

Data Transmission Method and Device

Technical Field

Embodiments of the present application relate to the field of communication, and more particularly, relate to a method and device for transmitting data.

Background

In a Carrier Aggregation scenario, data duplication function of a Packet Data Convergence Protocol (PDCP) may be used for transmitting repeated data, thus improving reliability of data transmission. Specifically, a PDCP layer firstly performs data replication to obtain a plurality of PDCP protocol data units (PDUs), maps the plurality of PDCP PDUs to different Radio Link Control (RLC) entities respectively, and a RLC layer may carry the plurality of PDCP PDUs through different logical channels. However, to a Media Access Control (MAC) layer, it is not known which logical channels transmit the same data. Therefore, the MAC layer cannot effectively schedule the data in the logical channels carrying duplicated PDCP PDUs, and thus frequency diversity gain cannot be obtained.

Summary

The embodiments of the present application provide a method and device for transmitting data, which may obtain the frequency diversity gain, thereby improving the reliability of data transmission.

In a first aspect, there is provided a method for transmitting data, including: determining a plurality of carriers or carrier groups for transmitting duplicated data according to a plurality of logical channels for carrying the duplicated data, wherein at least two logical channels in the plurality of logical channels correspond to different carriers or carrier groups for transmitting the duplicated data; and transmitting the duplicated data carried in the plurality of logical channels respectively by using the plurality of carriers or carrier groups.

Therefore, in the embodiment of the present application, the device for transmitting data may determine a plurality of carriers or carrier groups according to a plurality of logical channels carrying duplicated data, wherein at least two logical channels in the plurality of logical channels correspond to different carriers or carrier groups for transmitting the duplicated data, so that the duplicated data may be transmitted through at least two different carriers or

carrier groups, thereby obtaining the frequency diversity gain and further improving the reliability of transmission.

Optionally, logical channels and carriers or carrier groups may have a correspondence relationship, so that the device for transmitting data may determine a corresponding plurality of carriers or carrier groups according to a plurality of logical channels carrying the duplicated data and the correspondence relationship. Optionally, the correspondence relationship may be agreed in a protocol, or if the device for transmitting data is a terminal device, the correspondence relationship may be sent to the terminal device by a network device through a high level signaling.

In combination with the first aspect, in some implementations of the first aspect, the determining the plurality of carriers or carrier groups for transmitting duplicated data according to the plurality of logical channels for carrying the duplicated data, includes: determining the plurality of carriers or carrier groups according to respective indication information of each of the plurality of logical channels.

In combination with the first aspect, in some implementations of the first aspect, the respective indication information corresponding to each logical channel is included in an indication field of logical channel configuration information corresponding to the each logical channel.

Optionally, an indication field may be added in the logical channel configuration information corresponding to each logical channel to carry the indication information, or the original indication field may be multiplexed to carry the indication information, or a reserved field in the logical channel configuration information may be used for carrying the indication information.

Optionally, the respective indication information corresponding to each logical channel may be included in other attribute information of the each logical channel.

In combination with the first aspect, in some implementations of the first aspect, the logical channel configuration information corresponding to each logical channel is a radio resource control (RRC) information element of the each logical channel, and the RRC information element of the each logical channel is used for configuring channel parameters of the each logical channel.

In combination with the first aspect, in some implementations of the first aspect, the indication information includes first indication information corresponding to a first logical

channel of the plurality of logical channels, the first indication information is used for indicating a carrier identity (ID) of one carrier or a group of carriers, and the determining the plurality of carriers or carrier groups according to the respective indication information corresponding to each logical channel of the plurality of logical channels, includes: determining
5 that a first carrier corresponding to a carrier ID of one carrier or a first carrier group corresponding to a carrier ID of a group of carriers indicated by the first indication information is a carrier or a carrier group for transmitting the duplicated data carried in the first logical channel; the transmitting the duplicated data carried in the plurality of logical channels respectively by using the plurality of carriers or carrier groups, includes: transmitting the
10 duplicated data carried in the first logical channel by using the first carrier or part or all of carriers in the first carrier group.

Optionally, in the embodiment of the present application, the respective indication information corresponding to each of the plurality of logical channels may all indicate a carrier ID of one carrier, or may all indicate a carrier ID of a group of carriers, or indication
15 information corresponding to some logical channels indicates a carrier ID of one carrier respectively, while indication information corresponding to other logical channels indicates a carrier ID of a group of carriers respectively. In this case, it is only required that the carriers or carrier groups indicated by the indication information corresponding to at least two logical channels in the plurality of logical channels are different, so that the device for transmitting data
20 may schedule the duplicated data to be transmitted on different carriers or carrier groups.

In combination with the first aspect, in some implementations of the first aspect, the indication information includes second indication information corresponding to a second logical channel of the plurality of logical channels, the second indication information is identity information of other logical channels than the second logical channel in the plurality of logical
25 channels, and the determining the plurality of carriers or carrier groups according to the respective indication information corresponding to each logical channel of the plurality of logical channels, includes: determining that the duplicated data carried in the second logical channel and the other logical channels respectively correspond to different carriers or carrier groups according to the second indication information; the transmitting the duplicated data
30 carried in the plurality of logical channels respectively by using the plurality of carriers or carrier groups, includes: transmitting the duplicated data carried in the second logical channel and the other logical channels respectively by using the different carriers or carrier groups.

That is, respective indication information corresponding to each logical channel may

directly indicate a carrier or carrier group used for transmitting duplicated data carried in the each logical channel, so that the device for transmitting data may directly schedule the duplicated data carried in each logical channel according to the carrier or carrier group indicated by the indication information of the each logical channel. Or, the respective indication
 5 information corresponding to each logical channel may indicate identity information of a logical channel that transmits duplicated data together with the each logical channel, so that the device for transmitting data may determine which different carriers or carrier groups to schedule the duplicated data carried in each logical channel for transmission at a MAC layer.

In combination with the first aspect, in some implementations of the first aspect, the
 10 indication information includes third indication information corresponding to a third logical channel of the plurality of logical channels, the third indication information is used for indicating whether the duplicated data is carried in the third logical channel, and the determining the plurality of carriers or carrier groups according to the respective indication information corresponding to each logical channel of the plurality of logical channels, includes:
 15 determining that the duplicated data carried in the third logical channel and a fourth logical channel respectively correspond to different carriers or carrier groups if the third indication information indicates that the duplicated data is carried and fourth indication information corresponding to the fourth logical channel indicates that the duplicated data is carried; the transmitting the duplicated data carried in the plurality of logical channels respectively by using
 20 the plurality of carriers or carrier groups, includes: transmitting the duplicated data carried in the third logical channel and the fourth logical channel respectively by using the different carriers or carrier groups.

In combination with the first aspect, in some implementations of the first aspect, before the determining the plurality of carriers or carrier groups according to respective indication
 25 information of each of the plurality of logical channels, the method further includes: determining that there is an indication field including the indication information in logical channel configuration information of the each logical channel.

