multipath components at said second base station; and

10 determining a time difference between said first base station's second spread spectrum signal received at said first base station and at said second base station; and

wherein step (h) determines said subscriber unit's geographic location using said distance determinations and said determined time difference.

5. The method of claim 1 wherein said base station has first and second antennas each associated with a different fixed location and said second spread spectrum signal is received separately by said first and second antennas, further comprising the steps of:

5 determining the phase difference between the respective second spread spectrum signals received by said first and second antennas; and

calculating an angle associated with said base station and said subscriber unit based on said phase difference and the distance between the first and second antenna's fixed locations; and

10 wherein step (h) determines said subscriber unit's geographic location based on said distance determination and said calculated angle.

6. The method of claim 1 wherein said first signal and said second signal are pilot signals.

7. The method of claim 1 wherein said base station's fixed location is associated with a latitude and a longitude and step (h) determines said subscriber unit's geographical location based on said latitude, said longitude, and said distance determination.

8. The method of claim 1 further comprising the step of displaying said subscriber unit's geographic location on a map.

9. The method of claim 1 further comprising the step of displaying said subscriber unit's geographic location as an address.

10. The method of claim 1 wherein step (h) determines said subscriber unit's geographic location using said distance determination in a maximum likelihood estimation.

11. A method for determining a distance between a subscriber unit and a base station in a CDMA communication system, the method comprising:

(a) transmitting a first spread spectrum signal with a first pseudo random chip code sequence from a base station;

5 (b) receiving of said first spread spectrum signal including first signal multipath components at said subscriber unit;

(c) determining a first received component of the received first signal multipath components;

10 (d) transmitting a second spread spectrum signal with a second pseudo random chip code sequence from said subscriber unit, said second pseudo random chip code sequence being time synchronized with said received first spread spectrum signal;

(e) receiving said second spread spectrum signal including second signal multipath components at said base station;

15 (f) determining a first received component of the received second signal multipath components; and

(g) determining a distance between said base station and said subscriber unit based on the first received component of the second signal.

12. A spread spectrum CDMA communication system capable of geographically locating a subscriber unit, the system comprising:

means for determining said subscriber unit's geographic location based on a distance determination; and

5 at least one base station, each of said at least one base stations comprising:

means for transmitting a first spread spectrum signal with a first pseudo random chip code sequence;

means for receiving a second spread spectrum signal including second signal multipath components;

10 means for determining a first received component of said received second signal multipath components; and

means for determining a distance between said base station and said subscriber unit as said distance determination based on the first received component of said second signal; and

15 said subscriber unit comprising:

means for receiving said first spread spectrum signal including first signal multipath components;

means for determining a first received component of said received first signal multipath components; and

20 means for transmitting a second spread spectrum signal with a second pseudo random chip code sequence, said second pseudo random chip code sequence being time synchronized with said received first spread spectrum signal.

13. The system of claim 12 wherein:

said at least one base station is three base stations, each base station associated with a different fixed location;

5 said subscriber unit receiving means receives from each of said three base stations said respective first spread spectrum signal including respective first signal multipath components;

said subscriber unit first component determining means determines a respective first received component for each of said respective received first signal multipath components;

10 said subscriber unit transmitting means transmits three second spread spectrum signals, each associated with one of said three base stations, each with a respective second pseudo random chip code sequence, said respective second pseudo random chip code sequence being time synchronized with said respective received first spread spectrum signal from said respective one of said three base stations; and

15 said geolocation determining means determines said subscriber unit's
geographic location based on said distance determination from each of said three
base stations

14. The system of claim 12 wherein:

 said at least one base station is two base stations, each base station associated
with a different fixed location;

5 said subscriber unit receiving means receives from each of said two base
stations said respective first spread spectrum signal including respective first signal
multipath components;

 said subscriber unit first component determining means determines a
respective first received component for each respective received first signal
multipath components;

10 said subscriber unit transmitting means transmits two second spread spectrum
signals, each associated with one of said two base stations, each with a respective
second pseudo random chip code sequence, said respective second pseudo random
chip code sequence being time synchronized with said received first spread spectrum
signal from said respective base station;

15 said subscriber unit further comprising time difference means for determining
a time difference between said first base station's and said second base station's first
spread spectrum signals received at said subscriber unit;

 said geographic location determining means determines said subscriber unit's
geographic location using said distance determinations and said time difference; and

20 said first base station's first spread spectrum signal transmitted at said first
base station is time synchronized with said second base station's first spread
spectrum signal transmitted at said second base station.

15. The system of claim 12 wherein:

 said at least one base station is two base stations, each base station associated
with a different fixed location;

5 said first base station's first spread spectrum signal transmitted at said first
base station is time synchronized with said second base station's first spread
spectrum signal transmitted at said second base station;

 said subscriber unit receiving means receives from each of said two base
stations said respective first spread spectrum signal including respective first signal
multipath components;

10 said subscriber unit first component determining means determines a
respective first received component for each of said respective received first signal
multipath components;

15 said subscriber unit transmitting means transmits two second spread spectrum
signals, each associated with one of said two base stations, each with a respective
second pseudo random chip code sequence, each of said respective second pseudo
random chip code sequences being time synchronized with said received first spread
spectrum signal from said respective one of said two base stations; and

 said second base station further comprising:

20 means for receiving said second spread spectrum signal which is time
synchronized with said first base station's spread spectrum signal, said received first
base station's second signal including first base station's second signal multipath
components;

 means for determining a first received component of said received first base
station's second signal multipath components at said second base station; and

25 said geographic location determining means determines said subscriber unit's
geographic location using said distance determinations and a determined time
difference; and

 the system further comprising:

means for determining a time difference between said first base station's second spread spectrum signal received at said first base station and at said second base station as said determined time difference.

16. The system of claim 12 wherein:

said base station further comprising:

a first and second antenna, each associated with a different fixed location and said second spread spectrum signal is received separately by said first and second antennas;

means for determining the phase difference between the respective second spread spectrum signals received by said first and second antennas; and

means for calculating an angle associated with said base station and said subscriber unit based on said phase difference and the distance between the first and second antennas fixed locations; and

wherein said geographic location determining means determines said subscriber unit's geographic location based on said distance determination and said calculated angle.

17. The system of claim 12 further comprising means for displaying said subscriber unit's geographic location on a map.

18. The system of claim 12 further comprising means for displaying said subscriber unit's geographic location as a street address.

19. A CDMA communication system capable of determining a distance between a subscriber unit and a base station, the system comprising:

means for determining a distance between said base station and said subscriber unit based on the first received component of the second signal;

5 said base station comprising:

means for transmitting a first spread spectrum signal with a first pseudo random chip code sequence;

means for receiving a second spread spectrum signal including second signal multipath components; and

10 means for determining a first received component of the received second signal multipath components;

said subscriber unit comprising:

means for receiving said first spread spectrum signal including first signal multipath components;

15 means for determining a first received component of said received first signal multipath components; and

means for transmitting a second spread spectrum signal with a second pseudo random chip code sequence being time synchronized with said received first spread spectrum signal.

20. A subscriber unit for use in a CDMA communication system capable of geographically locating said subscriber unit, said subscriber unit comprising:

means for receiving a first spread spectrum signal with a first pseudo random chip code sequence, said first signal including first signal multipath components;

5 means for determining a first received component of said received first signal multipath components;

means for determining a delay associated with said first received component;

and

10 means for transmitting a second spread spectrum signal with a second pseudo random chip code sequence and a signal including said determined delay, said second pseudo random chip code sequence being time synchronized with said received first spread spectrum signal.
