

METHOD AND APPARATUS FOR CONTROLLING GAS FLOW TO A PROCESSING CHAMBER

BACKGROUND

Field of the Invention

[0001] Embodiments of the present invention generally relate to a method and apparatus for controlling gas flow to a processing chamber.

Description of the Related Art

[0002] Accurate control of gas flows is an important process control attribute critical to many microelectronic device fabrication processes. Providing gas between a substrate and a substrate support in a semiconductor processing chamber is a well-known method for improving heat transfer between the substrate and the substrate support, thereby enhancing the precision of substrate temperature control and uniformity. Additionally, precise control of process gas flows into the processing chamber are required in order to obtain desired processing results, particularly as critical dimensions and film thicknesses shrink. Furthermore, gases may be added to processing chamber effluent streams to mitigate the environmental impact of substrate processing. Good control of the gases added to the effluent stream is necessary to ensure both cost effective and proper remediation.

[0003] Conventional gas delivery systems used with semiconductor processing chambers generally include a mass gas flow meter (MFC) as the primary flow regulation device. However, the accuracy of MFC's may be affected by a plurality of factors that contribute to an uncertainty of the actual gas flow. For example, the accuracy of the MFC will typically vary with changes in temperature, line pressure and volume. Deviation from the gas flow set point due to MFC inaccuracy may contribute to processing defects, poor emission control and inefficient waste of costly gases.

[0004] Although conventional pressure control systems have proven relatively reliable, field experience with the existing technology has increased the demand for more accurate measurement of flow. For example, poor control of gas flows used in backside substrate cooling applications may result in poor

substrate temperature control, thereby causing poor film deposition or etching results, which cannot be tolerated in next generation circuit designs.

[0005] Moreover, conventional gas delivery systems generally have fixed conduits for routing gases from the gas sources into the processing chamber. Thus, only a predefined combination of process gases may be delivered to the processing chamber at any time. Such fixed gas delivery routing prevents process flexibility. For example, processing chambers having fixed gas delivery routes may not be able to accommodate new or revised process recipes that require a different combination of process gases. Additionally, a processing chamber having a fixed gas delivery route designed to deliver one combination of process gases to perform a first process may not be able to perform a second process that utilizes a different combination of gases, thereby preventing the processing chamber from being utilized for other processes and causing the FAB owner to invest in additional equipment. Thus, it would be desirable to devise a gas delivery system having greater flexibility.

[0006] Therefore, there is a need for an improved method and apparatus for controlling the delivery of gases to a semiconductor processing system.

SUMMARY

[0007] A method and apparatus for delivering gases to a semiconductor processing system are provided. In one embodiment, an apparatus for delivering gases to a semiconductor processing system includes a plurality of gas input lines each having an inlet port and a plurality of gas output lines each having an outlet port. A plurality of connecting lines are provided that couple a respective pairs of gas input and gas output lines. Connecting valves are arranged to control flow through the respective connecting lines. A plurality of mass gas flow controllers are arranged to control flow into a respective inlet port.

[0008] In another embodiment, a method of controlling gas flow to a processing system that includes a processing chamber coupled to a facility exhaust through a foreline is provided that includes providing a manifold having at least a first, second third and fourth inlet that may be selectively coupled to at least one of a first, second third and fourth outlet, flowing one or more gases through the manifold to a vacuum environment by-passing the processing chamber prior to processing or to a calibration circuit, and flowing the one or more gases into the processing chamber during substrate processing.

[0009] In another embodiment, a method of controlling gas flow to a processing system that includes a processing chamber coupled to a facility exhaust through a foreline is provided. The method includes flowing a first gas from a first gas source into a manifold having at least a first outlet port, a second outlet port, a third outlet port and a fourth outlet port, flowing a second gas from a second gas source into the manifold, selecting an operational state of valves within the manifold to cause the first and second gases to exit through at least one of the second or third outlet ports while in a processing mode, flowing the first and second gases through the manifold and into the foreline by-passing the processing chamber until a predefined state of the gases within the manifold is obtained, directing the first and second gases exiting the manifold into the processing chamber after the predefined state has been obtained, and processing a substrate within the processing chamber..

