

Description

Technical Field

The invention relates to thermal printers having printing elements driven by strobe pulses whose power may be adjusted. In particular, the invention relates to a method of adjusting power to such a printing element.

Background Art

In US-A-4,113,391, M. Minowa discloses a method for controlling the pulse width of strobe pulses applied to printing elements of a thermal printer. The system of Minowa is of the feedback type where a decrease in the print head element output voltage is measured and the width of a strobe pulse is correspondingly increased. Conversely, the pulse width is decreased in response to increases in the output voltage. In US-A-4,168,421, Y. Ito discloses a similar system using different circuit elements.

The prior art as disclosed in US-A-4113391 and in US-A-4168421 recognized that factors such as print element resistance, temperature and current level can affect print quality. Generally, the control mechanisms adapted to achieve a desired print quality involved simple models. For example, in the aforementioned patents, when voltage of the print element power supply dropped, the pulse width was increased and vice versa. Such models were quite useful, but did not take into account other factors which might cause the model to become nonlinear. For example, printing speed and history level were not taken into account. The latter parameter is associated with applications for multiple strobes or line passes, and is used to achieve the desired dot contrast relative to a print medium.

GB-A-2138190 discloses a method in accordance with the preambles of claims 1, 6 and 9 and shows a hand-held labeller employing a thermographic recording apparatus utilizing compensating circuitry for adjusting the energy applied to the print head to assure uniform printing over various operating conditions. The compensating circuit includes circuitry that adjusts the length of time that each printing element of the print head is energized as a function of battery voltage, ambient temperature, element resistance and the elapsed time since the element was previously energized. In addition, the monitoring of resistance and voltage permit detection of open or shorted printing elements and discharged or faulty battery cells. The energization times are determined on the basis of conditions prevailing before the energization is initiated.

An object of the invention was to more accurately control the power delivered to a printing element.

Summary of the Invention

The above object has been achieved in a printing method according to claims 1, 6 and 9 wherein print head pulse width is varied in accord with data derived from a look-up table. A predictive model of print element behavior is employed where the model relates variables such as speed, history level as well as voltage, temperature and resistance to strobe pulse duration. In accord with the present invention a memory array forms a look-up table for storing desired or target strobe pulse durations computed from various factors, such as power supply voltage levels, taking into account parameters mentioned above. Once the relationships are stored, a strobe pulse may be initiated at a print head element. Once the pulse is initiated, periodic real time measurements are made of power supply voltage levels. Reference is made to the look-up table to obtain the target pulse width value using the real time measurement. The actual strobe pulse is continued so long as the target pulse width has not been exceeded. Continued measurements of the power supply level are made and further look-up values are found. Each time a new pulse width is obtained from the table, a comparison must be made to see whether the actual elapsed time exceeds the target value. Once the target value is equaled or exceeded, the strobe pulse is terminated.

This procedure is repeated each time the thermal line array is turned on. The thermal line array may be turned on multiple times per scan line in order to adjust the energy applied to individual dot elements based on the amount of preheating they have experienced in previous scan lines. Each of these multiple strobes is assigned a history level which points to a section of the strobe width look-up table.

Brief Description of the Drawings

Fig. 1 is a flow diagram showing steps for establishing strobe pulse width in accord with the invention.

Fig. 2 is a timing diagram showing strobe width in comparison to print head power supply levels for different elapsed times.

Best Mode for Carrying Out the Invention

In thermal printing, it is desirable to obtain consistent print quality with minimal power consumption over a wide range of operating conditions. In accord with the present invention, a look-up table is created giving values for a target strobe width which depends upon power supply voltage, average resistance and print head element temperature. This equation is expressed as

$$W = V \times R \times T$$

where W is the strobe width, V is a voltage function,

R is a resistance function and T is a temperature function. The voltage function v is described by the following equation:

$$V = \frac{K0 - (K1 \times V)}{\sqrt{2}}$$

where K0 and K1 are empirical constants which are dependent on print speed and history level. The constants are assigned to each speed and to each history level, the history level relating to previously observed print characteristics whereby a desired level of contrast can be obtained. The voltage, V, is the measured power supply voltage and is the only quantity measured in real time. All other quantities are previously measured so that different strobe pulse widths are available for different previously measured functions.