In combination with the first aspect, in some implementations of the first aspect, the determining the plurality of carriers or carrier groups for transmitting the duplicated data
 30 according to the plurality of logical channels for carrying the duplicated data, includes: determining a plurality of media access control (MAC) entities according to the plurality of logical channels and a first correspondence relationship, wherein the first correspondence relationship is a correspondence relationship between logical channels and MAC entities, and

the plurality of logical channels and the plurality of MAC entities correspond one to one; determining the plurality of carriers or carrier groups according to the plurality of MAC entities and a second correspondence relationship, wherein the second correspondence relationship is a correspondence relationship between MAC entities and carriers or carrier groups, and the plurality of MAC entities and the plurality of carriers or carrier groups correspond one to one.

Optionally, the first correspondence relationship may be a one-to-one correspondence relationship, i.e., logical channels and MAC entities correspond one to one, so the device for transmitting data may determine a plurality of MAC entities according to the plurality of logical channels and the first correspondence relationship.

Optionally, the second correspondence relationship may be a one-to-one correspondence relationship or a one-to-many correspondence relationship, i.e., one MAC entity may correspond to one carrier or a carrier group, or one MAC entity may correspond to a plurality of carriers or carrier groups. Therefore, the device for transmitting data may determine a plurality of carriers or carrier groups according to the plurality of MAC entities and the second correspondence relationship, and then the device for transmitting data may transmit duplicated data carried in the plurality of logical channels through the plurality of carriers or carrier groups.

In combination with the first aspect, in some implementations of the first aspect, the first correspondence relationship is preconfigured by a high layer signaling.

Optionally, if the device for transmitting data is a terminal device, the first correspondence relationship may be preconfigured to the terminal device by a network device through a high level signaling, or the first correspondence relationship may be agreed between the terminal device and the network device, or the first correspondence relationship may be specified in a protocol. If the device for transmitting data is a network device, the first correspondence relationship may be preconfigured by the network device, or agreed between the network device and the terminal device, or the first correspondence relationship may be specified in a protocol.

In combination with the first aspect, in some implementations of the first aspect, the duplicated data is duplicated data obtained by duplicating the same packet data convergence protocol (PDCP) protocol data unit (PDU) by a PDCP split carrier.

In combination with the first aspect, in some implementations of the first aspect, carrying the duplicated data on the plurality of logical channels is preconfigured by a higher layer

signaling.

That is to say, which logical channels are to be used for transmitting duplicated data may be preconfigured through a high layer signaling, and when there is data transmission on these logical channels, the data transmitted on these logical channels may be considered as duplicated data. Optionally, the high layer signaling is an RRC signaling.

In combination with the first aspect, in some implementations of the first aspect, the high layer signaling is a radio resource control (RRC) signaling.

In a second aspect, there is provided a device for transmitting data, including units for performing the method in the first aspect or various implementations thereof.

In a third aspect, a device for transmitting data is provided, which includes a memory for storing a program, a transceiver, and a processor for executing the program, and when executing the program, the processor executes the method of the first aspect based on the transceiver.

In a fourth aspect, a computer readable medium is provided, which stores program codes for execution by a terminal device, wherein, the program codes includes instructions for executing the method in the first aspect.

The embodiments of the present application provide a method and device for transmitting data, which may obtain the frequency diversity gain, thereby improving the reliability of data transmission.

Brief Description of Drawings

FIG. 1 is a schematic diagram of a wireless communication system according to an embodiment of the present application.

FIG. 2 is a schematic flowchart of a method for transmitting data according to an embodiment of the present application.

FIG. 3 is a schematic diagram of an example of a method for transmitting data according to an embodiment of the present application.

FIG. 4 is a schematic block diagram of a device for transmitting data according to an embodiment of the present application.

FIG. 5 is a schematic block diagram of a device for transmitting data according to another embodiment of the present application.

Detailed Description

The technical solutions in embodiments of the present application will be described below with reference to the drawings in the embodiments of the present application.

5 The technical solutions of the embodiments of the present application may be applied to various communication systems, such as a Global System of Mobile communication (GSM), a Code Division A plurality of Access (CDMA) system, a Wideband Code Division A plurality of Access (WCDMA) system, a General Packet Radio Service (GPRS) system, a Long Term Evolution (LTE) system, an LTE Frequency Division Duplex (FDD) system, an LTE Time
10 Division Duplex (TDD) system, a Universal Mobile Telecommunication System (UMTS), a Worldwide Interoperability for Microwave Access (WiMAX) communication system, or a future 5G system.

FIG. 1 shows a wireless communication system 100 to which an embodiment of the present application is applied. The wireless communication system 100 may include a network
15 device 110. The network device 100 may be a device that communicates with a terminal device. The network device 100 may provide communication coverage for a specific geographical area and may communicate with terminal devices (e.g., UEs) located within the coverage area. Optionally, the network device 100 may be a Base Transceiver Station (BTS) in a GSM system or CDMA system, a NodeB (NB) in a WCDMA system, an Evolutional Node B (eNB or
20 eNodeB) in an LTE system, or a radio controller in a Cloud Radio Access Network (CRAN). Or, the network device may be a relay station, an access point, an on-board device, or a wearable device, a network side device in a future 5G network, or a network device in a future evolved Public Land Mobile Network (PLMN), etc.

The wireless communication system 100 further includes at least one terminal device 120
25 located within the coverage area of the network device 110. The terminal device 120 may be mobile or fixed. Optionally, the terminal device 120 may be referred to as an access terminal, a User Equipment (UE), a subscriber unit, a subscriber station, a mobile station, a mobile platform, a remote station, a remote terminal, a mobile device, a user terminal, a terminal, a wireless communication device, a user agent, or a user equipment. The access terminal may be
30 a cellular phone, a cordless phone, a Session Initiation Protocol (SIP) phone, a Wireless Local Loop (WLL) station, a Personal Digital Assistant (PDA), a handheld device with a wireless communication function, a computing device, or other processing devices connected to a

wireless modem, an on-board device, a wearable device, a terminal device in a future 5G network, or a terminal device in a future evolved PLMN, or the like.

Optionally, the 5G system or network may also be referred to as a New Radio (NR) system or network.

5 FIG. 1 exemplifies one network device and two terminal devices. Optionally, the wireless communication system 100 may include a plurality of network devices and other quantities of terminal devices may be included within a coverage area of each network device. The embodiments of the present application are not limited thereto.

10 Optionally, the wireless communication system 100 may further include other network entities such as a network controller, and a mobility management entity. The embodiments of the present application are not limited thereto.

It should be understood that the terms "system" and "network" are often used interchangeably herein. The term "and/or" in this document is merely an association relationship describing associated objects, indicating that there may be three relationships, for example, A and/or B may indicate three situations: A alone, A and B, and B alone. In addition, the character "/" in this document generally indicates that the objects before and after the character have an "or" relationship.