BRIEF DESCRIPTION OF THE DRAWINGS

[0010] So that the manner in which the above recited features of the present invention may be understood in detail, a more particular description of the invention, briefly summarized above, may be had by reference to embodiments, some of which are illustrated in the appended drawings. It is to be noted, however, that the appended drawings illustrate only typical embodiments of this invention and are therefore not to be considered limiting of its scope, for the invention may admit to other equally effective embodiments.

[0011] Figure 1 is a simplified schematic of a semiconductor processing chamber coupled to one embodiment of a gas delivery system of the present invention.

[0012] Figure 2 is a schematic diagram of one embodiment of a mixing manifold of the gas delivery system of Figure 1;

[0013] Figure 3 is a schematic diagram of another embodiment of a mixing manifold;

[0014] Figure 4 is a schematic diagram of one embodiment of two mixing manifolds coupled together;

[0015] Figure 5 is a simplified schematic of a semiconductor processing chamber coupled to another embodiment of a gas delivery system; and

[0016] Figure 6 is a simplified schematic of a semiconductor processing chamber coupled to another embodiment of a gas delivery system.

[0017] To facilitate understanding, identical reference numerals have been used, wherever possible, to designate identical elements that are common to the figures. It is contemplated that features of one embodiment may be beneficially incorporated in other embodiments without further recitation.

DETAILED DESCRIPTION

[0018] Figure 1 depicts a simplified schematic of a gas delivery system 100 utilized to supply gas to an exemplary semiconductor processing chamber 114. The processing chamber 114 may be configured to perform chemical vapor deposition (CVD), physical vapor deposition (PVD), etching process, ion implant, thermal processing, ashing, degassing, orientation or other vacuum processing technique. A controller 150 is coupled to the processing chamber 114 and gas delivery system 100 to control the operation thereof. The controller 150 generally includes a processor, support circuits and memory.

[0019] The gas delivery system 100 located outside of the processing chamber 114 includes a plurality of gas sources coupled to a gas manifold 134. The manifold 134 includes a plurality of valves (discussed further below) which enable any combination of gas sources to be coupled to the processing chamber 114. The manifold 134 also is configured to allow quick evacuation and flow verification of individual system components and conduits. Although the system 100 may be configured to interface with any number of gas sources, six gas sources 102A-F are shown in the embodiment depicted in Figure 1.

[0020] Each gas source 102A-F is coupled to a respective manifold inlet port 104A-F. A shut-off valve 142 and a mass flow meter (MFC) 170 are disposed between each gas supply source 102A-F and respective manifold inlet port 104A-F to control the flow of gas from each source 102A-F entering the manifold 134. The manifold 134 includes a plurality of manifold outlet ports 106A-F that may be selectively coupled to any one of the gas supply sources 102A-F through the manifold inlet ports 104A-F. At least one of the outlet ports 106A-F may be coupled to a calibration circuit 144 and/or a purge line 154.

[0021] In the embodiment depicted in Figure 1, six gas outlet ports 106A-F are provided. The first gas delivery outlet port 106A is coupled to the calibration circuit 144 that is configured to accurately measure gas flow. The

calibration circuit 144 includes an orifice 130 sized to provide a choked flow condition. In one embodiment, the orifice 130 is sized to provide a restriction that is substantially equal to that of the processing chamber 114. The orifice 130 creates flow conditions in the manifold 134 similar to conditions present when the gases are flowing into the processing chamber 114. The calibration circuit 144 may be utilized to perform flow verification of the MFC or other system components, while not requiring flow into the actual processing chamber 114. The orifice 130 may be determined by experimentation, empirical analysis or by other suitable method. In one embodiment, the orifice 130 may be determined by measuring the pressure downstream of the orifice 130 and adjusting the orifice size until a desired pressure is realized.