The resistance of function R is given by the following formula:

$$R = \frac{(R_A + R_D)^2}{R_A}$$

where R_A is the average element resistance and R_D is the resistance of the element driver so that R_A plus R_D are equal to the total resistance in the print head element circuit.

The temperature function is given by the following equation:

$$T = 1.0 + ((25.0 - T_p) \times 0.007)$$

where T_p is equal to print head temperature in degrees Celsius. The temperature function is supplied by the print element manufacturer.

With reference to Fig. 1, a print head strobe pulse is initiated at block 11. Shortly thereafter, power supply voltage is measured, as indicated by block 13. The supply measurement is converted to digital form and then the target strobe width is obtained from the look-up table, indicated by block 15. The target pulse width obtained from the table is compared to the actual elapsed time since the initiation of the strobe pulse. When the actual elapsed time is equal to or exceeds the target strobe the print head element is turned off, indicated by block 17 with the comparison indicated by block 19. If the measured strobe pulse width does not exceed the target width, as indicated by block 21, the strobe width is extended and new comparisons are made after obtaining further power supply voltage level measurements, indicated by line 23. The entire process is repeated until the pulse width of the strobe exceeds the target width from the table. As previously mentioned, the print head is then turned off, indicated by block 17.

With reference to Fig. 2, elapsed time of a strobe pulse width is shown on the lower plot in milliseconds. At time equals 0, the strobe pulse is initiated, indicated by the vertical line 31. Shortly after the strobe pulse is initiated, periodic measurements of the print head power supply level are made, indicated by the vertical lines 33 in the upper plot. The actual print head power supply level is indicated by the curve 35.

At the first measurement interval, indicated by the circle 37, a voltage measurement is made. The value found is below the upper level 39, existing at the initiation of the strobe pulse. The look-up table is consulted for the voltage level found within the circle 37 and a number is obtained from the table, corresponding to a target pulse width for this particular voltage. Assume that the target value is 190 microseconds. Since at the measurement time, only about 20 microseconds have elapsed, the strobe pulse is continued.

Other voltage levels may be read, indicated by the vertical lines parallel to 33, but a new reading is not necessary until the elapsed time matches the target value at 190 microseconds, indicated by point 41 on the voltage curve 35. At this point, the previous measured voltage level is read, indicated by circle 43. The look-up table is consulted for a new target pulse width value. Assume the value is 290 microseconds. The strobe pulse width is again extended and the next reading of the measured voltage level occurs when 290 microseconds have elapsed, approximately at point 45 on curve 35. The last measured voltage level of the strobe is read, indicated by the circle 47. The look-up table is consulted for this level and we may assume that the reading is 310 microseconds. At 310 microseconds of actual time, indicated at point 49, the power supply voltage level is read, indicated by circle 51 and a target strobe pulse length of 310 microseconds is found which has now been exceeded by the actual elapsed time. Accordingly, the strobe pulse is terminated, indicated by vertical line 53.

In the above description, single samples of the measured print head power supply voltage level were used in consulting the look-up table. As an alternative, average values relative to the start of the measurement may be made for an even more accurate determination. Values for the look-up table may be stored on a floppy disk and loaded into semiconductor volatile memory before printing or stored in a non-volatile memory. The look-up table permits complex and precise modeling of strobe duration as a function of various operating conditions. Good strobe pulse width compensation is particularly important in high speed, battery powered thermal printers, such as those used in battery powered facsimile machines, cardiographs and field data logging equipment.

In the above description, history level was used to adjust the energy applied to individual dot elements based on their recent history in order to obtain consistent contrast and eliminate tailing. History level could also be used to vary the contrast of individual dots in order to create gray-scale images.

Claims

1. A method of adjusting a strobe pulse width of a print head element comprising.

R is a resistance function and T is a temperature function. The voltage function v is described by the following equation:

$$V = \frac{K0 - (K1 \times V)}{V^2}$$

where K0 and K1 are empirical constants which are dependent on print speed and history level. The constants are assigned to each speed and to each history level, the history level relating to previously observed print characteristics whereby a desired level of contrast can be obtained. The voltage, V, is the measured power supply voltage and is the only quantity measured in real time. All other quantities are previously measured so that different strobe pulse widths are available for different previously measured functions.