In the prior art, in order to provide reliability of transmission, a PDCP layer may duplicate data. Specifically, a PDCP split carrier duplication function of the PDCP layer may duplicate a PDCP Service Data Unit (SDU) to obtain a plurality of PDCP PDUs, the plurality of PDCP PDUs have the same payload and the same header, and each PDCP PDU may be referred to as a duplicated data. The plurality of PDCP PDUs may be carried through a plurality of logical channels, but a MAC layer does not know that the data transmitted through the plurality of logical channels are duplicated data, that is, the same data, so when data are scheduled, the MAC layer would not consider scheduling the data in the plurality of logical channels to different carriers for transmission, and therefore, frequency diversity gain cannot be obtained.

30 In view of this, the embodiment of the present application provides a method for transmitting data, which may schedule duplicated data transmitted through a plurality of logical channels to at least two different carriers for transmission, thereby obtaining the frequency diversity gain and further improving the reliability for transmitting data.

FIG. 2 is a schematic flowchart of a method 200 for transmitting data according to an embodiment of the present application. The method 200 may be performed by the terminal

device 120 or the network device 110 in the communication system 100 described in FIG. 1. As shown in FIG. 2, the method 200 includes acts S210-220.

In S210, a plurality of carriers or carrier groups for transmitting duplicated data is determined according to a plurality of logical channels for carrying the duplicated data. Herein
5 at least two logical channels in the plurality of logical channels correspond to different carriers or carrier groups for transmitting the duplicated data.

In S220, the duplicated data carried in the plurality of logical channels are transmitted respectively by using the plurality of carriers or carrier groups.

The method 200 of the embodiment of the present application will be described below
10 with a device for transmitting data being an executing body, and the device for transmitting data may be a terminal device or a network device.

Therefore, in the embodiment of the present application, the device for transmitting data may determine a plurality of carriers or carrier groups according to a plurality of logical channels carrying duplicated data. Herein at least two logical channels in the plurality of logical
15 channels correspond to different carriers or carrier groups for transmitting the duplicated data, so that the duplicated data may be transmitted through at least two different carriers or carrier groups, thereby obtaining the frequency diversity gain and further improving the reliability of transmission.

Specifically, the device for transmitting data may generate a plurality of duplicated data at
20 a PDCP layer, the plurality of duplicated data are the same, and the plurality of duplicated data may be transmitted through a plurality of logical channels, that is, each logical channel may carry one duplicated data. The device for transmitting data may determine a plurality of carriers or carrier groups according to the plurality of logical channels. In one possible implementation, logical channels and carriers or carrier groups may have a correspondence relationship, so that
25 the device for transmitting data may determine a corresponding plurality of carriers or carrier groups according to a plurality of logical channels carrying the duplicated data and the correspondence relationship. Optionally, the correspondence relationship may be agreed in a protocol, or if the device for transmitting data is a terminal device, the correspondence relationship may be sent to the terminal device by a network device through a high level
30 signaling, and optionally, the high level signaling may be a Radio Resource Control (RRC) signaling.

Optionally, in some embodiments, logical channels may have a correspondence

relationship with MAC entities. For example, different logical channels may correspond to different MAC entities, and different MAC entities may correspond to different physical layer carriers or carrier groups, so that the device for transmitting data may determine a plurality of MAC entities corresponding to the plurality of logical channels according to the plurality of logical channels carrying the duplicated data and the correspondence relationship between the logical channels and the MAC entities, and further determine a plurality of carriers or carrier groups corresponding to the plurality of MAC entities. Since carriers or carrier groups corresponding to different MAC entities are different, the plurality of carriers or carrier groups are different. Optionally, the correspondence relationship between the logical channels and the MAC entities may be agreed in a protocol, or if the device for transmitting data is a terminal device, the correspondence relationship may be configured by a network device to the terminal device through a high level signaling, and optionally, the high level signaling may be an RRC signaling.

Optionally, the device for transmitting data may determine a plurality of carriers or carrier groups according to indication information corresponding to the plurality of logical channels. For example, the indication information may directly indicate the identities (IDs) of the carriers or carrier groups used for transmitting the duplicated data in the corresponding logical channels, so the device for transmitting data may determine an ID of a carrier or carrier group indicated by each piece of indication information according to the respective indication information corresponding to each logical channel after acquiring the duplicated data in the each logical channel at a MAC layer. Optionally, indication information corresponding to a first logical channel of the plurality of logical channels may indicate identity information of other logical channels than the first logical channel in the plurality of logical channels, so that the device for transmitting data may determine other logical channels that transmit duplicated data together with the first logical channel according to the indication information corresponding to the first logical channel, so that when the device for transmitting data schedules data at a MAC layer, duplicated data carried in the first logical channel and the other logical channels may be scheduled to be transmitted on different carriers or carrier groups, so that the frequency diversity gain may be obtained, and the reliability of transmission may be further improved.

Optionally, in some embodiments, the act of determining the plurality of carriers or carrier groups for transmitting the duplicated data according to the plurality of logical channels for carrying the duplicated data includes: determining the plurality of carriers or carrier groups according to respective indication information of each of the plurality of logical channels.

Specifically, a plurality of logical channels for carrying duplicated data may all correspond to corresponding indication information, and the device for transmitting data may determine a plurality of carriers or carrier groups for transmitting duplicated data carried in the plurality of logical channels according to the indication information. Optionally, the respective indication
 5 information corresponding to each logical channel may be included in logical channel configuration (LogicalChannelConfig) information corresponding to the each logical channel. Specifically, the logical channel configuration information corresponding to each logical channel may be an RRC Information Element of the each logical channel, and the RRC information element is used for configuring channel parameters of the each logical channel,
 10 such as information of a logical channel scheduling priority, and a logical channel group to which it belongs.

Optionally, a new indication field may be added in the logical channel configuration information corresponding to each logical channel to carry the indication information, or the original indication field may be multiplexed to carry the indication information, or a reserved
 15 field in the logical channel configuration information may be used for carrying the indication information. Optionally, the respective indication information corresponding to each logical channel may be included in other attribute information of the each logical channel, which is not limited by the embodiment of the present application.

Optionally, as one embodiment, the indication information includes first indication
 20 information corresponding to a first logical channel of the plurality of logical channels, the first indication information is used for indicating a carrier identity (ID) of one carrier or a group of carriers, and the determining the plurality of carriers or carrier groups according to the respective indication information corresponding to each logical channel of the plurality of logical channels, includes: determining that a first carrier corresponding to a carrier ID of one
 25 carrier or a first carrier group corresponding to a carrier ID of a group of carriers indicated by the first indication information is a carrier or a carrier group for transmitting the duplicated data carried in the first logical channel; the transmitting the duplicated data carried in the plurality of logical channels respectively by using the plurality of carriers or carrier groups, includes: transmitting the duplicated data carried in the first logical channel by using the first carrier or
 30 part or all of carriers in the first carrier group.