[0022] In one embodiment, the calibration circuit 144 includes a gas source, a diverter valve, an orifice, a regulating device and a sensing circuit. The regulating device is fluidly coupled between the gas source and an inlet of the diverter valve. The orifice is fluidly coupled to a first outlet of the diverter valve and has substantially the same flow resistance as a processing chamber. The sensing circuit is configured to receive the flow of gases passing through the orifice. In another embodiment, the calibration circuit 144 utilizes a calibrated volume for receiving the gas flow. From properties and/or attributes measured from the gas in the calibrated volume, the flow rate and/or pressure of the gas entering the sensing circuit may be verified. In another embodiment, the calibration circuit 144 utilizes a non-calibrated volume for receiving the gas flow. From changes in the properties and/or attributes measured over time of the gas in the non-calibrated volume, the flow rate and/or pressure of the gas entering the sensing circuit may be verified. In yet another embodiment, the calibration circuit 144 includes a vibrating member disposed in a calibrated volume. In other embodiments, the calibration circuit 144 may include a sensor configured to detect at least one of electrical or magnetic characteristics of gases disposed in the calibrated volume. In yet further embodiments, the calibration circuit 144 may include a tank supported by a cantilever.

[0023] The flow leaving the calibration circuit 144 is coupled to the purge line 154 by a calibration circuit outlet line 142. An isolation valve 140 selectively isolates calibration circuit 144 from the purge line 154. The purge line 154 is coupled to a foreline 138 exiting the processing chamber 114 which runs to the

facility exhaust 136.

[0024] The outlet ports 106B-E are coupled to one or more inlet ports of the processing chamber 114 to supply various process gases from the gas supply sources 102A-F. In the embodiment depicted in Figure 1, outlet ports 106B-E are respectively coupled to inlet ports 110A-D of the processing chamber 114. A plurality of final valves 116 may be respectively coupled between the manifold outlet ports 106B-E and chamber inlet ports 110A-D to serve as an on/off flow control of the gas flow into the processing chamber 114.

[0025] The sixth port 106F is coupled to the purge line 154 through an isolation valve 172. When the isolation valve 172 is opened, the purge line 154 provides a fast evacuation path that facilitates efficient removal of the gases from the gas manifold 134 and into the facility exhaust 136. A throttle valve 156 may be utilized to control the flow of gases through the purge line 154 from the manifold 134. The fast evacuation path allows quick gas changes with minimal cross-talk between gases.

[0026] The fast evacuation path may also be selectively coupled to the manifold outlet ports 106A-E and the calibration circuit 144. In the embodiment depicted in Figure 1, by-pass valves 108A-E are disposed between the manifold outlet ports 106A-E and the purge line 154. The by-pass valves 108A-E may be selectively operated to couple the outlet ports 106A-E to the foreline 138. For example, the by-pass valve 108A may be selectively operated to direct gas exiting the manifold outlet port 106A into the purge line 154, bypassing the calibration circuit 144. In another example, by-pass valves 108B-E may be selectively operated to direct gas exiting the manifold outlet ports 106B-E into the purge line 154, by-passing the processing chamber 114. Isolation valve 172 controls the flow from the sixth port 106F of the manifold 134 into the purge line 154.

[0027] Sensors 190 may also be provided at various locations in the gas delivery system 100 to provide a metric indicative of the gas flows and/or chemistries within the system 100. The metric provided by the sensors 190 may be utilized by the controller 150 to adjust the outputs of the MFC's 170 or other component of the gas delivery system 100 such that a desired composition, pressure, rate or volume of gases are provided to the chamber 114. The sensors 190 may be pressure sensor, chemistry sensor, flow rate sensor and the

like.

[0028] Figure 2 is schematic diagram of one embodiment of the manifold 134 depicted in Figure 1. Each manifold inlet port 104A-F is respectively coupled to an inlet gas delivery line 220A-F to facilitate transferring gases from the gas sources 102A-F into the manifold 134. Each manifold outlet port 106A-F is respectively coupled to an outlet gas delivery line 232A-F. Each of the gas delivery lines 232A-F may be selectively coupled to one or more of the inlet gas delivery lines 220A-F. Although the manifold 134 may be configured to interface with any number of inlet gas outlet gas delivery lines, six gas delivery lines 102A-F and six outlet gas delivery lines 232A-F are shown in the embodiment depicted in Figure 2. Normally, the number of gas inlet delivery lines is commensurate with the number of gas sources.