The resistance of function R is given by the following formula:

$$R = \frac{(R_A + R_D)^2}{R_A}$$

where R_A is the average element resistance and R_D is the resistance of the element driver so that R_A plus R_D are equal to the total resistance in the print head element circuit.

The temperature function is given by the following equation:

$$T = 1.0 + ((25.0 - T_P) \times 0.007)$$

where T_P is equal to print head temperature in degrees Celsius. The temperature function is supplied by the print element manufacturer.

With reference to Fig. 1, a print head strobe pulse is initiated at block 11. Shortly thereafter, power supply voltage is measured, as indicated by block 13. The supply measurement is converted to digital form and then the target strobe width is obtained from the look-up table, indicated by block 15. The target pulse width obtained from the table is compared to the actual elapsed time since the initiation of the strobe pulse. When the actual elapsed time is equal to or exceeds the target strobe the print head element is turned off, indicated by block 17 with the comparison indicated by block 19. If the measured strobe pulse width does not exceed the target width, as indicated by block 21, the strobe width is extended and new comparisons are made after obtaining further power supply voltage level measurements, indicated by line 23. The entire process is repeated until the pulse width of the strobe exceeds the target width from the table. As previously mentioned, the print head is then turned off, indicated by block 17.

With reference to Fig. 2, elapsed time of a strobe pulse width is shown on the lower plot in milliseconds. At time equals 0, the strobe pulse is initiated, indicated by the vertical line 31. Shortly after the strobe pulse is initiated, periodic measurements of the print head power supply level are made, indicated by the vertical lines 33 in the upper plot. The actual print head power supply level is indicated by the curve 35.

At the first measurement interval, indicated by the circle 37, a voltage measurement is made. The value found is below the upper level 39, existing at the initiation of the strobe pulse. The look-up table is consulted for the voltage level found within the circle 37 and a number is obtained from the table, corresponding to a target pulse width for this particular voltage. Assume that the target value is 190 microseconds. Since at the measurement time, only about 20 microseconds have elapsed, the strobe pulse is continued.

Other voltage levels may be read, indicated by the vertical lines parallel to 33, but a new reading is not necessary until the elapsed time matches the target value at 190 microseconds, indicated by point 41 on the voltage curve 35. At this point, the previous measured voltage level is read, indicated by circle 43. The look-up table is consulted for a new target pulse width value. Assume the value is 290 microseconds. The strobe pulse width is again extended and the next reading of the measured voltage level occurs when 290 microseconds have elapsed, approximately at point 45 on curve 35. The last measured voltage level of the strobe is read, indicated by the circle 47. The look-up table is consulted for this level and we may assume that the reading is 310 microseconds. At 310 microseconds of actual time, indicated at point 49, the power supply voltage level is read, indicated by circle 51 and a target strobe pulse length of 310 microseconds is found which has now been exceeded by the actual elapsed time. Accordingly, the strobe pulse is terminated, indicated by vertical line 53.

In the above description, single samples of the measured print head power supply voltage level were used in consulting the look-up table. As an alternative, average values relative to the start of the measurement may be made for an even more accurate determination. Values for the look-up table may be stored on a floppy disk and loaded into semiconductor volatile memory before printing or stored in a non-volatile memory. The look-up table permits complex and precise modeling of strobe duration as a function of various operating conditions. Good strobe pulse width compensation is particularly important in high speed, battery powered thermal printers, such as those used in battery powered facsimile machines, cardiographs and field data logging equipment.

In the above description, history level was used to adjust the energy applied to individual dot elements based on their recent history in order to obtain consistent contrast and eliminate tailing. History level could also be used to vary the contrast of individual dots in order to create gray-scale images.

Claims

1. A method of adjusting a strobe pulse width of a print head element comprising,

establishing a look-up table in a memory array having print element target pulse width information based on a plurality of variables and factors, with one or more variables to be tracked in real time and the others previously measured, and

commencing a strobe pulse for a print head element, characterized by, during the strobe in real time:

- keeping track of one or more variables and factors,
- referring to the look-up table location pointed to by the variables and factors to obtain a target pulse width,
- continuing the strobe pulse so long as the latest target pulse width exceeds the actual pulse width, and
- terminating the strobe pulse when the latest target pulse width has been equaled or exceeded.