Specifically, the indication information of each logical channel may indicate an ID of a carrier or carrier group used for transmitting duplicated data carried in the each logical channel. For example, the plurality of logical channels include a first logical channel, and indication

information corresponding to the first logical channel is denoted as first indication information for convenience of distinction and description, and the first indication information may indicate a carrier ID of one carrier or a group of carriers. That is to say, the first indication information may indicate the carrier ID of one or more carriers, and a carrier or carrier group corresponding to the carrier ID of the one or group of carriers may be used for transmitting duplicated data carried in the first logical channel. That is, the carrier or carrier group for transmitting the duplicated data carried in each logical channel may be indicated by the indication information corresponding to the each logical channel. Therefore, the device for transmitting data may schedule the duplicated data carried in the plurality of logical channels to be transmitted on at least two different carriers or carrier groups by configuring carriers or carrier groups corresponding to at least two logical channels for transmitting the duplicated data to be different, that is, carriers or carrier groups indicated by the indication information corresponding to at least two logical channels are different. For example, the plurality of logical channels include logical channel 1 and logical channel 2, respectively corresponding to indication information 1 and indication information 2. The indication information 1 indicates carrier ID1, and carrier ID1 corresponds to carrier 1. The indication information 2 indicates carrier ID2, and carrier ID2 corresponds to carrier 2. Then duplicated data carried in logical channel 1 and logical channel 2 may be transmitted through carrier 1 and carrier 2, respectively. Therefore, the device for transmitting data may transmit duplicated data through different carriers, thereby obtaining the frequency diversity gain and further improving the reliability of transmitting data.

Therefore, the device for transmitting data may determine a carrier or carrier group for transmitting duplicated data carried in each logical channel according to indication information corresponding to the each logical channel, so that the duplicated data carried in each logical channel may be transmitted on the carrier or carrier group for transmitting the duplicated data corresponding to the each logical channel. Specifically, if the plurality of logical channels include a first logical channel, first indication information corresponding to the first logical channel indicates a carrier ID of one carrier, and the device for transmitting data may transmit duplicated data carried in the first logical channel by using a carrier corresponding to the carrier ID indicated by the first indication information, or if the first indication information indicates a carrier ID of a group of carriers, the device for transmitting data may transmit duplicated data carried in the first logical channel by using part or all of carriers in a first carrier group corresponding to the carrier ID of the group of carriers. It should be understood that in the embodiment of the present application, a carrier ID of a group of carriers may be a group ID of

one carrier group, or may be carrier IDs of a plurality of carriers, which is not limited in the embodiment of the present application.

It should be understood that in the embodiment of the present application, the respective indication information corresponding to each of the plurality of logical channels may all
 5 indicate a carrier ID of one carrier, or may all indicate a carrier ID of a group of carriers, or indication information corresponding to some logical channels indicates a carrier ID of one carrier, while indication information corresponding to other logical channels indicates a carrier ID of a group of carriers. In this case, it is only required that the carriers or carrier groups indicated by the indication information corresponding to at least two logical channels in the
 10 plurality of logical channels are different, so that the device for transmitting data may schedule the duplicated data to be transmitted on different carriers or carrier groups.

Optionally, in some embodiments, the indication information includes second indication information corresponding to a second logical channel of the plurality of logical channels, the second indication information is identity information of other logical channels than the second
 15 logical channel in the plurality of logical channels, and the act of determining the plurality of carriers or carrier groups according to the respective indication information corresponding to each logical channel of the plurality of logical channels includes: determining that the duplicated data carried in the second logical channel and the other logical channels respectively correspond to different carriers or carrier groups according to the second indication information.
 20 The act of transmitting the duplicated data carried in the plurality of logical channels respectively by using the plurality of carriers or carrier groups includes: transmitting the duplicated data carried in the second logical channel and the other logical channels respectively by using the different carriers or carrier groups.

Specifically, the plurality of logical channels may include a second logical channel, and
 25 indication information corresponding to the second logical channel is denoted as second indication information for convenience of distinction and description, and the second indication information may indicate identity information of other logical channels than the second logical channel in the plurality of logical channels. Therefore, the device for transmitting data may determine, according to the second indication information, which logical channels are used for
 30 transmitting duplicated data, then the duplicated data carried in these logical channels may be scheduled to be transmitted on different carriers in a MAC layer, so that the frequency diversity gain may be obtained, and the reliability of transmitting data is further improved. For example, the plurality of logical channels include logical channel 1 and logical channel 2, and

corresponding logical channels are identified as LC1 and LC2 respectively, then indication information corresponding to logical channel 1 may indicate LC2, and indication information corresponding to logical channel 2 may indicate LC1, so that the device for transmitting data may know that the two logical channels are used for transmitting duplicated data, and then
 5 duplicated data in the two logical channels may be scheduled to be transmitted on different carriers, so that the frequency diversity gain may be obtained, and the reliability of transmission is further improved.

That is, respective indication information corresponding to each logical channel may directly indicate a carrier or carrier group used for transmitting plural data carried in the each
 10 logical channel, so that the device for transmitting data may directly schedule the duplicated data carried in each logical channel according to the carrier or carrier group indicated by the indication information of the each logical channel. Or the respective indication information corresponding to each logical channel may indicate identity information of a logical channel that transmits duplicated data together with the each logical channel, so that the device for
 15 transmitting data may determine which different carriers or carrier groups to schedule the duplicated data carried in each logical channel for transmission at a MAC layer.

Optionally, in some embodiments, the indication information includes third indication information corresponding to a third logical channel of the plurality of logical channels, the third indication information is used for indicating whether the duplicated data is carried in the
 20 third logical channel, and the determining the plurality of carriers or carrier groups according to the respective indication information corresponding to each logical channel of the plurality of logical channels, includes: determining that the duplicated data carried in the third logical channel and a fourth logical channel respectively correspond to different carriers or carrier groups if the third indication information indicates that the duplicated data is carried and fourth
 25 indication information corresponding to the fourth logical channel indicates that the duplicated data is carried; the transmitting the duplicated data carried in the plurality of logical channels respectively by using the plurality of carriers or carrier groups, includes: transmitting the duplicated data carried in the third logical channel and the fourth logical channel respectively by using the different carriers or carrier groups.

Specifically, the plurality of logical channels may include a third logical channel, indication information corresponding to the third logical channel is denoted as third indication information for convenience of distinction and description, the third indication information may indicate whether the third logical channel carries the duplicated data, indication information
 30

corresponding to a fourth logical channel may also indicate whether the fourth logical channel carries the duplicated data. If the device for transmitting data determines that the third indication information indicates that the duplicated data is carried, and the indication information corresponding to the fourth logical channel also indicates that the duplicated data is carried, the device for transmitting data may schedule the duplicated data carried in the third logical channel and the fourth logical channel to be transmitted on different carriers, thus obtaining the frequency diversity gain and further improving the reliability of transmission.

Optionally, in some embodiments, before the determining the plurality of carriers or carrier groups according to respective indication information of each of the plurality of logical channels, the method further includes: determining that there is an indication field including the indication information in logical channel configuration information of the each logical channel.