[0029] The inlet gas delivery lines 220A includes a plurality of connecting lines 250A-F coupling the inlet gas delivery line 220A to a respective outlet gas delivery line 232A-F. Connecting valves 204A-F are disposed in communication with the connecting lines 250A-F and may be operated to fluidly couple the inlet gas delivery line 220A to one or more of the outlet gas delivery lines 232A-F through the inlet gas delivery line 220A, depending on the selected operational state of the valves 204A-F. The connecting valves 204A-F selectively couple the gas source 102A to selected outlet ports 106A-F, thereby controlling the routing of gas provided from source 102A through the manifold 134. For example, if connecting valve 204A is in an open operational state while connecting valves 204B-F remain closed, gas from the source 102A is routed through the outlet port 106A to the calibration circuit 122. In another example, if connecting valves 204B-C are in an open operational state while connecting valves 204A, D-F remain closed, gas from the source 102A is routed through the outlet ports 106B-C. Each of the other inlet gas delivery lines 220B-F are similarly configured with connecting lines 250A-F and valves 204A-F for coupling the inlet gas delivery lines 220B-F to the respective outlet gas delivery lines 232A-F. Reference numerals 250A-F and 204A-F associated with the inlet gas delivery lines 220B-F have been omitted to avoid cluttering of Figure 2.

[0030] Figure 3 depicts an alternative embodiment of a gas manifold 334. The gas manifold 334 is substantially similar to the gas manifold 134 depicted in Figure 2, except wherein the gas manifold 334 includes a plurality of variable

connecting valves 304A-F coupling the gas inlet delivery line 220A to each gas outlet delivery line 232A-F. The variable connecting valves 304A-F may be adjusted to allow a proportion of the flow passing through the gas inlet delivery line 220A to enter the respective gas outlet delivery line. The variable connecting valve 304A-F may be a proportional valve, a pinch valve, a throttle valve, a mass flow controller, a needle valve or other flow control device suitable for regulating the flow between the inlet and outlet lines.

[0031] The operational state of the variable connecting valves 304A-F may be controlled to create a desired ratio of flow through the valve relative to flow bypassing the valve, such that the valves 304A-F operate as a flow ratio controller in the line 220A. The operational state of the variable connecting valves 304A-F may be adjusted by the controller 150 in response to a metric provided by the sensors 190 (not shown in Figure 3). In this manner, for example, the ratio of gases provided into two (or more) gas outlet delivery lines 232A-F from the single gas input delivery line 220A may be adjusted in response to the metric provided by the sensors 190 so that a target chemistry composition, flow rate and/or pressure may be realized at the output 106A-F of the manifold 334. Each of the other inlet gas delivery lines 220B-F are similarly configured with connecting lines 250A-F and valves 304A-F for coupling the inlet gas delivery lines 220B-F to the respective outlet gas delivery lines 232A-F. Reference numerals 250A-F and 304A-F associated with the inlet gas delivery lines 220B-F have been omitted to avoid cluttering of Figure 3.

[0032] Returning to Figure 2, the manifold 134 may additionally include a bridging circuit 202. The bridging circuit 202 includes a bridging line 260 that may be selectively coupled to each of the output lines 232A-F by a respective selector valve 262A-F. Using the bridging circuit 202, any of the flow components, for example, one of the connecting valves 204, may be coupled to the calibration circuit 144. The bridging circuit 202 also allows the MFC 170 associated with a fluid source, for example source 102A, to be coupled to the calibration circuit 144 via a secondary route that incorporates the resistance of the connecting valve 204A. Moreover, the bridging circuit 202 allows each output line 232A-E to be coupled (through the output line 232F) to the purge line 154 from opposite ends, thereby reducing the time required to purge the manifold 134.