2. The method of claim 1 wherein one of the variables in said plurality of variables and factors comprises average print head element resistance.

3. The method of claim 1 wherein one of the variables in said plurality of variables and factors comprises print head temperature.

4. The method of claim 1 wherein a factor in said plurality of variables and factors comprises print speed.

5. The method of claim 1 wherein a factor in said plurality of variables and factors comprises history level.

6. A method for establishing the duration of a strobe pulse for a thermal print head element in a multi-element print head comprising,

storing in a look-up table values related to target strobe pulse durations for computed functions of power supply voltage level and one of the following:

print head element temperature and average element resistance, and

commencing a strobe pulse for a print head element, characterized by, during the strobe in real time :

- periodically measuring the power supply voltage level of the strobe pulse,
- periodically referring to the look-up table for measured power supply levels to obtain a target strobe pulse width on each look-up,
- continuing the strobe pulse so long as the latest target pulse width exceeds the actual pulse width, and

- terminating the strobe pulse when the latest target pulse width has been equaled or exceeded.

7. The method of claim 6 further comprising determining stored look-up table values from previously measured print head element average resistance and temperature.

8. The method of claim 6 wherein the target strobe pulse width is a product of functions of measured power supply voltage, average element resistance and temperature for each print speed and history level.

9. A method for establishing the duration of a strobe pulse for a thermal print head element in a multi-element print head comprising,

storing in a look-up table values of target strobe pulse durations for computed functions of power supply voltage levels, print head temperature, average element resistance, paper speed, and history level, and

commencing a strobe pulse for a print head element, characterized by, during the strobe in real time :

- periodically measuring the power supply voltage level of the strobe pulse and computing an average voltage level relative to the beginning of the strobe pulse,
- periodically reading the look-up table location pointed to by the paper speed history level and average voltage level to obtain a target pulse width on each look-up,
- continuing the strobe pulse so long as the latest target pulse width exceeds the actual pulse width, and
- terminating the strobe pulse when the latest target pulse width has been equaled or exceeded.

10. The method of claim 9 further comprising determining stored look-up table values from previously measured print head element parameters including resistance and temperature.

Patentansprüche

1. Verfahren zum Einstellen einer Abtastimpulsbreite eines Druckkopfelementes, mit den Verfahrensschritten:

Einrichten einer Nachschlagetabelle in einer Speicheranordnung mit Druckelement-Sollimpulsbreiten-Information auf der Grundlage mehrerer Variablen und Faktoren, wobei eine oder mehrere Variablen in Echtzeit nachgeführt werden und die anderen im voraus gemessen werden

den, und Starten eines Abtastimpulses für ein Druckkopfelement, dadurch gekennzeichnet, daß während des Abtastimpulses in Echtzeit

- eine oder mehrere Variable verfolgt werden,
- auf die durch die Variablen und Faktoren bezeichnete Stelle der Nachschlagetabelle Bezug genommen wird, um eine Sollimpulsbreite zu erhalten,
- der Abtastimpuls so lange fortgesetzt wird, bis die späteste Sollimpulsbreite die tatsächliche Impulsbreite überschreitet, und
- der Abtastimpuls beendet wird, wenn die letzte Sollimpulsbreite erreicht oder überschritten ist.

2. Verfahren nach Anspruch 1, bei dem eine der Variablen von den mehreren Variablen und Faktoren einen mittleren Druckkopfelement-Widerstandswert umfaßt.

3. Verfahren nach Anspruch 1, bei dem eine der Variablen der mehreren Variablen und Faktoren eine Druckkopftemperatur umfaßt.