Specifically, in a MAC layer, the device for transmitting data may firstly determine whether there is an indication field for carrying the indication information in the logical channel configuration information corresponding to each logical channel. If there is the indication field, the device for transmitting data may schedule plural data carried in the plurality of logical channels to different carriers or carrier groups for transmission according to the method described in the above embodiment, otherwise, the device for transmitting data may schedule the data carried in the plurality of logical channels according to a scheduling method in the prior art.

Optionally, in some embodiments, the determining the plurality of carriers or carrier groups for transmitting the duplicated data according to the plurality of logical channels for carrying the duplicated data, includes: determining a plurality of media access control (MAC) entities according to the plurality of logical channels and a first correspondence relationship, wherein the first correspondence relationship is a correspondence relationship between logical channels and MAC entities, and the plurality of logical channels and the plurality of MAC entities correspond one to one; determining the plurality of carriers or carrier groups according to the plurality of MAC entities and a second correspondence relationship, wherein the second correspondence relationship is a correspondence relationship between MAC entities and carriers or carrier groups, and the plurality of MAC entities and the plurality of carriers or carrier groups correspond one to one.

Specifically, the logical channels and the MAC entities may have a first correspondence relationship, and the first correspondence relationship may be a one-to-one correspondence relationship, i.e., the logical channels and the MAC entities are one-to-one corresponding,

therefore, the device for transmitting data may determine a plurality of MAC entities according to the plurality of logical channels and the first correspondence relationship. Different MAC entities correspond to different carriers or carrier groups, that is, MAC entities and carriers or carrier groups may have a second correspondence relationship, which may be a one-to-one
 5 correspondence relationship or a one-to-many correspondence relationship, that is, one MAC entity may correspond to one carrier or carrier group, or one MAC entity may correspond to a plurality of carriers or carrier groups. Therefore, the device for transmitting data may determine a plurality of carriers or carrier groups according to the plurality of MAC entities and the second correspondence relationship, and then the device for transmitting data may transmit
 10 duplicated data carried in the plurality of logical channels through the plurality of carriers or carrier groups.

Optionally, in some embodiments, the first correspondence relationship is preconfigured by a high layer signaling.

Specifically, if the device for transmitting data is a terminal device, the first
 15 correspondence relationship may be preconfigured to the terminal device by a network device through a high level signaling, or the first correspondence relationship may be agreed between the terminal device and the network device, or the first correspondence relationship may be specified in a protocol. If the device for transmitting data is a network device, the first correspondence relationship may be preconfigured by the network device, or agreed between
 20 the network device and the terminal device, or the first correspondence relationship may be specified in a protocol.

Optionally, in the embodiment of the present application, the duplicated data is duplicated data obtained by duplicating the same packet data convergence protocol (PDCP) protocol data unit (PDU) by a PDCP split carrier.

25 In other words, the duplicated data may be a plurality of duplicated PDCP PDUs that a PDCP split carrier duplicates the same PDCP PDU to be, each of the plurality of duplicated PDCP PDUs may be referred to as a duplicated data, and each duplicated PDCP PDU has the same content, i.e., the same payload and header. In a RLC layer, the plurality of duplicated data are mapped onto a plurality of logical channels, that is, the plurality of duplicated data are
 30 respectively transmitted through the plurality of logical channels.

Optionally, in some embodiments, carrying the duplicated data on the plurality of logical channels is preconfigured by a higher layer signaling.

That is to say, which logical channels are to be used for transmitting duplicated data may be preconfigured through a high layer signaling, and when there is data transmission on these logical channels, the data transmitted on these logical channels may be considered as duplicated data. Optionally, the high layer signaling is an RRC signaling.

5 The method for transmitting data according to the embodiment of the present application will be described with reference to a specific example below. As shown in FIG. 3, a PDCP split carrier duplication function module of a PDCP layer may duplicate PDCP SDU1 into two PDCP PDU1s, the two PDCP PDU1s include the same data and header. In a RLC layer, the two PDCP PDU1s are respectively mapped to RLC logical channel 1 and RLC logical channel 2. In
10 one possible implementation, RRC information element of LogicalChannelConfig of each logical channel includes indication information indicating a carrier ID. For example, indication information corresponding to the RLC logical channel 1 indicates a carrier ID1 corresponding to carrier 1, the carrier 1 corresponds to HARQ entity 1 of a MAC layer, and indication information corresponding to the RLC logical channel 2 indicates a carrier ID2 corresponding
15 to a carrier 2, and the carrier 2 corresponds to HARQ entity 2 of the MAC layer. Therefore, the device for transmitting data may schedule the two PDCP PDU1s to be transmitted on the carrier 1 and carrier 2. As another example, the indication information corresponding to the RLC logical channel 1 indicates carrier ID1, carrier ID2, and carrier ID3, respectively corresponding to carrier 1, carrier 2, and carrier 3, and the indication information corresponding to the RLC
20 logical channel 2 indicates carrier ID4, carrier ID5, and carrier ID6, corresponding to carrier 4, carrier 5, and carrier 6. Therefore, the device for transmitting data may select a carrier for transmitting PDCP PDU1 in the RLC logical channel 1 among carrier 1, carrier 2, and carrier 3, i.e., transmit PDCP PDU1 in the RLC logical channel 1 on at least one of carrier 1, carrier 2, and carrier 3, and similarly, select a carrier for transmitting PDCP PDU1 in the RLC
25 logical channel 2 among carrier 4, carrier 5, and carrier 6, i.e., transmit PDCP PDU1 in the RLC logical channel 2 on at least one of carrier 4, carrier 5, and carrier 6.

Optionally, in another possible implementation, indication information of each logical channel indicates an ID of a logical channel. Indication information of the RLC logical channel 1 in FIG. 3 may indicate LC2, for the RCL logical channel 2, and indication information of the
30 RLC logical channel 2 may indicate LC1, for the RCL logical channel 1, that is, the RLC logical channel 1 and the RLC logical channel 2 are used for transmitting duplicated data. Therefore, the device for transmitting data may schedule duplicated data carried in the RLC logical channel 1 and the RCL logical channel 2 to be transmitted on different carriers. For

example, the duplicated data carried in the RLC logical channel 1 and the RCL logical channel 2 may be scheduled to be transmitted on carrier 1 and carrier 2 respectively.

Method embodiments of the present application are described in detail above with reference to FIGs. 2 to 3, apparatus embodiments of the present application are described in detail below with reference to FIGs. 4 to 5. It should be understood that the apparatus
 5 embodiments and the method embodiments correspond to each other, and similar descriptions may be referred to in the method embodiments.

FIG. 4 is a schematic block diagram of a device 400 for transmitting data according to an embodiment of the present application. As shown in FIG. 4, the terminal device 400 includes a
 10 determination module 410 and a communication module 420.

The determination module 410 is used for determining a plurality of carriers or carrier groups for transmitting duplicated data according to a plurality of logical channels for carrying the duplicated data, herein at least two logical channels in the plurality of logical channels correspond to different carriers or carrier groups for transmitting the duplicated data.