[0033] A plurality of disconnects may also be provided to allow coupling of multiple gas manifolds 134. In the embodiment depicted in Figure 2, a first group of disconnects 216A are disposed adjacent each outlet port 106A-F while a second group of disconnects 216B are disposed in the bridging circuit 202 between the bridging line 260 and the valves 262A-F. For example, as shown in Figure 4, the second group of disconnects 216B allows the bridging line 260 of a first manifold 434A to be removed and a first end 402 of the gas outlet delivery line 232A of the first manifold 434A to be coupled to a second end 404 of the outlet line 232A of a second manifold 434B using the mating portions of disconnects 216A, 216B of each manifold 434A, 434B. The other outlet lines 232B-F (not shown in Figure 3) are similarly coupled. It is contemplated that any number of manifolds may be coupled together in this manner.

[0034] Returning to Figure 2, one or more sensors 190 as described above may be interfaced with any of the lines 220A-F, 232A-F, 260, 154 to provide a metric indicative of the gas flows and/or chemistries within the system 100. The metric provided by the sensors 190 may be utilized by the controller 150 to adjust the operational state of the MFC's 170, valves 262A-F, 204A-F, 304A-F or other component of the gas delivery system 100 such that a desired composition, pressure, rate or volume of gases are provided to the chamber 114. The metric may also be utilized to monitor the composition of gases within various portions of the gas delivery system 100 so that the status of purging, chemical mixing, gas changes and the like may be detected in real time, thereby enhancing system response time and minimizing waste of expensive process gases.

[0035] Figure 5 depicts another embodiment of a gas delivery system 500 utilized to supply gas to a processing chamber 114. The gas delivery system 500 includes a manifold 134 coupled to gas sources 102A-F, purge line 154 and a calibration circuit 144 as described above. Outlet ports 106B-E of the manifold 134 are selectively coupled to inlet port 516, 518 of the processing chamber 114 to facilitate transferring gases to the processing chamber 114. In the embodiment depicted in Figure 5, two separate gas inlet ports 516, 518 are utilized to deliver gases supplied from the manifold 134 to the processing chamber 114. In one embodiment, the inlet port 516 provides gases to a center of the processing chamber 114, while inlet port 518 is disposed outward of the

inlet port 518 and provides gases to the outer regions of the processing chamber (e.g., to the perimeter of the substrate disposed within the chamber). For example, the inlet port 516 may provide gases to center regions of a showerhead while the inlet port 518 may provide gases to outer regions of the showerhead. In another example, the inlet port 516 may be disposed in a ceiling of a processing chamber and provide gases downwardly to a substrate while the inlet port 518 may be disposed in a sidewall of the processing chamber provide gases to outer regions of the substrate. In yet another embodiment, the gases may be provided separately through inlet ports 516, 518 such that mixing of the gases only occurs once within the interior volume of the processing chamber 114.

[0036] Flow ratio controllers (FRC) 502, 504 are coupled to each outlet ports 106D-E. The FRC's 502, 504 split the flows exiting each outlet ports 106D-E so that a predetermined flow ratio is provided between each inlet port 516, 518 of the processing chamber 114. The FRC's 502, 504 may have a fixed output ratio, or may have an adjustable output ratio. The output of the FRC's 502, 504 and the manifold output ports 106B-C are respectively combined into common delivery lines 522, 524. Flow through each delivery line 522, 524 is controlled by a final valve 508, 506 positioned just upstream of the inlet ports 516, 518 of the processing chamber 114.

[0037] By-pass valves 510, 512 are coupled to each delivery line 522, 524. The by-pass valves 510, 512 may be opened to couple each delivery line 522, 524 to the purge line 154.

[0038] The gas delivery systems described provides many advantages over conventional systems. In addition to the system's modularity, the gas delivery system may be operated to provide pre-flow path, a fast evacuation path, controlled chemical mixing, more efficient use of chemistries, sequenced reduced fill and evacuation times, closed loop control for fine tuning of chemistry delivery and flow verification.