4. Verfahren nach Anspruch 1, bei dem ein Faktor der mehreren Variablen und Faktoren die Druckgeschwindigkeit umfaßt.

5. Verfahren nach Anspruch 1, bei dem ein Faktor der mehreren Variablen und Faktoren einen Stammpegel umfaßt.

6. Verfahren zum Einrichten der Dauer eines Abtastimpulses für ein thermisches Druckkopfelement in einem Mehrelementen-Druckkopf, mit den Verfahrensschritten:

Speichern von Werten in einer Nachschlagetabelle, die Soll-Abtastimpulslängen für berechnete Funktionen eines Leistungsversorgungs-Spannungspegels und einen der folgenden Parameter betreffen: Druckkopfelement-Temperatur und mittlerer Widerstandswert eines Elementes, und Starten eines Abtastimpulses für ein Druckkopfelement, dadurch gekennzeichnet, daß während des Abtastimpulses in Echtzeit:

- der Spannungspegel der Leistungsversorgung des Abtastimpulses periodisch gemessen wird,
- periodisch auf die Nachschlagetabelle für gemessene Leistungsversorgungspegel zugegriffen wird, um bei jedem Nachschlagen eine Soll-Abtastimpulsbreite zu erhalten,
- der Abtastimpuls so lange fortgesetzt wird, bis die letzte Abtastimpulsbreite die tatsächliche Impulsbreite überschreitet, und
- der Abtastimpuls beendet wird, wenn die

letzte Sollimpulsbreite erreicht oder überschritten ist.

7. Verfahren nach Anspruch 6, bei dem ferner gespeicherte Nachschlagetabellenwerte aus dem vorher gemessenen mittleren Widerstandswert und der Temperatur des Druckkopfelementes ermittelt werden.

8. Verfahren nach Anspruch 6, bei dem die Soll-Abtastimpulsbreite ein Produkt der Funktionen der gemessenen Leistungsversorgungsspannung, des mittleren Elementenwiderstandswertes und der -Temperatur für jede Druckgeschwindigkeit und jeden Stammpegel ist.

9. Verfahren zum Einrichten der Dauer eines Abtastimpulses für ein thermisches Druckkopfelement in einem Mehrelementen-Druckkopf, mit den folgenden Verfahrensschritten: Speichern von Abtastimpulslängen-Sollwerten für berechnete Funktionen von Leistungsversorgungs-Spannungspegeln, Druckkopftemperatur, eines mittleren Elementenwiderstandswertes, einer Papierschwindigkeit und eines Stammpegel in einer Nachschlagetabelle und Starten eines Abtastimpulses für ein Druckkopfelement, dadurch gekennzeichnet, daß während des Abtastimpulses in Echtzeit:

- der Leistungsversorgungs-Spannungspegel des Abtastimpulses periodisch gemessen wird und ein mittlerer Spannungspegel relativ zum Anfang des Abtastimpulses berechnet wird,
- die durch den Papierschwindigkeits-Stammpegel und einen mittleren Spannungspegel bezeichnete Stelle in der Nachschlagetabelle periodisch gelesen wird, um bei jedem Nachschlagen eine Sollimpulsbreite zu erhalten,
- der Abtastimpuls solange fortgesetzt wird, bis die letzte Sollimpulsbreite die tatsächliche Impulsbreite überschreitet, und
- der Abtastimpuls beendet wird, wenn die letzte Sollimpulsbreite erreicht oder überschritten ist.

10. Verfahren nach Anspruch 9, bei dem ferner gespeicherte Nachschlagetabellen-Werte aus vorher gemessenen Druckkopfelementparametern, einschließlich dem Widerstandswert und der Temperatur, bestimmt werden.

Revendications

1. Procédé d'ajustement d'une largeur d'impulsion,

d'échantillonnage d'un élément de tête d'impression, comprenant les étapes consistant à :

établir une table à consulter dans un groupement de mémoires qui contient une information de largeur cible d'impulsion d'élément d'impression basée sur une pluralité de variables et facteurs, dont une ou plusieurs variables doivent être échantillonnées en temps réel, tandis que les autres ont été préalablement mesurées, et

faire débiter une impulsion d'échantillonnage pour un élément de tête d'impression, caractérisé par les étapes suivantes :

pendant l'échantillonnage en temps réel/conservation de la trace d'un ou plusieurs variables et facteurs,

- se reporter à l'emplacement de la table à consulter pointé par les variables et facteurs pour obtenir une largeur d'impulsion cible,

- continuer l'impulsion d'échantillonnage aussi longtemps que la dernière largeur d'impulsion cible excède la largeur d'impulsion actuelle, et

- interrompre l'impulsion d'échantillonnage lorsque la dernière largeur d'impulsion cible a été égalée ou dépassée.