15 The communication module 420 is used for transmitting the duplicated data carried in the plurality of logical channels respectively by using the plurality of carriers or carrier groups.

Optionally, in some embodiments, the determination module 410 is specifically used for: determining the plurality of carriers or carrier groups according to respective indication information of each of the plurality of logical channels.

20 Optionally, in some embodiments, the respective indication information corresponding to each logical channel is included in an indication field of logical channel configuration information corresponding to the each logical channel.

Optionally, in some embodiments, the logical channel configuration information corresponding to each logical channel is a radio resource control (RRC) information element of
 25 the each logical channel, and the RRC information element of the each logical channel is used for configuring channel parameters of the each logical channel.

Optionally, in some embodiments, the indication information includes first indication information corresponding to a first logical channel of the plurality of logical channels, and the determination module 410 is specifically used for: determining that a first carrier corresponding
 30 to a carrier ID of one carrier or a first carrier group corresponding to a carrier ID of a group of carriers indicated by the first indication information is a carrier or a carrier group for transmitting the duplicated data carried in the first logical channel.

The communication module 420 is specifically used for: transmitting the duplicated data carried in the first logical channel by using the first carrier or part or all of carriers in the first carrier group.

5 Optionally, in some embodiments, the indication information includes second indication information corresponding to a second logical channel of the plurality of logical channels, the second indication information is identity information of other logical channels than the second logical channel in the plurality of logical channels, and the determination module 410 is specifically used for: determining that the duplicated data carried in the second logical channel and the other logical channels respectively correspond to different carriers or carrier groups
10 according to the second indication information.

The communication module 420 is specifically used for: transmitting the duplicated data carried in the second logical channel and the other logical channels respectively by using the different carriers or carrier groups.

15 Optionally, in some embodiments, the indication information includes third indication information corresponding to a third logical channel of the plurality of logical channels, the third indication information is used for indicating whether the duplicated data is carried in the third logical channel. The determination module 410 is specifically used for: determining that the duplicated data carried in the third logical channel and a fourth logical channel respectively correspond to different carriers or carrier groups if the third indication information indicates
20 that the duplicated data is carried and fourth indication information corresponding to the fourth logical channel indicates that the duplicated data is carried.

The transmission module is specifically used for: transmitting the duplicated data carried in the third logical channel and the fourth logical channel respectively by using the different carriers or carrier groups.

25 Optionally, in some embodiments, the determination module 410 is specifically used for: determining that there is an indication field including the indication information in logical channel configuration information of each logical channel.

30 Optionally, in some embodiments, the determination module 410 is specifically used for: determining a plurality of media access control (MAC) entities according to the plurality of logical channels and a first correspondence relationship, wherein the first correspondence relationship is a correspondence relationship between logical channels and MAC entities, and the plurality of logical channels and the plurality of MAC entities correspond one to one;

determining the plurality of carriers or carrier groups according to the plurality of MAC entities and a second correspondence relationship, wherein the second correspondence relationship is a correspondence relationship between MAC entities and carriers or carrier groups, and the plurality of MAC entities and the plurality of carriers or carrier groups correspond one to one.

5 Optionally, in some embodiments, the first correspondence relationship is preconfigured by a high layer signaling.

Optionally, in some embodiments, the duplicated data is duplicated data obtained by duplicating the same packet data convergence protocol (PDCP) protocol data unit (PDU) by a PDCP split carrier.

10 Optionally, in some embodiments, carrying the duplicated data on the plurality of logical channels is preconfigured by a higher layer signaling.

Optionally, in some embodiments, the high layer signaling is a radio resource control (RRC) signaling.

Specifically, the terminal device 400 may correspond to a device for transmitting data in the method 200 for transmitting data according to an embodiment of the present application, and the device 400 may include entity units for executing a method executed by the device for transmitting data in the method 200 in FIG. 2. Moreover, various entity units in the device 400 and the other operations and/or functions described above are respectively for implementing the corresponding flows of the method 200 in FIG. 2, and will not be repeated here for the sake of
20 brevity.

FIG. 5 is a schematic block diagram of a terminal device according to an embodiment of the present application. The terminal device 500 of FIG. 5 includes a memory 510 for storing a program, a transceiver 520, and a processor 530 for executing the program. When the program is executed, the processor 530 transmits and receives signals through the transceiver 520 and
25 completes operations in the foregoing method embodiments.

Specifically, the processor 530 is used for determining a plurality of carriers or carrier groups for transmitting duplicated data according to a plurality of logical channels for carrying the duplicated data, wherein at least two logical channels in the plurality of logical channels correspond to different carriers or carrier groups for transmitting the duplicated data.

30 The transceiver 520 is used for transmitting the duplicated data carried in the plurality of logical channels respectively by using the plurality of carriers or carrier groups.

Optionally, in some embodiments, the processor 530 is specifically used for: determining

the plurality of carriers or carrier groups according to respective indication information of each of the plurality of logical channels.

Optionally, in some embodiments, the respective indication information corresponding to each logical channel is included in an indication field of logical channel configuration information corresponding to the each logical channel.

Optionally, in some embodiments, the logical channel configuration information corresponding to each logical channel is a radio resource control (RRC) information element of the each logical channel, and the RRC information element of the each logical channel is used for configuring channel parameters of the each logical channel.

Optionally, in some embodiments, the indication information includes first indication information corresponding to a first logical channel of the plurality of logical channels, and the processor 530 is specifically used for: determining that a first carrier corresponding to a carrier ID of one carrier or a first carrier group corresponding to a carrier ID of a group of carriers indicated by the first indication information is a carrier or a carrier group for transmitting the duplicated data carried in the first logical channel.

The transceiver 520 is specifically used for: transmitting the duplicated data carried in the first logical channel by using the first carrier or part or all of carriers in the first carrier group.

Optionally, in some embodiments, the indication information includes second indication information corresponding to a second logical channel of the plurality of logical channels, the second indication information is identity information of other logical channels than the second logical channel in the plurality of logical channels. The processor 530 is specifically used for: determining that the duplicated data carried in the second logical channel and the other logical channels respectively correspond to different carriers or carrier groups according to the second indication information.

The transceiver 520 is specifically used for: transmitting the duplicated data carried in the second logical channel and the other logical channels respectively by using the different carriers or carrier groups.

Optionally, in some embodiments, the indication information includes third indication information corresponding to a third logical channel of the plurality of logical channels, the third indication information is used for indicating whether the duplicated data is carried in the third logical channel, and the processor 530 is specifically used for: determining that the duplicated data carried in the third logical channel and a fourth logical channel respectively

correspond to different carriers or carrier groups if the third indication information indicates that the duplicated data is carried and fourth indication information corresponding to the fourth logical channel indicates that the duplicated data is carried.

5 The transmission module is specifically used for: transmitting the duplicated data carried in the third logical channel and the fourth logical channel respectively by using the different carriers or carrier groups.