PRE-FLOW PATH

[0039] In one mode of operation, a pre-flow path is defined through the gas delivery system 100 and provides a connection to the chemistry source (e.g., sources 102A-F) through one or more valves to a vacuum environment that is

separate from the processing chamber 114 (e.g., the foreline 138 through the purge line 154). Before gases are requested in the processing chamber 114, the gases may be supplied to the appropriate lines of the manifold 134 of the gas delivery system 100 in a condition that substantially matches the condition of the gas as if it was flowing into the processing chamber 114. This allows the gases within the manifold 134 to rapidly reach a steady state condition that is substantially maintained once the gases are diverted into the processing chamber 114. Since the pre-flow path allows the gases within the gas delivery system 100 to stabilize in a "process condition" before being delivered into the processing chamber 114, there is little or no change in the flow conditions within the delivery system 100 once flow to the chamber is commenced, unlike conventional gas delivery systems which typically experience a pressure drop and diminished flow rates. Thus, the uniformity of gas delivery in the processing chamber is quickly established because the pre-flow path provides substantially the same resistance and flow conditions as if the gases were flowing into the processing chamber. The throttle valve 144 may also be utilized to match the conditions in the pre-flow gas path to that of the processing chamber 114.

[0040] Additionally, any flow dividing devices, such as the flow ratio controllers 502, 504 or valves 304A-F, may have their outputs routed into the pre-flow path prior to processing so that the outputs of the dividing devices can be stabilized before flow is delivered to the processing chamber. In one embodiment, the pre-flow path is defined through the purge line 154 and the by-pass lines through the manifold outlets 106A-B through the by-pass valves 108A-F and into the purged line 154.

FAST EVACUATION PATH

[0041] In another mode of operation, a fast evacuation path is defined in the gas delivery system 100 and provides a connection from the manifold 134 to the foreline 138 through the purge line 154. The fast evacuation path provides a connection from the chemical delivery sources through the processing chamber delivery path through one or more valves to a vacuum environment that is separate from the processing chamber 114 (e.g., the foreline 138 through the purge line 154). The fast evacuation path is coupled to each chamber

connection such that there is at least one connection between any two flow restrictions, such as the flow ratio controllers 502, 504, valves 304A-F or other flow restriction. When it is required that the chemistry within the processing chamber 114 should change, the isolation valve 172 and by-pass valves 108A-E to the vacuum environment will be opened, removing the excess process chemicals from the chemical delivery path.

[0042] As discussed above, the operational state of the various valves within the manifold 134 may be sequenced such that the purge time of chemicals being removed from the gas delivery system 100 through the fast evacuation path is minimized. Additionally, the operational state of the valves 204A-F may also be sequenced so that as certain regions the manifold 134 are emptied of the chemicals utilized in the previous process, the emptied regions may be then filled with the new chemistry, such that the gases within the manifold 134 are replaced in the most efficient manner. Moreover, as certain portions of the manifold 134 are evacuated more quickly relative to other portions of the manifold, sequencing the valves 204A-F may be made in a manner that allows the new chemicals replacing the old chemicals to reach equilibrium (e.g., processing flow conditions) in the shortest time possible.

[0043] In one embodiment, higher pressure, volume and/or flow of replacement gases from the sources 102A-F may be provided to one or more regions of the manifold 134 to expedite changeover. As the flow of replacement gases exiting the manifold 134 approaches the desired chemical mix, pressure and/or volume, the flow of chemicals into the chemical delivery system 100 may be reduced to the desired levels in a manner that maintains a desired flow out of the manifold 134. In cases where the chemical delivery system 100 will be filled with chemicals from earlier processes, flows into the chemical delivery system may be altered (i.e., reduced or increased, depending on the desired effect) so that the desired flow into the processing chamber will reach the desired values as quickly as possible. As the chemical flow out of the manifold approaches the desired chemical mix and flow rate, the flow of chemicals into the manifold 134 will be adjusted toward the desired flow rates in a manner that maintains the desired flow into the processing chamber 114.