2. Procédé selon la revendication 1, dans lequel une des variables de ladite pluralité de variables et facteurs est constituée par la résistance moyenne d'un élément de tête d'impression.

3. Procédé selon la revendication 1, dans lequel une des variables de ladite pluralité de variables et facteurs est constituée par la température de la tête d'impression.

4. Procédé selon la revendication 1, dans lequel un facteur de ladite pluralité de variables et facteurs est constitué par la vitesse d'impression.

5. Procédé selon la revendication 1, dans lequel un facteur de ladite pluralité de variables et facteurs est constitué par un niveau historique.

6. Procédé pour établir la durée d'une impulsion d'échantillonnage pour un élément de tête d'impression thermique inclus dans une tête d'impression multi-élément :

mémoriser dans une table à consulter des valeurs concernant des durées cibles d'impulsions d'échantillonnage pour des fonctions calculées de niveau de tension d'alimentation en énergie et l'un des paramètres suivants : température de l'élément de tête d'impression et résistance moyenne de l'élément, et

faire débiter une impulsion d'échantillonnage pour un élément de tête d'impression, caractérisé en ce que, pendant l'échantillonnage en temps réel, on effectue les étapes suivantes :

- mesurer périodiquement le niveau de tension d'alimentation en énergie de l'impulsion d'échantillonnage,

- se reporter périodiquement à la table à consulter pour trouver les niveaux d'alimentation en énergie mesurés afin d'obtenir une largeur cible d'impulsion d'échantillonnage à chaque consultation,
- continuer l'impulsion d'échantillonnage aussi longtemps que la plus récente largeur cible d'impulsion excède la largeur d'impulsion actuelle, et
- interrompre l'impulsion d'échantillonnage lorsque la plus récente largeur cible d'impulsion a été égalée ou dépassée.

7. Procédé selon la revendication 6, comprenant en outre l'étape consistant à déterminer des valeurs mémorisées de la table à consulter à partir des valeurs mesurées précédemment de la résistance moyenne et de la température de l'élément de tête d'impression.

8. Procédé selon la revendication 6, dans lequel la largeur cible d'impulsion d'échantillonnage est le produit de fonctions de la tension d'alimentation en énergie, de la résistance et de la température mesurées pour chaque vitesse d'impression et pour chaque niveau historique.

9. Procédé pour établir la durée d'une impulsion d'échantillonnage pour un élément de tête d'impression thermique inclus dans une tête d'impression multi-élément comprenant les étapes consistant à :

mémoriser dans une table à consulter des valeurs de durées cibles d'impulsions d'échantillonnage pour des fonctions calculées de niveaux de tension d'alimentation en énergie, de température de tête d'impression, de résistance moyenne de l'élément, de vitesse du papier et de niveau historique, et

faire débiter une impulsion d'échantillonnage pour un élément de tête d'impression, caractérisé en ce que, pendant l'échantillonnage en temps réel, on effectue des étapes suivantes :

- mesurer périodiquement le niveau de tension d'alimentation en énergie de l'impulsion d'échantillonnage et calculer un niveau de tension moyen relatif au début de l'impulsion d'échantillonnage,
- lire périodiquement l'emplacement de la table à consulter pointé par le niveau historique de la vitesse du papier et par le niveau moyen de tension pour obtenir une largeur cible d'impulsion d'échantillonnage à cha-

que consultation,

continuer l'impulsion d'échantillonnage aussi longtemps que la plus récente largeur cible d'impulsion excède la largeur d'impulsion actuelle, et

- interrompre l'impulsion d'échantillonnage lorsque la plus récente largeur cible d'impulsion a été égale ou dépassée.

10. Procédé selon la revendication 9, comprenant en outre l'étape consistant à déterminer des valeurs mémorisées de la table à consulter à partir de paramètres de l'élément de tête d'impression précédemment mesurés, qui comprennent la résistance et la température.