Optionally, in some embodiments, the processor 530 is specifically used for: determining that there is an indication field including the indication information in logical channel configuration information of each logical channel.

10 Optionally, in some embodiments, the processor 530 is specifically used for: determining a plurality of media access control (MAC) entities according to the plurality of logical channels and a first correspondence relationship, wherein the first correspondence relationship is a correspondence relationship between logical channels and MAC entities, and the plurality of logical channels and the plurality of MAC entities correspond one to one; determining the
15 plurality of carriers or carrier groups according to the plurality of MAC entities and a second correspondence relationship, wherein the second correspondence relationship is a correspondence relationship between MAC entities and carriers or carrier groups, and the plurality of MAC entities and the plurality of carriers or carrier groups correspond one to one.

20 Optionally, in some embodiments, the first correspondence relationship is preconfigured by a high layer signaling.

Optionally, in some embodiments, the duplicated data is duplicated data obtained by duplicating the same packet data convergence protocol (PDCP) protocol data unit (PDU) by a PDCP split carrier.

25 Optionally, in some embodiments, carrying the duplicated data on the plurality of logical channels is preconfigured by a higher layer signaling.

Optionally, in some embodiments, the high layer signaling is a radio resource control (RRC) signaling.

30 It should be understood that, in an embodiment of the present application, the processor 530 may be a central processing unit (CPU), or the processor 530 may be other general purpose processor, a digital signal processor (DSP), an application specific integrated circuit (ASIC), a field programmable gate array (FPGA), or other programmable logic device, a discrete gate or a transistor logic device, or a discrete hardware component, etc. The general purpose processor

may be a microprocessor, or the processor may be any conventional processor or the like.

The memory 510 may include a read only memory and a random access memory and provide instructions and data to the processor 530. A portion of memory 510 may also include a non-volatile random access memory. For example, the memory 510 may also store device type information.

In an implementation process, the acts of the methods described above may be accomplished by integrated logic circuits of hardware in the processor 530 or instructions in a form of software. The acts of the method disclosed in connection with the embodiment of the present application may be directly embodied to be completed by an execution of a hardware processor or by a combination of hardware and software modules in a processor. The software modules may be located in typical storage medium in the art, such as a random access memory, flash memory, read-only memory, programmable read-only memory or electrically erasable programmable memory, or register. The storage medium is located in the memory, and the processor 530 reads the information in the memory and accomplishes the acts of the method with its hardware. In order to avoid repetition, it will not be described in detail here.

In a specific implementation, the communication module 410 in FIG. 4 may be implemented by the processor 530 of FIG. 5, and the communication module 420 in FIG. 4 may be implemented by the transceiver 520 of FIG. 5.

Those of ordinary skill in the art will recognize that the exemplary elements and algorithm acts described in connection with the embodiments disclosed herein may be implemented in electronic hardware, or a combination of computer software and electronic hardware. Whether these functions are implemented in hardware or software depends on the specific application and design constraints of the technical solution. Skilled artisans may use different methods to implement the described functions in respect to each particular application, but such implementation should not be considered to be beyond the scope of the present application.

Those skilled in the art may clearly understand that for convenience and conciseness of description, the specific working processes of the system, apparatus and unit described above may refer to the corresponding processes in the aforementioned method embodiments and will not be described here.

In several embodiments provided by the present application, it should be understood that the disclosed systems, apparatuses and methods may be implemented in other ways. For example, the apparatus embodiments described above are only illustrative, for example, the

division of the units is only a logical function division, and there may be other division manners in actual implementation, for example, a plurality of units or components may be combined or integrated into another system, or some features may be ignored or not executed. On the other hand, the mutual coupling or direct coupling or communication connection shown or discussed
5 may be indirect coupling or communication connection through some interface, apparatus or unit, and may be in electrical, mechanical or other forms.

The unit described as a separate component may or may not be physically separated, and the component shown as a unit may or may not be a physical unit, i.e., it may be located in one place or may be distributed over a plurality of network units. Some or all of the units may be
10 selected according to actual needs to achieve the purpose of the embodiments.

In addition, various functional units in various embodiments of the present application may be integrated in one processing unit, or the various units may be physically present separately, or two or more units may be integrated in one unit.

The functions may be stored in a computer readable storage medium if realized in a form
15 of software functional units and sold or used as a separate product. Based on this understanding, the technical solution of the present application, in essence, or the part contributing to the prior art, or the part of the technical solution, may be embodied in the form of a software product stored in a storage medium, including a number of instructions for causing a computer device (which may be a personal computer, a server, or a network device and the like) to perform all or
20 part of the acts of the method described in various embodiments of the present application. The storage medium includes U disk, mobile hard disk, read-only memory (ROM), random access memory (RAM), magnetic disk or optical disk, and other medium capable of storing program codes.

What are described above are merely exemplary embodiments of the present application,
25 but the protection scope of the present application is not limited thereto. Any variation or substitution that may be easily conceived by a person skilled in the art within the technical scope disclosed by the present application shall be included within the protection scope of the present application. Therefore, the protection scope of the present application shall be determined by the protection scope of the claims.

Claims:

1. A method for transmitting data, comprising:

determining a plurality of carriers or carrier groups for transmitting duplicated data according to a plurality of logical channels for carrying the duplicated data, wherein at least two
5 logical channels in the plurality of logical channels correspond to different carriers or carrier groups for transmitting the duplicated data;

transmitting the duplicated data carried in the plurality of logical channels respectively on the plurality of carriers or carrier groups.

2. The method according to claim 1, wherein the determining the plurality of carriers or
10 carrier groups for transmitting the duplicated data according to the plurality of logical channels for carrying the duplicated data comprises:

determining the plurality of carriers or carrier groups according to respective indication information of each of the plurality of logical channels.

3. The method according to claim 2, wherein the respective indication information of each
15 logical channel is comprised in an indication field of respective logical channel configuration information of the each logical channel.

4. The method according to claim 3, wherein the respective logical channel configuration information of the each logical channel is a respective radio resource control (RRC)
20 information element of the each logical channel, and the RRC information element of the each logical channel is used for configuring channel parameters of the each logical channel.

5. The method according to any one of claims 2-4, wherein the indication information comprises first indication information corresponding to a first logical channel of the plurality of logical channels, the first indication information is used for indicating a carrier identity (ID) of one carrier or a group of carriers, and the determining the plurality of carriers or carrier groups
25 according to the respective indication information corresponding to each logical channel of the plurality of logical channels comprises:

determining that a first carrier corresponding to a carrier ID of one carrier or a first carrier group corresponding to a carrier ID of a group of carriers indicated by the first indication information is a carrier or a carrier group for transmitting the duplicated data carried in the first
30 logical channel;

the transmitting the duplicated data carried in the plurality of logical channels respectively

on the plurality of carriers or carrier groups comprises:

transmitting the duplicated data carried in the first logical channel on the first carrier, or on part or all of carriers in the first carrier group.