[0044] In another embodiment, chemistry change may be expedited by sequencing the valves 204A-F such that only gas delivery lines 232A-F

containing gas which have not yet been replaced maintain coupled to the purge line 154. Once replacement gas is detected exiting the manifold 134 from one of the gas delivery lines 232A-F or at another predefined location, that gas delivery line 232A-F supplying the replacement gas is disconnected from the purge line 154 so that the replacement gas is not wasted. In one embodiment, the replacement gas may be diverted from the purge line 154 into the processing chamber 114 until the change over is completed. In this manner, the pumping capacity of the purge line 154 is dedicated to only those lines requiring gas removal so that change over of processing gases may be made in an efficient manner. It is also contemplated that the fastest evacuation path may include routing gas flows through the bridging circuit 202 to the purge line 154 for at least a portion of the change over time.

CHEMICAL MIXING AND CLOSED LOOP CONTROL

[0045] In another mode of operation, the gas delivery system 100 may be utilized to enhance chemical mixing. In one embodiment, chemical mixing may occur within the manifold 134 using the valves 304A-F or by coupling two or more sources 102A-F to a single gas outlet delivery line 232A-F.

[0046] In another embodiment, the sensors 190 may be utilized to provide closed loop control of the chemical mixing within the gas delivery system. By monitoring the chemistries entering the chamber 114, exiting the manifold 134 and/ or at any other point within the gas delivery system 100 using the sensors 190, real time adjustment of chemistry parameters, such as desired composition (e.g., gas mix), rate and/or pressure, may be realized. For example, if sensors detect an improper flow ratio of chemistry from sources 102A-B exiting the manifold at port 106C, the operational state of the valves 304C coupling inlet delivery lines 220A-220B to outlet delivery line 232C may be adjusted to bring the chemistry flows to a desired target ratio. The same process may be performed using the other valves or flow ratio controllers. Information from the sensors 190 may also be utilized to adjust the MFC settings, flow rates and/or pressures of the gases provided from the sources 102A-F.

CONSERVATION OF GASES/CHEMISTRIES

[0047] In another mode of operation, the gas delivery system 100 enhances efficient use of chemistries. For example, the sequence of in which the operational states of the valves 204A-F, 172, 108A-E, 262A-F are changed may be arranged in a manner that removes gases from the manifold 134 most effectively and with minimal mixing of gases, thereby allowing faster response time and reduced processing time. Thus, during gas changes, the rate that gases are drawn through the delivery path (e.g., through outlet lines 232A-F) and into the purge line 154 may be adjusted using the throttle valve 156 to advance the gases quickly through the manifold 134. Moreover, while the purge line 154 is drawing gases through the manifold 134, lines which contain gases ready for the next processing sequence, such as newly introduced gases, purge gas and/or the last remnants of gases previously contained in the manifold, may be diverted from the purge line 154 and flowed into the processing chamber 114. This allows the remaining lines coupled to the purge line 154 to be evacuated more rapidly. In one embodiment, a metric provided by the sensors 190 may be utilized to indicate when a diversion from the purge line 154 to the chamber 114 should occur, for example, by a change or stabilization in the composition of the gases, flow rate and or pressure of gases within the line.

FLOW VERIFICATION

[0048] In another mode of operation, the gas delivery system 100 may be utilized to verify the flow rates of any of the components within the system using the calibration circuit 144. For example, the valves of the system 100 may provide flow from any one of the inlet ports to the calibration circuit 144. In another example, flows divided by valves of the system may be verified for flow rates along each branch of the divided flow.

[0049] Figure 6 is a simplified schematic of a semiconductor processing chamber 114 coupled to another embodiment of a gas delivery system 600. The gas delivery system 600 is configured substantially similar to the gas delivery systems describe above, except wherein the system 600 includes a storage tank 630 coupled to at least one of the output ports 106A-F of the system's manifold 134. The storage tank 630 may be coupled to the at least one or more of the processing chamber 114, a second processing chamber 614 (shown in

phantom), a gas delivery system 100 (500 or 600) of the second processing chamber 614, the calibration circuit 144 or the facility exhaust 136. A sensor 190 may be provided to provide a metric indicative of the gas within the tank 630. In one embodiment, the metric may be indicative of the gas pressure, gas composition (*e.g.*, chemistry), temperature or other characteristic.

[0050] In one embodiment, each output port 106A-F may be individually coupled to the tank 630. In another embodiment, the tank 630 may be segmented (as shown in phantom) so that each 106A-F may be retained in the tank 630 without mixing, then individually coupled to the processing chamber 114. Alternatively, separate tanks 630 may be use. It is also contemplated that the inlet of the tank 630 may be utilized to deliver gases to the processing chamber 114.

[0051] Thus, gas delivery systems having fast evacuation paths that advantageously enable processing gases supplying from the gas delivery systems into a processing system with stable gas flow and minimum fluctuation. The fast evacuation paths are utilized to provide an alternative manner to verify and/or calibrate gas flows from the gas delivery systems, thereby providing good control of the gas flow supplying to the processing system.

[0052] While the foregoing is directed to embodiments of the present invention, other and further embodiments of the invention may be devised without departing from the basic scope thereof, and the scope thereof is determined by the claims that follow.

What is claimed is:

1. Apparatus for delivering gases to a semiconductor processing system, comprising:
 - a plurality of gas input lines each having an inlet port;
 - a plurality of gas output lines each having an outlet port;
 - a plurality of connecting lines, each connecting line coupling a respective pair of gas input and gas output lines;
 - a plurality of connecting valves, each connecting valve arranged to control flow through a respective connecting line; and
 - a plurality of mass gas flow controllers, each mass gas flow controller arranged to control flow into a respective inlet port.
2. The apparatus of claim 1 wherein the connecting valves are arranged in a grid pattern with the inlet ports arranged along a first axis of the grid and the outlet ports arranged along a second axis of the grid.
3. The apparatus of claim 1, wherein the plurality of connecting lines are embodied as one monolithic part.
4. The apparatus of claim 3 further comprising:
 - a second monolithic part coupled to the first monolithic part, the second monolithic part having connecting valves arranged in a grid pattern, wherein inlet ports of the second monolithic part are arranged along a first axis of the grid and outlet ports of the second monolithic part are arranged along a second axis of the grid.
5. The apparatus of claim 1 further comprising:
 - a calibration circuit coupled to at least one of the output ports.

6. The apparatus of claim 1 further comprising:
at least one sensor interfaced with at least one of the gas output lines, the gas input lines or the connecting lines, the at least one sensor arranged to provide a metric indicative of flow, pressure or chemistry.
7. The apparatus of claim 1, wherein at least one of the connecting valves further comprises:
at least two adjustable valves configured to divide flow from one of the input port between two or more of the outlet ports.
8. The apparatus of claim 7 further comprising:
a calibration circuit configured for calibrating an effective open area of the adjustable valves by measuring flow through the valves while critical (supersonic) flow is maintained through the valves.
9. The apparatus of claim 1, wherein at least one of the outlet ports is coupled to a facility exhaust by-passing the processing system.
10. The apparatus of claim 5, wherein the calibration circuit further comprises:
a flow restrictor having flow restriction similar to that of the processing system.
11. The apparatus of claim 1 further comprising:
a storage vessel coupled to at least one of the output ports.
12. The apparatus of claim 11 further comprising:
at least one sensor arranged to provide a metric of flow, pressure or chemistry within the storage vessel.

13. An apparatus of claim 11, wherein the storage vessel further comprises:
at least one outlet port connected to the processing system.
14. The apparatus of claims 11, wherein at least one outlet port of the storage vessel is connected to the processing system through a second group of connecting valves arranged in a second grid pattern, wherein inlet ports of the second grid pattern are arranged along a first axis of the second grid pattern and outlet ports of the second grid pattern are arranged along a second axis of the second grid pattern.
15. The apparatus of claim 11 further comprising:
a two position valve fluidly coupled between the storage tank and a facility exhaust which can be switched between fully closed, a preset restriction and fully open.