6. The method according to any one of claims 2-4, wherein the indication information
5 comprises second indication information corresponding to a second logical channel of the plurality of logical channels, the second indication information is identity information of other logical channels than the second logical channel in the plurality of logical channels, and the determining the plurality of carriers or carrier groups according to the respective indication information corresponding to each logical channel of the plurality of logical channels,
10 comprises:

determining that the duplicated data carried in the second logical channel and the other logical channels respectively correspond to different carriers or carrier groups according to the second indication information;

the transmitting the duplicated data carried in the plurality of logical channels respectively
15 on the plurality of carriers or carrier groups comprises:

transmitting the duplicated data carried in the second logical channel and the other logical channels respectively on the different carriers or carrier groups.

7. The method according to any one of claims 2-4, wherein the indication information
20 comprises third indication information corresponding to a third logical channel of the plurality of logical channels, the third indication information is used for indicating whether the duplicated data is carried in the third logical channel, and the determining the plurality of carriers or carrier groups according to the respective indication information corresponding to each logical channel of the plurality of logical channels comprises:

determining that the duplicated data carried in the third logical channel and a fourth logical
25 channel respectively correspond to different carriers or carrier groups if the third indication information indicates that the duplicated data is carried and fourth indication information corresponding to the fourth logical channel indicates that the duplicated data is carried;

the transmitting the duplicated data carried in the plurality of logical channels respectively
on the plurality of carriers or carrier groups comprises:

30 transmitting the duplicated data carried in the third logical channel and the fourth logical channel respectively on the different carriers or carrier groups.

8. The method according to any one of claims 3-7, wherein before the determining the plurality of carriers or carrier groups according to respective indication information of each of the plurality of logical channels, the method further comprises:

5 determining that there is an indication field comprising the indication information in logical channel configuration information of the each logical channel.

9. The method according to claim 1, wherein the determining the plurality of carriers or carrier groups for transmitting the duplicated data according to the plurality of logical channels for carrying the duplicated data comprises:

10 determining a plurality of media access control (MAC) entities according to the plurality of logical channels and a first correspondence relationship, wherein the first correspondence relationship is a correspondence relationship between logical channels and MAC entities, and the plurality of logical channels and the plurality of MAC entities correspond one to one;

15 determining the plurality of carriers or carrier groups according to the plurality of MAC entities and a second correspondence relationship, wherein the second correspondence relationship is a correspondence relationship between MAC entities and carriers or carrier groups, and the plurality of MAC entities and the plurality of carriers or carrier groups correspond one to one.

10. The method according to claim 9, wherein the first correspondence relationship is preconfigured by a high layer signaling.

20 11. The method according to any one of claims 1-10, wherein the duplicated data is duplicated data obtained by duplicating a same one packet data convergence protocol (PDCP) protocol data unit (PDU) by a PDCP split carrier.

12. The method according to any one of claims 1-11, wherein carrying the duplicated data on the plurality of logical channels is preconfigured by a higher layer signaling.

25 13. The method according to claim 12, wherein, the high layer signaling is a radio resource control (RRC) signaling.

14. A device for transmitting data, comprising:

30 a determination module, used for determining a plurality of carriers or carrier groups for transmitting duplicated data according to a plurality of logical channels for carrying the duplicated data, wherein at least two logical channels in the plurality of logical channels correspond to different carriers or carrier groups for transmitting the duplicated data;

a communication module, used for transmitting the duplicated data carried in the plurality of logical channels respectively on the plurality of carriers or carrier groups.

15. The device according to claim 14, wherein the determination module is specifically used for:

5 determining the plurality of carriers or carrier groups according to respective indication information of each of the plurality of logical channels.

16. The device according to claim 15, wherein the respective indication information of each logical channel is comprised in an indication field of respective configuration information of the each logical channel.

10 17. The device according to claim 16, wherein the respective logical channel configuration information of the each logical channel is a respective radio resource control (RRC) information element of the each logical channel, and the RRC information element of the each logical channel is used for configuring channel parameters of the each logical channel.

15 18. The device according to any one of claims 15-17, wherein the indication information comprises first indication information corresponding to a first logical channel of the plurality of logical channels, and the determination module is specifically used for:

20 determining that a first carrier corresponding to a carrier ID of one carrier or a first carrier group corresponding to a carrier ID of a group of carriers indicated by the first indication information is a carrier or a carrier group for transmitting the duplicated data carried in the first logical channel;

the communication module is specifically used for:

transmitting the duplicated data carried in the first logical channel on the first carrier, or on part or all of carriers in the first carrier group.

25 19. The device according to any one of claims 15-17, wherein the indication information comprises second indication information corresponding to a second logical channel of the plurality of logical channels, the second indication information is identity information of other logical channels than the second logical channel in the plurality of logical channels, and the determination module is specifically used for:

30 determining that the duplicated data carried in the second logical channel and the other logical channels respectively correspond to different carriers or carrier groups according to the second indication information;

the communication module is specifically used for:

transmitting the duplicated data carried in the second logical channel and the other logical channels respectively on the different carriers or carrier groups.

20. The device according to any one of claims 15-17, wherein the indication information
5 comprises third indication information corresponding to a third logical channel of the plurality of logical channels, the third indication information is used for indicating whether the duplicated data is carried in the third logical channel, and the determination module is specifically used for:

10 determining that the duplicated data carried in the third logical channel and a fourth logical channel respectively correspond to different carriers or carrier groups if the third indication information indicates that the duplicated data is carried and fourth indication information corresponding to the fourth logical channel indicates that the duplicated data is carried;

the transmission module is specifically used for:

15 transmitting the duplicated data carried in the third logical channel and the fourth logical channel respectively on the different carriers or carrier groups.

21. The device according to any one of claims 16-20, wherein the determination module is specifically used for:

determining that there is an indication field comprising the indication information in logical channel configuration information of the each logical channel.

20 22. The device according to claim 21, wherein the determination module is specifically used for:

25 determining a plurality of media access control (MAC) entities according to the plurality of logical channels and a first correspondence relationship, wherein the first correspondence relationship is a correspondence relationship between logical channels and MAC entities, and the plurality of logical channels and the plurality of MAC entities correspond one to one;

30 determining the plurality of carriers or carrier groups according to the plurality of MAC entities and a second correspondence relationship, wherein the second correspondence relationship is a correspondence relationship between MAC entities and carriers or carrier groups, and the plurality of MAC entities and the plurality of carriers or carrier groups correspond one to one.

23. The device according to claim 22, wherein the first correspondence relationship is

preconfigured by a high layer signaling.

24. The device according to any one of claims 14-23, wherein the duplicated data is duplicated data obtained by duplicating a same one packet data convergence protocol (PDCP) protocol data unit (PDU) by a PDCP split carrier.

5 25. The device according to any one of claims 14-24, wherein carrying the duplicated data on the plurality of logical channels is preconfigured by a higher layer signaling.

26. The device according to claim 25, wherein the high layer signaling is a radio resource control (RRC) signaling.
